# EANM'23

Annual Congress of the
European Association of Nuclear Medicine
September 9–13, 2023
Vienna, Austria

# Abstracts

European Journal of Nuclear Medicine and
Molecular Imaging (2023) 50 (Suppl 1): S1–S898

**This supplement was not sponsored by outside commercial interests. It was funded entirely by the association's own resources.**

Dear colleagues,

It is my great honour to invite you to the 36th Annual EANM Congress on behalf of the European Association of Nuclear Medicine. This year's event will be held in Vienna from September 9–13.

We are able to meet in person again for this edition of the EANM Congress, meaning we will enjoy the fantastic science and face-to-face interchange the occasion offers while also continuing to bolster our growth as a specialist community.

Our present is bright, and our future is even more promising. Our relevance for diagnostics and therapy continues to increase, new tools and tracers have been established, and ongoing research and innovation are consistently providing fresh solutions for validation and testing. The number of joint projects with other disciplines and societies continues to grow, with more and more communities recognising the important help that nuclear medicine can provide their patients and in answering their questions. This is the main reason for the unusual date of this year's EANM Congress, as we wanted to avoid clashing with another major event that many of our participants and industry partners will also want to attend. We plan to return to our usual mid-October dates in 2024.

The number of visitors to the Congress continues to rise year after year, with the 2022 edition of the event welcoming an unprecedented 7000 participants. The many innovative features you discovered and liked in Barcelona last year will be present once more, including sessions specifically devoted to exchange and discussion. Please prepare your questions across the year and get ready to challenge our experts during the congress! We want to make sure that you return home with input and suggestions that allow each and every one of you to contribute to the success of our field in your daily work.

Needless to say, we should not simply sit back and enjoy our success. We must continue to provide convincing evidence of the positive impact our chosen field has in a complex world of limited resources, meaning we should constantly strive for a more efficient, accessible and sustainable nuclear medicine. This year's scientific programme will help you deal with such issues thanks to superb material combined with multidisciplinary sessions. And as we know that fun helps foster collaboration and cooperation, and some will also be uniquely entertaining. On top of this, we hope you will provide numerous contributions and plenty of input via the abstract submission portal, which is now open. Share your work with the nuclear medicine community!

We have prepared content that will maximise opportunities for exchange and networking for all those who travel to Vienna for EANM'23. On the other hand, we still want to reach as large an audience as possible, just as virtual congresses have done, including anyone that cannot make it to Vienna for this year's congress. For this reason, selected content will also be made available online and will remain accessible afterwards so that everyone can benefit from it in a way which fits around each individual's schedule.

In summary, we are working to provide you all with a special, first-rate Congress tailored to your needs and wishes. Join us and savour every moment of it!

Valentina Garibotto
EANM Congress Chair 2023–2025

## Saturday, September 09, 2023

### OP-016

**Terbium-149 production: a pragmatic view of its clinical potential**

***N. van der Meulen***[1], *P. V. Grundler*[1], *Z. Talip*[1], *C. Favaretto*[1], *C. C. Hillhouse*[1], *U. Koester*[2], *K. Johnston*[3], *R. Schibli*[1], *R. Eichler*[1], *C. Mueller*[1];
[1]*Paul Scherrer Institut, Villigen, SWITZERLAND,*
[2]*ILL, Grenoble, FRANCE,* [3]*CERN, Geneva, SWITZERLAND.*

***Aim/Introduction:*** Terbium-149 was proposed as an attractive candidate for Targeted Alpha Therapy (TAT) in the late 1990's [1], due to its favourable physical decay properties ($T_{1/2}$ = 4.1 h, $E_{\alpha}$ = 3.97 MeV, 16.7 %; $E_{\beta+\ mean}$ = 720 keV, 7.11%) [2]. While preclinical studies demonstrated its potential for therapeutic purposes [3-5], it was also shown that it could be used for positron emission tomography [4]. ***Materials and Methods:*** Terbium-149 was produced at ISOLDE/CERN via spallation of a tantalum target using high-energy (1.4 GeV) protons, followed by resonant ionization of spallation products and online mass separation. The mass 149 isobars were implanted in a zinc-coated gold foil and shipped to Paul Scherrer Institute for processing. Terbium-149 was separated from its isobaric impurities, as well as the ion-implantation matrix, using cation exchange and extraction chromatography, employing an optimized process to that previously reported [5]. The quality of the radionuclide produced was assessed by means of radiolabelling and ICP-MS measurements. ***Results:*** Up to 450 MBq terbium-149 was collected daily and transported, with ~200 MBq activity received at PSI. The four-hour radiochemical separation process resulted in ~100 MBq obtained as final product. The radiochemical purity of the final product formulated in 1 mL 0.05 HCl was 99.8%. Quality control was performed using DOTATATE, which was successfully labelled at molar activities up to 20 MBq/nmol with >99% radiochemical purity - three times better than previously achieved [5]. The chemical purity was further proved by ICP-MS measurements, showing lead, copper, iron and zinc in ppb levels. ***Conclusion:*** Preclinical data using terbium-149 has indicated great potential towards TAT. The chemical separation procedure has steadily improved over the years, such that the quality of product can ensure more efficient labelling of small molecules. While only CERN/ISOLDE currently produces this radionuclide (where one has to lobby for beam time for one-to-two weeks' collection per year), CERN/MEDICIS is currently developing efficient methods to do so as well. The interest in the radionuclide remains high, with governments in Switzerland (IMPACT project) and Belgium (MYRRHA) having approved grants to fund facilities to upscale and produce large activities of terbium-149, amongst other interesting radionuclides, towards medical research and potential clinical application. ***References:*** [1] Allen. Australasian Radiology 1999, 43:480. [2] Singh & Chen. Nuclear Dataa Sheets 2022, 185:2 [3] Beyer et al. Radiochim Acta 2002, 90:247. [4] Müller et al. EJNMMI Radiopharm Chem 2016, 1:5. ### OP-017

**Small-scale production of $^{161}$Tb for preclinical studies**

***M. Skálová****, J. Kozempel, M. Vlk, K. Ondrák Fialová, L. Ondrák;*
*Department of Nuclear Chemistry, Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, CZECH REPUBLIC.*

***Aim/Introduction:*** Terbium-161 is promising theranostic radionuclide thanks to its good decay characteristics, i.e. its half-life of 6,89 d and emission of soft $\beta^-$ particles with $E_{\beta max}$ of 593 keV together with several conversion and Auger-Meitner secondary low energy electrons that contribute to the enhancement of the therapeutic effect. It also emits γ radiation with energy 74 keV, suitable for SPECT imaging and therapy follow-up monitoring. The most convenient method for no-carrier-added $^{161}$Tb production is the nuclear reactor irradiation of enriched $^{160}$Gd using indirect route of $^{160}$Gd(n,γ)$^{161}$Gd → $^{161}$Tb. The most common method used for separation of the prepared $^{161}$Tb from the bulk irradiated target is cation exchange chromatography with the 2-hydroxy-butyric acid. This method was implemented in small-scale production of this theranostic nuclide. ***Materials and Methods:*** The $^{161}$Tb was produced by the irradiation of highly enriched $^{160}$Gd (98,6 %) in the form of oxide or nitrate in the nuclear reactor LVR-15 (CV Řež, Czech rep.). The separation was performed using cation exchange chromatography on Dowex 50W×8 resin with α-hydroxyisobutyric acid as co-eluent. Different dimensions of glass chromatography columns were tested with respect to the target mass. The finally separated and purified $^{161}$Tb was formulated to 0.05 M HCl in the form of terbium chloride. The radionuclidic purity of prepared $^{161}$Tb was verified by gamma spectrometry on an HPGe detector, chemical purity was estimated by ICP-MS. Further, the labelling test with DOTA was performed to assess overall sample purity. ***Results:*** The $^{161}$Tb was successfully prepared with the highest amounts of up to 13 GBq and the highest activities of purified $^{161}$Tb samples reached almost 12 GBq (EOB). Dowex 50W×8 resin with 200-400 mesh size proved to be significantly better for both separation and purification process compared to higher granulosity sample. The radionuclidic purity of $^{161}$Tb was higher than 99,999 %, specific activity typically higher than 15 GBq/μg. ***Conclusion:*** Pure $^{161}$Tb samples for preclinical studies could be prepared reliably in a small scale by neutron irradiation of highly enriched $^{160}$Gd targets with subsequent separation and purification on a laboratory scale. Further method development and automation would enable wider availability of $^{161}$Tb for our studies. This work was supported by the project "Efficient Low-Energy Electron Cancer Therapy with Terbium-161" granted by the Norway and Technology Agency of the Czech Republic within the KAPPA Programme (grant No.: TO01000074). ***References:*** Gracheva, N., Müller, C., Talip, Z. et al. EJNMMI radiopharm. chem. 4, 12 (2019).

### OP-018

**Separation and Purification of $^{225}$Ac for Targeted Alpha Therapy Radiopharmaceuticals**

***E. Yalcintas Bethune****, J. F. Camacaro, S. Chatterjee, C. P. Dunckley, H. A. Fitzgerald, E. Harman, A. L. Lakes, Z. Liao, L. M. Lilley, R. C. Ludwig, K. M. McBride, A. Younes;*
*TerraPower LLC, Bellevue, WA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** In this work, we present the separation and purification of $^{225}$Ac from its highly radioactive and chemically variable source. $^{225}$Ac is a unique relatively short-lived ($t_{1/2}$ = 9.92 days) actinide that decays via four alpha particles, which makes it an attractive candidate for development of targeted alpha therapy

radiopharmaceuticals. Currently the world's supply of $^{225}$Ac cannot fulfill the needs of large-scale clinical trials or patient treatments. The most direct and radio-isotopically pure route to obtain $^{225}$Ac is routinely harvesting from its long-lived ($t_{1/2}$ = 7932 y) parent $^{229}$Th after it has naturally decayed to $^{225}$Ac via $^{225}$Ra. We are working with a U.S. federal contractor to recover $^{229}$Th from $^{233}$U stockpiles that would otherwise be irretrievably converted into final disposal form as a radioactive waste. ***Materials and Methods:*** The $^{229}$Th source in our facility contains a certain amount of the highly radioactive $^{228}$Th, which poses unique radiological challenges with handling this material. $^{225}$Ac production from this source requires development in three areas: i. consistent separation and purification of $^{229}$Th from its stable metal, uranic, and transuranic impurities; ii. separating $^{225}$Ac from $^{229}$Th and $^{225}$Ra parents while preserving them for later $^{225}$Ac in-growth; and iii. improving analytical methods to verify the high-grade $^{225}$Ac product. Chemical treatment and separation routes for purifying initial $^{229}$Th material must be tailored to the specific impurities of each batch received. The current processing scheme for routine isolation of $^{225}$Ac is based on an anion exchange separation of $^{225}$Ac/$^{225}$Ra from $^{229}$Th, where Th is retained on the anion exchange resin as the $[Th(NO_3)_6]^{2-}$ anion. The $^{225}$Ac/$^{225}$Ra separation is achieved through extraction chromatography using a UTEVA resin, followed by DGA resin and prefilter resins. Aliquots collected after each separation step and from the final $^{225}$Ac product have been analyzed by analytical methods, including HPGe, alpha spectroscopy, ICP-MS, and iTLC, to confirm that the $^{225}$Ac yield is as expected, there is no Th and $^{225}$Ra breakthrough, stable impurities are at the limit of detection, and high radiolabeling yield is achieved. ***Results:*** Our current method shows an excellent process yield of 98% for recovery of carrier-free $^{225}$Ac based on theoretical decay of $^{229}$Th. ***Conclusion:*** By setting up multiple $^{229}$Th generators operated in parallel, we seek to provide increased, stable supply of clinical grade $^{225}$Ac and thereby support radiopharmaceutical drug development to enable widespread treatment of cancer patients via $^{225}$Ac based targeted alpha therapy.

## OP-019

### Cyclotron based production of $^{64}$Cu/$^{67}$Cu diagnostic and theragnostic pair

***J. Lee***, *J. Park;*
*Korea Atomic Energy Research Institute, Jeollabuk-do Jeongeup-si, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Copper-64 ($^{64}$Cu) and Copper-67 ($^{67}$Cu) are two important isotopes of copper with significant importance in various fields such as nuclear medicine, radiopharmaceuticals and cancer therapy. The production of $^{64}$Cu and $^{67}$Cu requires specialized facilities and expertise, as well as careful handling of radioactive materials. However, despite these challenges, their potential applications in medical imaging and cancer therapy make them an important focus of research and development in the nuclear medicine field. In this study, we aim to discuss the research results on target preparation, proton beam irradiation, chemical separation, and quality control for the production of $^{64}$Cu and $^{67}$Cu. ***Materials and Methods:*** This study focuses on the production of radioisotopes, specifically $^{64}$Cu and $^{67}$Cu, through the proton beam irradiation process of electrodeposited targets of $^{64}$Ni and $^{70}$Zn. To enhance target cooling and increase production efficiency, a tilted target and a backside water cooling system were employed. The radioactive copper obtained from the target materials was purified through a solid-phase separation method to remove impurities and recover the target material. Quality control measures were taken to verify the radionuclidic purity and impurity metal content of $^{64}$Cu and $^{67}$Cu. ***Results:*** We used an electrodeposition method to uniformly distribute $^{64}$Ni and $^{70}$Zn onto a gold-coated copper and silver backing material, respectively, on a 5-degree tilted target optimized for proton beam irradiation efficiency. The target was then irradiated with proton beams at cumulative currents of 90 and 1200 uAh, and incident energies of 11 and 17.7 MeV, producing $^{64}$Cu and $^{67}$Cu at yields of 28.5 MBq/μAh and 0.58 MBq/μAh, respectively. We recovered over 98% of the irradiated target using a self-developed target dissolution device. The $^{64}$Cu and $^{67}$Cu were then chemically separated using an anion exchange resin and a copper selective resin, achieving a separation efficiency of >98%. Finally, quality control was performed through the evaluation of radionuclidic purity and impurity metal content, confirming results of >99.9% radionuclidic purity and <1 ppm impurity metal content. ***Conclusion:*** We produced pair-radioisotopes $^{64}$Cu and $^{67}$Cu with high yields and radioisotope purity using RFT-30 cyclotron, equipment, and chemicals. The electrodeposited targets provided advantages for beam irradiation and maximum irradiation area. We achieved >98% separation efficiency using ZR cartridges and resins. The final product was prepared under mild reaction conditions, and quality control ensured >99% radioisotope purity and <1 ppm metallic impurity content. Automation for separating apparatus is being studied for mass production.

## OP-020

### Production of Lanthanum-133 via the $^{134}$Ba(p,2n)$^{133}$La Nuclear Reaction with High Radionuclide Purity for Theranostic Purposes

***S. Brühlmann***[1,2], *M. Kreller*[1], *H. Pietzsch*[1], *K. Kopka*[1,2], *C. Mamat*[1,2], *M. Walther*[1], *F. Reissig*[1];
[1]*Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY,*
[2]*Technische Universität Dresden, Dresden, GERMANY.*

***Aim/Introduction:*** Actinium-225 has gained great importance in Targeted Alpha Therapy (TAT) due to its suitable physical and chemical properties. In past years, studies using $^{225}$Ac-PSMA-617 have shown promising results [1], however, the macropa chelator has proven more beneficial properties regarding labelling and stability in vivo as compared with DOTA. While $^{68}$Ga has been used for DOTA-based radioconjugates, the macropa chelator lacks an imaging radionuclide counterpart. For this purpose, the $\beta^+$-emitter $^{133}$La is an attractive candidate due to its physical properties and similar to $^{225}$Ac coordination chemistry. Following our recent publication [2], further optimization of the production of $^{133}$La with high radionuclidic purity (RNP) for theranostic purposes is presented. ***Materials and Methods:*** Lanthanum-133 was produced via the $^{134}$Ba(p,2n)$^{133}$La nuclear reaction. Proton irradiation (19 MeV, 35 μA, 30 min) was performed using the HZDR TR-FLEX (ACSI) cyclotron on silver discs filled with 25 mg of $[^{134}Ba]BaCO_3$ capped with a 25 μm aluminum foil. The solid target was opened and the powder dissolved in 2 mL of 1 M $HNO_3$. A one-step separation was carried out with a branched DGA resin cartridge after testing other resins. The $^{134}$Ba-containing fractions were collected and recycled through $[^{134}Ba]BaCO_3$ precipitation. Test radiolabelling of macropa-derived PSMA conjugates previously published by our group was performed in the MBq/nmol range [3]. ***Results:*** Lanthanum-133 yields of ca. 1.8 GBq for the described targets were reached at end of bombardment (EOB), accounting for about 65 % of the theoretical yield. After radiochemical separation, 1.2 GBq $^{133}$La were collected in 1 mL of

0.05 M HCl ready to label, with a RNP over 99.5 %. Further studies showed no detriment of the RNP by 21 MeV proton irradiation, thus being feasible irradiation of larger targets (prior thermal studies). Furthermore, quantitative radiolabeling was achieved with ligand concentrations down to 300 MBq/nmol. ***Conclusion:*** Lanthanum-133 of high RNP was produced for the first time. Considering future medical demands, the scale up to radioactivity amounts that are needed for clinical application purposes could be achieved by increasing the irradiation time. Alternatively, irradiation with higher currents or of thicker targets could also lead to higher activities. Based on these results, our group will attempt to establish a diagnostic platform for $^{225}$Ac-TAT based on $^{133}$La-macropa radioconjugates instead of the conventional $^{68}$Ga-DOTA application. ***References:*** [1] Kratochwil et al., J. Nucl. Med. 2016, 57, 1941-1944 [2] Brühlmann et al., Pharmaceuticals 2022, 15, 1167. [3] Reissig et al., Cancers 2021, 13, 1974.

## OP-021

### Neutron Capture-Based Production via Power Reactor and Potential Market Penetration

***C. Horne***[1], *J. Quirt*[1], *M. Flagg*[2];
[1]*Laurentis Energy Partners (subsidiary of Ontario Power Generation), Pickering, ON, CANADA,*
[2]*BWXT Medical, Kanata, ON, CANADA.*

***Aim/Introduction:*** This paper discusses non-proprietary aspects of neutron capture-based Mo99 production through a commercial CAndU reactor in Ontario, Canada and potential future market possibilities. ***Materials and Methods:*** Historically, the production of Molybdenum-99 (Mo99) via neutron capture has been limited, stemming from lower reaction efficiencies and extraction capacities based on low specific activity. A breakthrough in technetium generator technology, developed by BWX Technologies (BWXT) in the United States, has regained attention as a viable method for high-volume uranium-based Mo99 production. Through a partnership with Laurentis Energy Partners of Canada, a commercial CAndU (Canadian Atomic Natural Deuterium Uranium) nuclear reactor near Toronto, Canada, will generate Mo99 via neutron capture with subsequent processing at a local BWXT facility - both technologies being a first of a kind in the industry. Given the scale of power reactors, additional operating and safety considerations beyond those incorporated in research reactors will be required for the production and handling of Mo99 ***Results:*** The Mo99 Target Delivery System has been successfully installed and commissioned at low power and 100% power levels. ***Conclusion:*** Initial tests of Mo99 targets analyzed have been promising and allows for numerous possibilities of new isotope irradiations, as well as expansion to other CAndU reactors around the world.

## OP-022

### Testing new resins for $^{225}$Ac separation

***O. Lebeda***[1], *K. Ondrák Fialová*[1], *L. Ondrák*[1], *S. Happel*[2], *J. Ráliš*[1], *M. Kleinová*[1], *I. Dovhyi*[2];
[1]*Nuclear Physics Institute of the CAS, Husinec-Rez, CZECH REPUBLIC,* [2]*TRISKEM International, Bruz, FRANCE.*

***Aim/Introduction:*** All the ways for production of $^{225}$Ac in relevant amounts require its separation, concentration and conversion to chloride. Development of a suitable separation tool that may undertake efficiently these tasks is naturally highly desirable. We have, therefore, determined mass distribution coefficient DW and elution profiles for $^{225}$Ac of recently designed resins TK221 and TK222 in nitric and hydrochloric acids. Although these resins have been characterized with respect to the uptake of many stable elements, very little is known about actinium behaviour on them. ***Materials and Methods:*** TK221 and TK222 (50-100 µm) were synthesized in TRISKEM. The DW was determined by 1 hour long shaking of 50 mg of a given resin with 5 ml of $^{225}$Ac (25 kBq) solution in HCl or $HNO_3$ with molarities ranging between 0.01M and 10M. The mass distribution coefficient was deduced from the activity drop in filtered supernatant (1 µm glass fiber) compared to the initial $^{225}$Ac solution measured in an automated gamma counter equipped with well-type NaI(Tl) detector. Elution profile of $^{225}$Ac was determined on 2 ml columns filled with a given resin. Loading and rinsing of $^{225}$Ac (1 MBq) in optimal molarity $HNO_3$ was followed by elution of actinium into diluted HCl or $HNO_3$. Activity of the resulting fractions was measured either on an automated gamma counter equipped with well-type NaI(Tl) detector or on gamma-ray spectrometer with HPGe detector. ***Results:*** The DW values show high affinity of $^{225}$Ac to both resins in wide range of nitric acid concentrations. The affinity in hydrochloric acid dropped significantly with maximum shifted towards high acid concentrations. Diluted hydrochloric acid releases rapidly $^{225}$Ac from both resins after its loading in diluted or medium concentrated nitric acid. Elution of $^{225}$Ac from the resins into diluted nitric acid is also possible, the process is, however, very slow. ***Conclusion:*** The resins TK221 and TK222 have been characterized and its suitability for $^{225}$Ac separation/concentration/re-salting was tested. The obtained data clearly demonstrate that both resins have very favourable properties regarding efficient concentration of $^{225}$Ac from large volumes nitric acid solutions and elution into very small volumes of diluted hydrochloric acid. The TK221 obviously allows for extraction of $^{225}$Ac even from diluted nitric acid and its rapid conversion to chloride. The TK222 resin seems to be slightly superior to the TK221 regarding the elution volume.

## OP-023

### Production of gallium-68 using IBA and GE liquid target system - comparison and optimization

***A. Uhlending***, *V. Hugenberg;*
*Institute of Radiology, Nuclear Medicine and Molecular Imaging, Heart and Diabetes Center North Rhin, Bad Oeynhausen, GERMANY.*

***Aim/Introduction:*** The increasing demand for $^{68}$Ga-labelled radiotracers requires a secure supply of the nuclide gallium-68. A reliable method represents the cyclotron production of gallium-68 from liquid target. We have set Gallium-68-liquid target systems for our two cyclotrons (IBA 18/9 and GE PETtrace). The aim is the comparison and optimization both for a reliable $^{68}$Ga radiotracer production. ***Materials and Methods:*** For the production both cyclotrons are equipped with cooled niobium liquid targets and enriched zinc-68 nitrate solution was irradiate for 60 min. Differences between IBA and GE system exist in niobium target design, helium-cooling, degrading foils, target volumes and the post-processing. The IBA post-processing of the irradiated solution is accomplished via cation and anion exchange cartridges. The GE post-processing is performed using a 2-column solid phase method. Peptide labeling is performed on a cassette-based automated synthesis module. Quality control of [$^{68}$Ga]$GaCl_3$ and $^{68}$Ga-labelled peptides were carried out according to Ph. Eur. ***Results:*** Post-processing of the irradiated gallium-68 solution vary in the choice of cartridges and the used solutions. While the IBA method is based on cation and anion exchange cartridges using a combination of concentrated acid and organic solvent solutions, the GE process is based on a two-column approach using a ZR

resin and a TK200 resin, diluted acids and saline solutions. We optimized both systems by using larger capacity cartridges and additional rinsing steps. Quality control of the obtained [$^{68}$Ga] $GaCl_3$ solution revealed reproducible low zinc concentrations >0.2 mg/mL for both processes. In comparison to the volume the target yields are the same. Due to the larger volume of the IBA target produced more activity. Peptide labeling was successfully accomplished and improved by additional rinsing steps and the addition of sodium ascorbate to the reaction mixture. ***Conclusion:*** The routine production of gallium-68 via cyclotron using liquid targets from IBA and GE has been successfully implemented into the routine production of $^{68}$Ga-labelled radiotracers. Both systems reveal their advantages, while the IBA system due to the larger volume gives higher yields. In comparison to the volume the target yields are the same. The advantages of the GE system are no helium-cooling and less aggressive chemicals. ***References:*** Alves et al., (2018), Instruments, 2, 17. ## OP-024

### Radium targets for cyclotron production of Ac-225 in view of targeted alpha therapy

***A. Kellerbauer***[1], *R. Malmbeck*[1], *C. De Almeida Carrapiço*[1], *E. Jajcisinova*[1,2], *Rachel Eloirdi*[1], *Ondrej Lebeda*[3], *Alfred Morgenstern*[1]; *[1]European Commission, Joint Research Centre, Karlsruhe, GERMANY, [2]KU Leuven, Leuven, BELGIUM, [3]Nuclear Physics Institute of the CAS, Řež, CZECH REPUBLIC.*

***Aim/Introduction:*** Targeted alpha therapy using the radionuclide Ac-225 has shown remarkable benefit in clinical trials to patients suffering from various cancer types. Currently most Ac-225 is produced from a few sources of Th-229 existing worldwide. However, the total amount available is only sufficient for a few thousand patient doses. Given a projected demand that is several orders of magnitude higher, alternative paths for the production of Ac-225 must be developed. We have been investigating the route using the Ra-226(p,2n)Ac-225 reaction. It is particularly attractive due to its large cross-section near 17 MeV proton energy and because it can be readily employed at a large number of cyclotron facilities. The excitation function of this reaction has been previously measured by us for a few energies [1], but discrepancies with calculations remain. Hence, new irradiation experiments are required to improve the knowledge of the excitation function to support the industrial production of Ac-225 via this route. ***Materials and Methods:*** We have built a new electrodeposition setup to deposit homogeneous layers of Ra-226 on various substrates. The process is based on a mixed organic/aqueous solution and a custom-built electroplating cell using a platinum electrode and a high-voltage power supply. ***Results:*** A number of radium targets have been produced and examined to quantitatively determine the deposition efficiency as well as the homogeneity of deposition, which is crucial for highly precise cross-section measurements. ***Conclusion:*** In this talk, we will describe our electrodeposition setup and process, and report on the properties of the prepared Ra-226 targets. ***References:*** [1] C. Apostolidis et al., Appl. Rad. Isot. 62 (2005) 383

## Cutting Edge Science Track - TROP Session: Quality Control, Performance, Standardisation

## OP-025

### An academic/industrial PET raw data standardisation initiative

***K. Thielemans***[1], *A. L. Kesner*[2], *E. Asma*[3], *J. Cabello*[4], *M. J. Cook*[5], *M. Hansen*[6], *J. Jones*[4], *N. A. Karakatsanis*[7], *E. K. Leung*[8], *P. Markiewicz*[9], *S. Prevrhal*[10], *A. Rahmim*[11], *B. Saboury*[12], *J. Stairs*[6], *S. Stute*[13], *H. Tashima*[14], *G. Wells*[15];
*[1]Institute of Nuclear Medicine, London, UNITED KINGDOM, [2]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [3]Canon Medical Research UNITED STATES OF AMERICA, Vernon Hills, IL, UNITED STATES OF AMERICA, [4]Siemens Medical Solutions UNITED STATES OF AMERICA, Inc, Knoxville, TN, UNITED STATES OF AMERICA, [5]GE HealthCare, Waukesha, IL, UNITED STATES OF AMERICA, [6]Microsoft Research, Redmond, WA, UNITED STATES OF AMERICA, [7]Weill Cornell Medical College, Cornell University, New York, NY, UNITED STATES OF AMERICA, [8]UIH America, Inc., Houston, TX, UNITED STATES OF AMERICA, [9]University College London, London, UNITED KINGDOM, [10]Philips Research, Hamburg, GERMANY, [11]University of British Columbia, Vancouver, BC, CANADA, [12]National Institutes of Health (NIH) - Clinical Center, Bethesda, MD, UNITED STATES OF AMERICA, [13]Nantes University Hospital, CRCI2NA, Nantes, FRANCE, [14]National Institutes for Quantum Science and Technology, Chiba, JAPAN, [15]University of Ottawa Heart Institute, Ottawa, ON, CANADA.*

***Aim/Introduction:*** As the capabilities of computer hardware and software progresses, the importance of standardised data is becoming more relevant. In current PET practice, raw acquisition data are recorded in an intermediate listmode format before vendors apply the necessary processing to deliver standard, sharable, PET DICOM images. However, all current vendor formats differ, to accommodate different architectures and processing strategies. Our goals are to define an open, extendable, standardised and vendor-agnostic description of PET listmode and associated data; define a standard for storage and transmission of that data; and develop a standardised description of software to access and manipulate the standardised data, as well as prototype software. Such a standard will facilitate a new paradigm for PET innovation, including new opportunities for inter-scanner and inter-vendor harmonization and AI applications, and aide in development of advances in novel PET applications and analysis tools. ***Materials and Methods:*** An international working group comprised of PET imaging experts from academia and industry was formed in 2022 to establish a pathway for building the new standard format. This includes establishing the key informational elements to include in the standard, data container formats, and integration initiatives. All portions of the format, tools for accessing the data in the standardised format, and example data will be made open source and publicly available. ***Results:*** The initiative's "Data Elements" subgroup has defined a content description that is compatible with most major PET vendors. The content includes coincidence recording, scanner geometry, data corrections, normalisation, and concurrent physiologic signals. The "Container" subgroup has developed a meta-language called Yardl for defining data structure and protocols for accessing,

transferring, and storing data. The meta-language approach and associated tooling are also applicable to other modalities and are, for example, under consideration for a revision of the ISMRM Raw Data standard. A prototype of the meta-language standard definition and software for processing it into C++ subroutines are available in open source on GitHub. ***Conclusion:*** The PET standardisation initiative is being pursued as an opportunity for academia and industry to cooperatively expand the capacity of the future PET field, ensuring that we are able to build modern applications that make the most of PET clinical and preclinical data. The effort is ongoing, and we welcome interest, feedback, and support from the greater community.

## OP-026

### A reference-free PET quality metric using multi-scale sharpness index

***F. Moradi***[1], *P. Gurunath Bharathi*[1], *M. Khalighi*[1], *K. Su*[2], *M. Spangler-Bickell*[2];
[1]*Stanford University, Stanford, CA, UNITED STATES OF AMERICA,* [2]*GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Spatial resolution is critical in medical imaging. Detectability and accurate characterization of small lesions on PET are affected by actual (as opposed to nominal) resolution, which depend on positron range, instrumentation, reconstruction algorithm, post-reconstruction filtering/noise-reduction, and patient factors such as motion blur. Here we a propose a framework for assessing and quantifying image resolution and sharpness directly from actual patient FDG PET images, for which spatial features are not a priori known and images are subject to inherent complex non-uniform noise different from phantom studies. ***Materials and Methods:*** Fifty-two patients underwent standard of care oncologic FDG PET using a GE Discovery MI PET/CT scanner. Images (70 cm FOV, 256x256) were reconstructed reconstructed using Time-Of-Flight Block-Sequential Regularized Expectation Maximization (BSREM) using a range of β (400-1200) and time per bed (60s - 360s). We measured perceived sharpness of each scan using a 5-point Likert scale, blinded to reconstruction method/β. Images were cropped to 128x128 (to reduce empty area) and sharpness index (based on phase-coherence)[1] was calculated on each image and its scaled down versions (1/2, 1/4, 1/8, and 1/16th for size, 1/2, 1/3, and 1/4 SUV gamma scale). Together, these values provide a multiscale representation of sharpness for each image. We used logistic regression with 13-fold cross validation to explore the relationship between this multiscale representation and reconstruction parameter β. ***Results:*** For axial PET images, sharpness indices inversely correlated with β with some dependence on image noise (a function of acquisition time per bed) and values were not directly comparable across axial slices and different patients. Highest values were observed in areas of very high contrast (e.g., slices containing urinary activity in kidneys or bladder). However, a logistic regression model based on multiscale sharpness index for each image correlated strongly with β (cross-validated $R^2$=0.82) and was robust to noise and consistent across body position and patients (cross-validated $R^2$=0.91). ***Conclusion:*** Multiscale sharpness index provides a useful representation and can be used to derive a spatial resolution/sharpness image quality metric for PET without the need for a reference image or explicit assumptions about spatial features. ***References:*** G. Blanchet and L. Moisan, "An explicit sharpness index related to global phase coherence," 2012 IEEE International Conference on Acoustics, Speech and Signal Processing (ICASSP), Kyoto, Japan, 2012, pp. 1065-1068.

## OP-027

### Mitigating SUV Uncertainties Using Total Body PET Imaging

***C. L. C. Smith***[1,2], *G. J. C. Zwezerijnen*[1,2], *M. den Hollander*[1], *J. Weijland*[1], *M. Yaqub*[1,2], *R. Boellaard*[1,2];
[1]*Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Radiology and Nuclear Medicine, Boelelaan 1117, Amsterdam, NETHERLANDS,* [2]*Cancer Center Amsterdam, Imaging and Biomarkers, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Standardized uptake values (SUV) are commonly used as a quantitative assessment of lesion uptake in $^{18}$F-FDG PET/CT studies. However, SUVs may suffer from several uncertainties and errors. Long-axial field-of-view PET/CT systems enable image-based quality control (QC) by deriving $^{18}$F-FDG activity and patient weight from a total body (TB) $^{18}$F-FDG PET image. In this study, we aimed to develop image-based QC to reduce errors and mitigate SUV uncertainties. ***Materials and Methods:*** First, three phantoms were scanned to verify scanner calibration accuracy. Thereafter, 25 out of 81 patients were used as training dataset. Patients were accurately weighed on the day of the PET/CT study to determine if patient weight could be obtained from a TB and half-body (HB) $^{18}$F-FDG PET image. In addition, we developed an algorithm to derive the injected $^{18}$F-FDG activity from these scans. Finally, the other 56 patients were used as test dataset to study the agreement of image-derived activity and weight with reported $^{18}$F-FDG activity and weight. Moreover, we studied the impact of image-based values on the precision of liver SUVmean and lesion SUVpeak. ***Results:*** Reported activity and image-derived activity from the phantoms agreed within 5.8%. The training data showed that $^{18}$F-FDG activity and patient weight significantly predicted reported injected activity (r = 0.999) and weight (r = 0.999). The test dataset showed that $^{18}$F-FDG activity and patient weight can be accurately derived within 4.8% and 3.2% from TB $^{18}$F-FDG PET images and within 4.9% and 3.1% from HB $^{18}$F-FDG PET images, respectively. In addition, liver and lesion SUV variability decreased when image-derived values were used instead of reported values. ***Conclusion:*** Both HB and TB $^{18}$F-FDG PET images can be used to derive $^{18}$F-FDG activity and patient weight accurately. Furthermore, image-derived values increased liver SUV precision and corrected lesion SUV errors. Therefore, calculating SUVs based on image-derived information may be a good approach to correct for data entry or measurement errors. Image-derived values should be included as QC to generate a more reliable and reproducible quantitative uptake measurement.

## OP-028

### Calibration Procedures for Radionuclide Calibrators to Achieve Traceable Activity Measurements for Lu-177

***V. Reijonen***[1], *P. Toroi*[2], *M. Tenhunen*[1];
[1]*Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, FINLAND,* [2]*STUK - Radiation and Nuclear Safety Authority, Helsinki, FINLAND.*

***Aim/Introduction:*** The number of lutetium-177-based radiopharmaceutical treatments is increasing. The activity of the radiopharmaceutical (treatment dose) is measured with a radionuclide calibrator (RC). This measurement result needs to be traceable and accurate. The aim is to establish calibration procedures for Lu-177 settings of RCs in Finland. ***Materials and Methods:*** Two no-carrier-added Lu-177-chloride samples from an isotope technology provider were used: 1. Lu-177 standard sample (1.00 ml liquid, 10 ml P6-vial, ~1 GBq), and 2. Lu-177 technical sample (0.38 ml liquid, 3 ml V-vial, ~15 GBq). The sample

1 was used for calibration and the sample 2 to perform linearity check covering the scale of activity used in patient treatments. The sample 1 was provided with a calibration certificate stating activity, with relative uncertainty of 3% and traceability to an accredited laboratory using liquid scintillation counting. The reference activity of the sample 2 was defined by the provider with their RC. Repeated measurements were performed over a period of month with a secondary standard radionuclide calibrator (SSRNC) as well as six RCs from four manufacturers A-D: A1-A3 and B1 (new, with factory dial settings), C1 (five years old), and D1 (12 years old). Additional measurements were performed to determine the impact of the container type. ***Results:*** The activity measured with the SSRNC and given in the sample 1 certificate agreed within 0.2%. However, the activity of the sample 2 differed by -9.0% from the provider's reference data. For the RCs A1-A3, the activity reading of the sample 1 differed initially by +5.4%, +5.0%, and +5.8%. For the RCs B1, C1 and D1, the differences were -1.1%, +0.4%, and -3.1%, respectively. The Lu-177 dial setting of each calibrator was then tuned to match the calibration certificate reference value. During the following weeks, the linearity of all the RCs was excellent, and for the sample 1 differences in measured activity were on average 0.3% for all calibrators. However, measuring the sample 2 indicated an average difference of -7.2% compared to the provider's reference information, which is consistent with the results received with the SSRNC. According to our additional measurements, the difference in measuring geometry does not explain this discrepancy. ***Conclusion:*** Based on the SSRNC results it could be used as a reference standard for Lu-177 calibrations of RCs. Significant differences between RC models with factory dial settings were found, and thus calibration is strongly recommended. Regular verification is also needed.

## OP-029

### Accuracy of absolute quantification for high count rate holmium-166 SPECT/CT

***L. E. L. Westlund Gotby***[1], *D. Lobeek*[1], *J. Roosen*[1], *M. de Bakker*[1], *M. W. Konijnenberg*[1,2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of Radiology and Nuclear Medicine, Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Personalization of transarterial radioembolization with holmium-166 ($^{166}$Ho) microspheres could benefit from dosimetric information during or shortly after the therapy has been administered, and quantitative SPECT/CT imaging at high count rates is therefore desired. We aim to characterize the performance of a proprietary absolute quantification method and compare it with conventional relative quantification. ***Materials and Methods:*** A Jaszczak phantom with six fillable, spherical inserts (0.5, 2.0, 4.0, 8.0, 16.0, and 113mL) was filled with $^{166}$Ho-chloride. A 10:1 sphere-to-background activity concentration ratio was used (3.94:0.39MBq/ml at first scan). The phantom was imaged using a Symbia Intevo Bold (Siemens Healthineers) at 14 timepoints (activity range 3260-64MBq). Data were acquired with a photon peak window at 81keV (15% width), two adjacent scatter windows (8% width), 20s per projection, 2x60 projections, and medium energy low penetration collimators. Additionally the scanner was equipped with proprietary absolute quantification software (Broad Quantification) including an algorithm meant to improve the detector response at high count rates (TrueCalc). The data were reconstructed using both an ordered subset conjugate gradient method (OSCG; xSPECT reconstruction, 24 iterations 1 subset, 15mm post-reconstruction filtering) as well as an 3D ordered subset expectation maximization method (OSEM3D; Flash3D reconstruction, 10 iterations 8 subsets, no post-reconstruction filtering), both methods applying triple energy window scatter correction. Calibration of the OSCG method had been carried out prior to the experiment, enabling absolute quantification of the reconstructed images. The images derived from the OSEM3D method were quantified by applying a conversion factor based on the mean of the measured count rate density, and the known mean activity concentration in the phantom (relative quantification). The performance of the quantification was evaluated based on percentage recovered activity in the whole phantom (OSCG only) and the activity concentration recovery coefficient (ACRC). ***Results:*** The whole phantom percentage recovered activity ranged from 56% (highest activity) to 97% (lowest activity). The ACRC for the four largest spheres were consistently higher for OSEM3D than for OSCG. For the largest sphere, the ACRC range was 0.77-0.86 for OSEM3D and 0.36-0.74 for OSCG. The two smallest spheres were not detectable with either of the reconstruction methods. The range of ACRC in a volume-of-interest in the homogeneous background was 1.08-1.26 for OSEM3D and 0.73-1.11 for OSCG. ***Conclusion:*** The relatively quantified images had a higher ACRC for the detectable spheres than the images utilizing absolute quantification. The absolute quantification method underestimated the activity concentration at high count rates.

## OP-030

### Design and Development of a Phantom for Commissioning and Quality Assurance of Intraoperative Gamma Probes

***A. Stapleton****, O. Berry, J. Grey, R. Harding, L. McKinley, E. Norman; Royal Surrey County Hospital, Guildford, UNITED KINGDOM.*

***Aim/Introduction:*** Intraoperative gamma probes are used for the localisation of areas of radiopharmaceutical uptake in vivo to support effective surgical procedures such as sentinel lymph node removal. As for all Nuclear Medicine equipment, these systems should undergo commissioning for performance characterisation and assessment against the manufacturer's specification. Similarly, continuing quality assurance ensures their fitness for purpose when in clinical use and following repair. NEMA NU-3 2004 provides guidance for appropriate testing on such equipment, however no commercial solutions exist to enable reproducible measurements to be made for the recommended tests on these probes. This work describes the design and development of a phantom able to support these commissioning and quality assurance tests. ***Materials and Methods:*** The test phantom comprises of: a tank to enable tests to be performed both in a scatter medium and in air; two radioactive source holders which allow the straightforward completion of angular and spatial resolution measurements; and a gamma probe holder with inserts allowing for different probe end dimensions including with and without collimators. The source holders have adapters to hold either sealed or unsealed radioactive sources. The unsealed radioactive source option comprises a small fillable sphere, typically to be used with Tc-99m or other clinically appropriate isotopes. Optionally, the sealed source holder can be deployed which securely holds radioactive pen sources including Co-57 pens. ***Results:*** The phantom has been used in the testing of multiple intraoperative gamma probes following the NEMA NU-3 guidance. The phantom enables straightforward performance of the following tests using sealed and unsealed sources: sensitivity in air; sensitivity in scatter; spatial resolution in a scatter medium;

volume sensitivity to distributed activity in a scatter; short-term sensitivity stability; count rate capability in a scatter medium; and angular resolution in a scatter medium. ***Conclusion:*** The phantom developed allows for simple and reproducible measurements for commissioning, post repair testing, and ongoing quality assurance. ***References:*** NEMA NU 3-2004 Performance Measurements and Quality Control Guidelines for Non-Imaging Intraoperative Gamma Probes Radioactive Sample Counting Principles and Practice (Institute of Physics Publishing, 2022) by Sofia Michopoulou (Editor) et al.

## OP-031

### Design and manufacture of a 3D printed phantom for PET quality control

***J. Robinson***[1,2], *D. Rushforth*[1,2], *I. Murray*[1,2], *G. Flux*[1,2], *J. Gear*[1,2];
[1]*The Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM,* [2]*The Institute of Cancer Research, London, UNITED KINGDOM.*

***Aim/Introduction:*** Complex analysis of PET scanner performance typically requires time-consuming phantom preparation, with the filling of multiple compartments with different activity concentrations. Mistakes made during this stage can necessitate repeat scans, potentially increasing system downtime. Long-lived, sealed phantoms can also be used, but are only available with uniform activity distributions, limiting evaluation to measurement of SUV or uniformity. It has been proposed to incorporate radioisotopes into the resin material of 3D printers, facilitating the production of complex designs for more sophisticated analysis. This project aimed to demonstrate this possibility by producing a lesion detection phantom with associated software for PET QC and system benchmarking. ***Materials and Methods:*** Phantom design was developed based on analysis of existing phantoms, alongside clinical PET data, such that it would test PET scanners in a clinically relevant manner, using a design which introduces performance tests not currently possible using commercially available phantoms.Simulated PET data was created, by applying Gaussian blur, pixel resampling and adding noise to the digital data. Iterations of the simulated images were used to optimise the ideal range of insert sizes and contrast ratios. After finalising the design, 80MBq 89Zr was added to the support resin of an Objet30-Pro 3D-printer and printed alongside the build resin to create the desired activity geometry. The phantom (110mm length, 140mm diameter) contained 40 radioactive cylinders ranging from 1.3 to 13.9mm in diameter. The background to insert activity concentration varied down the phantom at ratios of 3:2, 2:1, 4:1, 8:1 and 1:0.Imaging was performed using a list mode acquisition on a 128-slice PET/CT scanner. Reconstructions were performed for acquisition durations from 3s to 1h, with and without partial-volume correction. Dedicated software was developed to conduct ROC analysis and calculate AUCs to quantify image quality. ***Results:*** The phantom took 94 hours to print with suitable print quality and matching the original design specification. 89Zr remained uniformly distributed within the resin. Visual inspection of the images highlighted significant differences between the images reconstructed with different parameters. Quantitative analysis showed AUC to increase with acquisition duration, ranging from 0.60 to 0.92. Reconstructions with partial-volume corrections produced higher AUC than those without for acquisitions up to 2 minutes, with a maximum improvement in AUC of 8.5%. Beyond 2 minutes, images without partial-volume correction had consistently higher AUCs. ***Conclusion:*** Radioactive 3D printing is a promising tool and could be utilised for the manufacture of PET QC phantoms.

## OP-032

### Automatic trending and analysis of SPECT daily quality control data with optical character recognition AI

***T. Pan****, S. Ding, O. Mawlawi;*
*The University of Texas, M.D. Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** We have developed a QC server with an optical character recognition (OCR) AI system to store and trend the intrinsic/extrinsic uniformities and center of rotation (COR) metrics reported daily and weekly on the 13 SPECT/CT scanners. The aims are to improve the efficiency of daily/weekly QC review, and to provide trending, storage and auditing of the SPECT QC data on a large hospital network. ***Materials and Methods:*** A SPECT QC server has been designed and implemented to automatically query QC data of 13 SPECT/CT scanners of various models across multiple campuses on our hospital network. The data are sorted according to extrinsic uniformity (daily), intrinsic uniformity (weekly), COR (weekly) and bar pattern (weekly). All the reported QC values of integral/differential uniformities of central FOV (CFOV) and useful FOV (UFOV), COR, axial shift and back projection angle are extracted from the screen captured QC images by an OCR AI system and compared with the manufacturer specifications automatically. Our AI system utilizes deep learning models, including residual network, visual geometry group 16, connectionist temporal classification, which are designed for efficiency and accuracy while minimizing computational requirement. The QC results are viewable on the server webpage by a computer or mobile device such as iPad or iPhone. The QC server is built on a computer with the open-source software Ubuntu, Python, and Dicom toolkit. ***Results:*** QC review is more efficient on the new server with an OCR AI than our previous manual QC review on the hospital PACS. The major improvements are (1) automatic query of the QC data from the scanners (2) automatic extraction of the QC results by the OCR AI compared with the vendor's specification, and (3) trending and documentation of scanner and service issues including artifact floods can also be captured on the server for follow-up. ***Conclusion:*** We have developed a SPECT QC server with an OCR AI system to increase efficiency of QC review of 13 SPECT/CT scanners on a large hospital network. ***References:*** Shi B, Bai X and Yao C. "An End-to-End Trainable Neural Network for Image-Based Sequence Recognition and Its Application to Scene Text Recognition." ## OP-033

### AI-Based Automatic Positioning in a Digital-BGO PET/CT Scanner: Efficacy and Impact

***J. Kennedy***[1,2], *T. Palchan-Hazan*[1], *Z. Keidar*[1,2];
[1]*Rambam - Health Care Campus, Haifa, ISRAEL,* [2]*Ruth and Bruce Rappaport Faculty of Medicine, Technion–Israel Institute of Technology, Haifa, ISRAEL.*

***Aim/Introduction:*** A recently released digital solid-state positron emission tomography/x-ray CT (PET/CT) scanner with bismuth germanate (BGO) scintillators coupled to silicon photomultipliers provides an artificial intelligence (AI) based system for automatic patient positioning. The efficacy of this digital-BGO system in patient placement at the isocenter and its impact on image quality and radiation exposure was evaluated. ***Materials and Methods:*** A new digital-BGO PET/CT with a 32 cm axial field of view (FOV) and AI-based auto-positioning was compared ($\chi^2$, t-tests) to a solid-state lutetium oxyorthosilicate (digital-LSO) PET/CT with manual positioning (n=432 and 343 studies each, respectively). The digital-BGO system results were split into two

groups: before (n=292) and after (n=140) a recalibration of the auto-positioning camera. To measure the transverse displacement of the patient center from the scanner isocenter, CT slices covering 30 cm axially below the diaphragm were retrospectively selected and automatically analyzed using in-house software. Noise was measured as the coefficient of variance of absolute HU (Hounsfield units) above $HU_{air}$ within a 25 mm circular region-of-interest in a homogenous region of the liver. Radiation exposure was recorded as dose-length product (DLP). The isocenter displacement measurement was validated by the precise placement of a cylindrical phantom at 13 positions throughout the transverse FOV. ***Results:*** The phantom validation study gave <1mm error in isocenter displacement measurements. Patient isocenter displacement was biased 1.83±1.86 cm (mean±standard deviation) in the posterior direction for the digital-BGO and 2.02±1.81 cm for the digital-LSO (p=0.007). Left lateral displacements were −0.26±1.06 cm and 0.80±1.43 cm respectively (p<0.001). The average total isocenter displacement was 2.68±1.47 cm for the digital-BGO before recalibration, compared to 2.77±1.31 cm (no significant difference) for the digital-LSO. After recalibration, the digital-BGO isocenter displacement improved to 1.93±1.63 cm (p<0.001) and was superior to the digital-LSO (p<0.001). Also, after recalibration, 26% (36/140) of the studies had isocenter displacements >2.5cm for the digital-BGO, which was significantly better than the 49% (142/292, p<0.001) before recalibration or the 56% (191/343, p<0.001) for the digital-LSO. On average, image quality was superior for non-obese patients (BMI<30 $kg/m^2$) with arms up who were most closely aligned with the isocenter: noise increased by 3.3±0.1% for every 1 cm increase in isocenter displacement. DLP increased by 177±10 Gy·cm for every 1 cm increase in anterior isocenter displacement. ***Conclusion:*** AI-based automatic positioning in a digital-BGO PET/CT scanner significantly improves patient placement with respect to the isocenter, thereby improving image quality and ensuring proper radiation exposure.

## Clinical Oncology Track - TROP Session: Prostate Cancer Staging

### OP-034

**Association of aggressive prostate cancer features on whole-mount pathology with quantitative measures on PSMA PET**

***I. Sonni***[1,2], *D. H. Kim*[1], *A. Ter-Pogosyan*[1], *T. Grogan*[1], *N. Barroso*[1], *P. Ahuja*[1], *J. Calais*[1], *A. Sisk*[1], *S. Raman*[1];
[1]*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Università Magna Graecia, Catanzaro, ITALY.*

***Aim/Introduction:*** Two distinct morphologic entities of prostate cancer (PC), the intraductal carcinoma (IDC) and the large cribriform growth pattern, are associated to more aggressive disease, high Gleason scores, advanced tumor stage, biochemical relapse, and distant metastasis. Predicting the presence of these pathology features could be of significant help in case whole-mount pathology (WMHP) is unavailable. The goal of this analysis was to assess the distribution of quantitative PSMA-PET parameters in lesions with and without cribriform/IDC patterns on pathology. We assessed the ability of pre-surgical PSMA-PET metrics to predict the presence of aggressive pathology features. ***Materials and Methods:*** With IRB approval and HIPAA compliance, we derived a study cohort of all PC patients who underwent 68Ga-PSMA-11 PET/CT (PSMA-PET) within 3 months of robotic radical prostatectomy (RALP) and WMHP and description of presence/absence of cribriform/IDC pattern between 05/2019 and 08/2022.A board-certified nuclear medicine physician contoured all PC lesions on PSMA-PET, matching each lesion with WMHP. PSMA-PET metrics (SUVmax, SUVmean, total lesion activity - TLA) were extracted for the image analysis.The analysis only included true positive lesions that were categorized as: (a) cribriform+/IDC- (b) cribriform+/IDC+, (c) cribriform-/IDC-. One way-ANOVA Welch test was used to identify differences among the imaging parameters in the three groups. The area under the curve (AUC) from ROC analysis was used to assess the ability to predict presence of cribriform and/or IDC pattern on pathology based on imaging parameters on PSMA-PET. ***Results:*** The study cohort comprised 77 patients (median age at time of RALP: 64±6.95 years), and 82 lesions on WMHP. The serum PSA levels at time of RALP was 9.07 ng/ml ± 5.8. On WMHP, cribriform+/IDC- was described in 21/83 lesions, cribriform+/IDC+ in 41/83 lesions, cribriform-/IDC- in 20/83 lesions. The SUVmean and TLA were statistically different among the three groups (p=0.003 and 0.039), whereas SUVmax was not (p=0.062). In the cribriform+/IDC-, cribriform+/IDC+, and cribriform-/IDC- group, average (SD) SUVmean was 6.7 (4.1), 5.9 (2.7), 4.5 (1), SUVmax was 13.7 (8.4), 11.7 (6.9), and 9.3 (4.1), and TLA was 27.1 (26), 53.8 (68.5), and 21.7 (26), respectively. AUC showed that SUVmean predicts the presence of features of aggressive PC on WMHP with 67% accuracy (p=0.03). ***Conclusion:*** SUVmean was significantly lower in cribriform-/IDC- lesions, TLA was significantly higher in cribriform+/IDC+ lesions. SUVmean on PSMA PET predicted aggressive pathology with moderate AUC on ROC analysis.

### OP-035

**The role of PSMA PET/CT in the diagnosis of clinically significant prostate cancer**

***A. Kibar***[1], *O. E. Sahin*[1], *S. Asa*[1], *M. Demirbilek*[2], *S. Bilgic*[3], *B. Onal*[2], *L. Kabasakal*[1];
[1]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Urology, Istanbul, TÜRKIYE,* [3]*Sirnak State Hospital, Department of Nuclear Medicine, Sirnak, TÜRKIYE.*

***Aim/Introduction:*** Follow-up of patients reported as Gleason 3+3 prostate cancer as a result of prostate biopsy is a controversial issue. It is an important decision which patients should be actively monitored and which should be referred for surgery. In our study, we wanted to investigate the guiding role of PSMA PET/CT imaging performed on patients whose prostate biopsy results were reported as Gleason 3+3, in the diagnosis of clinically important prostate cancer (ISUP 2 and above). ***Materials and Methods:*** 76 patients who were reported as Gleason 3+3 prostate cancer as a result of TRUS biopsy and who were operated afterwards, mostly due to abnormal MRI findings, were selected. Of these patients, 44 had PSMA PET/CT, 68 had MRI, 36 had both imaging. Patients who had Ga-68 PSMA PET imaging were classified according to their PRIMARY scores(1). They were divided into two groups as PRIMARY 1-2 (negative) and PRIMARY 3-4-5 (positive). Patients with MRI imaging were divided into two groups as those with PIRADS 1-2 (negative) and those with PIRADS 3-4-5 (positive).

The operation results of these groups (ISUP 1 vs >ISUP 2) were compared. ***Results:*** 15 patients were classified as PRIMARY 1-2 and 29 patients were classified as PRIMARY 3-4-5. The sensitivity, specificity, positive predictive value and negative predictive value were 80.77%, 55.56%, 72.41%, 66.67%, respectively. 54 patients were classified as PIRADS 1-2 and 14 patients were classified as PIRADS 3-4-5. The sensitivity, specificity, positive predictive value and negative predictive value were 83.33%, 26.92%, 64.81%, 50%, respectively. In 36 patients who underwent both PSMA PET and MR imaging; the sensitivity, specificity, positive predictive value and negative predictive value of PSMA PET were 76.19%, 60%, 72.73%, 64.29%, and MRI were 90.48%, 20%, 61.29%, 60%, respectively. Also, according to independent samples t-test, while PSMA PET can predict clinically important prostate cancer significantly, while MRI can not (P values: 0.0032 and 0.392 respectively). ***Conclusion:*** Ga-68 PSMA PET/CT can be an important guide, mostly because of its high positive predictive value, in diagnosing clinically important prostate cancer in patients with Gleason 3+3 as a result of biopsy and helps in deciding for follow-up or operation. In our study, PSMA PET's positive predictive value, negative predictive value and specificity were found to be higher than MRI. ***References:*** 1) Emmett L, Papa N, Buteau J, et al. The PRIMARY Score: Using Intraprostatic 68Ga-PSMA PET/CT Patterns to Optimize Prostate Cancer Diagnosis. J Nucl Med. 2022;63(11):1644-1650. doi:10.2967/jnumed.121.263448

## OP-036

### In-depth analysis of PSMA PET/CT and mpMRI discrepancies in prostate cancer detection with histopathology gold standard

***I. Sonni***[1,2], *S. Doddipalli*[1], *M. Deol*[1], *D. Ban*[1], *H. Kim*[1], *T. Grogan*[1], *N. Barroso*[1], *P. Ahuja*[1], *Y. Zong*[1], *A. Sisk*[1], *J. Calais*[1], *R. Reiter*[1], *S. Raman*[1];
[1]*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Università Magna Graecia, Catanzaro, ITALY.*

***Aim/Introduction:*** Multiparametric MRI (mpMRI) and PSMA-PET provide complementary information in the pre-surgical evaluation of patients with prostate cancer (PCa). The aim of this analysis was to evaluate the factors associated with PSMA-PET and MRI agreement/disagreement with each other and with gold standard histopathology. ***Materials and Methods:*** All patients who underwent radical prostatectomy (RP), pre-surgical PSMA-PET, and mpMRI were screened for this study. Included patients had two imaging scans done <3 months from each other, and whole mount histopathology (WMHP) slides available, with ISUP grade group (GG) classification. Two nuclear medicine physicians and 2 radiologists manually contoured PCa lesions on PSMA-PET and mpMRI, respectively. A consensus read was done with a third reader for each modality, and a majority rule was applied (2:1). Quantitative measures were extracted on a lesion-basis (SUVmean, SUVmax, tumor volume). A PET/MRI fusion was obtained, and agreement/disagreement was assessed visually, based on the overlapping lesion contours. WMHP slides were used to establish the agreement/disagreement between imaging-identified lesions and WMHP. One-way ANOVA and ROC analysis were used to assess differences among groups and accuracy in predicting agreement/disagreement. ***Results:*** The cohort included 114 patients, and 175 pathology lesions were identified (ISUP 3, n=22; ISUP>3, n=153). PSMA-PET and mpMRI identified 170 and 136 lesions, respectively. Sensitivity for ISUP>3 lesions was 80% and 87% for mpMRI and PSMA-PET, respectively. 117/153 (76%) ISUP>3lesions were correctly identified and 15/153 (10%) missed by both imaging modalities, respectively. 5/153 (3%) were correctly identified by mpMRI and missed by PSMA-PET, 16/153 (10%) were correctly identified by PSMA-PET and missed by mpMRI. Lesion's ISUP GG and size on pathology were significantly lower in PET- compared to PET+, and in mpMRI- compared to mpMRI+ lesions. Lesion's ISUP GG and size were significantly correlated to PSMA-PET and MRI agreement, whereas PSMA-PET metrics were not. SUVmax, SUVmean, and tumor volume on PSMA-PET were significantly higher in true positive (TP), compared to false positive (FP) lesions on PSMA-PET. ROC curve analysis showed that an SUVmax of 5.17, SUVmean of 4.67 and a tumor volume of 0.54 on PSMA-PET accurately discriminated a TP from a FP finding (AUC 0.85, 0.82 and 0.78, respectively). ***Conclusion:*** Higher SUVmax, SUVmean and tumor volume on PSMA-PET were associated with a TP finding on PSMA-PET, higher ISUP grade group and size on pathology were associated with a TP finding on both PSMA-PET and mpMRI, and with agreement between PSMA-PET and mpMRI.

## OP-037

### Baseline PSMA PET-CT is prognostic for treatment failure in men with intermediate-to-high risk prostate cancer: 54 months follow-up of the proPSMA randomised trial

***M. Hofman***[1], *V. Kasivisvanathan*[1], *E. Link*[1], *N. Lawrentschuk*[1], *J. O'Brien*[1], *J. P. Buteau*[1], *M. Roberts*[2], *R. Francis*[3], *C. Tang*[4], *I. Vela*[5], *P. Thomas*[6], *N. Rutherford*[7], *J. M. Martin*[6], *M. Frydenberg*[8], *R. Shakher*[9], *L. Wong*[10], *K. Taubman*[11], *S. Lee*[12], *E. Hsiao*[13], *M. Nottage*[14], *I. Kirkwood*[15], *A. Iravani*[1], *S. ***Aim/Introduction:*** The proPSMA randomised controlled trial demonstrated the superior accuracy of PSMA PET-CT over conventional imaging for detecting nodal and distant metastatic disease in prostate cancer[1]. However, the clinical implications of PET findings remain unclear. This pre-specified secondary objective evaluates the prognostic value of PET-detected nodal involvement in patients without distant metastases using baseline $^{68}$Ga-PSMA-11 PET-CT. ***Materials and Methods:*** Patients with intermediate-to-high risk prostate cancer (ISUP grade group 3-5, PSA ≥20 ng/ml or clinical stage ≥T3) received PSMA PET-CT as first or second-line imaging. Patients without distant metastatic disease (M0) were grouped based on PSMA PET-CT nodal status (N0 or N1) and monitored for up to 54 months. Treatment failure was defined by biochemical failure (PSA >0.2ng/ml after surgery or rise by 2ng/ml above nadir after radiotherapy), initiation of salvage therapy, or development of distant metastatic disease. Kaplan-Meier curves were used to estimate freedom from treatment failure based on PET-CT and CT/bone scan classifications for N0 and N1 cancer. Cox proportional hazards were employed to calculate hazard ratios (HR) for freedom from treatment failure. Clinical trial registry: ANZCTR12617000005358. ***Results:*** Among 302 patients randomised across 10 sites, 294 underwent a PSMA PET-CT. 251 patients with M0 disease and median follow-up

of 41.0 (95%CI 40.1-41.9) months were included in this analysis. Patients were treated with curative-intent surgery or radiotherapy with or without androgen deprivation. During follow-up, biochemical failure alone occurred in 48/251 (19%) patients, salvage therapy commenced in 57/251 (23%) and development of distant metastatic disease in 13/251 (5%) during follow-up. PSMA-PET defined N0M0 patients had longer freedom from treatment failure than N1M0 patients, with a HR of 2.1 (95%CI 1.2-3.7), p=0.01. At 3 years, 70% (95%CI 64 - 76) with N0M0 versus 46% (95%CI 26 - 64) with N1M0 remained free from treatment failure. CT and bone scan defined N1M0 versus N0M0 was not prognostic (HR 0.6, 95%CI 0.1-2.4, p=0.45). ***Conclusion:*** For patients with intermediate-to-high risk prostate cancer and no distant metastases, PSMA PET-CT regional nodal status is prognostic for medium-term oncologic outcomes, outperforming conventional imaging in identifying patients at higher risk of treatment failure.
***References:*** [1] Lancet. 2020 Apr 11;395(10231):1208-1216. doi: 10.1016/S0140-6736(20)30314-7.

## OP-038

### Radio-guided surgery with DROP-IN beta probe for 68Ga-PSMA, in high-risk prostate cancer patients eligible for robotic-assisted radical prostatectomy.

***F. Ceci***[1], *F. Collamati*[2], *S. Luzzago*[3], *F. A. Mistretta*[3], *L. Muraglia*[1], *G. Renne*[4], *R. Mirabelli*[2], *S. Morganti*[5], *O. De Cobelli*[3], *N. Fusco*[4], *G. Musi*[3];
[1]*Division of Nuclear Medicine, IEO European Institute of Oncology, IRCCS, Milan, ITALY,* [2]*INFN National Institute of Nuclear Physics, Section of Rome, Rome, ITALY,* [3]*Division of Urology, IEO European Institute of Oncology, IRCCS, Milan, ITALY,* [4]*Division of Pathology, IEO European Institute of Oncology, IRCCS, Milan, ITALY,* [5]*INFN National Institute of Nuclear Physics, Section of Rome, Milan, ITALY.*

***Aim/Introduction:*** The primary aim of this analysis was to evaluate the diagnostic accuracy of the combined approach with a DROP-IN positron detector (β-Probe) and 68Ga-PSMA-11 PET/CT (PSMA-PET) in the correct identification of lymph node metastases, in high-risk prostate cancer (PCa) patients undergoing robotic radical prostatectomy (RARP) and extended pelvic lymph-node dissection (ePLND). The standard of reference was the histopathological analysis. ***Materials and Methods:*** This is a prospective, single-arm, single-center, non-interventional, phase II trial (NCT05596851), aimed at enrolling fifteen (n=15) PCa patients. We present an interim analysis in the first eight consecutive (n=8) patients enrolled. Inclusion criteria were: a) biopsy proven, high-risk PCa; b) patients candidate to RARP + ePLND as primary therapy; c) PSMA-PET performed within 6 weeks prior to surgery; d) PSMA-positive nodes in PSMA-PET; e) age>18. The surgery procedure started with the intravenous injection of 1.1 MBq/Kg of 68Ga-PSMA-11 directly in the surgery theatre. After the injection the surgery procedure proceeded first with ePLND followed by RP. The in-vivo measurements of the surgery templates with β-Probe were performed with a DROP-IN system, inserting the probe into a trocar. All removed nodes were also measured ex-vivo. The tumor-to-background-ratio (TBR) was evaluated graphically in a display showing real-time counts per time. Furthermore, a dedicated, operator-independent, algorithm to reliably identify pathologic vs. non-pathologic nodes was developed. PSMA-staining was performed in all specimens. Data derived by the PSMA-PET, β-Probe and histopathological analysis were compared in a per-region analysis. ***Results:*** The live β-Probe-guided ePLND was a feasible procedure, without significant changes in the surgery practice. No side effects have been observed during ePLND. In total, 64 specimens were removed and analyzed. Pathology results were used to validate in vivo and ex-vivo β-Probe counts interpreted according to the operator-indipendent algorithm. Four (n=4) false positive and seven (n=7) false negative findings were detected. The intra-operative β-Probe sensitivity to detect PCa nodal metastasis was 76.7%, while specificity was 88.2%. ***Conclusion:*** These are the first ever published data derived from a live surgery experience using a β-Probe to identify PSMA-positive lymph nodes. This new approach proved to be feasible and safe. Visual TBR interpretation (operator-dependent) revealed to be more challenging than expected. After the implementation of a dedicated, operator-independent, algorithm for the identification of a cut-off in TBR analysis, the diagnostic accuracy improved. The completion of this phase II trial will provide more data about the efficacy of this new generation image-guided approach.

## OP-039

### [$^{68}$Ga]PSMA PET/CT vs. mpMRI in patients with suspicion of prostate cancer and previous negative biopsy: preliminary data from PROSPET-BX trial.

***E. Lopci***, *M. Lazzeri, L. Disconzi, P. Colombo, A. Saita, D. Maffei, V. Fasulo, R. Hurle, K. Marzo, L. Leonardi, R. Peschechera, A. Benetti, S. Zandegiacomo, L. Pasini, J. Jandric, R. Zanca, P. Casale, M. Rodari, L. Balzarini, G. Guazzoni, N. Buffi, G. Lughezzani;*
*IRCCS - Humanitas Research Hospital, Rozzano MI, ITALY.*

***Aim/Introduction:*** Herein we present the preliminary data obtained from our prospective trial, designed to compare in parallel [$^{68}$Ga]PSMA PET/CT with mpMRI/TRUS fusion prostate biopsy in men with high suspicion of prostate cancer (PCa) after at least one negative biopsy. ***Materials and Methods:*** Patients enrolled from April 2022 until April 2023, have been considered for the analyses. Inclusion criteria: PSA level >4.0ng/ml; free-to-total PSA ratio <20%; progressive rise of PSA levels; serum blood tests suspicious for PCa; at least one previous negative biopsy; ASAP and/or high-grade PIN; negative DRE. All eligible patients have undergone [$^{68}$Ga]PSMA PET/CT and mpMRI scans, followed by biopsy session within one month distance. TRUS-fusion needle biopsy has been performed for all lesions detected with PET and mpMRI. ***Results:*** At present, 60 patients have been enrolled, of which 50 have already completed the diagnostic pathway and have undergone prostate biopsy. Median age is 64 years (range 51-83) and median PSA 10.5 ng/ml (range 4.49-25). The majority of the patients had undergone one previous biopsy, while 8 patients (16%) had more biopsy sets. Median SUVmax and SUVratio of targeted areas resulted 3.7 (range 1.7-41.99) and 1.5 (range 0.74-14), respectively. According to re-biopsy results, 7 patients presented with clinically significant PCa (csPCa), 3 with GS 6, while the majority had a negative biopsy (80%). mpMRI showed the following findings: 31 patients with PI-RADS 2 (62%), 2 with PI-RADS 3 (4%), 12 patients with PI-RADS 4 (24%), and 5 patients with PI-RADS 5 (10%). Median SUVmax and SUVratio resulted 3.6 and 1.3 for benign versus 8.9 and 3.2 for malignant lesions, respectively (P<0.001). While csPCa presented with a median SUVmax and SUVratio of 12.8 and 6.7, respectively. ROC analyses allowed to identify optimal cut-off points for malignancy and csPCA, which resulted for SUVmax >6 (AUC 0.746) and >7.48 (AUC 0,819), respectively, whereas for SUVratio the cut-off was >2.79 in both cases (AUC 0.808 versus 0.833, respectively). When combining [$^{68}$Ga]PSMA PET/CT with mpMRI data, all unnecessary prostate re-biopsies could be spared, i.e. 80% of the cohort , while granting a detection rate of 90% for PCa. ***Conclusion:*** In these

very preliminary results, the combination of [$^{68}$Ga]PSMA PET/CT with mpMRI in patients candidate to rebiopsy, can help increase the detection rate of prostate cancer lesions up to 90%, by spearing all unnecessary repeat biopsies. ***References:*** This study is financially supported by Ministero della Salute with the Grant GR-2018-12366240.

## OP-040

### Pre-surgical $^{68}$Ga-PSMA-11 PET for biochemical recurrence risk assessment: a surrogate of Pelvic Lymph Node Dissection? Follow-up analysis of a Multicenter Prospective Phase 3 Imaging Trial.

***L. Djaileb***[1], *W. Armstrong*[2], *D. Thompson*[3], *A. Gafita*[2], *A. Farolfi*[2], *T. Grogan*[2], *M. Cooperberg*[4], *P. Carroll*[5], *S. Washington*[4], *R. Reiter*[6], *J. Czernin*[2], *H. Thomas*[3], *J. Calais*[2];
[1]*University Grenoble-Alpes, INSERM, CHU Grenoble Alpes, Nuclear Medicine Department, LRB, Grenoble, FRANCE,* [2]*UCLA, Los Angeles, CA, UNITED STATES OF AMERICA,* [3]*Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, UNITED STATES OF AMERICA,* [4]*Department of Urology, University of California, San Francisco, CA, UNITED STATES OF AMERICA,* [5]*Department of Urology, University of California, San Francisco, UCSF, CA, UNITED STATES OF AMERICA,* [6]*Institute of Urologic Oncology, University of California, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** To compare the prognostic value of presurgical PSMA-PET and pelvic lymph nodes invasion (pN1) for biochemical recurrence (BCR) free-survival (FS) in patients with intermediate-risk to high-risk prostate cancer (PCa) treated with radical prostatectomy (RP) and pelvic lymph node dissection. ***Materials and Methods:*** This is a follow-up study of the surgery cohort included in the multicenter prospective phase 3 imaging trial (n=277; NCT03368547, NCT02611882, NCT02919111). Each $^{68}$Ga-PSMA-11-PET scan was read by three blinded independent readers. Local histopathology risk score (CAPRA-S (Cancer of the Prostate Risk Assessment) score without pN data), PSMA-PET extra-prostatic disease (N1/M1), and pN were used to assess risk of BCR. Patients were followed up after RP by the local investigators using electronic medical records. BCR was defined by a prostate-specific antigen (PSA) level ≥0.2 ng/ml after RP or an initiation of PCa specific secondary treatment (>6 months after surgery). Univariate, multivariate Cox model, and c-statistic index were performed to assess the prognostic value of PSMA-PET, LNI and its added value to Local histopathology risk score. ***Results:*** From December 2015 to December 2019, 277 patients underwent surgery after PSMA-PET. Clinical follow-up was obtained in 240/277(87%) patients. Median follow-up from surgery was 32.4 (IQR 23.3-42.9) months. Ninety-one/240 BCR events (38%) were observed. PSMA-PET N1/M1 and pN1 were found in 41/240 (17%) and 67/240 (28%) patients respectively. Local histopathology risk score, PSMA-PET and pN were significant univariate predictors of BCR. Only Local histopathology risk score and PSMA PET were significant in multivariate analysis (HR [95% CI] 1.4 (1.2-1.5) p<0.0001) and (1.7 (1-2.9) p=0.03). Prognostic value of model combining local histopathology and PSMA-PET was not significantly different than model combining local histopathology and pN (c-statistic 0.74 (0.69-0.79) vs 0.73 (0.68-0.78); p= 0.69). In patient group with low-risk Local histopathology score and PSMA-PET N0-M0 only 4/109 (5%) were pN1. In patients with high-risk local histopathology score, a PSMA-PET N1/M1 was associated with a significant lower BCR-FS than a PSMA-PET N0-M0 (median survival (95% CI) 32.7 (14.9-NR) vs 8 (3.2-15.5) p= 0.001). pN1 was found in respectively 25/34 (74%) and 34/90 (38%)**.** ***Conclusion:*** Combination of pre-surgical PSMA-PET and Local histopathology was not statistically different than the reference standard, i.e local histopathology and pN to predict BCR-FS. Interestingly rate of discrepancy with pN was low among patient with low histopathology risk and PSMA-PET (N0-M0) and patient with high histopathology risk and PSMA-PET (N1/M1).

## OP-041

### Updated Automated PROMISE assessment: Treatment response evaluation approach on metastatic prostate cancer patients based on PSMA PET/CT

***S. Duriseti***[1,2], *H. Sahlstedt*[3], *J. Brynolfsson*[3], *G. Berenji*[1,2], *S. Tsai*[2], *N. Kane*[1], *W. Fendler*[4], *M. Rettig*[1,2], *N. Nickols*[1,2];
[1]*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Greater Los Angeles VA Medical Center, Los Angeles, CA, UNITED STATES OF AMERICA,* [3]*Exini Diagnostics AB, Lund, SWEDEN,* [4]*University of Essen, Essen, GERMANY.*

***Aim/Introduction:*** The response evaluation criteria in prostate-specific membrane antigen (PSMA) PET/CT (RECIP) were recently presented by Gafita et al. and has since been included in the second version of Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE v2). However, manual measurement of total tumour volumes (TTV) and lesion tracking between multiple time points are cumbersome. We evaluated software-aided longitudinal tracking of 18F-DCFPyL-avid lesions to generate a RECIP class for each evaluated patient. ***Materials and Methods:*** RECIP compares PSMA tracer-avid lesions from a baseline PET (bPET) and a follow-up PET image (fPET), and then classifies the response as either complete response (CR, no tracer avidity in the fPET), partial response (PR, TTV decrease of ≥30% without new lesions), progressive disease (PD, TTV increase ≥20% and new lesions), or stable disease (SD, defined as neither CR, PR, nor PD). Here, PSMA tracer-avid lesions were identified using an automated detection algorithm employing convolutional neural networks trained and validated on separate 18F-DCFPyL PET/CT image sets. The detected lesions were manually approved, and if needed, corrected by an experienced clinician. TTV was also calculated by the detection algorithm. The bPET and fPET were co-registered to automatically match individual lesions. Co-registered fPET and bPET lesions were considered a match if they were from the same anatomic disease compartment (prostate/prostate bed, lymph node, bone, or visceral) and had either overlap or a centre-of-masses distance <10 mm (for rib lesions, this distance was <50 mm to account for respiratory motion). The automated RECIP was evaluated on 33 patients, each with one bPET and one fPET acquired, both with 18F-DCFPyL. Of the 33 cases, 9 were manually categorized as CR, 8 as PR, 12 as SD, and 4 as PD.For each lesion annotated in the fPET, a match was sought in the corresponding bPET. If a match was not found, the lesion was denoted as a "new lesion". ***Results:*** The algorithm automatically assigned the correct RECIP classification in all cases. There were 217 total lesions identified in all bPET images, and 100 total lesions in the fPET images, respectively. The automated algorithm matched 61 bPET lesions to 53 lesions in the corresponding fPET. The remaining 47 fPET lesions were considered "new lesions." ***Conclusion:*** For response assessment using 18F-DCFPyL PET/CT and RECIP criteria, the automated algorithm and manual detection achieved the same clinical classifications. The precision and accuracy this automated process is being validated in prospective clinical studies.

## OP-042

### PSMA PET/CT for the Targeting of Prostate Biopsies: Additional Value over MRI?

***C. J. W. M. Morré***[1], *J. J. Boer*[1], *S. P. Rynja*[1], *M. J. Hagens*[2], *M. A. Noordzij*[1];
[1]*Spaarne Gasthuis, Hoofddorp, NETHERLANDS,* [2]*Antoni van Leeuwenhoek cancer institute, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Current guidelines recommend MRI-directed targeted prostate biopsies (TBx) and systematic prostate biopsies (SBx) for diagnosing prostate cancer (PCa), but performing only TBx has shown to miss approximately 15% of clinically significant PCa (csPCa) cases. While PSMA PET/CT is increasingly used for metastatic screening, recent literature has suggested its diagnostic value for detecting local disease and targeting prostate biopsies. This retrospective pilot study aimed to compare PSMA-directed biopsies to MRI-directed Tbx in detecting csPCa. ***Materials and Methods:*** The study identified men subjected to PSMA PET/CT between November 2020 and December 2022, within six months after prostate MRI and prostate biopsies from a comprehensive institutional database. Indications for PSMA PET/CT were: PSA > 20, stage $T_{3-4}$ and aggressive histology (ISUP ≥ 3). Abnormalities found on prostate MRI (PI-RADS classification V2.1), PSMA PET/CT (classified as normal, inconclusive, or suspect), and biopsies (ISUP grade groups) were localized according to the Ginsburg protocol, a protocol dividing the prostate into twenty-four sectors along the transversal plane. The study used $^{18}$F-JK-PSMA-7 as a PSMA tracer on a EARL accredited PET-CT scanner. The maximum standardized uptake value ($SUV_{max}$) was measured for each suspicious lesion on the PSMA PET/CT. The analysis was conducted on the level of the Ginsburg regions. ***Results:*** A total of 366 men were included in the analysis, with both TBx (PI-RADS 3-5 regions) as well as SBx (PI-RADS 1-2 regions) taken. PSMA PET/CT was concordant with MRI in 56.5% of regions (1237 of 2190). PSMA classification was strongly correlated with ISUP scores on prostate biopsies from the corresponding region (Chi2-test, p=<0.001). For normal MRI regions (PI-RADS 1-2), where SBx were taken, csPCa was found in 32% (194 of 611), of which PSMA PET/CT detected 88% (169), with specificity of 40%. The median $SUV_{max}$ per ISUP grade group was 4.8 for Ginsburg regions with benign histology, 10.6 for ISUP 1-2 (clinically insignificant PCa), and 17.5 for ISUP 3-5 (csPCa). Measured in the normal MRI regions, the $SUV_{max}$ was 5.0, 13.4, and 18.4, respectively. ***Conclusion:*** PSMA PET/CT identifies more csPCa cases compared to MRI while distinguishing high- from low-grade PCa. However, it results in more false-positive results. The $SUV_{max}$ appears to be a promising indicator for (cs)PCa. The retrospective design of this study makes it uncertain whether regions with high uptake without biopsy data may yield more false-positive results. Further research is needed to determine whether similar results are observed in a broader population.

### Aging and changes in intrinsic connectivity networks of the brain

***S. Ha****, I. Chung, W. Ryoo, J. Min, S. Kwon, J. O;*
*The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT scan evaluates glucose metabolism and can be used as a proxy for neural activity of brain. Local changes as well as the cooperative network characteristics of various regions of the brain are important in understanding how the human brain works. The purpose of this study is to observe changes in intrinsic brain networks during normal aging. ***Materials and Methods:*** A total of 827 PET/CT scans obtained from 357 healthy individuals (male/female=334/23, age=32-90) who underwent health checkups at a single institution from January 2009 to July 2022 were analyzed. The PET slices of the brain were separated and spatial and intensity normalized using Statistical Parametric Mapping (SPM) 8. Independent Component Analysis (ICA) with threshold Z >2 was used to generate masks of 21 intrinsic connectivity networks (ICN). The sum of SUVR in each ICN within each subject was defined as total glycolysis of ICN (ICN-TG). Spearman's test was performed on age and ICN-TG to test linear change during aging. Significant ICN-ICN interrelationship was identified with Spearman's test (rho) of ICN-TG for the entire age group. In order to find ICN-ICN combinations with age-related differences, Fisher's Z-test was used to examine the rho between the ICN-TGs of individuals in their 30s and 80s. The connectivity strength measured by Spearman's correlation, rho, of ICN-TG between the 30s and 80s was transformed as a Z-score for each age group (30's, 40's, 50's, 60's, 70's, and 80's) and analyzed using cubic regression according to age. Multiple testing correction was performed with the Benjamini-Hochberg procedure with adjusted p-value less than 0.05. ***Results:*** Among the 21 ICNs, negative correlations were found between age and ICN-TG in 20 ICNs. Twenty-seven ICN-ICN combinations showed significant connectivity across all ages, with differences in connection strength between individuals in their 30s and 80s. 26 ICN-ICN combinations showed significantly lower connection strength in individuals in their 80s compared to those in their 30s. The connectivity of 26 ICN-ICN combinations showed a good fit for cubic regression (R2, range 0.681-0.980; adjusted p <0.05) and demonstrated two decreasing slopes, one generally in ages 30s-40s and another for ages 60s and older. ***Conclusion:*** During normal aging, intrinsic brain networks may show a continuous

decline in neural activity, and the connectivity strength between functionally connected ICN-ICN may also gradually weaken. These aging-related weakening of connectivity accelerates during young adulthood, slows down in middle age, and accelerates again during old age.

## OP-045

### Dynamic reconfiguration of metabolic brain connectivity during progression from MCI to Alzheimer's disease dementia

***S. Caminiti***[1], *A. Galli*[2], *A. Sala*[3], *M. Inglese*[4], *L. Presotto*[5], *C. Tassorelli*[1], *D. Perani*[6], *the Alzheimer's Disease Neuroimaging Initiative;*
*[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, ITALY, [2]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, ITALY, [3]GIGA Consciousness, University of Liege, Liege, BELGIUM, [4]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Roma, ITALY, [5]Department of Physics, University of Milano-Bicocca, Milano, ITALY, [6]Vita-Salute San Raffaele University, Milano, ITALY.*

***Aim/Introduction:*** We investigate brain connectivity reconfigurations along the progression from mild cognitive impairment (MCI) to Alzheimer's disease (AD) dementia, using a longitudinal design based on brain metabolic information provided by FDG-positron emission tomography (FDG-PET) at three time points obtained from ADNI. ***Materials and Methods:*** We analyzed the FDG-PET images of patients with AD according to the ATN-classification in MCI (AD-MCI, N=31), mild dementia (mild-AD, N=31) and full-blown dementia (AD-D, N=20) stages. A group of age/sex-matched healthy controls (HC) was longitudinally evaluated for comparison. Grey-matter parcellation was applied for whole-brain network construction. Pearson correlations were calculated between each pair of regions across subjects to obtain adjacent matrices. Z-test was run between adjacent matrices of clinical group and matched HC group to extract metabolic connectivity alterations for each time point. Levels of connectivity alterations were quantified for each time point with summary indices. The obtained indices also served as input for k-means (KM) cluster analysis. In a first approach each time point was clustered individually to describe stage-specific connectivity alterations (KM1). A second approach clustered the three time points longitudinally, to describe patterns of connectivity reconfiguration along the AD course (KM2). ***Results:*** The AD-MCI showed less connectivity alterations than the mild-AD and AD-D, specifically characterized by relatively higher numbers of gained than lost connections. KM1 analysis identified two clusters: "altered cluster" and "spared cluster". In AD-MCI, altered cluster involved connections of subcortical and limbic regions, occipito-parietal cortices, and cerebellum. At mild-AD and AD-D stages, the altered cluster involved a large portion of connections within occipito-parietal cortices and cerebellum. The KM2 identified four different clusters: Cluster1 included nodes with low levels of lost and gained connections in frontal cortex, insula, and basal ganglia across the whole disease course; Cluster2 grouped nodes with high levels of gained connections in occipito-tempo-ro-parietal regions; Cluster3 grouped nodes with high levels of lost connections in subcortical and limbic regions; in Cluster4 only the precuneus showed the highest levels of connectivity alterations, both as loss and gain, which remained consistently present along the whole disease course. ***Conclusion:*** The connectivity alterations initially involve limbic and AD-prototypical cortical regions, with prevalent hyperconnectivity, which might represent an early phase response to the neurodegenerative processes. As disease progresses, the most altered connectivity is limited to the cortical associative regions and cerebellum only. Moreover, our results shed light on the critical role of precuneus in the dynamic connectivity reconfigurations of AD pathology.

## OP-046

### Is energy consumption linked to structural and functional connectivity in the healthy human brain?

***Y. Mayr***[1], *A. Lizarraga*[1], *A. Sala*[1,2,3], *I. Yakushev*[1];
*[1]Department of Nuclear Medicine, Klinikum rechts der Isar, Technical University of Munich, Munich, GERMANY, [2]Coma Science Group, GIGA-Consciousness, University of Liege, Liege, BELGIUM, [3]Centre du Cerveau2, University Hospital of Liege, Liege, BELGIUM.*

***Aim/Introduction:*** Operation of any communication system requires energy input. Consumption of glucose, the main source of energy for the brain, was shown to correlate with functional connectivity, while its relationship to structural connectivity remains unexplored. Here, we studied the relationship between glucose metabolism and structural as well as functional connectivity in the healthy human brain. ***Materials and Methods:*** We analyzed diffusion weighted imaging (DWI), resting-state functional magnetic resonance imaging (fMRI), and fluorodeoxyglucose (FDG) positron emission tomography (PET) data of 56 healthy, middle-aged individuals. Brain volumes were spatially parcellated into 106 regions. Regional standard uptake value ratio (SUVr) was calculated by division with the mean uptake in the whole gray matter. Structural connectivity (SC) was estimated from the DWI data by probabilistic tractography. Functional connectivity (FC) was estimated from the fMRI data. FC weights were computed as Pearson correlation between blood-oxygen-level-dependent signals of each pair of regions. Using graph theory, we calculated Spearman correlation (r) between node strength and regional SUVr. The node strength of a region is defined as the sum of all its connectivity weights. To understand how each connection individually contributes to regional SUVr, we fitted multiple linear regression (MLR) models between connectivity weights and SUVr. Herewith, the complete dataset was split into training (80%) and test (20%) sets, stratified by region. Significance level=0.05 with Bonferroni correction; confidence interval was estimated from 10,000 bootstraps. ***Results:*** Across subjects, median SUVr mildly correlated with median SC ($r=0.29$, $p=0.002$) and FC ($r=0.35$, $p<0.001$) node strength. With MLR, SC explained around half of the variance in SUVr (training $R^2=0.48$, test $R^2=0.49$), and 42 of the 106 predictors were statistically significant. The corresponding MLR model with FC explains a moderate portion of variance (training $R^2=0.22$, test $R^2=0.19$), and is not sufficient to analyze predictor importance. ***Conclusion:*** We found a positive relationship between glucose metabolism and connectivity in the healthy human brain. Notably, SC explained a much larger proportion of variance in glucose metabolism than FC did, suggesting that brain energy consumption is more strongly linked to its white matter infrastructure. Apart from neurobiological implications, these findings serve a reference for studying energy-connectivity (de) coupling in neurodegenerative and demyelinating diseases.

## OP-047

### Cortical stimulation-induced ictal [$^{99m}$Tc]Tc-HMPAO SPECT for surgery planning in epilepsy patients

***T. Pyka***[1], *S. Barlatey*[2], *K. Krieger*[1], *C. Friedrichs-Maeder*[3], *K. Schindler*[3], *A. Rominger*[1], *M. Baud*[3];
[1]*Department of Nuclear Medicine, Inselspital Bern, Bern, SWITZERLAND,* [2]*Department of Neurosurgery, Inselspital Bern, Bern, SWITZERLAND,* [3]*Department of Neurology, Inselspital Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Ictal [$^{99m}$Tc]Tc-HMPAO SPECT is an informative tool to detect and confirm epileptic foci for surgery planning. However, its diagnostic value crucially relies on prompt tracer injection after seizure onset, which for spontaneous seizures is often unpredictable. Triggering seizures by epileptogenic medication has been described [1], but is relatively unreliable with unclear safety and has not lead to a generalized adaptation of the method. In contrast, invasive cortical stimulation with grey matter stereoelectroencephalography (sEEG) is a mainstay investigation before epileptic surgery [2]. Our study combines for the first time this technique with a triggered ictal SPECT. ***Materials and Methods:*** At the time of writing, five patients with suspected temporal lobe epilepsy had been investigated in an ongoing prospective study (20 planned in total). Grey matter surface electroencephalography (sEEG) contacts were implanted and screened for triggering patient-typical seizures. On the next day, triggering was repeated and 406-511 MBq [$^{99m}$Tc]Tc-HMPAO were administered immediately after seizure confirmation. Clusters of hyperperfused voxels were determined by statistical parametric mapping using a normal template and compared with the signal of the implanted electrodes. Therefore, we computed bipolar traces of adjacent contacts and estimated seizure-power per dipole in terms of z-values over baseline. Cortical reconstruction based on MRI data was computed using FreeSurfer and imported into Lead-DBS for co-visualization with the SPECT z-map and sEEG contacts. ***Results:*** In all patients, ictal SPECT was successfully obtained with injection within 12 seconds of triggered seizure onset without any adverse event. In 4 out of 5 cases, there was a good correlation between deep electrode and SPECT signal, confirming a regional origin. In one case no clear ictal signal could be derived in SPECT nor sEEG. In two cases SPECT revealed areas of hyperperfusion in eloquent cortex that were not sampled by sEEG but corroborated patient-typical peri-ictal aphasia. ***Conclusion:*** Cortical stimulation-triggered ictal SPECT constituted a safe and easy-to-use method for imaging early seizure propagation networks, with good correlation with and complementing electrophysiological exploration. The method could lead to a revival of ictal SPECT imaging, as it is readily implementable at any specialized epilepsy center where sEEG is available. ***References:*** 1. ## OP-048

### The Value of $^{18}$F-FDG PET/MRI in the Preoperative Localization of Epileptogenic Zone in Patients With Drug-resistant Epilepsy

***C. Zeng***[1], *H. Zhou*[2], *X. Ling*[1], *Y. Tang*[1], *Z. Tan*[1], *H. Wu*[1], *Y. Cheng*[1], *J. Shang*[1], *Q. Guo*[3], *H. Xu*[1];
[1]*Department of Nuclear Medicine, The First Affiliated Hospital of Jinan University, Guangzhou, CHINA,* [2]*Department of Radiology, Central People's Hospital of Zhanjiang, Zhanjiang, CHINA,* [3]*Epilepsy Center, Guangdong 999 Brain Hospital, Affiliated Brain Hospital of Jinan University, Guangzhou, CHINA.*

***Aim/Introduction:*** Currently, there is a lack of large sample size clinical studies on the value of $^{18}$F-FDG PET/MRI for preoperative localization in patients with epilepsy. This study aimed to compare the localization rates of the epileptogenic zone (EZ) between invasive and noninvasive preoperative assessments based on a large sample size of clinical data, to explore in which situation noninvasive assessments may replace stereotactic electroencephalography (SEEG), and to further reveal the value of $^{18}$F-FDG PET/MRI for preoperative localization in patients with drug-resistant epilepsy. ***Materials and Methods:*** Patients with drug-resistant epilepsy who underwent surgery and preoperative $^{18}$F-FDG PET/MRI were retrospectively included, and all patients were followed up for at least 12 months after surgery. Patients underwent video electroencephalography (VEEG) and SEEG according to clinical indications. The correct localization rates of EZ were calculated for SEEG and noninvasive modalities, using the surgical resection site and postoperative follow-up for at least 12 months as reference standard. Chi-square test or Fisher's exact test was used to compare the localization rates of SEEG with noninvasive modalities. ***Results:*** A total of 594 patients, including MRI-negative (n = 104) and MRI-positive (n = 490), were included in this study, 273 of whom underwent SEEG. The localization rate of EZ with SEEG (83.9%) was comparable to PET-VEEG concordance in MRI-negative patients (75.0%, P = 0.875) and PET-MRI-VEEG concordance in MRI-positive patients (75.0%, P = 0.115). In temporal lobe epilepsy (TLE), the localization rate with SEEG (100.0%) was comparable to PET/MRI+VEEG in MRI-negative patients (100.0%) and PET/MRI+VEEG in MRI-positive patients (92.9%, P = 0.169). In extratemporal epilepsy (ETLE), the localization rate of EZ with SEEG (97.1%) was higher than PET/MRI+VEEG in MRI-negative patients (65.0%, P = 0.005) and PET/MRI+VEEG in MRI-positive patients (69.6%, P = 0.002). In multilobar epilepsy, the localization rate of EZ with SEEG (70.3%) was higher than PET/MRI+VEEG in MRI-negative patients (0.0%, P < 0.001) and PET/MRI+VEEG in MRI-positive patients (8.3%, P < 0.001). When the resection included insula, the localization rate of EZ with SEEG was significantly higher than noninvasive modalities. ***Conclusion:*** When the preoperative noninvasive modalities are concordant with each other, or when TLE is considered, patients with drug-resistant epilepsy can undergo direct surgery without SEEG if EZ does not involve the eloquent area. It is necessary to accept SEEG preoperatively when ETLE or multilobar epilepsy is considered. When insula is included in the resection, accepting SEEG preoperatively is necessary for patients.

***Aim/Introduction:*** Amyloid PET imaging is a valuable tool for early Alzheimer's diagnosis and management. However, visual interpretation has limitations, including inter-observer variability. Although quantitative software exists, it is not routinely used in clinical practice due to complexity and the need for MRI co-registration. We conducted a retrospective, multicenter, and multireader study to assess the efficacy of a deep learning-based quantification system that only uses amyloid PET images. Our goal was to evaluate if this system could improve inter-reader agreement and confidence in visual interpretation. ***Materials and Methods:*** We retrospectively collected 435 amyloid PET scans from 7 centers with mild cognitive impairment and early Alzheimer's disease. All collected PET scans were analyzed for this study. Deep learning-based quantification software which provides AI-based PET quantitative analysis without MR images was used for the amyloid PET reading [1]. For the randomized-blind-reader study, more than two readers were assigned to each center and reading was composed of two sessions: visual session (PET reading without aid of deep-learning quantification software) and quantification session (PET reading with aid of deep-learning quantification software). The order of visual and quantification session was randomly assigned, and the order of images between two sessions was randomly shuffled. The qualitative assessment was based on binary point scale (positive or negative for amyloid deposit). The confidence score for each session was evaluated by a 2-point scale (0: equivocal, 1: definite to decide). Inter-reader reliability was calculated based on Cohen kappa score. ***Results:*** Our results showed that the deep learning-based software improved inter-reader agreement and confidence of amyloid PET reading. Inter-reader reliability was measured median 0.80 (range, 0.39-1.00) and 0.92 (range, 0.39-1.00) for visual and quantification sessions, respectively. The pooled confidence score was 0.85 ± 0.35 and 0.93 ± 0.24 (mean ± standard deviation) for visual and quantification sessions. Four readers showed a significant increase in confidence score in the quantification session. ***Conclusion:*** The deep learning-based amyloid PET quantification software without MRI can increase inter-reader agreement and confidence of amyloid PET reading. This has strong clinical implications for the objective and accurate diagnosis of Alzheimer's disease. ***References:*** [1] Kang SK, Kim D, Shin SA, Kim YK, Choi H, Lee JS. ## OP-050

### Brain metabolic correlates of Cytokine Release Syndrome and Immune effector cell-associated neurotoxicity in patients with Diffuse Large B-Cell Lymphoma (DLCBL) treated with CAR-T

***T. Di Raimondo***[1], *M. Gambella*[2], *A. Raiola*[2], *F. D'Amico*[1], *L. Sofia*[1], *F. Lanfranchi*[1], *C. Ghiggi*[2], *C. Lapucci*[3], *G. Sambuceti*[1], *M. Bauckneht*[1], *M. Inglese*[3], *E. Angelucci*[2], *S. Morbelli*[1];
[1]*Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genova, ITALY,* [2]*Department of Hematology and Cellular Therapy, IRCCS Ospedale Policlinico San Martino, Genova, ITALY,* [3]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), IRCCS Ospedale Policlinico San Martino, University of Genoa, Genova, ITALY.*

***Aim/Introduction:*** Chimeric antigen receptor (CAR) T-cell therapy is potentially associated to treatment-related toxicities mainly consisting in cytokine release syndrome (CRS) and immune-effector cell-associated neurotoxicity syndrome (ICANS). We aimed to evaluate brain metabolic correlates of CRS with and without ICANS in DLBCL patients treated with CAR-T and to investigate the relationship between both baseline metabolic tumor volume (MTV) and total lesion glycolysis (TLG) and the occurrence of CRS and ICANS. ***Materials and Methods:*** Twenty-one patients with refractory DLCBL underwent whole-body and brain [18F]FDG PET just before and 30-days after treatment with CAR-T. Five patients did not develop inflammatory-related side effects, eleven patients developed CRS (CRS group), in further 5 patients CRS evolved in ICANS (ICANS group). Baseline and post-CAR-T brain FDG-PET were compared with a local controls dataset (SPM12) to identify hypometabolic patterns both at single-patient and group level ($p<0.05$ after correction for family-wise error (FWE) as significant). MTV and TLG were computed on baseline FDG-PET and compared between patients' subgroups (t-test). ***Results:*** After therapy with CAR-T, ICANS patients showed an extended and bilateral pattern of hypometabolism mainly involving orbito-frontal, frontal dorso-lateral cortex, anterior

cingulate (p FWE-corrected <0.003). Patients who experienced CRS without ICANS showed significant hypometabolism in less extended clusters mainly involving bilateral medial and lateral temporal lobes, posterior parietal lobes, anterior cingulate and cerebellum (FWE-corrected p<0.002). When ICANS and CRS subgroups were directly compared, patients with ICANS showed a more prominent hypometabolism in orbitofrontal and frontal dorso-lateral cortex in both hemispheres (FWE-corrected p<0.002). Mean baseline MTV and TLG were significantly higher in ICANS patients with respect to patients with CRS only (p<0.02). ***Conclusion:*** Patients with ICANS after treatment with CAR-T are characterized by a fronto-lateral hypometabolic signature in line with the hypothesis of ICANS as a predominant frontal syndrome and with the more prominent susceptibility of frontal lobes to cytokine-induced inflammation.

## OP-051

### A pilot study comparing myelin measurements from [18F]-Florbetaben PET and quantitative T1 map imaging in multiple sclerosis (MS)

***L. Sofia***[1], *M. Donegani*[1], *A. Donniaquio*[2], *A. Chincarini*[3], *L. Roccatagliata*[4], *M. Pardini*[2], *R. Gianeri*[3], *F. Sensi*[3], *F. D'Amico*[1], *T. Di Raimondo*[1], *C. Bagnara*[5], *M. Riondato*[1], *G. Novi*[6], *A. Laroni*[2], *A. Murialdo*[6], *G. Ribizzi*[6], *A. Uccelli*[2], *M. Inglese*[2], *S. Morbelli*[1]; [1]*Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY,* [2]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Genoa, ITALY,* [3]*National Institute of Nuclear Physics (INFN), Genoa section, Genoa., Genoa, ITALY,* [4]*Neuroradiology Unit, University of Genoa, Genoa, Genoa, ITALY,* [5]*Medical Physics, IRCCS Policlinico San Martino, Genoa, Genoa, ITALY,* [6]*Division of Neurology, IRCCS Policlinico San Martino, Genoa, Genoa, ITALY.*

***Aim/Introduction:*** PET imaging with β-amyloid ligands (amy-PET) is emerging as a molecular imaging technique targeting quantitative measurement of myelin content changes in MS. T1 relaxation time maps have been recently proposed for the qualitative and quantitative classification of MS lesions according to myelin content and to track lesional myelination changes over time. However, this MRI metrics has not yet been validated, and no data are to-date available on the relationship between T1-map and AMY-PET-based myelin measurements. We aimed to explore the correlation between lesional white matter (WM) amy-PET uptake and quantitative (q) T1 map metrics. ***Materials and Methods:*** Patients with relapsing-remitting (RR) and primary progressive (PP) MS were recruited in a project funded by the Italian Ministry of Health. All patients underwent both 3T MRI with standard sequences and qT1 map and dual dynamic amy-PET imaging with [18F]Florbetaben (early dynamic of the first 30 minutes and late steady-state acquisitions 90-110 minutes p.i.). Lesions were segmented on 3T MRI and for every lesion T1/T2 ratio (considered a rough measure of myelination) and intensity and coefficient of variance (capturing lesions' heterogeneity) on qT1 map were measured. PET images were spatially and intensity normalized. SUVratio was measured on early dynamic and late static PET images in the individual lesions and in the contralateral normal appearing white matter (NAWM). Correlation between WM amy-PET on one side and T1/T2 ratio and T1 map on the other were assessed by means of Pearson's correlation coefficient. ***Results:*** 607 WM lesions were analyzed in nineteen MS patients (10 primary-progressive, 9 relapsing-remitting) and were included in the analysis. In the lesion based analysis, both early-dynamic and steady state SUVr was significantly correlated with both T1/T2 and qT1 map. This correlation was significant with both lesions' intensity and coefficient of variation and was not affected by lesions' volume and patient's clinical phenotypes (p<0.0001 in both cases). When looking at the NAWM, the voxel-to-voxel correlation coefficient was higher in the gray-white matter transition zone. ***Conclusion:*** Both early and late steady state metrics derived from amy-PET correlate with advanced qT1 map data. Amy-PET seems to be able to reflect both the degree of demyelination and lesions' heterogeneity; however the potential influence of the topography of the lesions on PET signal seems to affect SUVr measurement and should be considered in more clinically-oriented studies.

***Aim/Introduction:*** FDG PET/CT represents an essential tool for pediatric Hodgkin lymphoma (HL). In this context, volumetric analyses might be a valuable tool to discriminate disease prognosis and response. To validate this assumption, the AIEOP Hodgkin Lymphoma Study Group has designed a parallel study of the cohort of patients enrolled in the EuroNet-PHL-C2 trial. Herein, we present the initial results obtained from this cohort. ***Materials and Methods:*** We analyzed data from the first 200 patients (94M, 106F; median age 15years) with HL enrolled in 24 Italian centers from January 2017 to December 2020 for the EuroNet-PHL-C2 protocol. The cohort was classified based on treatment level: TL1 (31 patients), TL2 (90 patients) and TL3 (79 patients), of whom 71 with bulky masses. Response was classified into adequate (AR) and inadequate response (IR) as per protocol. The primary objective of the study was to define the predictive role of volumetric and semiquantitative analyses, i.e., SUVmax, SUVmean, MTV and total lesion glycolysis (TLG), as well as lymphoma dissemination (Dmax), at FDG PET/CT at baseline and during therapy. In particular, treatment response was assessed at early (ERA) and late evaluation (LRA). Semi-automatically delineated contours of the lesions were performed by using a fixed SUV threshold of 2.5. All parameters and their variations (Δ) were analyzed with respect to response. ***Results:*** At baseline, our cohort presented a median SUVmax of 12.5 (95%CI: 12.1-13.1), median SUVmean

4.3 (95%CI: 4.2-4.5), median MTV 223 (95%CI: 183-264), median TLG 1009 (95%CI: 868-1213) and median Dmax of 18 (95%CI: 14.7-21.7). There was a statistically significant difference of median baseline SUVmax (P=0.002), MTV (P=0.022), TLG (P=0.005) and Dmax (P=0.003) and treatment evaluation at ERA PET. Median variations from baseline resulted respectively: 81% for SUVmax, 59% for SUVmean, 92% for MTV, 97% for TLG and 40% for Dmax, with ΔSUVmax and ΔSUVmean showing a significant correlation to LRA (P=0.027 and 0.020, respectively). There was a significant correlation of semi-quantitative and volumetric parameters at baseline also at logistic regression for SUVmax (P=0.0025), MTV (P=0.0272), TLG (P=0.0078) and Dmax (P=0.0045). While pooled together with other clinical data (i.e. stage, TL, and bulky masses), multiple regression defined as independent predictive factors TL and bulky masses (P=0.0071 and 0.0078, respectively). ***Conclusion:*** Semi-quantitative and volumetric FDG PET/CT parameters correlate to ERA results and their variations show a statistically significant correlation to LRA. Dmax seems to have a potential role as predictor of response in pediatric HL.

## OP-053

### Interim TLG and MTV vs Deauville Score as Predictors in Pediatric Non-Hodgkin Lymphoma Patients

***G. KAYA***[1], *B. Volkan Salancı*[1], *B. Aydın*[2], *P. Özgen Kıratlı*[1];
[1]*Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University Medical School Department of Pediatric Oncology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Evaluation of interim FDG PET/CT scans of pediatric Non-Hodgkin lymphoma (NHL) patients is still a challenge. Apart from Deauville Score (DS), total lesion glycolysis (TLG) and metabolic tumor volume (MTV) are semiquantitative parameters originated from PET/CT data. The aim of this study is to assess the role of interim DS, TLG, and MTV in pediatric NHL patients. ***Materials and Methods:*** Interim PET images of pediatric FDG avid NHL patients were evaluated retrospectively. $MTV_{2.5}$ and $TLG_{2.5}$ values were calculated according to "SUVmax cut-off: 2.5", as well as DS of interim scans. $MTV_{2.5}$ and $TLG_{2.5}$ values ">0" and DS "≥3" were accepted as residual disease. Survival analysis and diagnostic parameters of each parameter were analyzed. Death and disease progression were accepted as an event. ***Results:*** The study group included 119 PET scans of 119 children (F/M: 36/83, mean age: 9.6y (SD 4.6) diagnosed as NHL, between 2011-2022. High-grade B cell lymphoma (47.5%), lymphoblastic lymphoma (28.3%), and anaplastic large cell lymphoma (11. 7%) composed the majority of the study group. On interim PET scans, median $MTV_{2.5}$ was 0 $cm^3$ (range: 0-453), $TLG_{2.5}$ was 0 (range: 0-3163) and DS was 1 (range: 1-5). Twenty-four patients were accepted positive for the minimal residual disease on MTV and TLG analysis, while 39 were positive in the DS group. There were no patients evaluated as positive on DS but negative on $MTV_{2.5}$ and $TLG_{2.5}$. Patients evaluated as positive in these methods significantly differ from each other ($p<0.001$). Kaplan-Meier analysis showed mean time-to-event was significantly shorter (6.7 years; $p<0.001$) in patients who were positive in TLG&MTV. The estimated median survival was not reached for only-DS-positive patients and also patients evaluated as negative on both methods. Cox analysis showed that the proportional hazard ratio was 5.4 for TLG&MTV positivity (lower 2.2 and upper 13.1, CI 95%; $p<0.001$). The negative predictive value of interim PET/CT was 86.3%. ***Conclusion:*** The results of this ongoing study suggest that $MTV_{2.5}$ & $TLG_{2.5}$ and DS assessments significantly differ in pediatric NHL patients. $MTV_{2.5}$ & $TLG_{2.5}$ exceed DS in the estimation of disease progression significantly in this group of patients.

## OP-054

### Application value of 18F-FDG PET/MR whole body imaging in children's rhabdomyosarcoma staging

***S. Yun****;*
*Hangzhou Universal Imaging diagnostic center, Hangzhou, CHINA.*

***Aim/Introduction:*** To evaluate the value of a Hybrid $^{18}$F-FDG PET/MR in staging of pediatric nephroblastoma. ***Materials and Methods:*** The clinical data of 77 patients who were diagnosed as nephroblastoma were retrospectively analyzed from April 2017 to July 2019.Patients were divided into the pre-treatment group ( n=40) and post-treatment group (n=37).The PET/MR characteristics was analyzed, and the size,shape, signal characteristics, relationship with surrounding tissues, SUVmax value, metastasis and staging characteristics of the tumor were observed. Pathological and clinical diagnosis results are the gold standard. ***Results:*** Based on NWTS-V staging,the 40 cases pre-treatment group included 3 cases (7.5%) in stage I, 5 cases (12.5%) in stage II, 14 cases (35.0%) in stage III, 16 cases (40.0%) in stage IV and 2 cases (5.0%) in stage V.20 (50.0%) tumors occurred in the right kidney, 17 (42.5%) in the left kidney, 2 (5.0%) in both kidneys, and 1 (2.5%) outside the kidney (in the spinal canal). The average maximum diameter of the lesions was 10.25 ± 4.12 cm; The average value of SUVmax was 13.58 ± 6.74. 28 cases (70%) had smooth and clear boundary and pseudocapsule; There were 26 cases (65%) with uneven density, necrosis, hemorrhage and cystic transformation; "Residual kidney sign" was found in 28 cases (70%), and 8 cases (20%) were of whole kidney invasion type. Tumor thrombus in renal vein or inferior vena cava in 5 cases (12.5%); Lymph node metastasis occurred in 21 cases (52.5%); 17 cases (42.5%) had distant metastasis, including 9 cases of lung metastasis, 8 cases of bone metastasis, 2 cases of liver metastasis and 2 cases of brain metastasis. In the post-treatment group, 12 cases (32.4%) had lymph node metastasis and 10 cases (27.0%) had remote metastasis.Staging after PET/MR imaging: 15 patients (37.5%) in the pre-treatment group had stage changes, 11 of them increased from III to IV, 4 from II to IV. In the post-treatment group, 12 cases (32.4%) had stage changes, of which 7 cases increased from stage 0 to stage IV, 2 case increased from stage III to stage IV, 3 cases decreased from stage IV to stage 0 due to negative FDG uptake. ***Conclusion:*** $^{18}$F-FDG PET/MRI is superior to clinical in staging of pediatric nephroblastoma.It has more advantages in detecting the invasion and distant metastasis around the tumor, and obviously improves the accuracy of the primary staging and re-staging of the nephroblastoma.

## OP-055

### Prognostic Value of 18FDG PET/CT Parameters for the Outcome in Pediatric Sarcoma Patients

***B. Soydas Turan***[1], *B. Volkan-Salancı*[2], *G. B. Aydın*[3], *P. Özgen Kıratlı*[2];
[1]*Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [3]*Hacettepe University Faculty of Medicine, Department of Pediatric Oncology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** To explore which metabolic 18FDG PET/CT parameters acquired at staging are predictive of overall survival (OS) and progression-free survival (PFS) in children with bone or soft tissue sarcomas. ***Materials and Methods:*** Pediatric patients with histologically proven Ewing sarcoma (ES), Osteosarcoma (OST) and Rhabdomyosarcoma (RMS) who referred to 18FDG PET/CT for staging before any treatment between January 2010 and

December 2020 were retrospectively enrolled. SUVmax, metabolic tumor volume (MTV), total lesion glycolysis (TLG) of primary tumor were obtained. MTV was defined with a threshold of 40% of SUVmax. TLG was defined as the product of MTV and SUVmean. MTV and TLG of all FDG avid metastatic lesions were also noted. Summation of MTV and TLG of all pathological lesions yielded the wb-MTV and wb-TLG, respectively. Kaplan-Meier curves and log-rank test were used to compare survival experience between PET parameters on cut-off values (median/upper quantile). ***Results:*** PET/CT scan of 87 patients with ES (n: 46, mean age 10.22 ± 3.79 years, 17 females), OST (n: 26, mean age 11.35 ± 3.17 years, 11 females) and RMS (n: 15, mean age 8.27 ± 5.35 years, 7 females) were analyzed. 19 patients (41.3%) with ES, 8 (30.8%) with OST and 9 (56.3%) with RMS presented with metastases. Median follow-up was 55 months (range 7-125). 36 patients (41.3%; 19 ES, 11 OST, 6 RMS) had relapse/progression and 28 patients (32.2%; 11 ES, 12 OST, 5 RMS) deceased. In ES group, patients with SUVmax > 7.25 (70 vs 108 months, p: 0.013), wb-MTV > 129.36 (66 vs 109 months, p: 0.028) and wb-TLG > 719.10 (47 vs 109 months, p: 0.003) had lower OS. Also, wb-TLG > 719.10 was significantly associated with early progression (37 vs 83 months, p: 0.048). Patients with wb-MTV > 129.36 had shorter PFS but not reaching statistical significance (53 vs 85 months, p: 0.088). In OST group, SUVmax > 7.17 (48 vs 90 months, p: 0.026) and wb-MTV > 134.25 (40 vs 85 months, p: 0.017) were associated with increased mortality. No relationship was found in RMS group, possibly due to limited number of patients. ***Conclusion:*** Staging 18FDG PET parameters can be used as a prognostic indicator in ES and OST. High SUVmax and wb-MTV were associated with worse OS. Additionaly, high wb-TLG was associated with poor OS and PFS in ES.

## OP-056

### Bone marrow involvement detection by FDG PET-CT in newly diagnosed Ewing Sarcomas : comparison to bone marrow aspiration and biopsy, and assessment of visual interpretation criteria with junior doctors

***V. Isnardi***[1], *A. Guinot*[1], *H. Bahri*[1], *E. Paquet*[1], *M. Fazel*[1], *L. Besson*[2], *M. Brahmi*[1], *N. Corradini*[1], *P. Marec-Berard*[1];
[1]*Lumen Centre Léon Bérard, Lyon, FRANCE,*
[2]*University Hospital, Saint Etienne, FRANCE.*

***Aim/Introduction:*** Ewing sarcoma (ES) is an aggressive tumour with an unfavourable prognosis when bone marrow metastasis are present at diagnosis. Cancer staging identifies 30% of patients as metastatic at diagnosis, among them 20 % presents bone marrow involvement or bone metastasis. The overall 5 years survival is approximately 70% without metastasis and drop to 25% in case of bone marrow involvement. Bone marrow aspiration and biopsy (BMAB) are the gold standard for bone marrow assessment. However recent studies suggest that these invasive and painful procedures could be replaced by FDG PET-CT (FDG PET). FDG PET is indeed a sensitive technique for the detection of ES metastasis and typical sinctigraphic patterns could easily distinguish bone marrow involvement and focal bone metastasis. ***Materials and Methods:*** We compared the FDG-PET results of 180 patients with newly diagnosed ES, recorded at the Centre Léon Bérard over the past 10 years, with BMAB results. Marrow metastatic status was determined by the nuclear physician's interpretation at diagnosis. A blinded centralized review of positive or suspicious FDG PET was performed by an experienced nuclear medicine physician. Scintigraphic pattern of bone marrow involvement was defined by a diffuse, and frankly heterogeneous hypermetabolism of the axial and proximal appendicular skeleton, and focal bone metastase was defined by intense focal uptake. Then 3 junior doctors performed a blind review of an extracted panel of 24 FDG PET of the 180, including discordant ones according to the previous centralized review. They had to classify images as bone marrow involvement, focal bone metastasis or negative. ***Results:*** Of the 180 FDG-PET, 12 were true positive, one false positive, 166 true negative, one false negative. The sensitivity of FDG PET was 92.3% and the specificity 99.4%. The three junior doctors (2 nuclear medicine physicians, one oncologist) correctly classify 22, 21 and 20 on the panel of 24 FDG-PET respectively. In addition to the false positive case and the false negative case previously described, they misclassified none, one patient, and 2 patients respectively. ***Conclusion:*** FDG PET demonstrated a high sensitivity and specificity as well as a good repeatability and reproducibility, even by junior doctor. These results suggest that, excepted in situation of clinical research protocol, BMAB should no longer be systematically performed for the staging at the diagnosis of ES in case of typical scintigraphic pattern of bone marrow involvement on FDG PET and in case of localised ES or pulmonary metastasis alone.

## OP-057

### Role of F18 FDG PET/CT inEwing's Sarcoma Family Of Tumours (ESFT)

***A. Tiwary Vyas***[1], *A. Vyas*[2];
[1]*Janakpuri Superspeciality Hospital, New Delhi, INDIA,* [2]*Max Superspeciality Hospital Vaishali, New Delhi, INDIA.*

***Aim/Introduction:*** The role of F-18 FDG PET/CT in staging, restaging and response assessment of Ewing's Sarcoma Family of Tumors (ESFT) - an Indian experience ***Materials and Methods:*** 37 patients of ESFT were assessed by FDG PET/CT after histopathological diagnosis. The patients had mean age of 21 years (range 5-45 years); male :female - 4.2: 1. Response was assessed as per PERCIST 1.0 criteria by follow up PET/CT in 26 cases after completion of treatment (surgery for resectable tumors & chemotherapy / radiotherapy for advanced tumors). Data was interpreted using qualitative (liver & mediastinal blood pool) & semi-quantitative (Standardized Uptake Value- SUV max). Resolution of metabolic activity was marker of response to therapy. ***Results:*** Out of 37, 29 cases were of skeletal Ewing's sarcoma (ES) - 17spinal & 12 extra-spinal,04 Extraskeletal Ewing's (ESE), 02 Askin`s tumour of chest wall & 02 PNET (in brain and orbit). 16 (43.2%) cases of stage IIa, 01 (2%) IIb, 01 (2%) III, 08 (21%) IVa & 11 (29.7%) IVb. Spine was the most frequent primary involvement, followed by extremities. A mixed sclerotic- lytic lesion is seen with associated soft tissue component and variable heterogeneous FDG uptake was seen in most of the skeletal lesions. Mean SUVmax of primary lesion 6.1(range 2.5 to 19.3). Regional lymphnodes (57 % cases) were most common site of metastases, 37% distant metastases. Lung (21.6 %) followed by bone(18.9 %). there was CMR 09 /26(34.6%), PMR 07/26 (26.9%), SD 01/26 (3%) & PD 09/26 (34.6%) respectively. ***Conclusion:*** Molecular imaging with F-18 FDG PET/CT is a helpful tool for staging & restaging of ESFT as well as for localization of distant metastases. It is a valuable in response assessment of all the types of Ewing sarcoma family of tumors by using qualitative & semi-quantitative (SUVmax) methods.Further prospective studies are recommended. ***References:*** 1.Iwamoto Y (February 2007)."Diagnosis and treatment of Ewing sarcoma". ## OP-058

### Pediatric tumor patients scanned with a long axial field of view scanner - a single center experience of reduced administered doses of [$^{18}$F]FDG

***C. Bregenzer***[1], *K. Krieger*[1], *H. Sari*[1,2], *K. Zeimpekis*[1], *N. Gözlügöl*[1], *Â. Cardoso*[1], *Â. Mendes*[1], *A. Rominger*[1], *A. Afshar-Oromieh*[1]; [1]*Department of Nuclear Medicine, Inselspital, University Hospital Bern, University of Bern, Bern, SWITZERLAND,* [2]*Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** The administered activity for [$^{18}$F]FDG-PET/CT in children has always been a subject of discussion. Current guidelines recommend a dose of 3.7-5.2 MBq/kg body weight (BW), although the consensus is to use lowest doses as reasonably possible. The advent of latest generation scanners offers the opportunity of reducing the administered dose. Here we report our first experiences with pediatric patients scanned with reduced doses using a long axial field of view (LAFOV) PET/CT scanner. ***Materials and Methods:*** Twenty-seven [$^{18}$F]FDG-PET/CT scans from 21 children and adolescences (age limit 18 y/o) with different tumors were included in this retrospective analysis. Amongst them, three groups were identified depending on the administered activity: 1 MBq/kg BW, 2 MBq/kg BW and 3 MBq/kg BW. Acquisition duration was 10 minutes beginning 1h post injection. A LAFOV-PET/CT scanner (field-of-view: 106cm) was used for all scans. In addition to the aforementioned groups, a fourth group was formed by simulating 0.5 MBq/kg BW by histogramming only the first 5 minutes of PET data obtained with 1 MBq/kg scans. The quality of all scans was assessed in a blinded manner by two readers using a 5-point Likert scale, with 5 being the best quality and 1 the worst. ***Results:*** The children's average age was 11.8 ± 5.6 years, the average body weight was 42.3 ± 22.1 kg. The average Likert scale of the different groups were as follows: 2.7 ± 0.7 for 0.5 MBq/kg (n=10 scans); 3.4 ± 0.8 for 1 MBq/kg (n=10); 4.4 ± 0.5 for 2 MBq/kg (n=9) and 5.0 ± 0 for 3 MBq/kg (n=8). There was a significant association between higher doses and higher Likert scales: p=0.004 for the comparison between group 1 MBq/kg vs. group 0.5 MBq/kg, p=0.002 for the comparison between group 2 MBq/kg vs. group 1 MBq/kg and p=0.013 for the comparison between group 3 MBq/kg vs. group 2 MBq/kg. ***Conclusion:*** The image quality obtained with 3 MBq/kg and the LAFOV-PET/CT scanner was outstanding, although this dose is lower than recommended by the guidelines. As expected, image quality decreased significantly with lower doses of [$^{18}$F]FDG. The results indicate that scans with 0.5 MBq/kg were lower quality and this dose might not be suitable with 10-min long pediatric scans. Currently we are pursuing further assessments including lesion detectability and a comparison with scans derived from a standard PET/CT-scanner, which shall help to find the best compromise between 1 and 3 MBq/kg.

## OP-059

### Sedation-free pediatric $^{18}$F-FDG imaging on totalbody PET/CT with the assistance of artificial intelligence

***X. Zhou***[1], *S. Xue*[2], *Q. Xia*[1], *A. Rominger*[2], *J. Liu*[1], *K. Shi*[2]; [1]*Shanghai Jiaotong University, Shanghai, CHINA,* [2]*Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Sedation is frequently used to ensure that PET examinations of infants and small children maintain their diagnostic quality, despite known side effects. However, there are two key challenges to achieving sedation-free pediatric PET imaging: fast imaging and CT-free attenuation and scatter correction (ASC). This study focuses on developing solutions to these challenges on a total-body PET scanner. ***Materials and Methods:*** First, we explored the solutions based on retrospective investigation of sedated total-body PET (uExplorer) imaging of 20 pediatric patients (<3 years old) to determine the shortest time of acceptable PET imaging and to check the feasibility of CT-free ASC. We assessed the image quality by a 5-point scale and quantitative metrics including signal to noise ratio (SNR), tumor-to-background ratio (TBR), root mean square error (RMSE), and peak-to-mean ratio (PMR) of liver, mediastinum, and lesions. The deep learning-based method was adapted for the pediatric CT-free ASC [1]. Then, we validated the proposed solutions on PET imaging of 5 young children without sedation. ***Results:*** Compared to standard imaging of 300 s, there was no significant difference in the diagnostic sensitivity, specificity and quantification of tumor lesions for fast imaging until the reduction to 15s ($p>0.05$). The image quality of MIP and lesion in 15s total-body PET scan is more than 2 score. Compared with 300s, there was no significant difference in PMR of liver, mediastinal and lesion for 15s imaging ($p>0.05$). The RMSE of 15s was 27.16±10.58. Only liver lesions smaller than 1 cm and SUVmax < 2.5 may be missed in 15s imaging. The deep learning-based CT-free ASC can accurately correct ultrafast PET images. NRMSE and PSNR are 0.52%+ 0.03%, 48.1+4.5. With the two solutions, we successfully anesthesia-free PET imaging in 5 children. ***Conclusion:*** The proposed solutions of 15s ultrafast total-body PET imaging and CT-free ASC has the potential to preserve the image quality and diagnostic requirements for sedation-free pediatric PET imaging. ***References:*** [1] Guo R, Xue S, Hu J, et al. Using domain knowledge for robust and generalizable deep learning-based CT-free PET attenuation and scatter correction. Nature communications. 2022;13:5882.

**SPECT and SPECT/CT Somatostatin Receptor Scintigraphy in the Follow-Up of Neuroendocrine Neoplasms of Appendix**

***V. Artiko***, *J. Petrovic, D. Sobic Saranovic, N. Petrovic;*
*Center for Nuclear Medicine, University Clinical Center of Serbia, Faculty of Medicine University of Belgrade, Belgrade, SERBIA.*

***Aim/Introduction:*** Neuroendocrine tumors of appendix (ANETs), are rare tumors, usually discovered during emergency surgical conditions. In spite of lot of data of somatostatin receptor scintigraphy (SRS) in gastrointestinal neuroendocrine tumors, there is no much data about ANETs particularly. Our aim was to establish the role of somatostatin receptor scintigraphy (SRS) in the follow-up of these patients. ***Materials and Methods:*** The total of 58 patients was investigated, 36 females and 22 males, average age (48.3 ± 17.8 years). All patients had histological diagnosis of ANET (55 carcinoids of appendix and 3 tubular carcinoid). Majority of tumors (38) have been found incidentally during surgery, while 20 patients had diagnosis of appendiceal tumor before the surgery. Twenty two patients had tumor grade (G) G1, 19G2 and 17G3. The right hemicolectomy was performed in 32, while the rest of the patients had appendectomy only. SRS was performed for restaging in all the patients after surgery early (2 h) and late (24 h) after i.v. application of 740 MBq Tc-99m-HYNIC TOC. In 45 patients only planar viewes and SPECT were performed, while SPECT/CT was performed in 13. ***Results:*** There were 23 true positive (TP), 29 true negative, 4 false positive and 2 false negative SRS results. Sensitivity of the method (including both SPECT and SPECT/CT) was 92%, specificity 87.9%, positive predictive value 85.2%, negative predictive value 93.6% and accuracy 89.7%. Receiver operating characteristics analysis showed that SRS scintigraphy is a good test for detection of TP cases (area under the curve of 0.850, 95% confidence interval (CI): 0.710-0.990, P < 001). SPECT contributed to diagnosis in 12 TP findings in comparison to planar images. SPECT/CT contributed in 7/15 patients, in 5 confirming the positive finding (Krenning score 2) and in 2 excluding it in comparison to SPECT. In 12 patients Krenning score was 4, in 6 patients 3 and in 5 patients 2. In 21 patients SRS significantly changed the management of the patients (in 8 surgery was repeated, in 10 somatostatin analogues included and in 3 peptide receptor radionuclide therapy performed). Median progression-free survival in SRS positive patients was 53 months (95%CI: 39.8-118.1 months) while in SRS negative patients it was 61 month (95%CI: 42.9-77.9 mo), without statistically significant difference between the two groups (P = 0.434). ***Conclusion:*** SRS proved the value in the follow-up of the patients with ANETs after surgery, with added value with SPECT and particularly with SPECT/CT.

### EPS-003

**Total tumour volume in a GEP-NET patient cohort treated with intraarterial Lu-177 DOTATATE PRRT**

***H. Schmid***, *S. Kunte, G. Sheikh, A. Holzgreve, P. Bartenstein, L. Unterrainer, M. Zacherl;*
*Departement of Nuclear Medicine University Hospital, LMU Munich, Munich, GERMANY.*

***Aim/Introduction:*** Peptide radio-receptor therapy (PRRT) with Lu-177 DOTATATE has been approved for the treatment of patients with well-differentiated gastroenteropancreatic neuroendocrine tumours (GEP-NET). In the case of predominantly hepatic metastasis, attempts have been made to achieve an increased therapeutic effect on these metastases by local intraarterial PRRT. Different results have been published regarding a possible therapeutic benefit. Hence, to the best of our knowledge for the first time in our study we investigate a new approach, the influence of local intraarterial and intravenous tumour therapy on the total tumour volume (TTV) in an inter-individual comparison. ***Materials and Methods:*** 20 patients with GEP-NET undergoing Lu-177 DOTATATE therapy were retrospectively included in the study. Of these, 10 patients received PRRT intraarterially via port catheters placed in the hepatic arterial vessels. The comparison group of 10 patients was treated with intravenous infusion of PRRT. The matched comparison group was primarily selected according to visual hepatic tumour burden and primary location of the neuroendocrine tumours. The total tumour volume (TTV) in Ga-68 DOTA-TATE PET/CT was determined at fixed thresholds. Clinical and laboratory parameters as well as follow up imaging were evaluated before and after two cycles of Lu-177 DOTATATE therapy. ***Results:*** The mean baseline TTV was comparable with 764.0 ml vs 864.2 ml for the intraarterial and intravenous patients, respectively, with a reduction to 703.3 ml vs 753.1 ml after two cycles of therapy, a mean percentage reduction corresponding to -10.8% vs -21.0 % respectively. There were no significant differences in TTV after two cycles in either the intraarterial or intravenous groups (p=0.55 vs p=0.13). There was no significant difference in the change of laboratory parameters, such as the renal retention parameter creatinine (p>0.99 vs p=0.26) and the tumour marker chromogranin A (p=0.09 vs p=0.62) or the PET parameters SUVmax (p=0.19 vs p=0.22) and SUVmean (p=0.22 vs p=0.70). In contrast, serotonin showed a significant decrease in both patient groups (p=0.002 vs p=0.04). In a direct comparison of both patient groups, there was no significant difference in the percentage decrease of TTV (p=0.82), the renal retention parameters creatinine (p=0.58) and TER (MAG3) (p=0.73) or the PET parameters SUVmax (p=0.91) or SUVmean (p=0.32). ***Conclusion:*** Total tumour volume (TTV) did not show significant difference in reduction between patients receiving intraarterial and intravenous Lu-177-DOTATATE therapy in a comparable patient population. The percentage changes in TTV also did not show significant correlations with the clinical and imaging data.

## EPS-004

### Somatostatin receptor antagonist PET/CT imaging provides better staging of lymph node than contrast enhanced CT prior to lymph node dissection in patients with duodenum and pancreatic neuroendocrine tumors

***W. Zhu***, *B. Yin, X. Wang, M. Liu, Q. Xu, W. Wu, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Somatostatin receptor (SSTR) antagonist PET/CT is an effective modality to evaluate well-differentiated neuroendocrine tumors (NETs). For patients with pancreatic NET (pNET), especially those with small tumors, lymph node dissection is not routinely planned and sometimes enucleation is performed. However, this would leave the patients at risk of recurrence if there is lymph node metastasis. There's, so far, few evidence regarding the value of presurgical SSTR-targeted imaging in the assessment of lymph node metastasis in these patients. In this study, we aim to assess the value of presurgical antagonist PET/CT imaging using pathological results as ground truth and compare it to presurgical contrast-enhanced CT (ceCT). ***Materials and Methods:*** We retrospectively reviewed patients who had presurgical SSTR antagonist PET/CT as well as ceCT and underwent surgical resection in our hospital. The surgical procedure, whether lymph node dissection was performed, the number of lymph node dissected, and the number, location, and size of metastatic lymph nodes were recorded. The PET/CT images and ceCT images were also reviewed. The number and location of positive lymph nodes were recorded, respectively. ***Results:*** A total of 28 patients were reviewed, of whom 9 patients did not have lymph node dissection (enucleation in 4 patients) and were ruled out in the further analysis. In the remaining 19 patients (12 pancreatic NETs, 7 duodenum NETs), a total of 230 lymph nodes were dissected. Of them, 19 metastatic lymph nodes were found in 9 patients. The patient-level sensitivity, specificity, and accuracy were 78% (7/9), 100% (10/10), and 89% (17/19) for antagonist PET/CT and 33% (3/9), 100% (10/10), and 68% (13/19) for ceCT, respectively. The lesion-level sensitivity, specificity, and accuracy were 47% (9/19), 98% (207/211), and 94% (216/230) for antagonist PET/CT and 26% (5/19), 100% (211/211), and 94% (216/230) for ceCT, respectively. The average size of detected and undetected metastatic lymph nodes was 0.71 cm (0.3 - 1.2cm) and 0.34 cm (0.2 - 0.5 cm), respectively. ***Conclusion:*** Antagonist PET/CT is better than ceCT for lymph node staging prior to lymph node dissection in patients with duodenum and pancreatic NET.

## EPS-005

### Normalization and 2-bit-quantization of PSMA-PET using the visual miPSMA Score for training an deep learning AI for prostate cancer detection

***B. Schemmer****;*
*Uniklinik Bonn, Bonn, GERMANY.*

***Aim/Introduction:*** Prostate cancer is a leading cause of death in men worldwide, early detection is crucial for effective treatment. Positron Emission Tomography (PET) is a widely used imaging modality for prostate cancer detection with the standard uptake value (SUV) commonly used as a measure of tumor activity. However, SUV has limitations, and new methods are being developed to improve the value of PET imaging. One such method is the miPSMA Score, which uses a visual qualitative scoring system for the interpretation of tumor uptake with blood-pool, liver and parotid gland as references for uptake. ***Materials and Methods:*** We included patients with histologically confirmed prostate cancer who underwent PSMA-PET/CT imaging for primary staging or biochemical recurrence with at least one PSMA-PET study and one PSA-value per patient, to train and validate our AI model. We included 50 patients, median age 71 years (range, 55-86 years). The majority had intermediate-risk or high-risk disease (78%), most had a PSA-level >5 ng/mL (61%). The AI was based on deep learning and provided with whole-body PET-images as well PSA-values. The AI was specifically not trained to find any subtle metastasis with uptake below blood-pool. The PET-images were preprocessed, uptake values below blood-pool were no longer present in the training images. Detection was evaluated as successful when there was a corresponding labeled metastasis in the data. To increase the amount of training data, the whole bodies were presented as single image slices (~50*400 images). ***Results:*** The results of the study showed that using the visual miPSMA Score as quantization/normalization method for AI training a reliable detection of suspicious lesions is possible with a small dataset. We achieved a good sensitivity of 74% (mainly due to low uptake lesions in the pelvis and lesions close to other higher uptake lesions). However specificity was only 62% due to misinterpretation of unspecific findings such as ureter, inflammation and vaccination, on the other hand only lesions that need human interpretation were detected. ***Conclusion:*** This study demonstrates the potential of normalization and 2-bit-quantization of PSMA-PET using the visual miPSMA Score for deep learning AIs as a method to eliminate irrelevant image findings from PET images, thus reducing the workload of the reader. The AI itself currently still has a lot to learn, especially in regard to unspecific findings and low uptake lesions.

## EPS-006

### Retrospective Analysis of 666 Gallium-68 Labeled Somatostatin Receptor Antagonist PET/CT Imaging in Over 500 Patients: Experience from a Single Center in China

***W. Zhu***[1], *M. Liu*[1], *Y. Cheng*[1], *R. Jia*[2], *C. Bai*[1], *L. Huo*[1];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*The Fifth Medical Center, General Hospital of PLA, Beijing, CHINA.*

***Aim/Introduction:*** Somatostatin receptor (SSTR) antagonist is a type of somatostatin analogues characterized by low internalization rate and high tumor affinity. Promising results have been observed in preclinical and small-sample clinical studies using Gallium-68 labelled SSTR2 antagonist to characterize neuroendocrine tumors (NETs). We present here a large cohort of SSTR antagonist imaging studies in patients with confirmed/suspected NETs. ***Materials and Methods:*** We retrospectively reviewed all SSTR antagonist PET/CT imaging studies performed at our center from Nov 2018 to Mar 2023. The patient's demographic characteristics, indication, primary tumor, tumor grade, imaging probe, and imaging results (binary and quantitative) were recorded. A final clinical diagnosis was made for each patient based on all information available, including pathological results, clinical characteristics, complementary imaging modalities, and follow-up. It was recorded as positive/negative for NETs and served as ground truth to calculate the patient-level diagnostic efficacy of antagonist imaging. Comparative imaging was also performed in some patients using either $^{68}$Ga-DOTATATE or another SSTR antagonist. The quantitative parameters and binary imaging results were compared. ***Results:*** A total of 666 antagonist studies were reviewed in 593 patients. In 25 patients, the final diagnosis could not be made based on current information and required further follow-up. In the other 568 patients, 641 antagonist studies were performed, 64% (411/641) of which

were performed with $^{68}$Ga-NODAGA-LM3, 9% (58/641) with $^{68}$Ga-NODAGA-JR11, 16% (105/641) with $^{68}$Ga-DOTA-LM3, and 10% (67/641) with $^{68}$Ga-DOTA-JR11. The indications included NET (98%, 555/568) and PPGL (2%, 13/568). The primary locations of NET were from pancreas (54%, 301/555), rectus (12%, 66/555), small intestine (11%, 61/555), stomach (5%, 29/555), lung (5%, 27/555), thymus (3%, 17/555), others (4%, 21/555), and unknown (6%, 33/555). The patient-level sensitivity, specificity, and accuracy of antagonist imaging (all tracers combined) were 88.9% (487/548), 94.6% (88/93), and 89.7%(575/641), respectively. In particular, the patient-level sensitivity, specificity, and accuracy of $^{68}$Ga-NODAGA-LM3 was 89.1% (310/348), 93.7% (59/63), and 89.8% (369/411). Overall, the SUVmax of antagonist imaging is similar to agonist (39.6 vs. 39.5, n=133). However, remarkable differences were noted between different antagonists. While $^{68}$Ga-NODAGA-LM3 demonstrated higher uptake than $^{68}$Ga-DOTA-TATE (57.1 vs 40.0, n=30), $^{68}$Ga-NODAGA-JR11 (39.7 vs. 34.3, n=23) and $^{68}$Ga-DOTA-LM3 (38.0 vs. 37.8, n=40) showed similar uptake compared to $^{68}$Ga-DOTA-TATE and $^{68}$Ga-DOTA-JR11 showed the lowest uptake (28.1 vs. 43.8, n=40). ***Conclusion:*** Antagonist PET/CT is a powerful tool for NET imaging with high diagnostic efficacy. Of different antagonists, $^{68}$Ga-NODAGA-LM3 seems to have the best imaging profile.

## EPS-007

### [$^{18}$F]F-Al-NOTA-Octreotide versus [111In]In-DTPA-Octreotide for neuroendocrine tumours imaging: results of first 10 patients

***B. Arruda Matheos de Lima***[1], *R. C. M. Felix*[1], *P. B. Pujatti*[1], *D. A. Bulzico*[1], *M. P. Carneiro*[1], *M. A. S. Cardoso*[1], *M. L. Gomes*[1], *T. T. Guimarães*[1], *J. W. E. Silva*[1], *E. R. Oliveira*[1], *C. H. F. Costa*[1], *R. G. Silva*[1], *A. C. Bispo*[2], *D. M. Zouain*[2];
[1]*Brazilian National Cancer Institute, Rio de Janeiro, BRAZIL,* [2]*R2IBF Radiopharmaceuticals, Rio de Janeiro, BRAZIL.*

***Aim/Introduction:*** SPECT with [$^{111}$In]In-DTPA-octreotide is still an option in the context of public health systems of developing countries for neuroendocrine tumor (NET) imaging. However, it is well known this technique has several limitations that adversely affect its accuracy. Positron emission tomography (PET/CT) imaging using [$^{18}$F]F-AlF-NOTA-Octreotide would be a viable option, as it offers greater spatial resolution and better anatomical localization than SPECT/CT and the radiopharmaceutical is superior in technical aspects of its implementation and costs, being the choice for services that could not prepare [$^{68}$Ga] Ga-somatostatin analogues. ***Materials and Methods:*** This study was a prospective, non-randomised, controlled and blinded clinical trial, designed to compare, for the first time, the effectiveness of PET/CT with [$^{18}$F]F-AlF-NOTA-Octreotide and SPECT/CT with [$^{111}$In] In-DTPA-octreotide, in detecting lesions during staging, restaging and follow-up of neuroendocrine tumors. Patients referred to the nuclear medicine service of a public hospital for SPECT with [$^{111}$In]In-DTPA-octreotide were invited to also undergo the PET/CT with [$^{18}$F]F-AlF-NOTA-Octreotide; no later than three weeks after SPECT. ***Results:*** So far, 10 patients were included, seven female; mean age 57.7 ± 11.9 years; grade I (n = 2) and grade II (n = 8); gastrointestinal (n = 6), pancreatic (n = 2), lung (n = 1) or primary unknown NET (n = 1). [$^{111}$In]In-DTPA-octreotide identified hepatic metastasis in seven patients - one patient with one, one with 2-5 and five with >5 lesions (Kreening 3-4) - and [$^{18}$F]F-AlF-NOTA-Octreotide in eight patients - three with 2-5 and five patients with >5 lesions [SUVmax 19.07 ± 8.1 and tumour-to-background ratio (TBR) 4.16 ± 1.2]. Positive lymph nodes were found in three patients with [$^{111}$In]In-DTPA-octreotide - one in two patients and 2-5 in one patient (Kreening 3) - and five in PET/CT with [$^{18}$F] F-AlF-NOTA-Octreotide - one in one patient; 2-5 in two and >5 in five patients (SUVmax 8.94 ± 8.5; TBR 0.61 ± 0.3) in PET/CT (p = 0.345). In addition, [$^{18}$F]F-AlF-NOTA-Octreotide imaged lesions in pancreas in two patients (SUVmax 16.00 ± 8.7; TBR 3.10 ± 0.9) and in bone in three patients (SUVmax 3.05 ± 1.8; TBR 0.50 ± 0.0), which were not previously identified by [$^{111}$In]In-DTPA-octreotide. ***Conclusion:*** These preliminary results showed that PET/CT with [$^{18}$F]F-AlF-NOTA-Octreotide detected a greater number of lesions than SPECT/CT with [$^{111}$In]In-DTPA-octreotide in liver and lymph nodes and extra-hepatic disease, not identified in SPECT/CT with [$^{111}$In]In-DTPA-octreotide (upstaging) and a high liver TBR, which enables better lesion delineation.

## EPS-008

### Quantification of $^{177}$Lu-DOTATATE uptake in neuroendocrine tumors using a fast whole-body 360° CZT-SPECT/CT camera for monitoring and prediction of treatment response

***C. Boursier***[1,2,3], *J. Grangeret*[1], *E. Chevalier*[1], *G. Karcher*[3], *L. Imbert*[1,2,3], *P. Marie*[1,2,3];
[1]*Université de Lorraine, Department of Nuclear Medicine, CHRU Nancy, Vandoeuvre-les-Nancy, FRANCE,* [2]*Université de Lorraine, IADI, INSERM U1254, Nancy, FRANCE,* [3]*Nancyclotep Imaging Platform, Nancy, FRANCE.*

***Aim/Introduction:*** This study aimed to assess the results provided by whole-body SPECT images recorded after $^{177}$Lu-DOTATATE injection using a high-speed whole-body 360° CZT-SPECT camera for monitoring and prediction of treatment response in patients with metastatic neuroendocrine tumors (NET), with a comparison to pre-therapeutic $^{68}$Ga-DOTATOC PET. ***Materials and Methods:*** We included consecutive patients with metastatic NET treated by 2 to 4 injection-cycles of $^{177}$Lu-DOTATATE and who underwent a pre-therapeutic $^{68}$Ga-DOTATOC PET and subsequently, 18-minute whole-body $^{177}$Lu 360° CZT-SPECT recording after each $^{177}$Lu-DOTATATE injection. The tumor Standardized Uptake Values (SUV) were compared according to the presence or absence of a significant volume change (> 28%) between pre- and post-therapeutic MRI investigations. ***Results:*** A total of 39 tumors from 14 patients (67±11 years, 7 women) were considered and among these tumors, 8 from 4 patients had a decreased volume (V-), 24 from 11 patients had an unchanged volume (V±), and 7 from 5 patients had an increased volume (V+) during treatment. The V- NETs were strongly predicted by high tumor SUV measured on either: (i) the $^{177}$Lu-DOTATATE SPECT recorded after the first injection (for SUV mean, V-: 17.9±8.4 vs. V±: 8.5±4.8 or V+: 4.7±5.0, both $p \leq 0.001$) or (ii) the pre-therapeutic $^{68}$Ga-DOTATOC PET (V-: 42.9±21.9 vs. V±: 13.0±6.4 or V+: 10.8±7.2, both $p<0.001$). However, this initial higher uptake within V- NETs was not observed on the $^{177}$Lu-DOTATATE SPECT recorded after the 2$^{nd}$, 3$^{rd}$, or 4$^{th}$ injections and there was no difference in all SUV comparisons made between V± and V-. The tumor uptake of $^{177}$Lu-DOTATATE exhibited a decrease during treatment in V- (p=0.01 for both SUV max and SUV mean), whereas no significant changes with time were observed on SUV from the V± or V+ tumor groups. ***Conclusion:*** The shrinkage of NETs treated by $^{177}$Lu-DOTATATE may be predicted by a particularly high tumor uptake on the whole-body $^{177}$Lu-SPECT recorded after the first injection, and a similar prediction may be achieved on a pre-therapeutic $^{68}$Ga-DOTATOC PET. By contrast, the $^{77}$Lu-SPECT recorded after the 2nd, 3rd or 4th $^{177}$Lu-DOTATATE injections are poorly predictive, presumably because of treatment-related remodeling factors.

## EPS-009

### Bone marrow absorbed doses during treatment with [177Lu]Lu-DOTATATE assuming a specific uptake in the red marrow

***L. Hagmarker***[1], *J. Svensson*[2], *T. Rydén*[1], *M. Van Essen*[3], *A. Sundlöv*[4], *P. Gjertsson*[3], *K. Sjögreen Gleisner*[5], *P. Bernhardt*[1]; [1]*Department of Radiation Physics, Gothenburg, SWEDEN,* [2]*Sahlgrenska Academy, Gothenburg, SWEDEN,* [3]*Department of Clinical Physiology, Gothenburg, SWEDEN,* [4]*Department of Oncology and Pathology, Clinical Sciences, Lund, SWEDEN,* [5]*Department of Radiation Physics, Lund, SWEDEN.*

***Aim/Introduction:*** Treatment with [177Lu]Lu-DOTATATE irradiates the radiosensitive hematopoietic stem cells in red marrow causing grade ¾ hematological toxicities in up to 10% of patients. Expression of somatostatin receptors subtype 2 on CD34+ stem cells has been previously identified, potentially leading to retention in the bone marrow cavities. Accurate yet accessible dosimetry methods are crucial to understand and potentially prevent hematological toxicities in the future as peptide receptor radiotherapies are increasingly utilized. Considering the specific uptake in red marrow, our aim has been to investigate a new hybrid dosimetry method. ***Materials and Methods:*** The study includes the first two treatment fractions of 49 patients treated with [177Lu]Lu-DOTATATE. 4 planar images (2, 24, 48 and 168 h.p.i.) and a SPECT-CT (24 h.p.i.) were collected. In planar images, the body was divided into a high-uptake compartment (HC) consisting of liver, spleen, kidneys, and tumours, and a low-uptake compartment (LC) consisting of the rest of the body. The bone marrow absorbed dose (BM) was calculated as the sum of the cross-doses from the HC and LC and the self-dose, estimated using the kinetics from the planar images, adjusted by the activity concentration in the lumbar vertebrae in the SPECT images. Two methods were employed: utilizing the kinetics of the LC or the HC. ***Results:***The median BM where estimated to 0.32 Gy/7.4 GBq and 0.29 Gy/7.4 GBq using the kintics of LC for treatment fraction one and two, respectively. Using the kinetics of the HC, the median BMs were 0.39 and 0.40 Gy/7.4 GBq. The correlation between the BM and the level of platelet counts were significant for both methods after treatment fraction one and two with r-values at 0.43 and 0.72 using the kinetics of the LC and 0.45 and 0.65 using the kinetics of the HC. ***Conclusion:*** Due to the prolonged retention observed for [177Lu]Lu-DOTATATE in bone cavities, the kinetics of the bone marrow was equated to that of the high-uptake compartment. The correlation between BM and platelet count was expected to be stronger when utilizing the kinetics of the HC. However, this was only achieved after treatment fraction one. ***References:*** Hagmarker L, Svensson J, Rydén T, Gjertsson P, Bernhardt P. Segmentation of Whole-Body Images into Two Compartments in Model for Bone Marrow Dosimetry Increases the Correlation with Hematological Response in $^{177}$Lu-DOTATATE Treatments. Cancer Biother Radiopharm. 2017 Nov;32(9):335-343. doi: 10.1089/cbr.2017.2317. Epub 2017 Nov 10. PMID: 29125780.

## EPS-010

### Inpatient admissions for hormone secretion management in patients with neuroendocrine neoplasms treated with [177Lu]Lu-DOTA-Octreotate therapy over a 3-year period at a single high volume treatment centre

***L. Neeson***[1], *E. Boehm*[1], *T. Akhurst*[2], *R. Alipour*[1], *A. Cardin*[1], *C. Chiang*[1], *M. Hofman*[1], *M. Lee*[1], *M. Michael*[2], *A. S. Ravi Kumar*[2], *N. Sachithanandan*[1], *J. Saghebi*[1], *H. Wong*[1], *G. Kong*[2]; [1]*Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [2]*Peter MacCallum Cancer Centre and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** Peptide Receptor Radionuclide Therapy (PRRT) is an effective therapeutic option for patients with somatostatin receptor expressing neuroendocrine neoplasms. However, patients with functional tumours may develop an acute flare of symptoms during or after PRRT. The aim of this study was to review the incidence and outcomes of patients requiring hospital admission for hormone secretion within the 14 days following [177Lu]Lu-DOTA-Octreotate (LuTate) at one NET centre. Outcomes measured were elective versus unplanned admissions, length of stay and level of care required. ***Materials and Methods:*** A retrospective review of all patients who received LuTate between March 1 2020 and March 31 2023 was performed. Before treatment, all patients were reviewed by the Nuclear Medicine Team and identified as high risk if they had any of the following risk factors: a functional tumour with high tumour markers, previous hospital admissions for functional syndromes, high burden of disease or baseline uncontrolled symptoms on maximal medical therapy. Patients were discussed at a Multi Disciplinary Meeting to determine requirements for elective inpatient LuTate. Prior to elective admission the oncology, endocrinology, high-acuity management teams, and ward staff were formally notified, and patients' medical status optimised by specialist physicians. ***Results:*** 265 patients (150 males, age range 11 to 94 years, median 65 years) received a total of 716 cycles of LuTate. 20 patients (8%), 24 treatments, were admitted electively for hormone secretion management (12 phaeochromocytoma/paraganglioma, 7 carcinoid, 3 insulinoma, 2 Cushing's), of whom 7 patients (9 treatments total, 38% of admitted treatments) experienced a flare in hospital. Only one patient had an unplanned admission due to hormonal flare post LuTate (management of Cushing's syndrome). Median length of stay was 2 days (range 2-19) for the elective group vs the 14 day stay for the single unplanned admission. All patients received multidisciplinary inpatient care. None of the elective/unplanned admissions required escalation of care above ward level management. There were no deaths in this time period. ***Conclusion:*** This study suggests that hormone flare should be considered as a risk for patients with functional NET undergoing PRRT. With identification of high-risk patients, adequate pre-treatment patient preparation, and planned multidisciplinary involvement, the incidence of unplanned admission for hormone flare and requirement for intensive care utilisation is very low at our hospital after LuTate treatment.

## EPS-011

### Impact of volumetric parameters applied to $^{177}$Lu-DOTATATE SPECT-CT in the survival of NET patients after PRRT

***S. Menendez-Sanchez***[1], *V. Betech-Antar*[1], *E. Guillen*[2], *J. Rosales*[1], *L. Garcia-Belaustegui*[2], *A. Bronte*[1], *J. Bastidas*[1], *T. Cuenca*[1], *P. Echegoyen*[1], *A. Chopitea*[1], *E. Prieto*[1], *J. Martí-Climent*[1], *J. Arbizu*[1]; [1]*Clínica Universidad de Navarra, Pamplona, Navarra, SPAIN,* [2]*Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** To evaluate differences in volumetric parameters of 177Lu-DOTATATE SPECT/CT between PRRT cycles as a potential marker of survival prognosis. ***Materials and Methods:*** We studied 19 NET patients (5 foregut / 5 midgut / 5 hindgut /3 pheochromocytoma-paraganglioma / 1 lung), mean age 55yo [±14.2], 52.6% males, referred to PRRT using 177Lu-DOTATATE. Mean activity was 28.8 GBq [±2.05]). Volumetric parameters of SPECT-CT performed 24 hours after first (C1) and fourth (C4) cycles included Metabolic -Tumor- Volume (MTV) and

Total- Lesion -Activity (TLA) of selected regions. MTV and TLA were obtained using both three-dimensional volume-of-interest isocontouring and whole-body thresholding techniques combined with automated segmentation of liver, and skeleton on CT images, with lesions outside those organs separately assigned to abdomen as appropriate, using work in progress syngo.via MI General Anatomy Segmentation software (Siemens Healthineers, Knoxville, TN). Sign test and Cox regression statistical analyses of volumetric parameters between C1 and C4 PRRT cycles with respect to PFS and OS were conducted. ***Results:*** Changes in the calculated MTV and TLA values between C1 and C4 cycles in the selected regions of the whole population didn't reach statistical significance (table 1). On the other hand, TLA in the selected regions, when present, remained stable in 11 patients, decreased in 7 patients and increased in 1 patient, but didn't correlate with survival. PFS rates at one, two and three years after PRRT were 81.7% (95% CI: 0.53 - 0.93), 44.95% (95% CI: 0.19 - 0.68) and 33.7% (95% CI: 0.10 - 0.59), respectively. OS rates were 88.8% (95% CI: 0.62 - 0.97), 73.79% (95 CI: 0.43 - 0.89) and 59.03% (95 CI: 0.23 - 0.82)respectively.Patients with reductions in Liver MTV and TLA showed a longer OS (HR:0.99; p=0.03; and HR:0.99; p=0.06, respectively), but does not correlate with increase of PFS (p=0.36). However, neither Abdomen nor Skeleton MTV and TLA reductions showed a longer OS or PFS (table 2). ***Conclusion:*** Liver MTV and TLA reduction between PRRT cycles correlate with longer OS and might be used as an effective tool for PRRT response assessment. Validation of the results with a larger cohort is recommended.

## EPS-012

### Metabolic tumor volume response on FDG-PET after [$^{131}$I]MIBG radiotherapy in patients with metastatic pheochromocytomas and paragangliomas predicts their prognosis

***J. Takenaka***[1,2], *S. Watanabe*[1,2], *T. Abe*[3], *T. Tsuchikawa*[4], *S. Takeuchi*[5], *K. Hirata*[1,2,6], *R. Kimura*[1,7], *N. Wakabayashi*[1,2], *N. Shinohara*[3], *K. Kudo*[1,6,7];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [3]*Department of Renal and Genitourinary surgery, Hokkaido University Graduate School of Medicine, Sapporo, JAPAN,* [4]*Department of Gastroenterological Surgery II, Hokkaido University Graduate School of Medicine, Sapporo, JAPAN,* [5]*Department of Medical Oncology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [6]*Division of Medical AI Education and Research, Hokkaido University Graduate School of Medicine, Sapporo, JAPAN,* [7]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.*

***Aim/Introduction:*** Pheochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine tumors producing catecholamines. Radionuclide therapy with [$^{131}$I]metaiodobenzylguanidine(MIBG) is a first-line treatment for MIBG-avid unresectable or metastatic PPGLs. Previously, we reported high metabolic tumor volume (MTV) can be a poor prognosis factor. In this study, we evaluated metabolic response (i.e., MTV change) to first [$^{131}$I]MIBG therapy in unresectable or metastatic PPGLs patients in relation to other clinical factors. ***Materials and Methods:*** Between 2001 and 2020, 28 patients with unresectable or metastatic PPGL could be followed up for at least 1 month after the first [$^{131}$I]MIBG therapy at our institute. Excluding patients with unavailable prognosis data, clinical data insufficiency except FDG-PET, we analyzed 20 patients undergoing FDG-PET before and after first [$^{131}$I]MIBG therapy. We utilized a single dose of 5.5GBq of [$^{131}$I]MIBG three times basically, although for some cases the number of treatments were increased or decreased considering treatment efficacy and side effects. MTV was calculated using liver SUV (mean+3SD) as a threshold on the free software Metavol (Hirata K, et al. PLoS ONE. 2014). Partial remission (PR) was defined as a ≥30% decrease in MTV, progressive disease (PD) as a ≥30% increase, and stable disease (SD) as a change between -30% and +30%. We divided the patients into PD group and non-PD group and OS of each group was compared using log-rank test. Relationship between metabolic response and other factors (age, sex, tumor type (pheochromocytoma vs. paraganglioma), metastatic sites, history of chemotherapy or external radiation, and 24-hour urine catecholamine levels) were evaluated using logistic regression analysis. ***Results:*** Median follow-up time was 55.5 months (range: 2-136) and 9 (45%) patients died. The number of [$^{131}$I]MIBG therapy per patient ranged 1 to 8 (median 3[HK1] ). Semi-quantitative analysis showed median pre- vs. post-treatment MTV 1. 63×10 (range: 0-2.02×10$^2$) mL vs. 2.12×10 (range: 0-8.60×10$^2$) mL. Two patients were classified as PR, 10 patients as SD, and 8 patients as PD There was a significant difference in prognosis between the PD and non-PD groups as assessed by MTV (p = 0.0141). Higher urinary dopamine was significantly associated with poor metabolic response ([OR] = 1.002, p = 0.029); however, the other clinical parameters were not significant. ***Conclusion:*** Poor metabolic response, measured with MTV, to first [$^{131}$I]MIBG therapy in unresectable or metastatic PPGLs was related to shorter OS. Poor metabolic response can be predicted using urinary dopamine level.

## EPS-013

### Late toxicity after peptide receptor radioligand therapy (PRRT) therapy in neuroendocrine neoplasm.

***D. Handkiewicz-Junak****, A. Sygula, A. Ledwon, K. Hassse-Lazar, B. Jurecka-Lubieniecka, E. Paliczka-Cieślik, A. Kropinska, T. Olczyk, T. Gawlik;*
*Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice, POLAND.*

***Aim/Introduction:*** Radioligand therapy is an effective treatment of neuroendocrine tumors. Apart from efficacy toxicity is a important factor when establishing the best therapeutic approach. The aim of our study was to evaluate late toxicity of PRRT in patients with well differentiated neuroendocrine tumors. ***Materials and Methods:*** The study enrolled 115 NET patients treated with PRRT therapy from 08.2005 to 11.2012. Patients were treated either with 4 cycles of 90Y-DOTATATE (80 mCi per cycle) or 4 cycles of 90Y-DOTATATE (80 mCi per cycle) and 1 cycle of 177Lu-DOTATATE (200 mCi). After the completition of the theraoy patients were randomly assigned to somatostatin analouges therapy or observation. ***Results:*** The mean follow-up time from the first cycle of isotopic treatment to the last observation or death was 6.6 (3.18-10.22) years. During this time late and persistent creatinine elevation occurred in 46/115 patients (40%) and was of G1 grade in almost half of the patients 22 (19.1%). Eleven 11/115 (9.6%) developed G3/4 nephrotoxicity. In the univariate analysis, there was no statistically significant correlation between - chemotherapy, MIBG therapy, computed tomography with iodinated contrast, hypertension/diabetes, age or with somatostatin analogues after PRRT - and elevated creatinine.Acute bone marrow damage after isotope treatment was mostly mild and reversible, occurring in 33/115 (28.7%) patients, mainly in grade G1/G2 3(0/115 patients; 26%). In 3 patients (2,6%) thrombocytopenia G3 was

diagnosed. In 4/115 (3.5%) patients serious, late haematological complications were diagnosed. In 1 patient, acute myeloblastic leukemia was diagnosed approximately 10 years after completion of chemotherapy (platinum based) and 8 years after completion of isotope treatment. Three patients underwent only isotopic treatment. No other malignancies were diagnosed. ***Conclusion:*** PRRT treatment is well tolerated but serious, late toxicity is diagnosed in up to 10% of patients.

## EPS-014

### RadioLigand Therapy: is it time to move towards a different dosimetric approach?

***A. Filice***[1], *R. Durmo*[1], *F. Fioroni*[2], *E. Grassi*[2], *C. Coruzzi*[1], *G. Besutti*[3], *S. Fanello*[4], *A. Frasoldati*[5], *S. Cavuto*[6], *L. Savoldi*[6], *A. Versari*[1];
[1]*Nuclear Medicine Unit Azienda USL-IRCCS, Reggio Emilia, ITALY,* [2]*Medical Physics Unit Azienda USL-IRCCS, Reggio Emilia, ITALY,* [3]*Radiology Unit, Azienda USL-IRCCS, Reggio Emilia, ITALY,* [4]*Medical Oncology Unit Azienda USL-IRCCS, Reggio Emilia, ITALY,* [5]*Department of Endocrinology and Metabolism Unit Azienda USL-IRCCS, Reggio Emilia, ITALY,* [6]*Clinical Trials and Statitistics Unit Azienda USL-IRCCS, Reggio Emilia, ITALY.*

***Aim/Introduction:*** The correlation between the tumour absorbed dose and radioligand therapy (RLT) response is very difficult to assess and so far, it has not been established. RLT has been shown to be very effective in patients with neuroendocrine tumours (NETs) but disease progression is reported in 20%-30% of patients. Treatment failure probably depends on many factors and our hypothesis is that it could also depend on the lower dose received by some lesions during treatment. Hence, we aim to evaluate a dose-response correlation for NET patients treated with RLT. ***Materials and Methods:*** The DOTATER-1 trial consisted in the administration of tandem Y90/177Lu-DOTATOC therapy in patients with advanced NET in a prospective, single-center, non-randomized phase II clinical study (EudraCT:2015-005546-63). 177Lu-DOTATOC was administered during the first course of therapy in order to obtain tumour absorbed dose, derived from the acquisition of 4 sequential SPECT/CT. An experienced nuclear medicine physician (AF) manually segmented lesions on 24-h SPECT/CT. Therapy response was assessed 3 months after RLT by CT using response assessment criteria in solid tumours (RECIST 1.1) or MRI, in particular for bone lesions. For statistical analysis, logistic regression for repeated measures was used. ***Results:*** Fifty-five patients 69.62%) with stable disease (SD) or partial response (PR) were classified as responders and 24 (30.38%) as non-responders. In total 258 lesions were analyzed: 209 (81%) with SD or PR classified as responders and 49 (19%) as non-responders. Hepatic lesions were 164 (63.6%), lymph node 40 (15.5%), bone 20 (7.7%), lung 4 (1.6%), pancreas 13 (5%), intestinal lesions 4 (1.6%) and other organs 13 (5%). Higher total lesion absorbed dose (TLAD) was related to PRRT response (OR 0.52, 95% CI 0.3-0.91; p=0.02). There was a statistically significant association between TLAD and response status for lymph node (OR = 1.20, p=0.0007; median dose 67 vs 6 Gy) and bone (OR = 1.13, p = 0.0147; median dose 88 vs 15 Gy) and a borderline result for liver (OR = 1.01, p=0.0595; median dose 105 vs 71 Gy). Finally, in terms of trend, the result obtained for other organs (OR = 1.02, p=0.0967; median dose 53 vs 35 Gy) was also interesting, considering the limited number of available lesions. ***Conclusion:*** Based on dosimetric evaluation significant results were obtained exploring the correlation between tumour absorbed dose and RLT response. These results suggest that dosimetric approach may be useful for predicting treatment response.

## EPS-015

### Value Of Early Metabolic Response For Predicting Axillary Pathological Complete Response During Neoadjuvant Systemic Therapy In Triple-negative And Her2-positive Breast Cancers: Impact Of Molecular Subtypes

***L. Guichard****, P. Nunes, C. Jankowski, A. Bertaut, S. Ladoire, E. Michel, C. Coutant, A. Cochet, J. Alberini;*
*Centre George Francois Leclerc, Dijon, FRANCE.*

***Aim/Introduction:*** In the era of therapeutic de-escalation, the opportunity to move from systematic axillary lymph node dissection (ALND) to sentinel lymph node (SLN) or target axillary dissection (TAD) in axillary node-positive breast cancer patients after neoadjuvant systemic therapy (NST) is currently considered. The purpose of this study was to identify FDG-PET parameters associated with axillary pathological complete response (pCRAx) in the most proliferative molecular subtypes, eg triple negative (TN) and Her2+. ***Materials and Methods:*** Patients with newly-diagnosed TN or Her2+ breast cancer, with histologically-proven axillary node metastasis, no distant metastasis and indication of NST were prospectively included. FDG PET/CT scans were performed at baseline and after one cycle of NST. Metabolic parameters at baseline (1) and their variations (Delta Δ) were assessed: Standard Uptake Values (SUVmax, ratio SUVmax/SUVmax hepatic, SUVpeak, SUVmean), Total Lesion Glycolysis (TLG), Metabolic Total Volume (MTV) for axillary node (Ax). All patients underwent ALND after NST. Logistic regressions with ROC curves were used to determine parameters associated with pCRAx. Optimal thresholds for quantitative parameters were determined using the Youden index method. ***Results:*** 61 patients (24 TN (a), 19 non-luminal Her2+ (b) and 18 luminal Her2+ (c)) were recruited. pCRAx was observed for 35 patients (54%, 79% and 39% in a, b and c groups). Median value of Axillary SUVmax at baseline (AxSUVmax1) were 7.9, 7.0 and 5.2 and of Axillary DeltaSUVmax (AxΔSUVmax) -62%,-60% and -47% in a, b and c groups, respectively. In univariate model, in the whole population, AxΔSUVmax showed the greatest AUC for prediction of pCRAx (0.72 [95%CI: 0.59-0.85]), whereas AxSUVmax1 AUC was not statistically significant (AUC=0.6 [95%CI: 0.46-0.74]). Specificity and sensitivity of AxΔSUVmax were 96% and 49% respectively for predicting pCRAx with an optimal threshold of -69%. Odd Ratio (OR) associated with AxΔSUVmax<-69% compared to ≥-69% was 24.0 [95%CI: 2.9-194]. In multivariate model, adjusted on molecular subtypes, AxΔSUVmax was still significantly associated with pCRAx (OR=20.7 [95%CI: 2.5-172]). AUCs adjusted on the molecular subtype were not significantly modified compared to univariate model (for AxΔSUVmax: AUC=0.72 [95%CI: 0.59-0.85]; p=0.45 compared to unadjusted AUC) suggesting that thresholds were not significantly different in each molecular subtype. ***Conclusion:*** Axillary DeltaSUVmax seems to be the most relevant metabolic parameter to predict an axillary pathological complete response and early metabolic response could be a valuable tool for selecting patients eligible for axillary surgical de-escalation after NST, regardless molecular subtypes.

## EPS-016

### Detection of HER2-low lesions using HER2-targeted PET imaging in patients with HER2-negative metastatic breast cancer

***R. Yeh***[1], *S. K. Lyashchenko*[1], *B. M. Zeglis*[1,2], *J. S. Lewis*[1], *G. A. Ulaner*[3,1];
[1]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Hunter College - City University of New York, New York, NY, UNITED STATES OF AMERICA,* [3]*Hoag Family Cancer Institute, Irvine, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Trastuzumab deruxtecan (T-DXd), a HER2-targeted antibody-drug conjugate, has led to a major paradigm shift in the treatment of patients with HER2-low breast cancer and established HER2-low as a new targetable patient population, shifting away from the historical binary categorization of HER2 status as either HER2-positive or -negative. Our prior experience with HER2 PET imaging with radiolabeled anti-HER2 antibodies demonstrated a high number of false positives for HER2-positive malignancy when compared to biopsy, limiting clinical utility (1-3). We hypothesize that HER2 PET imaging may be detecting HER2-low lesions in addition to HER2-positive lesions, thus possibly explaining the high false positive rate. ***Materials and Methods:*** We retrospectively reviewed the pathology and imaging results from a prior prospective clinical trial (ClinicalTrials.gov NCT02286843) evaluating HER2 PET imaging with 89Zr-trastuzumab and 89Zr-pertuzumab PET/CT in women with HER2-negative breast cancer. In this study, patients with tracer avid lesions underwent biopsy. HER2 status was determined using HER2 immunohistochemistry (IHC) and in situ hybridization (ISH). HER2-positive was defined as IHC 3+ or 2+ with positive ISH, HER2-low as IHC 1+ or 2+ with negative ISH, and HER2-zero as IHC 0. ***Results:*** Forty-four patients underwent HER2 PET imaging, 20 patients with 89Zr-trastuzumab and 24 patients with 89Zr-pertuzumab. In the 89Zr-trastuzumab cohort, 9 out of 20 patients had suspicious tracer-avid lesions with subsequent biopsies demonstrating 6 HER2-low (66.7%) and 3 HER2-positive lesions (33.3%). In the 89Zr-pertuzumab cohort, 7 out of 24 patients had suspicious tracer-avid lesions with subsequent biopsies demonstrating 5 HER2-low (71.4%) and 2 HER2-positive lesions (28.6%). No lesions were classified as HER2-zero. ***Conclusion:*** We performed a re-analysis of our prior prospective clinical trial of HER2 PET imaging in the context of HER2-low breast cancer and found that most tracer-avid lesions previously classified as HER2-negative were in fact HER2-low. This finding most likely explains what we previously considered false positive HER2 PET scans and suggests that HER2 PET may be useful for detecting HER2-low lesions and allow patients to qualify for T-DXd therapy. ***References:*** 1.Ulaner,G, et al., Identification of HER2-Positive Metastases in Patients with HER2-Negative Primary Breast Cancer by Using HER2-targeted (89)Zr-Pertuzumab PET/CT. ***Aim/Introduction:*** Clinical trials demonstrated increased rates of pathologic complete response (pCR) at the time of surgery with the addition of pembrolizumab, an anti-PD1 immune checkpoint inhibitor (ICI), to neoadjuvant chemotherapy (NAC) for patients with early triple-negative breast cancer (eTNBC). However, ICI leads to immune-related adverse events (irAEs). We aimed to determine if pretreatment [18F]FDG PET/CT could contribute to predicting pCR after NAC +/- pembrolizumab (NAC vs NAC+p) and the risk of developing ICI-induced hypothyroidism. ***Materials and Methods:*** In this retrospective bicentric study, we included eTNBC patients who underwent [18F]FDG PET/CT before NAC +/- pembrolizumab between March 2017 and August 2022. Clinical, biological and pathological data were collected. Endpoints were the rate of pCR and the occurrence of ICI-induced hypothyroidism. Total metabolic tumor volume (TMTV: p [primary] +/- ln [lymph node(s)] using a 41%-SUVmax threshold), tumor (p or ln) and thyroid SUVmax were measured. Cut-off values were determined by maximizing the Younden index. A multivariable model was developed using logistic regression to predict pCR. ***Results:*** A total of 191 patients were included (n=91/NAC; n=100/NAC+p). pCR rates were 53% and 70% in patients treated with NAC and NAC+p, respectively ($p<0.01$). In univariable analysis, high Ki67, high tumor SUVmax (>12.3) and low TMTV (≤ 3.0 cm3) were predictors of pCR in the NAC cohort while tumor staging classification (<T3), BRCA1/2 germline mutation, high tumor SUVmax (>17.2) and low TMTV (≤ 7.3 cm3) correlated with pCR in the NAC+p cohort. In multivariable analysis, only high tumor SUVmax (NAC: OR 8.8, $p<0.01$; NAC+p: OR 3.7, $p=0.02$) and low TMTV (NAC: OR 6.6, $p<0.01$; NAC+p: OR 3.5, $p=0.03$) were independent factors for pCR in both NAC and NAC+p patients, albeit at different thresholds. ICI-induced hypothyroidism was diagnosed in 10 patients (10%) in the NAC+p cohort. Thyroid SUVmax before pembrolizumab exposure predicted ICI-induced hypothyroidism with an area under the ROC curve of 0.67. Thyroid SUVmax was higher in patients who developed ICI-induced hypothyroidism compared to patients who did not without reaching statistical significance. ***Conclusion:*** High tumor metabolism and low tumor burden on pretreatment [18F]FDG PET/CT could predict pCR after NAC regardless of the addition of pembrolizumab. Our data suggest that high thyroid uptake may help in the early detection of patients at higher risk of developing ICI-induced hypothyroidism. Further validation studies are needed to determine how these biomarkers could be used to develop more personalized and effective treatment strategies for TNBC patients.

## EPS-018

### Dynamic $^{18}$F-FLT PET Radiomics: a Novel and Promising Approach for an Improved Breast Cancer Prognosis Prediction

***M. Inglese***[1,2], *M. Ferrante*[1], *T. Boccato*[1], *N. Toschi*[1,3];
[1]*University of Rome Tor Vergata, Rome, ITALY,*
[2]*Imperial College London, London, UNITED KINGDOM,*
[3]*Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Breast cancer (BC) is the most prevalent malignancy among women[1]. Existing imaging techniques for BC categorization and prediction are limited in sensitivity and specificity due to clinical and technological factors[2]. In this context, positron emission tomography (PET) identifies abnormal metabolic activity, offering crucial qualitative and quantitative tumor-related metabolic data[3]. In particular, $^{18}$F-Fluorothymidine (FLT), a labeled thymidine analogue, exhibits correlations with Ki-67 in breast, lung, and brain cancers, and generally demonstrates higher specificity and reproducibility[4,5] as compared to conventional tracers[6].While PET data is commonly processed through radiomics approaches in a static manner, in this study we posit that extending radiomics techniques to the time domain ("dynamic radiomics") has the potential to extract more clinically useful information from the dynamic PET signal. ***Materials and Methods:*** A public clinical dynamic 18F-FLT PET dataset (44 BC patients from The Cancer Imaging Archive-ACRIN 66888-10, comprising 19 partial (PR) and 12 complete responders (CR)) was employed[7,8,9]. An experienced radiologist manually contoured volumes of interest around tumor and healthy regions on static PET images. 107 radiomic features for each dynamic PET frame were extracted using the Pyradiomics module (Python), after which their median and median absolute deviation(MAD) across time were computed and reduced to 7 features using principal component analysis(on training sets only - the transformation matrix was then reapplied to test sets). We used the XGBoost model in 5-fold nested cross-validation fashion, including hyperparameter optimization(inner loop) and performance quantification(outer loop) to discriminate 1) tumor vs. reference tissue and 2) CR vs. PR with both conventional static and dynamic radiomic features. Dynamic radiomics (using median, MAD and median + MAD radiomic feature values) was also compared to raw PET data given as input to deep learning models used in[10]. ***Results:*** Tumor vs. reference tissue: radiomics (both static and dynamic) surpassed standard PET image use, achieving 94% accuracy (0.94 AUC) compared to 61% accuracy(0.59 AUC) and 75% accuracy(0.81 AUC) obtained with 3D and 4D PET data, respectively. CR/PR classification: dynamic radiomics attained the highest performance at 86% accuracy (0.83 AUC), outperforming both static radiomics (71% accuracy, 0.67 AUC) and standard PET data (both static(59% accuracy, 0.51 AUC) and dynamic(60% accuracy, 0.59 AUC)). ***Conclusion:*** This study marks the first application of a radiomic approach to dynamic FLT-PET data, demonstrating its superiority in assessing treatment response compared to the conventional static radiomic approach, which is only adequate for simpler tasks, such as lesion/reference tissue classification. ***References:*** 1. ### The Influence of Histological Subtypes and Tumour Grade on the Performance of [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT in Staging Patients with Estrogen Receptor Positive Breast Cancer

***J. J. Knip***[1,2], *R. Iqbal*[1,2], *A. van Zweeden*[3], *L. H. Mammatas*[4], *J. J. M. Teunissen*[4], *S. van der Velde*[1], *E. Barbé*[1], *K. M. Duvivier*[1], *D. E. Oprea-Lager*[1], *A. D. Windhorst*[1], *R. Boellaard*[1], *C. W. Menke-van der Houven van Oordt*[1,2];
[1]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*Cancer Center Amsterdam, Amsterdam, NETHERLANDS,*
[3]*Ziekenhuis Amstelland, Amstelveen, NETHERLANDS,*
[4]*Reinier de Graaf Gasthuis, Delft, NETHERLANDS.*

***Aim/Introduction:*** Patients with clinical stage II/III or locoregional recurrent (LRR) estrogen receptor positive (ER+) breast cancer (BC) have a significant risk (10-25%) of metastatic disease at presentation. Correct identification of all tumour lesions (i.e., staging) is paramount for an optimal treatment plan. Current guidelines advise staging with positron emission tomography (PET) using 2-[$^{18}$F]fluoro-2-deoxy-D-glucose ([$^{18}$F]FDG), combined with diagnostic computed tomography (CT). However, [$^{18}$F]FDG-PET/CT can be false negative with lobular and low-grade ER+ BC. An alternative is 16α-[$^{18}$F]-fluoro-17β-estradiol ([$^{18}$F]FES), a PET tracer which accumulates in ER+ lesions regardless of metabolic activity. The aim of this study was to investigate the influence of histological subtypes and tumour-grade on the performance of [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT in staging patients with ER+ BC. ***Materials and Methods:*** We analysed patients with stage II/III or LRR ER+ BC that were included in a prospective multicentre clinical trial (NCT03726931). All patients underwent an [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT within a time-frame of 21 days with at least 24h between the scans. Both scans were independently assessed. Visually suspect lesions for malignancy were verified pathologically (by biopsy or fine needle aspiration) or by conventional imaging (mammography, ultrasound, magnetic resonance imaging, CT). The stage of disease was determined independently, based on conventional diagnostics (conventional imaging and pathology) and [$^{18}$F]FDG-PET/CT or [$^{18}$F]FES-PET/CT, respectively. ***Results:*** 40 patients were included, with 43 primary breast tumours. For invasive lobular carcinoma (ILC), [$^{18}$F]FDG-PET/CT correctly staged 9/15 (60%), whereas [$^{18}$F]FES-PET/CT correctly staged 14/15 (93%). All 6 patients incorrectly staged with [$^{18}$F]FDG-PET/CT were correctly staged with [$^{18}$F]FES-PET/CT, with up-staging in 5 patients and down-staging in one. For grade-1 ILC (n = 3), staging by [$^{18}$F]FDG-PET/CT was incorrect in all cases, while [$^{18}$F]FES-PET/CT was correct. For invasive ductal carcinoma (IDC), [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT correctly staged 21/26 (81%) and 22/26 (85%), respectively. Of the 5 patients incorrectly staged with [$^{18}$F]FDG-PET/CT, 3 were correctly staged with [$^{18}$F]FES-PET/CT with up-staging in 2 and down-staging in one. For grade-1 IDC (n = 7), [$^{18}$F]FDG-PET/CT correctly staged 5/7 (71%), and [$^{18}$F]FES-PET/CT correctly staged 7/7 (100%). For all grade-1 tumours combined, [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT correctly staged 6/12 (50%) and 11/12 (92%), respectively. ***Conclusion:*** Both histological subtype and tumour-grade influence staging based on [$^{18}$F]FDG-PET/CT and [$^{18}$F]FES-PET/CT. The largest benefit of additional staging with [$^{18}$F]FES-PET/CT is seen in ILC and grade-1 tumours. These data can help to further define the role of [$^{18}$F]FES-PET/CT in staging patients with stage II/III and LRR ER+ BC.

## EPS-020

### Utility of 18F-FDG PET-CT in the evaluation of para-aortic lymph nodes in the staging of locally advanced cervical cancer

***G. Cuesta Domingo***[1], *C. Rodríguez Rey*[1], *A. Ortega Candil*[1], *R. Cano Carrizal*[2], *P. Nespral*[1], *P. Bascuñana*[1], *P. Romero Fernández*[1], *A. Berardinelli Isea*[1], *M. Meneses Navas*[1], *M. Cabrera Martín*[1]; [1]*Department of Nuclear Medicine, Instituto de Investigación Sanitaria San Carlos (IdISSC). Hospital Clínico San Carlos, Universidad Complutense., Madrid, SPAIN,* [2]*Department of Cardiology, Hospital Infanta Sofia, Madrid, SPAIN.*

***Aim/Introduction:*** In locally advanced cervical cancer (LACC), the status of para-aortic lymph nodes is crucial in planning radiotherapy treatment. There is controversy regarding the best method for para-aortic lymph node staging: para-aortic lymphadenectomy (PLND) versus imaging staging (PET-CT). The aim of our study is to analyze the negative predictive value (NPV) of PET-CT in detecting para-aortic lymph node involvement when there are positive pelvic lymph nodes. ***Materials and Methods:*** Retrospective study between 2010-2023 that includes 188 patients with LACC (stages IB3-IVA) who come to our center for staging. Those patients with pelvic lymph node involvement and without para-aortic involvement on PET-CT who underwent subsequent PLND were included in the analysis, resulting in a final sample of 42 patients. ***Results:*** The mean age of the patients was 48.54±11.10 years. 69.05% (29) were stage IIB, being squamous cell carcinoma (88.10%) the most frequent histological subtype. Of the 42 patients included, 19 (45.24%) had pathological uptake in unilateral pelvic lymph nodes (more frequently on the left side, 63.16%) and 23 (54.80%) in bilateral pelvic lymph nodes. Of the 42 patients, 5 (11.9%) had para-aortic lymph node involvement on PLND, resulting in a NPV of PET-CT of 88.10%. The proportion of patients with para-aortic involvement on PLND was similar in those with bilateral or unilateral pelvic lymph node involvement (8.70% vs 15.79%; p=0.48). ***Conclusion:*** PET-CT shows a high NPV in detecting retroperitoneal lymph node involvement in LACC when there is pelvic lymph node affectation. However, we cannot ignore the number of false negatives of the technique, so it would be necessary to appropriately select, based on risk, those patients who would benefit from PLND.

## EPS-021

### Surgical evidence-based comparison of $^{68}$Ga-FAPI PET/MRI and DW-MRI for assisting debulking surgery decision in ovarian cancer

***X. Li***[1], *F. Kang*[1], *S. Liu*[2], *T. Han*[3], *J. Wang*[1]; [1]*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA,* [2]*Department of Gynaecology and Obstetrics, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA,* [3]*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** Imaging assessment of tumor burden is important for debulking surgery choice in ovarian cancer patients. This study aims to evaluate the diagnosticefficiency of fibroblast activation protein (FAP) targeted $^{68}$Ga-FAPI PET/MRI and DWI-MRI for assessing abdominopelvic tumor burden of ovarian cancer and its impact to debulking surgery decision. ***Materials and Methods:*** Thirty-six patients were prospectively enrolled and underwent integrated $^{68}$Ga-FAPI PET/MR-DWI scan before debulking surgery. The $^{68}$Ga-FAPI PET/MRI and DWI-MRI results were independently analyzed by per-lesion comparison referenced with surgical proof. The accuracy, sensitivity, specificity, missing rate, consistency and inconsistency of the two modalities were analyzed in region/ patient-based manner. Relationship of FAP expression and implants size were also analyzed. ***Results:*** $^{68}$Ga-FAPI PET/MRI outperformed DWI-MRI in 11/19 patients (57.9%), and most abdominal/pelvic regions (19/24). $^{68}$Ga-FAPI PET/MRI displayed higher accuracy (84.9% vs. 80.7%), higher sensitivity (76.8% vs.59.9 %), and lower missing rate (23.2% vs. 40.1%) than DWI-MRI. Furthermore, the accuracy of $^{68}$Ga-FAPI PET/MR is higher than DWI-MRI in PDS patients but lower in IDS patients who already received chemotherapy. About 15% lesions displayed inconsistency between the two modalities, of them, $^{68}$Ga-FAPI PET/MRI correctly identified more lesions than DWI-MRI, particularly in PDS patients. In addition, FAP expression was independent of metastatic lesion size. ***Conclusion:*** $^{68}$Ga-FAPI PET/MRI shows superior efficiency than DWI-MRI for assessing abdominopelvic tumor burden of OC. Integrated $^{68}$Ga-FAPI PET/MR-DWI imaging may be a valuable method for debulking surgery decision in ovarian cancer patients. ***References:*** 1. Liu S, Feng Z, Xu X, Ge H, Ju X, Wu X, et al. **Role and Impact of Anaesthetic Procedures for Preclinical Radiotracer Development Using Small Animal Positron Emission Tomography-Computed Tomography Imaging**
***T. Ebenhan***[1,2], *C. H. S. Driver*[1,3], *C. Swanepoel*[1], *J. Visser*[1];
[1]*Preclinical Imaging Facility, Nuclear Medicine Reseach Infrastructure NPC, Pretoria, SOUTH AFRICA,* [2]*Nuclear Medicine, University of Pretoria, Pretoria, SOUTH AFRICA,* [3]*Radiochemistry, Necsa, Pelindaba, SOUTH AFRICA.*

***Aim/Introduction:*** Non-invasive, functional imaging techniques such as Positron Emission Tomography-Computed Tomography (PET-CT) provide the means for studying physiological and pharmacological processes in real-time, both within the preclinical and clinical setting. PET-CT imaging has made a major footprint in preclinical research of pharmacology and medical sciences which has an impact on how we study neurological or oncological disease, detect inflammation/infection and conduct cardiovascular research. This investigation aims to systematically align different anaesthetics with common radiotracers for PET-CT imaging studies to provide information that can enhance the radiotracer representation according to their targeting mechanism in rodents to advance quality and translatability of microPET/CT-derived data. ***Materials and Methods:*** The following anaesthetics were mainly assessed for suitability towards imaging

with [18F]FDG-, but also for [68Ga]Ga-DOTA-TATE-, and [68Ga]Ga-PSMA-11-microPET-CT diagnostics: isoflurane, sevoflurane, pentobarbital, propofol, or combination of fentanylcitrate-fluanisone/diazepam, and ketamine/xylazine. These anaesthetic agents were compared based on animal physiology (respiration rate, body temperature, apparent glucose metabolism and expected radiotracer biodistribution). ***Results:*** The investigated anaesthetics caused altered respiration rate, body temperature, glucose metabolism and have effects on target organs which affected radiotracer biodistribution. Isoflurane inhalation is the most desired anesthetic procedure; however, both sevoflurane and isoflurane (also ketamine/xylazine administration) induced hypoglycemia. Sevoflurane can be suggested over isoflurane for cardiac imaging. Propofol is suitable for [18F]FDG imaging but should be avoided for neuroimaging causing decreased cerebral glucose metabolism. Pentobarbital does not alter the blood glucose metabolism but has a lower safety margin for rodent anesthesia. Fentanylcitrate-fluanisone/diazepam the preferred injectable anesthetic option for [18F]FDG being the least interfering with glucose metabolism. Tumor imaging quality using [68Ga]Ga-DOTA-TATE- or [68Ga]Ga-PSMA-11-microPET-CT was supported by isoflurane or sevoflurane; however, higher glucocorticoid levels and certain neuroendocrine abnormalities occurred (may originated by hypothermia). ***Conclusion:*** This investigation proves that anaesthetics used for preclinical research using microPET/CT-imaging need to be carefully aligned with the radiotracer half-life, and metabolism, to warrant an uninterrupted image acquisition of high quality. Better understanding of the interplay between radiotracers and available anesthesia agents can allow for the best choice of anesthesia that will improve the performance and outcome of imaging studies. Thus, radiotracers are supported to show their full research potential to become non-invasive in vivo biomarker or sensitive drug efficacy monitoring tools.

## OP-077

### Feasibility of in vivo small animal imaging using a clinical total-body PET/CT scanner

***J. Mannheim***[1,2], *W. Lan*[3], *M. A. Krueger*[1], *C. la Fougère*[2,3], *F. P. Schmidt*[1,3];
[1]*Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard-Karls University Tuebingen, Tuebingen, GERMANY,* [2]*Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tuebingen, Tuebingen, GERMANY,* [3]*Department of Nuclear Medicine and Clinical Molecular Imaging, University hospital Tuebingen, Tuebingen, GERMANY.*

***Aim/Introduction:*** Utilizing clinical PET scanners for preclinical animal imaging has been of interest ever since preclinical in vivo research has gained its importance. Constraints in this regard were the limited spatial resolution and sensitivity of clinical scanners compared to dedicated preclinical scanners. With the availability of total-body PET scanners with axial FOVs longer than 1 m, the limitation of sensitivity has been overcome. The aim of this study was to evaluate the in vivo quantification accuracy for 9 mice scanned simultaneously on a total-body PET/CT scanner compared to individual scans on a dedicated preclinical PET scanner. ***Materials and Methods:*** 9 healthy mice were injected with n 13.4 ± 0.4 MBq [18F]FDG. After 1h uptake time, mice were sacrificed and flash-frozen in the same position. 90 min p.i., static scans were performed for each animal individually on a dedicated preclinical PET scanner. All mice were subsequently transferred to a clinical total-body PET/CT scanner and a static scan was performed for all 9 mice simultaneously in a back-to-back arrangement to cover the 106 cm axial FOV. Preclinical images were also Gauss filtered to match the voxel size of the clinical system. VOIs were placed in the liver, muscle, left and right striatum, cortex and cerebellum. $SUV_{mean}$ was calculated; one-way ANOVA was performed to test for statistically significant differences between the PET scans. ***Results:*** Reproducible $SUV_{mean}$ values between the clinical total-body and preclinical PET scanner (original and filtered data) were determined for the liver and muscle, as well as for the right striatum and cortex. Furthermore, liver and muscle uptake were reproducible for frame durations as short as 10 s for the clinical total-body PET/CT scanner. For the left striatum and cerebellum, significant differences were determined between the original and filtered preclinical data (p=0.0495 and p=0.0363, respectively), whereas reproducible uptake was determined between the preclinical and clinical scans for these regions. ***Conclusion:*** Although the spatial resolution is considerably different between a preclinical and clinical PET scanner (~1 mm vs. 3-4 mm), it was feasible to perform reproducible mice studies with a clinical total-body PET/CT system due to the high sensitivity. Our study demonstrated that - with optimized protocols - clinical total-body PET/CT scanners can be utilized for preclinical in vivo imaging with the unique advantage of scanning multiple animals (>10) simultaneously. Future work will focus on a voxel-wise comparison of the individual regions.

## OP-078

### Is multiple-mouse PET/MR imaging possible in preclinical oncology?

***A. Courteau***[1,2], *A. Oudot*[2], *R. Garipov*[3], *P. Doughty*[3], *J. McGrath*[3], *A. Cochet*[1,2,4], *F. Brunotte*[1], *J. M. Vrigneaud*[1,2];
[1]*ICMUB laboratory, UMR CNRS 6302, University of Burgundy, Dijon, FRANCE,* [2]*Georges-François Leclerc Cancer Centre, Unicancer, Dijon, FRANCE,* [3]*MR Solutions Ltd, Guildford, UNITED KINGDOM,* [4]*CHU François Mitterrand, Dijon, FRANCE.*

***Aim/Introduction:*** Although integrated positron emission tomography (PET)/magnetic resonance (MR) imaging provides high tissue contrast facilitating organ segmentation, the low throughput of PET/MR limits its widespread use. We present here preliminary results obtained with a mouse multibed accessory to overcome this limitation. ***Materials and Methods:*** The accessory consisted of a triangular arrangement of mouse cradles fitting a birdcage radiofrequency (RF) coil specifically designed and fine-tuned for mouse multibed imaging on our integrated 7 T preclinical PET/MR system. Firstly, three mouse-sized homogeneous cylinders were injected with 10.2 ± 0.3 MBq of 18F-fluorodeoxyglucose prior to a 30-min PET acquisition. Data were reconstructed with ordered-subset expectation maximization algorithm applying 2 iterations, 32 subsets, corrections for scatter, random, decay, normalization, and dead-time. A volume of interest extending over 75% of the phantom length and diameter was drawn to measure standardized uptake value (SUV) and coefficient of variation (CoV) per phantom. Regarding MRI, multi-echo gradient echo (GRE), and double flip angle (FA) GRE sequences were used to produce respectively principal magnetic field (B0) distortion maps in part per million (ppm), and FA maps representing RF field variations. Complementary axial and coronal two-dimensional (2D) fast spin echo T1- and T2-weighted and three-dimensional (3D) fast-low angle shot acquisitions were tested to assess the homogeneity and absence of artifacts. These MR scans were repeated during an in vivo imaging session on subcutaneous tumor-bearing mice. Acquisition parameters were modulated to achieve an optimal trade-off between image quality, tissue contrast, and acquisition duration.

***Results:*** SUV of 1.00, 1.00, and 0.99 and CoV of 4.2%, 3.9%, and 5.9% were measured respectively on left, right, and top positions. The MR image homogeneity and absence of artifacts was verified with 2D and 3D imaging. On the three phantoms the measured B0 distortion was lower than 0.3 ppm/cm in the coronal plane, and the average FA variation did not exceed 3 degrees from the expected value. PET quantification accuracy and MR fields homogeneity were consistent with single-phantom results obtained on the same system. In vivo, an optimal MR image quality was obtained applying four signal averages, leading to an acquisition duration of seven to eleven minutes per sequence. Tumour heterogeneity was clearly visible in T2-weighted imaging, and the contouring of abdominal and pelvic organs was possible on the three animals. ***Conclusion:*** Preliminary results from the on-going study suggest that this system provides high tissue discrimination and quantitative PET data in a multi-bed configuration.

## OP-079

### In situ tumour response PET imaging without radiopharmaceuticals in particle therapy: a feasibility study in rats

***C. Toramatsu****, A. Mohammadi, N. Nitta, C. Seki, Y. Ikoma, I. Kanno, T. Yamaya;*
*National Institutes for Quantum Science and Technology (QST), Chiba, JAPAN.*

***Aim/Introduction:*** Positron emission tomography (PET) has been used for treatment verification in charged particle therapy. Without using radiopharmaceuticals, positron emitters such as $^{15}O$ and $^{11}C$, which are produced through fragmentation reactions in a patient, are imaged. For accurate dose verification, modelling and correction of the biological washout effect of the positron emitters, which is influenced by the tumour vasculature condition, has been an issue. Conversely, the biological washout effect may indicate changes of the tumour vasculature condition, which is known to influence radiation response. At present, blood circulatory changes in a tumour are measured clinically using dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) to evaluate tumour radiation response [1]. Here, measuring of the biological washout rate of the produced positron emitters may also function to evaluate tumour radiation response, in a similar manner to DCE-MRI. The aim of this study is the comparison of the washout rates in rats between in-beam PET during treatment beam ($^{12}C$ ion) irradiation and DEC-MRI. ***Materials and Methods:*** Different vascular types of the tumour model were prepared using six nude rats. The tumour of each nude rat was irradiated by a $^{12}C$ ion beam and, at the same time, scanned by an in-house-made in-beam PET system on the first day. On the second day, the DCE-MRI experiment was performed for the same six nude rats. The main washout rate of the produced positron emitters ($k_{2,1st}$) and the MRI contrast agent ($k_{2a}$) were derived using the single tissue compartment model which is commonly used in nuclear medicine. ***Results:*** A linear correlation was observed between $k_{2,1st}$ and $k_{2a}$. A heterogeneous morphology, which corresponds to a low metabolic area such as necrosis and haemorrhage, was observed in the MRI images of each tumour. The values for the ratio of the volume of the necrotic area to the volume of the whole tumour (fractional necrotic volume) was inversely related to the biological washout rate ($k_{2,1st}$ and $k_{2a}$). ***Conclusion:*** This was the first study that reported the biological washout rate of the positron emitters produced via a nuclear fragmentation reaction correlates to the washout of the MRI contrast agent administrated intravenously, which reflects a tumour vascular condition. The rat study findings suggest that the washout rate in in-beam PET may function as a predictor of tumour response in particle therapy. ***References:*** 1) Zahra MA et al 2007 Lancet Oncol 8 63-74

## OP-080

### Demonstrating the Quantitative Potential of Terbium-161 SPECT/CT Imaging: An Anthropomorphic Phantom Study

***F. Westerbergh****[1], N. P. van der Meulen[2,3], C. Müller[3], A. Grings[4], P. Ritt[4], P. Bernhardt[1,5];*
*[1]Department of Medical Radiation Sciences, Institute of Clinical Sciences, University of Gothenburg, Gothenburg, SWEDEN, [2]Laboratory of Radiochemistry, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND, [3]Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND, [4]Clinic of Nuclear Medicine, University Hospital Erlangen, Erlangen, GERMANY, [5]Department of Medical Physics and Biomedical Engineering (MFT), Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Due to the large proportion of Auger and conversion electrons emitted in its decay, $^{161}Tb$ has been proposed as a superior alternative to $^{177}Lu$—especially in the treatment of single cancer cells and small metastases. Much like $^{177}Lu$, $^{161}Tb$ emits photons imageable by the γ-camera, making SPECT-based $^{161}Tb$ dosimetry a topic of interest. The study aimed to evaluate the quantitative potential of $^{161}Tb$ SPECT imaging by assessing activity quantification errors for a patient-like source geometry. ***Materials and Methods:*** Imaging was performed on a Discovery NM/CT 670 Pro system with a 5/8" NaI(Tl) crystal, using three different collimators: low-energy high-resolution (LEHR), extended low-energy general-purpose (ELEGP), and medium-energy general-purpose (MEGP). A 74.6 keV±10% photopeak window with two adjacent ±5% scattering windows was employed. Projections were acquired with a 256×256 matrix and 3° angular sampling. Reconstruction was performed with a Monte Carlo-based OSEM algorithm with 6 iterations and 10 subsets. Uniformity maps were acquired separately for each collimator using a $^{161}Tb$-filled flood source phantom. A cylindrical, homogeneously filled phantom (V = 6.89 L; C = 45.7 MBq/L) was used to establish SPECT calibration factors. Recovery coefficients (RCs) for partial volume correction were determined with a Jaszczak Phantom™ with six spherical inserts (V = 0.5-16 mL; C = 0.78 MBq/mL). To evaluate the quantitative accuracy, an anthropomorphic phantom study was carried out using an Elliptical Lung-Spine Phantom™, containing eight fillable spheres (V = 2, 4, 8, and 16 mL, two per volume; C = 1.35 MBq/mL) mounted in various positions. Different activity levels were explored: i) a "cold" background; ii) a sphere-to-background ratio (SBR) of 20:1; iii) a SBR of 10:1. Listmode data was retrieved to enable spectral analyses. ***Results:*** The highest RCs were obtained with LEHR (0.32-0.70), followed by ELEGP (0.26-0.67) and MEGP (0.27-0.63). The mean relative quantification error in the anthropomorphic measurements was -2.63±9.04% for LEHR, -0.18±6.44% for ELEGP, and 3.58±6.41% for MEGP, respectively. Generally, errors decreased with increasing sphere volume. With LEHR, an underestimation of activity was observed at higher activity levels (i.e., SBR = 10:1 and 20:1). Spectra acquired with LEHR and ELEGP revealed distinct peaks at 292 and 475 keV, with subsequent down-scatter. Peaks were removed with MEGP. ***Conclusion:*** Accurate SPECT-based $^{161}Tb$ activity quantification using a 74.6 keV±10% photopeak window appears feasible. Although LEHR produces the highest resolution, this collimator option may not be optimal for quantification purposes due to penetration from higher-energy emissions.

## OP-081

### RadioFACS reveals [$^{18}$F]FDG uptake in a KRAS induced lung cancer model is driven by immune cells but not tumor cell metabolism

***C. Vraka***[1], *M. Homolya*[2], *T. Patsch*[1], *A. Spittler*[3], *E. Casanova*[2], *S. Grünert*[1], *M. Hacker*[1], *C. Philippe*[1];
[1]*Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Institute of Pharmacology, Center of Physiology and Pharmacology, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Core Facility Flow Cytometry and Department of Surgery, Research Laboratories, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Cellular heterogeneity within and across tissues has been a major obstacle in treating cancer, but bulk analysis of tissues masks their complex heterogeneity. 2-[$^{18}$F] fluoro-2-desoxy-D-glucose Positron Emission Tomography ([$^{18}$F] FDG-PET) enables non-invasive functional in vivo imaging and is successfully used for tumor diagnostics and metastases discovery in cancer patients. However, the relatively poor resolution of PET limits the appraisal of tumor heterogeneity and the contribution of the tumor microenvironment (TME). Consequently, little is known about the uptake of tracers by different cell types, which however may hold critical information on the course of a pathology. The aim of this work was to investigate the [$^{18}$F] FDG uptake on single-cell level in the TME of a KRAS induced lung cancer mouse model using the novel method radioFACS. ***Materials and Methods:*** A C57BL6/N KRAS (K-ras$^{G12D}$:p53$^{\Delta Lep/\Delta Lep}$) orthotopic transplantation mouse model [1] was injected with [$^{18}$F] FDG intravenously. After 60 min tracer distribution in conscious animals, a 10 min static µPET/CT was conducted under isoflurane anesthesia. Subsequently, animals were sacrificed and lungs were harvested for gamma counting, Fluorescence Activated Cell Sorting (FACS), autoradiography and immunofluorescence. For radioFACS, single cell suspensions were obtained with a tumor dissociation kit, labelled with fluorescent antibodies and sorted by a ARIAFusion cell sorter. The sorted cell fractions were immediately measured in a gamma-counter and normalized to $10^5$ cells. ***Results:*** [$^{18}$F]FDG uptake in the total lung was 5.8±1.6%ID/cc and 3.5±0.3%ID/g. RadioFACS analysis of these lungs showed a robust cell type specific uptake pattern across experiments. We present that the PET signal predominantly derives from [$^{18}$F]FDG uptake in the immune cells (CD45+, F4/80-: 78.3±6.6% and macrophages: 13.9±4.3%), whereas tumor cells (dTom+) only contributed with 2.8±1.0%, which was in the same range as structural cells (CD45-, dTom-: 5.0±2.3%). Normalization depicted that macrophages have the highest glucose metabolism (61.5±3.8%CPM/$10^5$) followed by the remaining immune cells (27.2±0.7%CPM/$10^5$). Tumor cells had a significantly lower glucose metabolism rate (7.1±2.7%CPM/$10^5$). The results were confirmed by autoradiography overlayed with immunofluorescence of dTom-expressing tumor cells. Additionally, ex vivo cell sorting and subsequent in vitro cell uptake of [$^{18}$F]FDG showed 7.0±10.0%CPM/$10^5$ in sorted macrophages and 1.0±1.0%CPM/$10^5$ tumor cells. ***Conclusion:*** RadioFACS was able to uncover that the [$^{18}$F]FDG signal mainly results from infiltrated immune cells and not tumor cells. These results indicate that the impact of immune cell infiltration upon therapy should be considered when interpreting [$^{18}$F]FDG uptake in tumor lesions to assess therapy response. ***References:*** [1] Breitenecker et al., Sci Transl Med (2021);13(601):eabc3911.

## OP-082

### Impact of inoculation-driven immune response on TSPO and amino acid PET imaging in experimental orthotopic glioblastoma

***L. Gold***[1], *E. Barci*[2], *M. Brendel*[1], *M. Orth*[3], *J. Cheng*[2], *S. V. Kirchleitner*[4], *L. M. Bartos*[1], *L. M. Unterrainer*[1], *L. Kaiser*[1], *S. Ziegler*[1], *L. Weidner*[5], *M. J. Riemenschneider*[5], *M. Unterrainer*[1], *C. Belka*[3], *J. Tonn*[4], *P. Bartenstein*[1], *M. Niyazi*[3], *L. von Baumgarten*[4], *R. Kälin*[2], *R. Glass*[2], *N. L. Albert*[1], *A. Holzgreve*[1];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Neurosurgical Research, Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Department of Radiation Oncology, University Hospital, LMU Munich, Munich, GERMANY,* [4]*Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY,* [5]*Department of Neuropathology, Regensburg University Hospital, Regensburg, GERMANY.*

***Aim/Introduction:*** The translocator protein (TSPO) has proven great potential as a target for PET-imaging of glioblastoma. However, there is an ongoing debate about the potential various sources of the PET-signal, since TSPO has been shown to be highly overexpressed both in glioblastoma cells and in inflammatory cells. This work investigates the impact of the inoculation-driven immune response on the PET-signal in experimental orthotopic glioblastoma. ***Materials and Methods:*** We conducted a longitudinal dual tracer TSPO and amino acid PET study in direct comparison to tissue-based analyses. Serial [$^{18}$F]GE-180 and [$^{18}$F] FET PET-scans were performed at day-7/8 and day-14/15 after inoculation of GL261 mouse glioblastoma cells (n=24) or saline (sham, n=6) into the right striatum of immunocompetent C57BL/6 mice. Additional n=25 sham mice underwent [$^{18}$F]GE-180 PET and autoradiography (ARG) at days 7, 14, 21, 28, 35, 50 and 90 in order to monitor potential reactive processes that were solely related to the inoculation procedure. In vivo imaging results were directly compared to tissue-based analyses including ARG and immunohistochemistry. ***Results:*** We found that the inoculation process represents an immunogenic event which significantly contributes to TSPO-radioligand uptake. [$^{18}$F]GE-180 uptake in GL261-bearing mice surpassed [$^{18}$F]FET uptake both in the extent and the intensity, e.g., mean target-to-background ratio ($TBR_{mean}$) in PET at day-7/8: 1.22 for [$^{18}$F]GE-180 vs. 1.04 for [$^{18}$F]FET, $p<0.001$. Sham mice showed increased [$^{18}$F]GE-180 uptake at the inoculation channel, which however continuously decreased over time (e.g., $TBR_{mean}$ in PET: 1.20 at day-7 vs. 1.09 at day-35, $p=0.04$). At the inoculation channel, the percentage of TSPO/IBA1 co-staining decreased, whereas TSPO/GFAP co-staining increased over time ($p<0.001$). ***Conclusion:*** We found that the invasive inoculation process used for generating preclinical glioblastoma in vivo models represents a relevant immunogenic event which significantly contributes to TSPO-radioligand uptake in glioblastoma-bearing and sham-operated mice. The inoculation-driven immune response should therefore be considered for the planning of PET imaging studies in orthotopic glioblastoma models. Furthermore, we provide information about the longitudinal changes of TSPO PET findings and the underlying TSPO-positive cell populations after penetrating traumatic brain injury.

## OP-083

### From 2D to 3D: Developing an improved in vitro model for radiopharmaceutical evaluation

***L. van den Brink***, *M. J. Klomp, S. Erkens-Schulze, W. M. van Weerden, S. U. Dalm;*
*Erasmus Medisch Centrum, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** In vitro cell assays are one of the first methods used for evaluating the potential of newly developed radiopharmaceuticals. Currently, two-dimensional (2D) cell cultures are commonly used to assess binding capability, specificity and efficacy of radiopharmaceuticals. However, with recent advances in three-dimensional (3D) cell culture techniques, we can now much better recapitulate true tissues with important aspects such as target heterogeneity, perfusion and, importantly for determining efficacy, the irradiation range of radionuclides. This information is normally only taken into account at later stages when in vivo animal studies are conducted. Moreover, such an approach would serve to reduce the animals use as much as possible as well as reduce costs. With the aim of creating a more relevant in vitro model, we studied 3D spheroids for radiopharmaceutical evaluation. ***Materials and Methods:*** Prostate-specific membrane antigen (PSMA)-expressing human prostate cancer LNCaP cells were cultured in 2D and 3D setting. To obtain 3D spheroids, single cells were plated in natural extracellular matrix-based matrigel or synthetic noviogel, and subsequently cultured for seven days to form multiple 3D spheroids per gel dome. Uptake and viability studies were performed in 2D and 3D. Uptake was determined by incubating cells for 4h or 22h with 1nM [$^{111}$In]In-PSMA-I&T (20MBq/nmol) +/- 1μM unlabeled tracer. Cell viability was determined using CellTiter Glo six days after 4h incubation with 0.1-4MBq/mL (60MBq/nmol) of [$^{177}$Lu]Lu-PSMA-I&T or [$^{177}$Lu]Lu-DTPA. ***Results:*** At both time points, specific uptake of [$^{111}$In]In-PSMA-I&T was significantly higher in 2D versus 3D (approximately 2-3-fold, $p<0.05$ for both 3D systems). No differences in uptake were measured between spheroid cultures in matrigel or noviogel. Cell viability was therefore only determined for 2D and 3D-matrigel cultured cells, showing a similar reduction in viability despite the difference observed in uptake between the two models. No significant effect of [$^{177}$Lu]Lu-DTPA on viability was observed. ***Conclusion:*** We successfully used a spheroid model to test selectivity, uptake and cytotoxicity studies of radiopharmaceuticals. Tracer uptake in cells was lower in de 3D versus 2D system, possibly because of radiopharmaceutical perfusion through the gel. Interestingly, cells cultured in spheroids needed less dose to achieve the same reduction in viability, which is most likely due to cross-fire radiation. These preliminary results demonstrate the feasibility and additional value of 3D models for radiopharmaceutical studies. We are further optimizing and evaluating the developed method e.g. using radionuclides with different linear energy transfer, such as 161-Tb and 225-Ac.

## OP-084

### Theranostic Digital Blueprint Predicts Higher Therapeutic Efficacy using Radiopharmaceuticals with Higher Albumin Affinity

***A. Fele Paranj***[1], *C. Uribe*[1], *F. Benard*[2], *A. Rahmim*[1], *B. Saboury*[3];
[1]*University of British Columbia, Vancouver, BC, CANADA,*
[2]*BC Cancer, Vancouver, BC, CANADA,* [3]*National Institutes of Health (NIH), Bethesda, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Radiopharmaceutical therapy (RPT) is a promising approach to cancer treatment, and efforts are ongoing to improve its efficacy. One such effort is the development of radiopharmaceuticals with varying albumin affinities. Albumin, the most abundant protein in the serum, has numerous important roles in the body and can potentially be utilized to enhance RPT. However, in vivo and in vitro studies to evaluate the use of albumin in RPT are costly and time-consuming. In this study, we developed a physiologically based pharmacokinetic (PBPK) model to study the kinetics of radiopharmaceuticals, taking into account varying albumin affinities and their potential role in increasing treatment efficacy. ***Materials and Methods:*** Our PBPK model incorporates subcompartments of organs and tumors, including vascular, interstitial, binding sites, and internalization into cells. We implemented the model in the SimBiology toolbox in Matlab using realistic population averaged values for the model parameters. In a virtual in-silico experiment, we injected 11.7GBq of 177Lu-PSMA with a specific activity of 104MBq/μg and varying albumin affinities (KD of albumin-binding ranging from 1-200nanomole/liter). The time-integrated-activity (TIA) in tumors and organs at risk (OARs) which include kidney and salivary glands was calculated to determine the absorbed dose to tissue. Therapeutic-efficacy (TE) was defined as the tumor-to-OAR-dose-ratio normalized to the same ratio if albumin binding was off. ***Results:*** We found that a lower dissociation constant for albumin-binding decreases the delivered dose to tumors and OARs, reducing the delivery yield (about a 3-fold decrease). However, a lower dissociation constant for albumin binding enhances RPT treatment by enhancing the differential dose delivery to the tumor with respect to OARs (up to a 2-fold increase). Albumin-bound radiopharmaceuticals do not enter the interstitial media of OARs, but due to the mechanical properties of the tumor vasculature structure, albumin leaks to the tumor interstitial medium, improving the tumor targeting index for the radiopharmaceuticals. Changes in different parameters and modeling components may alter these results, providing insight into subtle aspects of radiopharmaceutical deliveries and varied findings in experimental studies. ***Conclusion:*** Our PBPK model fine-tuned for radiopharmaceuticals with albumin affinity shows that a low dissociation constant for albumin binding can enhance the tumor-targeting efficacy of radiopharmaceuticals (up to 2-fold increase), despite potentially reducing the delivery yield (about 3-fold decrease). These findings have implications for the development and optimization of radiopharmaceutical therapies for cancer treatment. ***References:*** Paranj AF, et al. Non-linearities in the Transition from Imaging Radiotracers to Therapeutic Radiopharmaceuticals. JNM.2022;63:2821-2821.

***Aim/Introduction:*** Accurate staging of gastric cancer is crucial to prevent futile gastrectomies. Recently, a Dutch multicentre study investigated the role of visual assessment of [$^{18}$F]FDG-PET/CT in staging [1]. The aim of this side-study was to improve identification of peritoneal and distant metastases in locally advanced gastric cancer using [$^{18}$F]FDG-PET radiomics. ***Materials and Methods:*** [$^{18}$F]FDG-PET scans of 206 patients acquired in 16 different Dutch hospitals in the prospective multicentre PLASTIC-study were analysed. Tumours were delineated using an adaptive threshold of 50% $SUV_{peak}$ and 105 radiomic features were extracted. Three classification models were developed to identify peritoneal and distant metastases (incidence: 21%): a model with clinical variables, a model with radiomic features, and a clinicoradiomic model, combining clinical variables and radiomic features. To exclude features with high mutual correlations, redundancy filtering of the Pearson correlation matrix was performed (r=0.9). A least absolute shrinkage and selection operator (LASSO) regression classifier was trained and evaluated in a 100-times repeated random split, stratified for the presence of peritoneal and distant metastases. Model performances were expressed by the area under the receiver operating characteristic curve (AUC). In addition, subgroup analyses based on Lauren classification were performed. ***Results:*** None of the models could identify metastases with low AUCs of 0.59, 0.51, and 0.56, for the clinical, radiomic, and clinicoradiomic model, respectively. Subgroup analysis of intestinal and mixed-type tumours resulted in low AUCs of 0.67 and 0.60 for the clinical and radiomic model, and a moderate AUC of 0.71 in the clinicoradiomic model. Subgroup analysis of diffuse-type tumours did not improve the classification performance. ***Conclusion:*** Similarly to qualitative assessment of [$^{18}$F]FDG PET, [$^{18}$F]FDG-PET-based radiomics did not contribute to the preoperative identification of peritoneal and distant metastases in patients with locally advanced gastric carcinoma. In intestinal and mixed-type tumours, the classification performance of the clinical model slightly improved with the addition of radiomic features, but this slight improvement does not outweigh the laborious radiomic analysis. ***References:*** 1. Gertsen et al. 18F-Fludeoxyglucose-Positron Emission Tomography/Computed Tomography and Laparoscopy for Staging of Locally Advanced Gastric Cancer: A Multicenter Prospective Dutch Cohort Study (PLASTIC). ### OP-087
**Feasibility and reproducibility of radiomic features in real world whole-body [$^{18}$F]FDG PET/CT oncology studies**
***C. S. Constantino***, *M. Silva, F. P. M. Oliveira, D. C. Costa;*
*Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, PORTUGAL.*

***Aim/Introduction:*** The use of radiomics has been increasing in clinical studies to characterize disease and/or predict treatment response. Our goal is to study the feasibility and reproducibility of radiomic features to characterize lesions in whole-body [$^{18}$F]FDG PET/CT images from oncology patients. ***Materials and Methods:*** Fifty-three oncologic patients with diverse primary tumors were studied twice in two distinct scanners after a single injection of [$^{18}$F]FDG (246±60 MBq). The second scan started immediately after the first. Approximately half of the patients performed the first scan in one equipment (Philips GEMINI TF16) and the other half in the other equipment (Philips Digital Vereos). Both acquisition and reconstruction protocols are in accordance with EARL1 standards. Voxels are isotropic (4×4×4 $mm^3$). Lesions were identified by an experienced nuclear medicine physician and were all visible in both scanner-based images. Then, they were segmented automatically and independently using a validated and robust Bayesian-based method [1]. 103 radiomic features compliant with the image biomarker standardisation initiative (IBSI) were extracted using LIFEx software [2]. They were subdivided into morphological (12), intensity-based (19), histogram intensity-based (17) and textural features (55). The intraclass correlation coefficient (ICC) for absolute agreement between the correspondent lesion features was assessed and used as a measure of reproducibility. ***Results:*** A total of 289 [$^{18}$F]FDG avid lesions were identified. Following IBSI guidelines, only 103 lesions had the minimum size (>64 voxels) for textural analysis. Thus, only these were included in the statistical analysis. All morphological features showed excellent agreement (ICC≥0.90) between the lesions extracted from the two scanner-based images. Intensity-based features showed good or excellent agreement (ICC≥0.75). The majority of histogram-based features showed moderate to poor agreement, although good agreement in a few cases (0.28≤ICC≤0.86). Textural features had a wide variety of agreement results (0.29≤ICC≤0.96), with more than 50% of the features with poor or moderate agreement. ***Conclusion:*** In the real world application, morphological and intensity-based features are more reproducible than textural and histogram-based features and can be computed in small lesions. Extraction of texture features is only feasible in large lesions; 36% of our dataset. In addition, poor or moderate reproducibility is frequent. Therefore, independently of their value, application in the real world is limited. ***References:*** [1] Constantino et al., Journal of Digital Imaging 2023; https://doi.org/10.1007/s10278-023-00823-y [2] Nioche C. et al., Cancer Research 2018; https://doi.org/10.1158/0008-5472.CAN-18-0125

## OP-088

### Explainable machine learning model to diagnose giant cell arteritis based on texture features in aortic [18F]FDG-PET images

***H. Vries***[1,2], *G. van Praagh*[1], *P. Nienhuis*[1], *L. Alic*[2], *R. Slart*[1,2];
[1]*University Medical Centre Groningen, Groningen, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS.*

***Aim/Introduction:*** Accurate diagnosis for giant cell arteritis (GCA) is important to prevent serious side effects involved in treatment by high-dose glucocorticoids. Current-standard-of-care to diagnose GCA involves 2-deoxy-2-[18F]fluoro-D-glucose([18F]FDG) positron emission tomography (PET) imaging. However, distinguishing between GCA and atherosclerosis can be visually challenging, as both conditions show similar elevated [18F]FDG uptake. Therefore, the primary aim of this study was to investigate the feasibility of an explainable machine learning (ML) model to differentiate between GCA and atherosclerosis in aortic [18F]FDG-PET images. The secondary aim was to compare the ML model with the clinical assessment of the nuclear medicine physician to detect active GCA in follow-up [18F]FDG-PET images. ***Materials and Methods:*** In total, 64 [18F]FDG-PET scans (i.e., 34 with GCA, and 34 with type 2 diabetes mellitus - as this group contains high incidence of atherosclerotic plaques) were retrospectively included. The aorta was delineated into four segments (ascending, arch, descending, and abdominal aorta). From each segment, 93 radiomic features, $SUL_{mean,}$ and $SUL_{max}$ were extracted from each segment. All segments were randomly split into a training (n=190; 80%) and test set (n=48; 20%). A total of 441 ML models were trained using ten-fold cross-validation: i.e., a combination of seven feature selection methods, seven classifiers, and nine individual number of features. Performance of the model was assessed by area under the curve (AUC), accuracy, positive predictive value (PPV), and negative predictive value (NPV). The best performing ML model (based upon test set) was compared to the clinical assessment by a nuclear physician in 19 follow-up scans (7 active GCA, 12 inactive GCA). An occlusion sensitivity map of the follow-up scans was created to illustrate the regions of the aorta contributing to the ML model. ***Results:*** The fifteen-feature model with feature selection method ANOVA and classifier extra-tree-classifier, showed the highest performance (accuracy=0.84, PPV=0.87, NPV=0.81, and AUC=0.91) to distinguish GCA from atherosclerosis. Compared with the clinical report in the follow-up scans, this model showed a higher NPV (0.83 and 0.79), equal accuracy (0.79 and 0.79), and lower PPV (0.71 and 0.80, respectively) in the detection of active GCA. The occlusion map illustrated the descending aorta as important segments contributing to the prediction of the ML model. ***Conclusion:*** The ML model based upon textural features in [18F]FDG-PET scans was able to differentiate GCA from atherosclerosis. The performance of this model was comparable to the clinical report findings in the detection of active GCA in follow-up [18F]FDG-PET.

## OP-089

### PET-CT Radiomics of Lung Cancer with Local Nodes; Dissemination Features are Linked to Survival

***K. Albattat***, *C. Marshall, R. Smith, N. Morley;*
*Cardiff University, Cardiff, UNITED KINGDOM.*

***Aim/Introduction:*** Lymph Node (LN) stage is strongly related to prognosis in Non-Small Cell Lung Cancer (NSCLC). Few studies have investigated PET radiomics with inclusion of metastatic LN. Complex morphology and controversy about integration of multiple sites make this more difficult than analysis of a primary mass, but also likely to be more important. Recent EANM/SNMMI radiomics guideline [1] discusses this issue. We utilize a dissemination feature and asses it's performance along with radiomic features (RF) from LNs in assessing NSCLC survival. ***Materials and Methods:*** 224 LNs from 208 patients with NSCLC, stage IIb-IIIB (N≥1) were included. Primary endpoint was overall survival in days (OS) over a 3-year follow-up. LNs segmented and analysed as a single structure. Several lesion RF selection/aggregation methods were explored e.g. the average RFs from the lesions (LNs) (model 1), RFs from LNs with highest SUV (model 2), RFs from LNs with largest MTV (model 3) and conventional metrics (SUVmax, MTV, TLG etc.) along with a dissemination feature ( average distance of all nodes from primary) (model 4). 204 RFs (5 conventional PET, 23 morphological, 41 intensity, 135 texture) were extracted for an assessment of patient-level disease burden. Multivariate regression prognostic models assessed RF's correlation with OS. Univariate testing initialized variable selection, multicollinearity was assessed using the variance inflation factor. 8 RF with P values (<0.05) were included (stat-COV, GLCM-contrast, GLRLM-glnu, GLRLM-percentage, GLSZM-hgze, GLSZM-szhge, GLDZM-variance, NGTD-complexity). Regression coefficients, hazard ratios and confidence intervals were estimated for the models. ***Results:*** GLRLM-percentage and GLSZM-szhge from model 1 showed significantly higher prediction of OS (HR 7.172 P-value 0.007 and HR 4.752 p-value 0.029 respectively). None of the RFs from model 2 or model 3 showed significant prediction of OS. An interesting initial finding is that the dissemination features (node-tumor spread by measuring Euclidian distance) from dataset of patients with > 2 metastatic LNs showed significant prediction of survival rate (HR 5.729, p-value 0.017) as compared to the textural RFs extracted from this cohort, which displayed no significant predictive ability. Risk of death in NSCLC with more than 2 metastatic LNs demonstrates a ~6-fold increase. ***Conclusion:*** This early work investigating different approaches for assessing radiomics of metastatic lymph nodes. We demonstrate a dissemination feature is highly predictive of survival that could contribute to discussions of clinical prognosis. Embracing radiomics of multiple disease sites will be crucial to advance this work. ***References:*** [1] Joint EANM/SNMMI guideline on radiomics in nuclear medicine (2023)

## OP-090

### The Effect of Feature Selection Methods on Prognostic Analysis of 18F-FDG PET Radiomics in Lymphoma

***L. Yong***[1], *X. Wong*[1], *Y. Chen*[2,3], *S. Liu*[1,3], *H. Lin*[4,5], *K. Lue*[1];
[1]*Tzu Chi University of Science and Technology, Hualien, TAIWAN,* [2]*Tzu Chi University, Hualien, TAIWAN,* [3]*Hualien Tzu Chi Hospital, Hualien, TAIWAN,* [4]*Chang Gung University, Taoyuan, TAIWAN,* [5]*Keelung Chang Gung Memorial Hospital, Keelung, TAIWAN.*

***Aim/Introduction:*** 18F-FDG PET radiomic features have prognostic value in patients with lymphoma. However, it is unclear whether different feature selection methods affect survival prediction outcomes. This study aimed to investigate the performance of various feature selection methods for 18F-FDG PET radiomics-based survival prediction in patients with lymphoma. ***Materials and Methods:*** One hundred and eleven patients with a pathological diagnosis of lymphoma who underwent baseline 18F-FDG PET were retrospectively enrolled in our study. The 18F-FDG-avid lesions were segmented using a standardised uptake value threshold above 4.0 to measure the total metabolic tumour volume (TMTV). The volumes of interest based on TMTV were used to compute 93 radiomic features. To ensure generalisability, we

preselected 22 radiomic features that were robust to the $^{18}$F-FDG tracer uptake time, image acquisition/reconstruction parameters, and respiratory motion. Six feature-selection approaches were employed for the preselected features, encompassing filter, wrapper, and embedded types. After selecting the features, the Cox proportional hazard regression models were used to assess their correlation with progression-free survival (PFS) and overall survival (OS). The prognostic performances of the models were evaluated using the Harrell's C-index. The survival curve was plotted using the Kaplan-Meier method, and the survival difference between subgroups was estimated using a log-rank test. ***Results:*** The median follow-up period of the patients was 47.9 months (interquartile range, 18.7-86.9 months). The 5-year PFS and OS rates were 58.6% 67.8%, respectively. Our results indicated that different feature selection approaches (based on chi-square test, minimum redundancy, maximum relevance, Relief algorithm, support vector machine, random forest, and least absolute shrinkage selection operator) identified different potential radiomic features for survival prediction. The multivariate Cox analysis further identified features that maintained prognostic significance. Prognostic models were constructed by integrating the Ann Arbor stage and TMTV (widely suggested as a prognostic factor in the literature) with selected radiomics features using estimated Cox regression coefficients. Survival curves showed significant differences in PFS and OS among the distinct risk groups. The C-indices for evaluating the survival prediction performance (ranging from 0.630 to 0.673 for both PFS and OS) did not significantly differ among the feature selection approaches. ***Conclusion:*** Different feature selection approaches can be used to identify different radiomic features for survival prediction. The performance of the prognostic model based on the selected radiomic features was comparable. A standardised feature selection method should be considered for $^{18}$F-FDG PET radiomics-based survival predictions for lymphomas.

## OP-091

### Exploring Correlations between PSA Levels and PSMA-PET Images in Recurrent Prostate Cancer using Machine Learning, Tensor Radiomics and Deep Features Analysis

***A. Toosi***[1], *S. Harsini*[2], *H. Abdollahi*[1], *F. Bénard*[2,3], *C. F. Uribe*[2,3], *A. Rahmim*[1,4,3];
[1]*Department of Integrative Oncology, BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA,* [3]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA,* [4]*Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA.*

***Aim/Introduction:*** While prostate-specific antigen (PSA) is a widely used biomarker for prostate cancer (PCa) diagnosis and treatment decisions, its correlation with prostate-specific membrane antigen (PSMA) positron-emission tomography/computed tomography (PET/CT) imaging findings is still being investigated. We aimed to study correlations between PSA level at PET/CT and characteristics of metastatic lesions on PSMA PET images. ***Materials and Methods:*** This is a post-hoc analysis of a prospective clinical trial. In 380 whole-body [$^{18}$F]DCFPyL PET/CT images of patients with biochemical recurrence following initial curative-intent treatment, all active lesions were delineated by a nuclear medicine physician. Each image had 1.92±1.21 lesions with average active volume of 4.03±7.02 ml. One hundred fifty radiomics features were calculated on the most active lesions. Nine different filters were utilized in radiomics features extraction. Six pre-trained CNNs were used for deep feature extractors. Random forest regression models were trained to predict the PSA levels at PET/CT. To better highlight the relation between metastatic tumors' features and the corresponding PSA levels, PSA levels were dichotomized in a range (2 - 20 ng/mL). Two classification methods were used to investigate the relation between the PSA range and the features of the most active metastatic lesions. Fifty-repetition-5-fold cross-validation was used for evaluations. ***Results:*** Pearson correlation analysis of 10 highest scoring features showed a range of correlations of 0.2 to 0.39 (negative and positive) between the most active lesion's features and the PSA levels. Highest correlated features are related to the entropy features of lesions (0.38-0.39). Besides, only one feature is extracted from CT images while others are from filtered PET images. Classification analysis on the range of PSA levels shows a consistent pattern indicating that with a cut-off between 14 to 16, there is a strong relation between the appearance of metastatic lesions and PSA levels. Comparing classification results of tensor radiomics [1] and deep features, there is a visible increase in area under the ROC curve using deep features to explain the appearance of the metastatic lesions (AUC 0.6-0.8). ***Conclusion:*** The correlation we observed between the extracted radiomics features of metastatic PCa lesions and the PSA level suggests that these features could be used as additional biomarkers to assess disease progression and guide treatment decisions. Further studies are warranted to validate these findings and optimize their clinical utility. ***References:*** [1] Rahmim, Arman, et al. "Tensor Radiomics: Paradigm for Systematic Incorporation of Multi-Flavoured Radiomics Features." arXiv preprint arXiv:2203.06314 (2022).

## OP-092

### Improving Outcome Prediction in Multicentric Data: Novel Harmonization Techniques and MCA-Based Imputation for Radiomic Feature Analysis

***N. Abdallah***[1], *J. Marion*[2], *C. Tauber*[1], *T. Carlier*[3], *P. Chauvet*[2], *M. Hatt*[4];
[1]*Imaging & Brain, INSERM, Tours, FRANCE,* [2]*LARIS, Angers, FRANCE,* [3]*CRCINA, INSERM, CNRS, Université d'Angers, Université de Nantes, Nantes, FRANCE,* [4]*LaTIM, INSERM, Brest, FRANCE.*

***Aim/Introduction:*** This study aimed at developing an outcome prediction pipeline incorporating novel harmonization techniques to explicitly address the multicentric nature of the data and to evaluate the benefit of imputing missing clinical variables using Multiple Correspondence Analysis (MCA). ***Materials and Methods:*** We proposed two ComBat-alternative harmonization techniques, including rescaling data through mean and standard deviation, and rescaling based on the extent of variable distribution. Missing clinical variables were imputed using MCA, and its effectiveness was compared to other popular machine learning-based methods (Extra Trees and K-Nearest Neighbours). We conducted sensitivity analyses on the imputer and survival methods' hyperparameters. Our survival analysis methods included Random Survival Forest (RSF) and Gradient Boosting (GB). We used the HECKTOR 2021 dataset containing 325 head and neck cancer patients from six clinical centers for evaluation, which included FDG PET/CT images. Moreover, clinical variables such as age, gender, T, N, and M stages, treatment, and HPV status were available but with missing values, particularly for HPV status (e.g., ~65 patients provided HPV status, and 74 patients reported tobacco and alcohol status). All models were evaluated using the concordance index (C-index) on the test set (101 patients out of the 325). ***Results:*** The best model achieved a c-index of 0.73 ( beating the

highest score of 0.72 in in HECKTOR), using radiomic features and MCA-based imputation. The harmonization approach increased the c-index from 0.655 to 0.715 using RSF and from 0.668 to a maximum of 0.721 using GB. The first harmonization approach achieved a maximum c-index of 0.712 using RSF and 0.717 using GB. ComBat also showed comparable performance with a maximum c-index of 0.713 using RSF and 0.719 using GB. Results obtained with the Extra Trees and K-Nearest Neighbours methods were poor ( 0.57 and 0.55, respectively). ***Conclusion:*** This study emphasizes the importance of imputation and harmonization in a multicentric context. The proposed harmonization techniques and MCA-based imputation significantly improved models performance. One advantage of these harmonization transformations is their applicability to novel datasets without the need to retrain the model, like for ComBat. Further research is needed to enhance imputation and harmonization techniques. Future work will focus on strengthening these results using the larger HECKTOR 2022 dataset.

## OP-093

### DEBI-NN: Distance-Encoding Biomorphic-Informational Neural Networks in PET Radiomics

***B. Ecsedi***, *D. Haberl, C. P. Spielvogel, T. Traub-Weidinger, M. Hacker, L. Papp;*
*Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Modern artificial neural networks (ANNs) are challenging to apply in fields operating with small, albeit representative healthcare data and are prone to overfitting due to their large trainable parameter counts. A novel distance-encoding biomorphic-informational neural network (DEBI-NN) [1] has been proposed to significantly minimise the number of trainable parameters compared to traditional ANNs. For a 3D animation of the DEBI-NN training example, see [2]. This analysis aims to investigate the predictive performance of DEBI-NN in comparison with a traditional neural network (NN) model in the selected PET radiomic datasets that are small, albeit clinically relevant and challenging to be leveraged by most ANNs. ***Materials and Methods:*** This study involved 86 $^{11}$C-MET PET glioma cases to predict three-year survival [3], and 52 [$^{68}$Ga]Ga-PSMA-11 prostate cancer cases to predict low-vs-high risk [4]. A 100-fold Monte Carlo cross-validation scheme was performed with 90-10% train-test ratio in both cohorts. Data pre-processing including redundancy reduction, class imbalance correction, and feature ranking was performed in all training subsets. Confusion matrix analytics were utilised across all test subset cohorts. The analysis was conducted on the DEBI-NN in comparison with a fully-connected feedforward neural network with harmonised and comparable network configurations and hyperparameters. ***Results:*** The DEBI-NN yielded a balanced accuracy (arithmetic mean of sensitivity and specificity) of 65% and 74%, while the baseline NN produced 63% and 50%, resulting in a difference of +2% and +24% for the glioma and prostate datasets, respectively. In the prostate cancer cohort, in particular, the DEBI-NN resulted in a more balanced classifier with 72% sensitivity and 75% specificity compared to the baseline NN which yielded 100% sensitivity and 0% specificity. ***Conclusion:*** While small medical datasets remain a challenge for traditional ANNs to successfully utilise, our initial findings are encouraging for clinical applications. The DEBI-NN - operating with a fraction of the trainable parameters in conventional NNs - has shown a more balanced behaviour over the baseline NN, even on datasets with high imbalance. Our findings imply the DEBI-NNs have the potential to become widely applicable in future radiomic studies.

## OP-095

### Significance of $^{11}$C-acetate PET/CT for the prediction of complete remission post induction therapy in newly diagnosed multiple myeloma: a prospective study

***S. Chen***, *Y. Wong, K. Wu, J. C. Chim, C. Ho;*
*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

***Aim/Introduction:*** The International Myeloma Working Group (IMWG) has recently accepted PET/CT as a new modality for assessment of Bone status in the "CRAB" criteria for evaluation of organ damage in active multiple myeloma (MM). Our previous studies showed that $^{11}$C-acetate (ACT) was a better molecular biomarker than $^{18}$F-FDG (FDG) for diagnosis and prognostic prediction of active MM. On the other hand, the advent of novel agents in induction therapy for MM improves the complete remission (CR) rate. In this prospective study, we aim to evaluate whether baseline ACT-PET/CT might predict CR post induction therapy in newly diagnosed MM. ***Materials and Methods:*** From Mar-2019 to Dec-2021, clinically suspected MM patients were referred for ACT and FDG (dual-tracer) PET/CT. Clinical criteria for active MM was ≥10% clonal plasma cells in bone marrow plus at least one CRAB criterion defined by IMWG. PET/CT criteria for active MM were: (1) focally hypermetabolic bone lesions (FBLs) avid for ACT or FDG, and/or (2) diffusely increased marrow metabolism with L3 vertebra ACT-$SUV_{max\_}$ L3>=3.8 or FDG-$SUV_{max\_}$ L3>=3.0 (from prior database). Induction therapy to active MM patients was initiated after baseline PET/CT. Post-induction MM patients achieving "serological CR" (by IMWG criteria) underwent post-treatment dual-tracer PET/CT for evaluation of "molecular CR": metabolic quiescence in all the FBLs with ACT-$SUV_{max\_}$ L3<3.8 and FDG-$SUV_{max\_}$ L3<3.0. The pretreatment factors for univariate prediction of CR were: (1)%clonal bone marrow plasma cells, (2) beta-2 microglobulin, (3)no. of ACT-avid FBLs, (4)ACT-$SUV_{max\_}$ L3; (5)no. of FDG-avid FBLs, (6)FDG-$SUV_{max\_}$ L3. ROC curve analysis was performed. ***Results:*** 62 patients (M:F=32:30; age range:44-87 years, mean=59.7±9.7 years) were finally confirmed as active MM by IMWG criteria. ACT-PET/CT identified 59/62 (95.2%) and FDG-PET/CT identified 34/62 (54.8%). After induction therapy, 39/62 (62.9%) patients achieved serological CR, and of these 39 serological CR patients, 35/39 (89.7%) achieved molecular CR, while 4/39 (10.3%) patients had minimal residual disease in FBLs or mild ACT activity in bone marrow seen on PET/CT, hence continued with consolidation therapy. Among all the 6 pretreatment factors, only ACT-$SUV_{max\_}$ L3 was the significant predictor for CR post induction therapy ($SUV_{max\_}$ L3=4.59+/-1.62 vs. 6.88+/-1.86 for CR vs. non-CR).

ROC curve analysis identified baseline "ACT-$SUV_{max}$_L3<5.45" as the cut-off for the prediction of CR (AUC=0.834, P<<0.05). ***Conclusion:*** $^{11}$C-acetate is the preferred molecular PET biomarker for diagnosis and prediction of CR after induction therapy in MM. It is also a recommended PET tracer to monitor residual disease. MM patients achieving serological plus molecular CR need further follow-up to evaluate overall survival.

## OP-096

### A prospective comparison of $^{68}$Ga-Pentixafor PET/CT and $^{18}$F-FDG PET/CT for the detection of intramedullary and extramedullary lesions in multiple myeloma

***S. Tang****, Y. Wang, Y. Tian, C. Li, Z. Xiao, J. Chen, Y. He;*
*Department of nuclear medicine, Zhongnan Hospital of Wuhan University, Wuhan, Hubei, CHINA.*

***Aim/Introduction:*** Chemokine receptor 4 (CXCR4) is a key factor for tumor growth and metastasis in multiple myeloma (MM). Since $^{18}$F-FDG PET/CT has some limitations in evaluating MM, we design the study to compare the ability of $^{68}$Ga-Pentixafor PET/CT targeting CXCR4 and $^{18}$F-FDG PET/CT for the detection of intramedullary and extramedullary lesions in MM. ***Materials and Methods:*** The study included 38 newly diagnosed MM patients who had undergone paired $^{68}$Ga-Pentixafor PET/CT and $^{18}$F-FDG PET/CT in a week. The diagnostic performance of the two tracers was calculated and compared for intramedullary and extramedullary lesions with the reference standards from histopathological findings, typical radiological appearances, and clinical imaging follow-up. Intramedullary lesions were divided into seven regions (skull, cervical spine, thoracic spine, lumbar spine, pelvis, long bones, ribs and the rest) and scored by a scoring system to compare. The characteristics of extramedullary lesions in each patient were recorded for two imaging methods separately. Furthermore, we assessed the maximum standardized uptake value (SUVmax), tumor-to-mediastinal blood pool ratio (TBR), and tumor-to-liver ratio (TLR) for paired positive patients in both intramedullary and extramedullary lesions. ***Results:*** $^{68}$Ga-Pentixafor PET/CT had a higher positive rate than $^{18}$F-FDG PET/CT in subjects (97.4% [37/38] vs. 73.7% [28/38], p< 0.05). In intramedullary lesions analysis, the scores of each region and the total of the whole bone marrow were all significantly higher in $^{68}$Ga-Pentixafor PET/CT than in $^{18}$F-FDG PET/CT (all p< 0.05). It also showed higher median SUVmax (11.95 vs. 4.90), TBR (3.81 vs. 1.80), and TLR (3.82 vs. 1.29) than those with $^{18}$F-FDG PET/CT in the intramedullary lesions (all p< 0.05). As for extramedullary lesions, $^{68}$Ga-Pentixafor PET/CT showed slightly more patients with positive extramedullary lesions (50% [19/38] vs. 47.4% [18/38]) and with mildly higher median SUVmax (10.00 vs. 7.10), TBR (3.27 vs. 2.61), although neither of them had statistical difference (all p> 0.05). However, the TLR of $^{68}$Ga-Pentixafor PET/CT was approximately two times that of $^{18}$F-FDG PET/CT in extramedullary lesions (3.85 vs. 2.16, p< 0.05). Especially for lymph nodes of extramedullary lesions, $^{68}$Ga-Pentixafor PET/CT detected more positive lesions than $^{18}$F-FDG PET/CT (43 vs. 26, p< 0.05). ***Conclusion:*** $^{68}$Ga-Pentixafor PET/CT is significantly more sensitive than $^{18}$F-FDG PET/CT in all regions of intramedullary lesions. As for detecting extramedullary lesions, $^{68}$Ga-Pentixafor PET/CT has a slight advantage over $^{18}$F-FDG PET/CT. Moreover, it has a better positive rate in hematogenous spread lymph nodes by lesion-based analysis, which shows the potential for prognostic stratification.

## OP-097

### Assessment of the Diagnostic and Staging Potential of $^{68}$Ga-Pentixafor PET/CT in Multiple Myeloma - A Comparison With $^{18}$F-FDG PET/CT

***L. Aridhasan Meenakshi****, V. Rajaraman, B. Dubashi, D. Halanaik;*
*Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, INDIA.*

***Aim/Introduction:*** $^{68}$Ga-Pentixafor Positron Emission Tomography/ Computed Tomography (PET/CT) localises the expression of Chemokine receptor-4 (CXCR4), a receptor which is overexpressed in Multiple Myeloma. We aim to assess and compare the diagnostic and staging potential of $^{68}$Ga-Pentixafor with $^{18}$F-Fluorodeoxyglucose (FDG) PET/CT. ***Materials and Methods:*** Twenty-one (10F; 11M; Median Age= 57.7 years) newly diagnosed treatment-naive Multiple Myeloma patients were enrolled prospectively from January 2021 to April 2023. All participants underwent $^{68}$Ga-Pentixafor and $^{18}$F-FDG PET/CT imaging within one week. $^{68}$Ga-Pentixafor (130-174 MBq) was injected intravenously followed by PET/CT acquisition at 45 minutes. The positivity rate and pattern of disease involvement were evaluated for both tracers. Quantitative parameters including Standardised Uptake Value - Maximum (SUVmax) and Tumour-to-Background Ratio (TBRmax) were calculated and compared for both tracers. Durie Salmon Plus (DSP) Stage was assigned based on CT, $^{68}$Ga-Pentixafor PET/CT and $^{18}$F-FDG PET/CT separately. ***Results:*** 68Ga-Pentixafor PET/CT showed a higher positivity rate of 100% (21/21), as compared to 90.5% (19/21) with $^{18}$F-FDG PET/CT. $^{68}$Ga-Pentixafor PET/CT showed significantly (p=0.028) higher TBRmax values (5.5; IQR6.6) as compared to $^{18}$F-FDG PET/CT (2.2; IQR1.61). However, no significant difference (p=0.053) in SUVmax values was observed between $^{68}$Ga-Pentixafor PET/CT (3.3; IQR 2.97) and $^{18}$F-FDG PET/CT (2.2; IQR1.61). $^{68}$Ga-Pentixafor PET/CT and $^{18}$F-FDG PET/CT detected paramedullary lesions in 11 and 9 patients, respectively. One extramedullary lesion in the renal cortex was picked up by both modalities. Three patients had extramedullary $^{68}$Ga-Pentixafor uptake but no $^{18}$F-FDG uptake, of which one was histopathologically evaluated, and found to be benign. SUVmax and TBRmax of both tracers did not show any significant correlation with plasma cell percentage and beta-2-microglobulin levels. Out of 21 patients, 14 patients fell under the same DSP stage in CT, $^{18}$F-FDG and $^{68}$Ga-Pentixafor PET/CT. 2 patients (10%) were upstaged by $^{18}$F-FDG PET/CT and 6 patients (29%) were upstaged by $^{68}$Ga-Pentixafor PET/CT. ***Conclusion:*** A significant proportion of patients undergo a change in staging and prognostication due to the higher disease burden estimation by $^{68}$Ga-Pentixafor PET/CT as compared to $^{18}$F-FDG PET/CT. Improved comprehension of tumour heterogeneity in Multiple Myeloma can be achieved through the use of dual tracer imaging. With the recent progress in CXCR4-based therapeutics, the expanding role of $^{68}$Ga-Pentixafor imaging in Multiple Myeloma is inevitable. ***References:*** Pan Q et al. Chemokine receptor-4 targeted PET/CT with 68Ga-Pentixafor in assessment of newly diagnosed multiple myeloma: comparison to 18F-FDG PET/CT. Eur J Nucl Med Mol Imaging. 2020 Mar;47(3):537-46.

## OP-098

### Prognostic value of FDG PET/CT biomarkers in patients withrecurrent/refractary MM treated with CAR-T Cells

***V. Betech-Antar***, *F. Minguez, L. Tamariz, A. Bronte, M. Romera, J. Rosales, J. Bastidas, S. Menendez-Sanchez, M. Panizo, S. Huerga, J. San-Miguel, P. Rodriguez-Otero, M. García-Velloso;*
*Clínica Universidad de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** To analyse the prognostic value of FDG PET/CT biomarkers at diagnosis, 1-month and 3-months after treatment with CAR-T Cells in patients with recurrent/refractary MM ***Materials and Methods:*** Whole-body $^{18}$F-FDG PET/CT scans were performed in patients with recurrent MM before and after Chimeric antigen receptor T-cell (CAR-T) therapy targeted against B-cell maturation antigen (BCMA). The five-point Deauville scale (DS) was applied to describe 18F-FDG uptake in bone marrow (BM) and focal lesions (FL). The number of FL, presence of paramedullary disease (PMD) and extramedullary disease (EMD) were recorded. ***Results:*** Fifty-nine patients (29 male, 30 female; median age 59 years) were included. One-month after CAR-T 14/59 (23.7%) patients had complete response by PET (PETCR), and 3-months after CAR-T 13 more patients (22%) achieved PETCR. Patients without PETCR 3-months after CAR-T had shorter PFS (median 5.3 months [95% CI 2.5- 10.8] versus 11.9 [95% CI 5.7 - 16] (p = 0.001) and shorter OS (median 7.8 months [95% CI 5.1 - 18.4] versus 16 [95% CI 8.9 - 25.9] (p = 0.004); than those with PETCR (n = 24 [44%]). ***Conclusion:*** These results indicate that PET-CR can predict durable remission after CAR-T Cells. Further analysis with larger population could inform early post-CAR-T management and response-adapted stratification in clinical trials.

## OP-099

### Multicenter development of a PET-based risk assessment tool for product-specific outcome prediction in large B-cell lymphoma patients undergoing CAR T-cell therapy

***C. Voltin***[1], *S. Flossdorf*[2], *A. Paccagnella*[3], *M. Winkelmann*[4], *J. Heger*[1], *B. Casadei*[3], *L. Beckmann*[1], *K. Herrmann*[2], *N. Kutsch*[1], *P. Borchmann*[1], *S. Fanti*[3], *W. G. Kunz*[4], *M. Subklewe*[4], *C. Kobe*[1], *P. L. Zinzani*[3], *M. Stelljes*[5], *K. S. Roth*[1], *A. Drzezga*[1], *R. Noppeney*[2], *H. C. Reinhardt*[2], *B. von Tresckow*[2], *R. Seifert*[2,5], *J. C. Albring*[5], *V. Blumenberg*[4], *A. Farolfi*[3], *P. Gödel*[1], *C. Hanoun*[2];
[1]*University of Cologne, Cologne, GERMANY,* [2]*University of Duisburg-Essen, Essen, GERMANY,* [3]*University of Bologna, Bologna, ITALY,* [4]*Ludwig Maximilian University of Munich, Munich, GERMANY,* [5]*University of Münster, Münster, GERMANY.*

***Aim/Introduction:*** Chimeric antigen receptor (CAR) T-cell therapy fundamentally changed the management of individuals with relapsed and refractory large B-cell lymphoma. However, real-world data have shown divergent outcomes for the approved constructs. The present study therefore aimed to evaluate potential risk factors in a larger cohort. ***Materials and Methods:*** Our analysis set included 88 patients, from four German university hospitals and one Italian center, who underwent $^{18}$F-fluorodeoxyglucose positron emission tomography (PET) before CAR T-cell therapy with tisagenlecleucel (n = 62) or axicabtagene ciloleucel (n = 26). We first determined the predictive value of conventional risk factors, treatment lines, and response to bridging therapy for progression-free survival (PFS) through forward selection based on Cox regression. In a second step, the additive potential of two common PET parameters was assessed. Their optimal dichotomizing thresholds were calculated individually for each CAR T-cell construct. ***Results:*** Extra-nodal involvement emerged as the most relevant of conventional tumor and patient characteristics. Moreover, we found that inclusion of metabolic tumor volume (MTV) further improves outcome prediction. The hazard ratio for a PFS event was 1.68 per unit increase of our proposed risk score (95% confidence interval [1.20, 2.35], p = 0.003) which comprised both lymphoma burden and extra-nodal disease. While the most suitable MTV cut-off among patients receiving tisagenlecleucel was 11 mL, a markedly higher threshold of 259 mL showed optimal predictive performance in those undergoing axicabtagene ciloleucel treatment. ***Conclusion:*** Our analysis demonstrates that the presence of more than one extra-nodal lesion and higher MTV in large B-cell lymphoma are associated with inferior outcome after CAR T-cell treatment. Based on an assessment tool including these two factors, patients can be assigned to one of three risk groups. Importantly, as shown by our study, metabolic tumor burden might reflect the extent of bridging therapy needed individually for each construct.

## OP-100

### Performance of PET/CT using [$^{18}$F]Fludarabine for initial staging and therapeutic evaluation of symptomatic multiple myeloma (MM) patients in first line treatment or first relapse : preliminary results of an exploratory multicenter phase 2 study

***Aim/Introduction:*** [$^{18}$F]Fludarabine showed promising results in human lymphoproliferative disease imaging and in a murine MM model. To investigate its potential usefulness in human MM, we propose a prospective phase II clinical study comparing $^{18}$F-Fludarabine-PET/CT (FludaPET) with $^{18}$F-FDG-PET/CT (FDG-PET) for initial staging and therapeutic evaluation of symptomatic MM patients. ***Materials and Methods:*** This study aims to include 35 symptomatic MM patients according to IMWG criteria. Whole-body PET/CT are acquired 60 minutes after injection of 4 MBq/kg of [$^{18}$F]Fludarabine and 3 MBq/kg of [$^{18}$F]FDG. PET/CT are interpreted by MM experts nuclear medicine physicians defining focal lesion (FL), paramedullary disease (PMD), extra-medullary disease (EMD), and diffuse bone marrow involvement (BMI). The maximal standardized uptake value (SUVmax) and the target to pool ratio (TBR), defined as SUVmax/SUVblood pool, are calculated for BMI, FL, PMD and EMD. ***Results:*** At the time of analysis, 9/35 patients were included, 7 underwent both FludaPET and FDG-PET (2 screen failures). Both FludaPET and FDG-PET were performed for initial staging. No adverse effects were reported. Per-patient analysis : PET/CT showed abnormalities in all 7 patients, with 1 normal FludaPET and 2 normal FDG-PET. FludaPET and FDG-PET were concordant for patient 2 with FL+PMD and discordant for the 6 other patients :

for patients 1 and 5, FL+BMI with FludaPET and FL with FDG, for patient 3 BMI with FludaPET but FL with FDG, for patient 4 FL with FDG but negative FludaPET and, for patients 6 and 7 BMI with FludaPET and negative FDG-PET. Per-lesion analysis : FludaPET detected 11 FL, 1 PMD and 5 BMI, while FDG-PET identified 25 FL, 1 PMD and no BMI. In total, both methods detected 27 FL, 1 PMD and 5 BMI. SUVmax and TBR of FL/PMD ranged from 2.6 to 5.05 and 1.63 to 3.78 with FludaPET, and from 3 to 13.20 and 1.3 to 3.88 with FDG, respectively. For BMI, SUVmax and TBR ranged from 3.77 to 5.43 with FDG and from 2.23 to 4.08 with FludaPET. Fluda-PET showed uptake in supra and infra-diaphragmatic lymph nodes in 4 patients, but its nature remains unclear at the time of analysis. In 3 patients, FDG-PET detected bone and vertebral fractures, without significant [$^{18}$F]Fludarabine uptake, consistent with weaker [$^{18}$F]Fludarabine uptake in inflammatory processes. High presumably physiological splenic uptake was also observed (SUVmax 3.85-7.48). ***Conclusion:*** These first images of $^{18}$F-fludarabine-PET/CT in MM suggest potential complementarity with $^{18}$F-FDG-PET/CT, particularly for the detection of BMI.

## OP-101

### Patterns of PET positive residual tissue at early interim staging and risk of treatment failure in advanced-stage Hodgkin's Lymphoma: an analysis of the randomized phase III HD18 trial by the German Hodgkin Study Group

***J. Ferdinandus***[1], *L. van Heek*[1], *K. S. Roth*[1], *M. Dietlein*[1], *H. Eich*[2], *C. Baues*[1], *P. Borchmann*[1], *C. Kobe*[1], *German Hodgkin Study Group;*
[1]*University Hospital Cologne, Cologne, GERMANY,*
[2]*University Hospital Münster, Münster, GERMANY.*

***Aim/Introduction:*** The randomized phase III HD18 trial introduced PET-2 adapted chemotherapy with eBEACOPP and demonstrated that reduction of chemotherapy in PET-2 negative patients is possible without loss of efficacy. [1] The aim of this study is to describe the patterns of PET-2 positivity in HD18 and determine wether multifocal residual disease is associated with inferior progression-free survival (PFS) compared to uni- or oligofocal disease. ***Materials and Methods:*** We analyzed data from all PET-2 positive patients included in HD18 (NCT00515554). Residual tissue was visually compared with reference regions according to the Deauville score (DS). PET-2 positivity was defined as residual tissue with uptake above the liver (DS4). PFS was defined as the time from completion of staging until progression, relapse, or death from any cause, or to the day when information was last received on the patient's disease status and analyzed according to Kaplan-Meier, using Cox regression for comparisons. ***Results:*** Between May 2008 and July 2014, 2101 patients aged 18-60 years with newly diagnosed, advanced-stage cHL were recruited in HD18. Of these, 480 patients had a positive PET-2 (DS4) and were therefore eligible for this analysis. The upper and lower mediastinum was involved in almost half of all patients: 230 (47.9%) and 195 (40.6%), respectively. A majority of patients had few positive regions in PET-2; 210 (43.8%) had one positive region, and 1-2 or 1-3 involved regions were observed in 372 (77.5%) and 433 (90.2%) patients, respectively. 5y-PFS for patients with 1-2 regions was 91.2% (CI95: 88.2-94.2) vs. 81.2% (CI95: 73.6% vs 89.5%) for those with >2 regions with a corresponding hazard ratio of 2.1 (CI95: 1.2-3.8). ***Conclusion:*** PET-2 positive residuals of cHL are most often located in the mediastinum and a majority of patients have 1-2 affected regions. In comparison, risk of progression was twofold higher in patients with more than two positive regions in PET-2. ***References:*** [1] Borchmann P, Goergen H, Kobe C, et al. PET-guided treatment in patients with advanced-stage Hodgkin's lymphoma (HD18): final results of an open-label, international, randomised phase 3 trial by the German Hodgkin Study Group. Lancet. 2017 Dec 23;390(10114):2790-2802. doi: 10.1016/S0140-6736(17)32134-7. Epub 2017 Oct 20. PMID: 29061295.

***Aim/Introduction:*** Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive non-Hodgkin lymphoma, with 70% of patients achieving curative responses to first-line treatment. The 5-point visual Deauville score (DS) assesses therapy response at End-of-Treatment (EoT) FDG PET. Although the Negative Predictive Value (NPV) is 85%, the Positive Predictive Value (PPV) using traditional DS criteria at EoT PET is suboptimal, ranging between 38 and 80%. This ongoing study, aims to determine if PPV could be improved without affecting NPV by using quantitative PET characteristics both at baseline and at EoT assessment. ***Materials and Methods:*** DLBCL patients from the PETRA database (www.petralymphoma.org) with a baseline and a positive EoT PET (DS4-5) were included. Lymphoma lesions were segmented on EoT and baseline PET using an adaptive semi-automatic delineation approach that applies either the SUV4.0 or MV3 method depending on tumor uptake values (Zwezerijnen et al. J. Nucl. Med 2021). Total Metabolic Tumor Volume (TMTV), $SUV_{peak}$, Total Lesion Glycolysis (TLG), Tumor-to-Liver ratio SUV metrics, and the absolute and relative difference in SUV for both timepoints were obtained. The outcome measure was 2-year progression-free

survival (2-yr-PFS). Descriptive statistics and Wilcoxon-rank testing with Bonferroni correction were applied to evaluate differences in TMTV and SUV metrics between patients with and without 2-yr-PFS. The predictive ability of each quantitative PET feature for 2-yr-PFS was assessed using the Receiver Operating Characteristic curve, from which the optimal threshold and performance metrics, such as positive predictive value (PPV), negative predictive value (NPV), and accuracy, were determined. ***Results:*** 140 DLBCL patients were included. Significant differences were detected in TMTV (median 5.2 vs 29.5mL), $SUV_{peak}$ (3.9 vs 9.6), TLG (19.4 vs 174.7), and $TumorSUV_{peak}$/$LiverSUV_{mean}$-ratio (1.7 vs 4.3) at EoT between patients with and without 2-yr-PFS. Furthermore, compared to baseline, the relative change in $SUV_{peak}$ (77.4 vs 45.2%) at EoT showed significant differences in 2-yr-PFS. The $\%\Delta SUV_{peak}$ showed the highest accuracy (71%) in predicting 2-yr-PFS, followed by $SUV_{peak}$ (56%), $TumorSUV_{peak}$/$LiverSUV_{mean}$-ratio (56%), TMTV (53%), and TLG (54%). The PPV values ranged from 45% (TMTV and TLG) to 60% ($\%\Delta SUV_{peak}$), while the NPV values ranged from 73% (TLG) to 88% ($TumorSUV_{peak}$/$LiverSUV_{mean}$-ratio) within this DS4-5 group. ***Conclusion:*** This ongoing study suggests that several quantitative PET parameters, such as TMTV and $SUV_{peak}$, can be used to improve prediction of 2-yr-PFS in DLBCL patients with DS4-5 at EoT. Moreover, relative changes in uptake at EoT compared to baseline PET may further add to improved 2-yr-PFS prediction.

**Quantification of baseline amyloid load in individuals with subjective cognitive decline can identify future risk of amyloid accumulation**

***G. Kolinger***[1], *M. Marquié*[2,3], *O. Sotolongo-Grau*[2], *N. Roé-Vellvé*[1], *E. Pérez-Martínez*[1], *N. Koglin*[1], *A. Stephens*[1], *J. Tartari*[2], *Á. Sanabria*[2,3], *A. García-Sánchez*[2], *L. Tárraga*[2,3], *A. Ruiz*[2,3], *S. Bullich*[1], *M. Boada*[2,3];
[1]*Life Molecular Imaging GmbH, Berlin, GERMANY,* [2]*Ace Alzheimer Center Barcelona – Universitat Internacional de Catalunya, Barcelona, SPAIN,* [3]*Centro de Investigación Biomédica en Red de Enfermedades Neurodegenerativas (CIBERNED), Instituto de Salud Carlos III, Madrid, SPAIN.*

***Aim/Introduction:*** Amyloid-beta (Aβ) positron emission tomography (PET) with [$^{18}$F]florbetaben is an established tool for detecting in-vivo Aβ deposition in the brain. The quantitative analysis of such brain PET images allows for a precise measurement of the Aβ deposition and can be a powerful tool for assessing longitudinal changes in Aβ load. This study aimed to determine whether Centiloid (CL) at baseline can identify groups with distinct Aβ load increase. ***Materials and Methods:*** 197 subjects with subjective cognitive decline (SCD) enrolled in the Fundació ACE Healthy Brain Initiative (FACEHBI) study underwent at least two [$^{18}$F]florbetaben PET/CT scans. The latest follow-up scans were performed two, three, or five years after baseline (n=51, 27, and 119, respectively). Scans were quantified and classified according to CL cut-offs: Aβ-negative (Aβ-, CL≤20), Grey Zone (GZ, 20<CL≤35), and Aβ-positive (Aβ+, CL>35). A CL-based progression was established given each subject's baseline and follow-up PET scan quantification. Statistical comparisons were carried using a Wilcoxon rank sum test. ***Results:*** Mean age of participants was 65.6±7.2 years at baseline, 63.5% were females, and had 15.2±4.5 years of education. At baseline, 169 subjects (85.8%) were Aβ-. In their latest follow-up (4.2±1.5 years after baseline), 153 remained negative, 9 progressed to the GZ and 7 to Aβ+. Within the 8 subjects in the GZ at baseline, 6 increased their CL above the Aβ+ threshold. All 20 Aβ+ subjects remained in the same group on follow-up. There was a statistically significant ($p<0.001$) group difference on baseline CL ($CL_{bl}$) between the stable Aβ- subjects ($CL_{bl}$ = -2.15±6.24; CL accumulation ($CL_{acc}$) = 0.20±1.37/year) and the ones that progressed from Aβ- to GZ ($CL_{bl}$ = 7.36±4.21; $CL_{acc}$=4.04±1.86/year) and from Aβ- to Aβ+ ($CL_{bl}$ = 12.2±5.5; $CL_{acc}$ = 6.37±1.22/year). There were not enough subjects in the baseline GZ group for a comparison between the stable GZ subjects and those that progressed to Aβ+. The Aβ- subjects with higher CL values at baseline ($10<CL_{bl}<20$) showed a significantly higher ($p<0.01$) CL yearly increase rate than those with lower CL values ($CL_{bl}\leq10$) ($CL_{acc}$ = 3.22±3.53/year vs $CL_{acc}$ = 0.43±1.66/year, respectively). ***Conclusion:*** Baseline CL value was able to differentiate SCD individuals who accumulated amyloid load over time from those who remained stable. Most subjects in the GZ at baseline continued to accumulate Aβ longitudinally and progressed to the Aβ+ group. Similarly, Aβ- subjects showed a higher Aβ accumulation rate when their CL at baseline was closer to the GZ threshold.

### OP-104

**Association of plasma glial fibrillary acidic protein with neurofibrillary tau tangles in the brain and cognitive decline independent of amyloid-B**

***D. Peretti***[1], *F. Ribaldi*[1,2], *C. Boccalini*[1,3,4], *M. Marizzoni*[5], *N. Ashton*[6,7,8], *H. Zetterberg*[6,9,10], *K. Blennow*[6], *G. Frisoni*[1,2], *V. Garibotto*[1,2];

***Aim/Introduction:*** Alzheimer's disease (AD) is pathologically defined by the accumulation of extracellular amyloid plaques and intracellular neurofibrillary tangles of hyperphosphorylated tau. Increasing evidence shows that neuroinflammation is a possible modulator of the effects of tau spread on cognitive impairment in AD. Circulating plasma markers of neuroinflammation have recently become available, and first observations suggest a robust association with AD pathology. Among these, one of the most promising is the glial acidic fibrillary protein (GFAP). The aim of this study was to assess the correlation between plasma GFAP and topographical tau pathology, and its interaction with cognitive decline. ***Materials and Methods:*** A cohort of 123 subjects from the Geneva Memory Centre underwent amyloid- and tau-PET, blood collection, and mini-mental state examination (MMSE). Amyloid uptake was calculated as centiloid values and tau was quantified as standardised uptake value ratio (SUVR). Voxel-based linear regression to assess the topographical correlation between

tau SUVR and plasma GFAP was performed, corrected for age, education, gender, and amyloid accumulation. A sub-sample of 95 subjects underwent a follow up MMSE at least 1 year after baseline. Linear regression was used to assess the effect of GFAP on the annual rate of change of MMSE (corrected for centiloid, global tau, age, gender, and education), and a Wilcoxon test was performed to assess significant differences in GFAP values between subjects that presented cognitive decline or not. ***Results:*** The mean (SD) age of the participants was 72.6 (7.6) years, and 50% of subjects were men. GFAP was associated with increased tau-PET uptake in the lateral temporal and inferior frontal lobes independently of amyloid, gender, age, education, and MMSE scores after multiple comparisons corrections (β=0.001, p<0.01). The annual rate of MMSE change was significantly correlated with GFAP (β=0.006, p<0.01), and a global measure of tau SUVR (β=3.9, p<0.01), but not with amyloid burden. A significant difference in GFAP values was found between stable subjects and decliners (W=1325, p<0.01). ***Conclusion:*** Elevated plasma GFAP levels are associated with increased tau deposition in lateral temporal and frontal regions and also associated with accelerated cognitive decline, independently from tau and amyloid load. These results support neuroinflammation and astrogliosis as a relevant contributor to AD pathology, which can be monitored in blood, and suggest neuroinflammation as a potential target for future disease-modifying therapeutic trials targeting tau pathology.

## OP-105

### The functional long-distance relationship of amyloid and tau pathology

***M. Hoenig***[1], *A. Weller*[2], *E. Doering*[3], *G. Bischof*[4], *A. Drzezga*[4], *T. van Eimeren*[4];
[1]*Research Center Juelich, Juelich, GERMANY,* [2]*University of Cologne, Cologne, GERMANY,* [3]*German Center for Neurodegenerative Diseases, Bonn, GERMANY,* [4]*University Clinic Cologne, Cologne, GERMANY.*

***Aim/Introduction:*** We recently identified spatial patterns of baseline regional amyloid-burden that were associated with spatially diverging patterns of tau-pathology spread (e.g. frontal baseline amyloid pattern was linked to temporal and precuneal tau increase). Given the spatial divergence between these identified spatial patterns of baseline amyloid and subsequent tau-pathology increase, we assessed whether functional connectivity serves as a mediator bridging the observed spatial gap between these proteinopathies. ***Materials and Methods:*** The regional patterns of baseline amyloid (18F-AV45) and subsequent tau-pathology increase (longitudinal 18F-AV1451 time points) were derived using parallel independent component analysis (pICA) based on data of 98 amyloid-positive subjects from the ADNI cohort. The pICA yielded six component pairs linking spatial patterns of baseline amyloid (i.e. regional amyloid pattern) to longitudinal tau increase (i.e. regional tau increase pattern). The degree of spatial divergence of the corresponding component patterns of each pair was quantified using Dice Similarity Coefficient (DSC). To examine the potential role of functional connectivity as mediator bridging the spatial gap between regional amyloid and tau-pathology increase, we used the region of maximum coefficient per component (of the respective regional amyloid or the regional tau increase pattern of each component pair) as seeds for functional connectivity analyses in a dataset of younger healthy controls. This resulted in six pairs of amyloid- and tau-derived seed-based networks (SBN). Subsequently, the spatial overlap between these SBNs and the respective component patterns (regional baseline amyloid OR tau increase pattern of each pair) and the combined component pairs (regional amyloid And tau increase pattern) were quantified. ***Results:*** Using pICA, we identified six component pairs of regional amyloid and tau increase that partly spatially overlapped, but also spatially diverged. Amyloid-derived SBNs presented greater spatial overlap with their respective amyloid components (24%-54%) than the tau-derived SBNs with the respective tau increase components (16%-40%). Importantly, the spatial combination of the regional baseline amyloid and tau increase component pairs showed highest spatial overlap with the amyloid-derived SBNs (up to 62% vs. 39% for the tau-derived SBNs) suggesting that amyloid causes initial tau spread within the same network. ***Conclusion:*** Mechanistically, it appears that the regional associations of amyloid and tau-pathology are driven by underlying large-scale functional networks. Functional connections may thereby transmit soluble amyloid to remote brain regions within the same network. The transmission of soluble amyloid likely results in increased phosphorylation of tau, which eventually triggers insoluble tau-pathology aggregation and spread outside the initially affected network.

## OP-106

### Validation of a topographic visual assessment method for $^{18}$F-Flortaucipir based on Subtype and Stage Inference Model (SuStaIn)

***G. Mathoux***[1,2], *C. Boccalini*[3,4], *A. Arnone*[3], *D. E. Peretti*[3], *M. Scheffler*[5], *G. B. Frisoni*[6,7], *V. Garibotto*[2,3,8];
[1]*Università degli Studi di Milano-Bicocca, Monza, ITALY,* [2]*Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospitals, Geneva, SWITZERLAND,* [3]*Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocenter and Faculty of Medicine, University of Geneva, Geneva, SWITZERLAND,* [4]*Università Vita e Salute San Raffaele, Milano, ITALY,* [5]*Division of Radiology, Geneva University Hospitals, Geneva, SWITZERLAND,* [6]*Memory Clinic, Department of Rehabilitation and Geriatrics, Geneva University and University Hospitals, Geneva, SWITZERLAND,* [7]*Laboratory of Neuroimaging of Aging (LANVIE), University of Geneva, Geneva, SWITZERLAND,* [8]*CIBM Center for Biomedical Imaging, Geneva, SWITZERLAND.*

***Aim/Introduction:*** Substantial variability in the spreading pattern of tau pathology in Alzheimer's disease (AD) population is widely accepted. The Subtype and Stage Inference algorithm (SuStaIn) has distinguished four distinct spatiotemporal trajectories of tau pathology [1]: the limbic (S1), medial temporal lobe-sparing (S2), posterior (S3), and lateral temporal (S4). However, the validation of a visual method to identify them has not yet been proposed and would be important for its clinical translation. Our study aims to provide evidence for tau accumulation subtypes in a clinical setting applying a topographic visual method for tau-PET based on SuStaIn staging. ***Materials and Methods:*** We included 245 participants from the Geneva Memory Clinic, who underwent $^{18}$F-Flortaucipir-PET. Three blinded physicians visually evaluated all scans for tau (T) status and SuStain subtypes. In case of discordance, a consensus was reached. Standardized uptake value ratio (SUVr) values were obtained from a global meta-region of interest (ROI).To test the agreement between raters we used Cohen's kappa (k). Chi-squared and Kruskal-Wallis tests were used to test the differences in clinical features, tau, and amyloid (Aβ) loads between the subtypes. Differences in cognitive trajectories between subtypes were tested using linear mixed-effects models. ***Results:*** Our study showed good agreement between different raters in visually interpreting tau pattern subtypes (k>0.65, p<0.001). T+ individuals performed worse on the MMSE than T-

independently from the subtypes (p<0.001). Individuals with S2 subtype were younger than S1 and S3 individuals (p<0.001) and had worse MMSE scores (p<0.05) than S4 and S1. We observed a systematic increase in global tau SUVr in T+ individuals compared to T- individuals (p<0.001), with the higher accumulation in S2 subtype compared to S1, S3, and S4 (p<0.05). Similarly, Aβ burden was found to be systematically increased in T+ individuals compared to T- individuals (p<0.001).T+ individuals showed significantly faster cognitive decline than T- group (p<0.001), with the S2 subtype exhibiting the fastest decline, with a greater slope in comparison with other subtypes. ***Conclusion:*** Our results support the existence of different tau accumulation subtypes, based on SuStaIn staging, that can be visually assessed with a good inter-rater agreement. Visually identified tau subtypes differ in tau and amyloid loads, clinical profiles, and long-term prognoses. Thus, the visual detection of different patterns might be useful for personalized clinical care and, ultimately, individualized therapy. ***References:*** 1. ***Aim/Introduction:*** Alzheimer's disease (AD) is characterized by the cerebral accumulation of amyloid-beta (A), tau (T), and progressive neurodegeneration (N). The widely used ATN system, with regard to positron emission tomography (PET) biomarkers, categorizes AD based on the mean signal in specific regions of interest (ROI). However, this procedure disregards the spatial extent of pathology and neurodegeneration. Here, we propose an alternative quantification of the volume, i.e., fill states, of A, T, and N in (pre-)clinical AD. ***Materials and Methods:*** We analyzed data from the Tau Propagation over Time (T-POT) study, including cognitively unimpaired individuals (CU, n=58), and patients with mild cognitive impairment (MCI, n=20) or AD dementia (n=4). C11-PIB-PET (A), 18F-AV1451 (T) and perfusion-phase 18F-AV1451 scans (N) were spatially and intensity-normalized (reference: cerebellum). To quantify the volume of A, T and N, we z-standardized and subsequently binarized all scans within-modality using a z-score threshold. Fill states were then computed as the sum of abnormal voxels relative to a whole-brain mask. Finally, mean fill states were compared across groups of clinical status (CU, MCI, AD) and partial correlations of either fill states or mean PET signal in established, tracer-specific ROIs with cognitive performance (Mini-Mental State Examination; MMSE) were computed, adjusting for age, sex and education. ***Results:*** Mean fill states reflected clinical status, as they increased with disease progression (CU: A=4%, T=4%, N=3%; MCI: A=15%, T=11%, N=4%; AD dementia: A=20%, T=23%, N=5%). Moreover, A and T fill states were negatively associated with MMSE ($rho_A$ = -.299, p < .001; $rho_T$ = -.318, p < .01; $rho_N$ = -.147, p = .20), while associations of mean PET signal and MMSE tended to be weaker ($rho_{A(global)}$ = -.255, p = .03; $rho_{T(temporalmetaROI)}$ = -.275, p = .01; $rho_{N(MetaROI)}$ = .179, p = .12). ***Conclusion:*** We present a competitive volume-based staging scheme for AD that is associated with both, clinical status and cognitive performance. These results, while currently validated in a larger sample, suggest that the spatiotemporal dynamics of pathology and neurodegeneration in the AD continuum are well captured by our multi-parametric approach, which is possibly superior compared to classification from mean PET signal intensity. The extended cross-sectional and longitudinal comparison of the two classification schemes is a matter of ongoing research.

## OP-108

### [$^{18}$F]PI-2620 PET Imaging of 3R Pick Tau in Frontotemporal Lobar Degeneration - A Multi-Centre Study

***H. Barthel***[1], *M. Brendel*[2], *V. Villemagne*[3], *K. Marek*[4], *T. van Eimeren*[5], *M. Rullmann*[1], *M. Schroeter*[1], *D. Saur*[1], *M. Patt*[1], *J. Classen*[1], *J. Seibyl*[4], *A. Drzezga*[5], *O. Sabri*[1], *German Imaging Initiative for Tauopathies;*
[1]*Leipzig University Medical Centre, Leipzig, Germany, GERMANY,* [2]*Ludwig Maximillian University Munich, Munich, GERMANY,* [3]*University of Pittsburgh, Pittsburgh, AL, UNITED STATES OF AMERICA,* [4]*InviCRO, Boston, MA, UNITED STATES OF AMERICA,* [5]*University of Cologne, Cologne, GERMANY.*

***Aim/Introduction:*** Certain types of frontotemporal lobar degeneration (FTLD) are histopathologically characterized by 3R Pick tau aggregates. These aggregates cannot be imaged so far in vivo. This shortcoming provided motivation to investigate the respective potential of the second-generation tau PET tracer [$^{18}$F]PI-2620. ***Materials and Methods:*** In this observational study we included participants from five centres, 46 patients with FTLD according to established clinical criteria (50% females, age 65±10yrs, symptom duration 3.7±2.1yrs, MMSE scores 24±6, Neuropsychiatric Inventory scores 8±9) and 26 age- and gender-matched HCs. The FTLD group consisted of Aβ(PET or CSF sampling)-negative patients with behavioural-variant frontotemporal dementia (bvFTD, n=18), semantic-variant primary progressive aphasia (svPPA) (n=7), or non-fluent-variant (nfv)PPA (n=17), as well as of Aβ-positive patients with logopenic-variant (lv)PPA (n=4). [$^{18}$F]PI-2620 PET data were acquired dynamically 0-60min p.i. Parametric distribution volume ratio (DVR) images were obtained from kinetic modelling (MRTM2, reference region=lower cerebellum) and analysed globally (AAL template) as well as for four Pick tau stage VOIs which were created according to histopathology literature. ***Results:*** [$^{18}$F]PI-2620 DVRs were significantly higher in the FTLD patients as compared to the HCs in several frontal and temporal cortical regions as well as in cingulate gyrus, striatum, thalamus, cerebellar cortex, medulla/midbrain/pons, and cerebral/cerebellar white matter brain regions. This was also the case for the Pick tau stage 1_limbic (p=0.016), stage 1_neocortical (p=0.011), stage 2 (p<0.001), and all stages/meta (p<0.001) VOIs. On an individual level, 87% of the FTLD patients were positive (>mv+2sd of the HCs) in at least one of the Pick tau stage VOIs. These were 41%, 46%, 83%, 2%, and 13% for the Pick tau stage 1_limbic, 1_neocortical, 2, 3, and 4 VOIs. 67%

of the FTLD patients followed a hierarchical staging. With regard to the FTLD subtypes, 100% of the nfvPPAs, 100% of the lvPPAs, 78% of the bvFTDs, and 71% of the svPPAs were PET-positive. ***Conclusion:*** In conclusion, PET imaging of 3R Pick tau in FTLD seems to be possible by [$^{18}$F]PI-2620. To further understand the tracer behaviour in this dementia category, we will also focus on alternatives to the current hierarchical Pick tau staging system, on the question of how the diagnostic potential of our tracer relates to that of structural MRI/[$^{18}$F]FDG PET imaging, and on elucidating the potential impact of TDP-43 pathology on the PET readouts.

## OP-109

### Tau-PET signal in Alzheimer's disease is related to immune activation and synaptic signaling measured with CSF proteomics

***E. Van de Giessen****, R. M. Rikken, E. Vromen, E. M. Coomans, D. Visser, F. Barkhof, L. E. Collij, R. Boellaard, S. V. S. Golla, B. N. M. van Berckel, R. Ossenkoppele, A. den Braber, J. Vijverberg, W. M. van der Flier, Y. A. L. Pijnenburg, C. E. Teunissen, P. J. Visser, B. Tijms; Amsterdam UMC, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Tau tangles are one of the pathological hallmarks of Alzheimer's disease (AD) and can be quantified using PET. It remains unclear which molecular processes are related to tau aggregation. Protein levels in CSF can be used to study such underlying processes. This study aims to identify biological processes related to tau-PET using unbiased CSF proteomics in participants along the AD continuum. ***Materials and Methods:*** We included 89 participants with CSF proteomic and [$^{18}$F]flortaucipir (tau)-PET data available from the Amsterdam Dementia Cohort and the EMIF-preclin AD study (N=68 with abnormal CSF Aβ42 [64.7% cognitively impaired, 67.6% tau-PET visual read positive] and N=21 controls [normal cognition and normal CSF AD biomarkers]). [$^{18}$F]flortaucipir $BP_{ND}$ was quantified in the temporal meta-ROI (Braak I, Braak III, Braak IV). CSF proteomics was measured using untargeted LC-MS/MS based on TMT labelling. We included proteins available in the whole sample (n=1421 proteins). Protein concentrations were normalized to the control group. We determined the relationship between tau-PET $BP_{ND}$ (outcome) with protein levels (determinant) using linear regressions with sex and age as covariates, stratified for group. GO database was used for biological pathway enrichment analyses within the AD group for proteins thresholded at $p<0.05$ for positive and negative associations separately. ***Results:*** Higher CSF tau levels were associated with higher tau-PET $BP_{ND}$ (β=0.092, p=0.002). In total, 458 proteins were associated with tau-PET $BP_{ND}$ in AD. A higher tau-PET $BP_{ND}$ was related to higher levels of 140 proteins and lower levels of 318 proteins. Proteins that showed higher levels with increasing tau-PET $BP_{ND}$ were mainly involved in immune system processes, while the proteins with lower levels were predominantly related to synaptic processes and cell signaling. No significant associations were found within controls. ***Conclusion:*** Using CSF proteomics, we identified 458 proteins associated with tau-PET in AD. Higher tau burden was associated with increased levels of proteins involved in immune activation suggesting a role of the immune system in tau accumulation. Furthermore, higher tau burden was associated with lower levels of proteins related to synaptic process hinting at a role for tau in synaptic degeneration.

## OP-110

### Regional Desynchronization of Microglial Activity is Associated with Cognitive Decline in Alzheimer's Disease

***Aim/Introduction:*** Microglial activation is a hallmark of Alzheimer disease (AD) neuropathology, but the regional interaction of microglia cells in the brain is poorly understood. To address this, we explored the existence and accessibility of a microglia connectome in both mouse models and humans with AD and performed a translational assessment of microglial desynchronization as a potential AD biomarker. ***Materials and Methods:*** To validate the concept, we depleted the microglia using CSF1R inhibition in wild-type mice and examined whether interregional correlation coefficients (ICC) of 18kDa translocator protein (TSPO)-PET with [$^{18}$F]GE-180 were affected by the lack of microglia. We further investigated the effect of dysfunctional microglia ($TREM2^{-/-}$) and AD pathophysiology (β-amyloidosis, tauopathy) on TSPO-PET ICC in mouse brain, and then extended the methodology to analyze a human TSPO-PET dataset comprising of cognitively normal individuals and patients with prodromal and dementia stages of AD. We explored stage-dependent differences of microglia synchronicity and correlated personalized microglia desynchronization index (DI) in AD-specific subregions with cognitive performance measured by Mini-Mental State Examination (MMSE) score. ***Results:*** Microglia-depleted mice demonstrated a dramatic reduction of TSPO-PET ICCs among all compartments of the brain. Wild-type mice and APPPS1 mice with TREM2 deficiency indicated significant reductions of TSPO-PET ICC when compared to $TREM2^{+/+}$ groups. Our study revealed

substantial alterations in TSPO-PET ICC in all the investigated AD models when compared to the age-matched controls. Notably, we observed these changes not only in mice with moderate neuropathology (5.0-6.0 months of age), but also in mice at the neuropathology onset (2.0-2.5 months of age). Humans with AD indicated a stage-depended reduction of both the number of significant connections and microglia DI in six parietal and four temporal regions. Strong negative correlations were observed between the MMSE score and microglia DI in four parietal and two temporal regions. ***Conclusion:*** Using TSPO-PET imaging of mice with depleted microglia, we provide the first evidence that a microglia connectome can be assessed in the mouse brain. Microglia synchronicity is closely associated with cognitive decline in AD and could be utilized as an independent personalized biomarker for neuroinflammation-associated disease progression.

## OP-111

### PET-based synaptic density measure, its amyloid-independent association with APOE e4 in cognitively impaired individuals

***K. He***[1], *F. Xie*[1], *Y. Huang*[2], *K. Chen*[3], *Y. Guan*[1], *B. Li*[4], *J. Wang*[5], *Q. Huang*[5];
[1]*Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*PET Center, Department of Radiology and Biomedical Imaging, Yale University School of Medicine, New Haven, New Haven, CT, UNITED STATES OF AMERICA,* [3]*Banner Alzheimer Institute, Arizona State University, University of Arizona and Arizona Alzheimer's Consortium, Phoenix, AZ, UNITED STATES OF AMERICA,* [4]*Clinical Neuroscience Center, Ruijin Hospital,Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [5]*Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** Apolipoprotein &#9494 (APOE &#9494) is the strongest genetic risk factor for sporadic Alzheimer's disease (AD). However, the relationship of the APOE induced synaptic loss and the cognitive impairment is still not fully understood. Investigation of the effect of APOE on synaptic loss is significant for the development of genotype-specific therapy in AD. We aimed to investigate the effect of APOE &#9494 on synaptic density and the associations between synaptic density and AD biomarkers in cognitively impaired (CI) participants. ***Materials and Methods:*** Fifty-eight cognitive impaired(CI) participants and 27 cognitively normal (NC) participants who underwent amyloid positron emission tomography (PET) with florbetapir and synaptic density PET with $^{18}$F-SynVesT-1 were included. Thirty-seven participants underwent tau PET scanning with $^{18}$F-MK6240. Analyses were stratified by APOE genotype. ***Results:*** Among the CI participants, APOE &#9494 carriers displayed significant synaptic loss in the medial temporal and neocortices compared to APOE &#9494 noncarriers. Synaptic loss was mainly in the bilateral hippocampal bodies and tails. Similar results were found in the comparisons between APOE &#9493 homozygotes and APOE &#9494 heterozygotes. Female APOE &#9494 carriers displayed significantly decreased synaptic density in the medial temporal cortex compared with female APOE &#9494 noncarriers. Global amyloid deposition was only associated with hippocampal synaptic density in APOE &#9494 carriers, but it was associated with synaptic density in the hippocampus and parahippocampal gyrus in APOE &#9494 noncarriers. However, significant associations between synaptic density with tau pathology and hippocampal volume were observed in the APOE &#9494 carriers ***Conclusion:*** APOE plays a significant role in synaptic density loss. APOE &#9494 carriers showed a significantly decreased synaptic density in medial temporal and neocortices compared to noncarriers, and only one copy of the APOE &#9494 allele reduced the synaptic density in the hippocampus. Furthermore, the effects of the APOE &#9494 allele on synaptic density were observed only in females. APOE &#9494 also potentiated the associations of synaptic density with tau pathology and hippocampal volume. Our study supports the hypothesis that the APOE &#9494 allele affects synaptic density in individuals with cognitive impairments.

### Gravity-Assisted Diuresis Renography with method F+10(sp) for clinical management and post-operative assessment of primary megaureter.

***G. Tartaglione***[1], *F. P. Ieria*[1], *N. Foschi*[2];
[1]*Cristo Re Hospital, Nuclear Medicine, Rome, ITALY,* [2]*Urology, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY.*

***Aim/Introduction:*** Primary obstructive megaureter is an uncommon disease defined as intrinsic ureteral dilatation caused by congenital abnormality of the lower ureteral tract. It may be discovered earlier by ultrasound, or later in life by imaging studies for urinary tract infections. When obstruction is not present, conservative management is the best treatment choice; otherwise, ureteroneocistostomy (UCNS) is recommended. Reflux is usually diagnosed with no difficulty on voiding cystography, while the

major diagnostic challenge is to recognize obstruction. Imaging tests in supine position may be misleading, because due to the dilated collecting system, the drainage of the urine is delayed also in the absence of true obstruction. Currently, renal scintigraphy is the key test to opt for surgical or conservative treatment, but only the drop of split renal function (SRF) is often a criterion for surgical treatment. We propose gravity-assisted diuresis renography with F+10(sp) (seated position) method for clinical management of primary megaureter. ***Materials and Methods:*** Twenty-six patients (15 m, 11 f), median age 42 y (18-73 y), median serum creatinine level 1.0 mg/dL (0.75-1.69). Based on radiological findings, megaureter was bilateral in 2 pts, and unilateral in 24 pts. 11 patients underwent a UCNS, and 15 patients received conservative treatment. In total 41 Diuresis Renography (82 kidneys) were assessed. We studied patients in seated position, using F+10(sp) method. We injected IV a dose of 150-200 MBq, 99mTc-MAG3 at time 0', and a dynamic study started at once after tracer injection. The patient drank 400-500 mL of water at 5 min and received IV a dose of 0.25 mg/Kg (maximum 20 mg) of Furosemide at 10 min. SRF, Tmax, Ratio 20 min/peak, were measured. ***Results:*** SRF (NV = 0.45-0.55) was decreased in 27 (32.9%) kidneys (14 Left, 13 Right). Tmax (NV <6 min) was increased in 43 (52.4%) kidneys (24 Left, 19 Right). Ratio 20min/peak (NV <0.25) was abnormal in 30 (36.6%) kidneys (16 Left, 14 Right). Serum creatinine level was >1.2 mg/dL in 4 (9.5%) studies. In post operative assessment, we found a discordance between SRF and Ratio findings in 14 (17.1%) kidneys. No adverse events have been observed. ***Conclusion:*** The Ratio 20min/peak, measured in condition of favorable gravity with F+10(sp) method, improves accuracy in obstruction detection and in post operative assessment of obstructive megaureter, preventing renal impairment. A drop of SRF is a late index of obstruction, his diagnostic value is limited in post-operative assessment of obstructive megaureter.

### Evaluation of the use of [$^{99m}$Tc]Tc-MAG3 in the quantification of effective renal plasmatic flow in patients with autosomal dominant renal polycystosis. Preliminary data

***L. Baz-Sanz****, R. Maestre-Cutillas, G. Rubio-Fernández, M. Álvarez-Nadal, L. Cebollada-Cameo, R. Castro-Velasco, C. Juan-Piriz, J. Pérez-Iruela;*
*Hospital Ramón y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease with a prevalence of 5-10 cases/10,000 people. Factors predicting the rate of disease progression are genetic, total kidney volume (TKV) and effective renal plasma flow (ERPF). Identification of rapid progressors is beneficial for initiating treatment with tolvaptan. Due to the correlation of renal clearance of [$^{99m}$Tc]Tc-MAG3 with ERPF, this can be used as a predictor. The aim of this work is to validate our technique by correlating our preliminary [$^{99m}$Tc]Tc-MAG3 clearance data with VKT. ***Materials and Methods:*** ERPF was quantified by the Russell method in 41 patients with ADPKD divided into four groups (1A, 1B, 1C and 1D) according to Mayo Clinic criteria. The technique was performed using the radiopharmaceutical [$^{99m}$Tc]Tc-MAG3, which was prepared according to the technical data sheet. Two doses of 1mCi/1ml were prepared, one for intravenous administration and the other for the preparation of the standar. Blood was withdrawn 43min post-injection and centrifuged 10min/3900rpm. 2ml of plasma and standard were pipetted in triplicate. Their activity was determined with a gamma counter. ***Results:*** The mean clearance of the radiopharmaceutical and VKT of each group was calculated:[$^{99m}$Tc]Tc-MAG3 clearance: 1A(n=4), 167±40.00ml/min; 1B(n=20), 136±43.53ml/min; 1C(n=16), 119±47.43ml/min; 1D(n=1), 98ml/min. VKT: 1A(n=4), 282.25±88.75ml; 1B(n=20), 708.44±189.43ml; 1C(n=16), 1189.25±327.66ml; 1D(n=1), 1796ml. Pearson's correlation between radiopharmaceutical clearance and VKT: r=-0.487 and p=0.001. ***Conclusion:*** We obtained a moderate correlation between [$^{99m}$Tc]Tc-MAG3 clearance results and VKT, which indicates that our preliminary data are encouraging for future validation of our technique, expanding the number of patients. It is a simple, fast and convenient test for the patient, the implementation of which would be a benefit compared to diagnostic tests with a longer waiting list and more expensive, such as MRI.

## EPS-024

### Comparison Between In Vivo Gates Method and In Vitro Plasma Sampling Technique for Glomerular Filtration Rate Measurement in Voluntary Kidney Donors

***M. Radulovic****, M. Sisic, B. Miljuš, L. Radosavcev, B. Ajdinovic;*
*Institute of Nuclear Medicine, Military Medical Academy, Belgrade, SERBIA.*

***Aim/Introduction:*** Glomerular Filtration Rate (GFR) is defined as the volume of plasma that is filtered by the glomeruli per unit of time. Experience from our country shows that potential donors have been frequently assessed as ineligible due to lower GFR measured by in vivo Gates method. Aim of this study was to compare GFR measured by the radionuclide plasma sampling technique with Gates camera based method. ***Materials and Methods:*** Patient preparation consisted of the placement of intravenous cannula and adequate hydration. Before the beginning of renography study, preinjection syringe containing 185MBq of Tc-99m diethylenetriaminepentaacetic acid (DTPA) was counted using dual head gamma camera. Then a bolus dose of the tracer was intravenously administrated and the time recorded. Radiorenography was performed in 44 patients, potential kidney donors, for 35 minutes (30 frames lasting 2 seconds followed by 136 frames lasting 15 seconds) in the posterior position. The post-injection syringe was counted at the end of the study. Sampling: venous blood was taken according to required schedule - 180 minutes after administration of radioactive tracer. The samples of 10ml were taken from the arm contralateral to the administration site. Vials containing blood samples were centrifuged without postponement for 10 minutes at 1000 RPM. Two plasma samples, 1ml each, were taken from vials. A standard solution was prepared with 185MBq of Tc-99m in 1000ml of demineralized water. Standard sample containing 1ml of solution was prepared and counted after aprox. 24 hours using gamma counter. At that point, plasma samples were also counted. The decay of radioactivity was corrected. GFR was calculated according to guidelines. Gates GFR was calculated using gamma camera's software. Region of interest (ROI) for each kidney was drawn manually, and background ROIs were placed around the lower outer renal margins. Each patient provided serum creatinine findings within 48 hours of the study. ***Results:*** Mean values of GFR estimated using plasma sampling and Gates method were 82.26±16.05 ml/min/1.73m$^2$ and 69.93±15.57 ml/min/1.73m$^2$, respectively. There was significant difference between these values. Additionally, GFR was calculated using creatinine based equations (MDRD, CKD-EPI). The results showed that there was also significant difference between GFR estimated by radionuclide plasma sampling and creatinine based equations. ***Conclusion:*** Gates method tended to underestimated GFR

compared to plasma sampling method. Thus, calculation of GFR using in vitro radionuclide plasma method is essential in donor's work up protocol for kidney transplantation.

## EPS-025

### Glomerular filtration rate quantification in patients on antiretroviral therapy. Preliminary data

***L. Baz-Sanz***, *R. Maestre-Cutillas, G. Rubio-Fernández, V. Lopes-Martin, L. Cebollada-Cameo, M. Vaquero-Palomo, S. Horcas-Villaverde, J. Pérez-Iruela;*
*Hospital Ramón y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** Some antiretroviral drugs inhibit tubular secretion of creatinine (Cr) without causing renal toxicity. Thus, an increase in plasma Cr concentration has been observed, with a consequent decrease in its estimated clearance, without producing a decrease in the actual glomerular filtration rate (GFR). The aim of this work is to identify whether patients really suffer a decrease in their GFR or, on the contrary, they are patients with a decrease in their tubular Cr secretion who do not need a change in their therapeutic planning. For this purpose, GFR estimation using serum Cr-based estimation formulae, such as MDRD4, will be compared in patients on antiretroviral therapy with the radioisotopic technique using the radiopharmaceutical [$^{99m}$Tc]Tc-DTPA, where the increase in serum Cr does not affect its determination. ***Materials and Methods:*** GFR was determined in 17 patients on antiretroviral therapy whose GFR estimates using the MDRD4 formula were below reference ranges. For this purpose, the radiopharmaceutical [$^{99m}$Tc]Tc-DTPA will be used, which was labelled according to the technical data sheet. A standard dose and a patient dose of 500 µCi were prepared. After administration of the radiopharmaceutical, blood samples were drawn at 2, 3 and 4 hours. Plasma was quantified in a gamma counter and GFR was determined using the Christensen and Groth method.They were divided into 2 groups: group 1, whose GFR estimated by isotopic method was>75ml/min/1.73m$^2$ (normal GFR); group 2, patients with GFR<75ml/min/1.73m$^2$. ***Results:*** Within group 2, only one patient required treatment modification due to a decrease in GFR, while the rest of the patients underwent closer monitoring without modification of their therapeutic regimen. The Mann-Whitney U-test was performed comparing both techniques in the two groups and statistically significant differences were obtained (p<0.05), so the null hypothesis is rejected. ***Conclusion:*** The analysis of results reveals that there are statistically significant differences between GFR determined by the MDRD4 method and the radioisotopic technique in patients on antiretroviral therapy. This supports the idea that antiretrovirals may underestimate GFR when using plasma Cr methods. In these cases, it may be advisable to use the radioisotopic technique, where increases in plasma Cr are not affected.

## EPS-026

### Body surface area as a determining factor in assessing glomerular filtration rate

***G. Rubio-Fernández***, *R. Maestre-Cutillas, L. Baz-Sanz, L. Cebollada-Cameo, V. Lopes-Martín, M. Vaquero-Palomo, S. Horcas-Villaverde, J. Pérez-Iruela;*
*Hospital Ramón y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** The objective is to assess how body surface area index (BSI) affects glomerular filtration rate (GFR) by comparing the radiopharmaceutical test performed with [$^{99m}$Tc]Tc-DTPA with the biochemical, MDRD4 equation, which does not take into account BSI. ***Materials and Methods:*** An observational and retrospective study of the GFR of 47 patients with different pathologies who had undergone a test to determine GFR between 2019-2023 with two techniques, one biochemical (MDRD4) and one with radioisotopes (radiopharmaceutical [$^{99m}$Tc]Tc-DTPA). The BSI according to Dubois and Dubois is considered high if it is >1.9m$^2$ in men and >1.6m$^2$ in women. The radiopharmaceutical was administered to patients and samples were collected at 2, 3 and 4 hours. Plasma was quantified in a gamma counter and GFR was determined using the Christensen and Groth method. A GFR >75ml/min/1.73m$^2$ is considered normal. ***Results:*** 35/47(74.46%) patients are male and 12/47(25.53%) are female. Of the males 22/35(62.85%) have high ISC(>1.9m$^2$) whose GFR with [$^{99m}$Tc]Tc-DTPA and MDRD4 respectively are: 68.62±20.79ml/min/1.73m$^2$ and 49.45±9.86 ml/min/1.73m$^2$.86ml/min/1.73m$^2$ and of the females 11/12(25.53%) have high BSI (>1.6m$^2$) whose GFR with [$^{99m}$Tc]Tc-DTPA and MDRD4 respectively is: 50.01±23.71ml/min/1.73m$^2$ and 43.26±16.04ml/min/1.73m$^2$. Of the men with high BSI 19/22(86.36%) had a higher GFR with [$^{99m}$Tc]Tc-DTPA than with the MDRD4 equation (73.42±17ml/min/1.73m$^2$ and 50.32±9.16ml/min/1.73m$^2$ respectively). 16 ml/min/1.73m$^2$ respectively) and in the case of women with high BSI 7/11(63.63%) had a higher GFR with [$^{99m}$Tc]Tc-DTPA than with MDRD4 (57.98±26.68ml/min/1.73m$^2$ and 43.14±20.48ml/min/1.73m$^2$ respectively). The results obtained on GFR revealed in the case of the [$^{99m}$Tc]Tc-DTPA test that 34/47(72.34%) had a value <75ml/min/1.73m$^2$ while according to MDRD4 it was 46/47(97.87%). 39/47(82.97%) patients have a higher GFR with the radiopharmaceutical test than with MDRD4 (61.94±22.74ml/min/1.73m$^2$ and 46.55±11.57ml/min/1.73m$^2$ respectively. Comparing patients with high ISC in the radiopharmaceutical test and the MDRD4 equation yields p>0.05. ***Conclusion:*** The values obtained with the MDRD4 method have a lower GFR than those obtained with [$^{99m}$Tc]Tc-DTPA. It is observed that a high percentage of both male and female patients tested have a high BSI. Those patients with a high BSI had a lower GFR with MDRD4. Despite a decrease in GFR with MDRD4 compared to [99mTc]Tc-DTPA, there is no statistically significant difference. Obesity increases the risk of chronic kidney disease, therefore we found that many of these patients have an elevated BSI. This is probably due to the fact that the MDRD4 equation does not take into account the BSI unlike the [$^{99m}$Tc]Tc-DTPA test, which does.

## EPS-027

### Estimation of GFR Using Camera Based Method- Is There Any Role of CT?

***S. Garg***[1], *S. G. Ravindra*[1], *A. Khurana*[1], *K. J. Das*[2], *A. Singhal*[2], *V. Jaiswal*[2], *C. S. Bal*[1];
[1]*All India Institute of Medical Sciences, New Delhi, INDIA,*
[2]*National Cancer Institute - AIIMS, Jhajjar, INDIA.*

***Aim/Introduction:*** There are various methods available for estimation of Glomerular Filtration Rate(GFR) using the renal radiopharmaceutical Technetium-99m-diethylenetriaminepentaacetic acid. Amongst these, the camera based methods are convenient as they do not require blood sampling. ***Materials and Methods:*** This is a prospective study wherein patients underwent a renal dynamic scan and a low dose CT scan simultaneously using GE NM/CT 870 DR. The GFRs were calculated using the following methods: 'GE Renal Analysis' software without filling the renal depth; formulae (Tonnesen's, Itoh K's, and Taylor's) based estimation of renal depths; CT based estimation of renal depth. The renal depths measured by the above mentioned techniques were compared to the Modified estimated GFR (eGFR) calculated using CKD-EPI equation. Statistical analysis was performed using

MedCalc Software with a p-value < 0.05 considered statistically significant. ***Results:*** Twenty-six patients were enrolled. The mean age and gender distribution (male: female) of patients was 44.7 ± 17.0 years and 12:14. The mean modified eGFR was 120.5 ± 69.6 mL/min. The mean GFRs calculated by the system, three formulae and CT were 68.7 ± 26.9, 68.4 ± 25.3, 81.7 ± 29.3, 78.2 ± 25.3 and 80.5 ± 30.4 respectively. All of them correlated well with modified eGFR with p<0.01. A good consistency was seen between the calculated GFR by system's inherent calculation technique, Tonnesen's, Itoh K's, Taylor's formulae, CT guided renal depth estimation and the modified eGFR(p<0.01). The right renal depth was significantly smaller using Tonessen's formula than those measured using the other two formulae but was not significantly different when compared to CT scan depth. The left renal depth measurement was not significantly different using any of the above methods(p>0.01). The right renal depth (6.1 cm, CI-5.8-6.5) was always larger than the left (5.9 cm, CI-5.7-6.2) (p<0.01). On pairwise comparison, system calculated (68.9 ± 27.0) and Tonessen's formula (68.4 ± 25.3) GFR(ml/min) were significantly lower as compared to CT aided(80.5 ± 30.4), Itoh K's(81.7 ± 29.3), Taylor's method(78.2 ± 25.3) GFR(ml/min). ***Conclusion:*** GFR calculated with CT guided, Itoh K's and Taylor's method is consistently higher than that calculated using system's inherent calculation technique and Tonessen's method. The Itoh K's and Taylor's method calculated renal depth correlates nicely with the CT aided depth measurement. These findings prove valuable as incorporation of low dose CT scan causes additional radiation burden to the patient.

## EPS-028

### Predictive role of $^{18}$F-FDG PET/CT in renal function in patients with kidney disease

***H. Jiao***, *Y. Qiu, Z. Chen, Y. Fan, L. Kang;*
*Peking University First Hospital Beijing, CHINA.*

***Aim/Introduction:*** Kidney disease appears to be both a potential cause and consequence of cancer. For patients with kidney disease, timely detection of tumors is particularly important. The $^{18}$F-FDG distribution in tissues can reflect the level of local glucose metabolism. However, it has not been demonstrated by any studies yet whether detecting $^{18}$F-FDG uptake in the renal cortex can provide relevant clinical information. In this study, we aimed to evaluate the value of $^{18}$F-FDG PET/CT in patients with kidney disease. ***Materials and Methods:*** We retrospectively reviewed 182 $^{18}$F-FDG PET/CT subjects diagnosed with kidney diseases and 32 subjects without any kidney disease from January 2018 to May 2022 in our hospital. Patients with kidney disease were divided into three groups: AKD, A/C, and CKD. The CKD groups were divided into G1, G2, G3, G4+G5 upon CKD-EPI-based estimated glomerular filtration rate (eGFR). The regions of interest (ROIs) were drawn in the left renal cortex of both upper and lower poles, liver, aorta and lesions with abnormal uptake. The SUVmax and SUVmean were measured for each ROI. The ratios of renal cortex SUVmax to the liver SUVmean and to the blood pool SUVmean were obtained, respectively. Statistical analysis was performed using the Kruskal-Wallis test and Spearman relation analysis. ***Results:*** Among 182 patients, 154 patients were found with abnormal FDG uptake (84.6%), of which the SUVmax of malignant lesions was significantly higher than that of benign lesions. The three most common malignant lesions included multiple myeloma, lymphoma and lung cancer. The sensitivity and specificity of PET/CT in the diagnosis of malignant lesions were 89.5% and 100%, respectively. The renal cortex SUV values of AKD, A/C and CKD group were significantly different from the normal group, and the renal cortex SUV values of the AKD group were also significantly higher than those of the CKD group. There were significant differences in the renal cortex SUVmax and SUVmean between G1 and G4+G5. In addition, there were significant differences in the renal cortex SUV values between primary kidney disease and secondary kidney disease. In CKD group, increased renal cortex SUVmax and SUVmean were associated with decreased serum creatinine, blood urea nitrogen, and increased eGFR. ***Conclusion:*** For patients with kidney disease, $^{18}$F-FDG PET/CT can be used to systematically screen tumors and other abnormal uptake lesions. The $^{18}$F-FDG uptake of renal cortex may predict different types of kidney diseases and be associated with renal function.

## EPS-029

### Clinical Significance of SPECT/CT Imaging in Dynamic Renal Scintigraphy for Work-up of Patients with Different Nephro-urological Conditions

***T. Sofiyanski***[1], *S. Sergieva*[1], *M. Dimcheva*[1], *B. Robev*[2];
[1]*Sofia Cancer Center, Sofia, BULGARIA,* [2]*University Hospital St. Ivan Rilski, Sofia, BULGARIA.*

***Aim/Introduction:*** Dynamic $^{99m}$Technetium diethylenetriaminepetaacetic acid ($^{99m}$Tc-DTPA) renal scintigraphy is a generally used imaging technique for evaluating renal function of patients with various nephron-urological conditions. The additional value of subsequent SPECT/CT to the renal scintigraphy has rarely been discussed in the medical literature. The aim of the study was to evaluate the benefits of subsequent SPECT/CT to the dynamic renal scintigraphy in the management of patients with different nephron-urological conditions. ***Materials and Methods:*** Thirty two patients /21 females and 11 males, aged 17-83 years/ underwent dynamic nephroscintigraphy with subsequent SPECT/CT. A dose of 185MBq (5mCi) $^{99m}$Tc-DTPA was administered i.v. to perform dynamic imaging followed by SPECT/CT. The CT scan was performed with a low dose protocol. ***Results:*** Our analysis demonstrated impaired relative renal function in various degrees of left kidney in 18 patients and of the right kidney in 14 patients. SPECT/CT imaging revealed the specific cause, responsible for the renal dysfunction in the cases. The hybrid imaging demonstrated calculosis in 11 patients, postoperative strictures of ureter in 5 patients, tumor formation of kidney, ureter of urinary bladder in 4 patients, external compression of ureter from ovarian cyst in 1 patient and compression of ureter due to nephroptosis in 1 patient as a possible obstructive cause. In 9 patients congenital renal anomalies were the identified causes of impaired renal function - hypoplastic kidney in 3 patients, duplex kidney in 2 patients, multiple cortical cysts in 2 patients, aberrant vessel obstructing the pyelo-ureteral segment in 1 patient and horseshoe kidney in 1 patient. ***Conclusion:*** The combination of conventional dynamic renal scintigraphy and SPECT/CT could provide not only functional and anatomical information of kidneys and ureters in the evaluation of obstructive uropathies and congenital renal abnormities, but may also show the cause of the disease in the right patient. Our study indicated the usefulness of hybrid imaging in renal scintigraphy that can change the clinical management.

## EPS-030

### Added value of SPECT/CT to Planar Lymphoscintigraphy in Patients with Secondary Extremity Lymphedema: A Retrospective Cohort Study

***H. Yoon***[1], *D. Kim*[2], *K. Woo*[3], *B. Kim*[1], *J. Kim*[4];
[1]*Department of Nuclear Medicine, Ewha Womans University School of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Emergency Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, KOREA, REPUBLIC OF,* [3]*Department of Plastic Surgery, Ewha Womans University School of Medicine, Seoul, KOREA, REPUBLIC OF,* [4]*Department of Nuclear Medicine Ewha Womans University Mokdong Hospital, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Lymphoscintigraphy is a standard modality to examine the functional status of the lymphatic system. In this study, we investigated the added value of SPECT/CT over planar lymphoscintigraphy for initial staging in patients with secondary extremity lymphedema. Furthermore, we developed a hybrid SPECT/CT classification combining dermal backflow (DBF) of SPECT and honeycomb pattern (HP) of CT, correlated it with lymphoscintigraphic staging and clinical severity. ***Materials and Methods:*** We retrospectively evaluated 41 patients with secondary extremity lymphedema who underwent lymphoscintigraphy with SPECT/CT from April 2022 to December 2022. Lymphoscintigraphic staging was performed according to the Taiwan Lymphoscintigraphy Staging (TLS) staging system, and clinical severity was evaluated using CT volumetry. Both CT-based and SPECT-based quantitative analyses were conducted. We examined the changes in TLS staging when SPECT/CT was added to planar scintigraphy alone. We analyzed quantitative parameters of CT-based (HP volume ratio) and SPECT-based (DBF volume ratio), as well as the hybrid classification according to the presence of HP and DBF, based on clinical severity and TLS staging. ***Results:*** Adding SPECT/CT to planar scintigraphy showed a 19.5% modification rate in TLS staging. HP volume ratio significantly differed among clinical severity groups and increased with severity ($p<0.001$) and among TLS staging groups with an increase in stage ($p=0.001$). DBF volume ratio did not differ significantly among clinical severity groups ($p=0.256$). However, DBF volume ratio showed significant differences according to TLS staging with an expected increase and decrease pattern ($p=0.008$). Hybrid SPECT/CT lymphoscintigraphic classification showed strong positive correlation with clinical severity and TLS staging. ***Conclusion:*** Our results demonstrated substantial modification of lymphoscintigraphic staging by adding SPECT/CT to a conventional planar scintigraphy. In addition, a hybrid SPECT/CT is expected to provide new indicators reflecting lymphoscintigraphic staging and clinical severity by providing both of functional DBF and anatomical HP information. ***References:*** Rockson, Stanley G. "Lymphedema after breast cancer treatment." New England Journal of Medicine 379.20 (2018): 1937-1944.Bae, Jae Seok, et al. ## EPS-031

### Analysis and clinical response to bile acid sequestrants of patients with diarrhoea and borderline $^{75}$SeHCAT results

***S. Bondia-Bescós***, *P. Notta, M. Pudis, B. Hervás-Sanz, J. Díaz-Moreno, A. Rodriguez-Gasen, A. Palomar-Muñoz, J. Robles-Barba, M. Cortés-Romera;*
*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** The aim of this study is to evaluate the prevalence of bile acid diarrhoea (BAD) in patients with an abdominal retention score (ARS) 10-15% in $^{75}$SeHCAT tests and to assess the clinical response to bile acid sequestrants (BAS) in those patients. ***Materials and Methods:*** A retrospective evaluation of $^{75}$SeHCAT test results performed between April 2010 and January 2020. The SeHCAT test was performed as a measurement of the 7-day ARS. Oral administration of 370KBq of tauroselcholic acid and a collimated gamma camera was used in all cases. We divided SeHCAT results into three groups: A = ARS<10% (positive result), B = ARS between 10-15% (borderline result) and C = ARS>15% (negative result). Clinical data regarding response to BAS was obtained from the medical records of group B patients. ***Results:*** A total of 2678 SeHCAT tests were evaluated. ARS results on 7-day was, group A = 1144p, group B = 413p (275 women) and group C = 1025p. A total of 122 patients of group B received treatment with BAS, but in 20p it was not possible to know the response to BAS. 13p without follow-up just after the test were excluded. A good response to treatment in group B was obtained in 61.8% (63/102), intolerance in 12.7% (13/102) and non-response in 25.5% (26/102). In table 1 we divided the response to treatment of group B patients according to the type of BAD. ***Conclusion:*** In our study, a high percentage of patients with borderline SeHCAT results (ARS 10-15%) had a suitable clinical response to BAS. BAD type II subgroup showed the best response to BAS followed by BAD type III, therefore patients with borderline ARS results should be considered candidates to BAS treatment for correct clinical management. ***References:*** Barkun AN, Love J, Gould M, Pluta H, Steinhart H. ## EPS-032

### Ukrainian experience of interictal FDG PET/CT brain scan for pharmacoresistant epilepsy in children as a part of a presurgical assessment

***O. Oliinichenko***[1], *M. Tkachenko*[2];
[1]*Kyiv Center of Nuclear Medicine, Kyiv, UKRAINE,*
[2]*Bogomolets National Medical University, Kyiv, UKRAINE.*

***Aim/Introduction:*** The aim of this study is introduction in practice in Ukraine routine use of brain $^{18}$F-FDG PET/CT scans before surgical treatment of pharmacoresistant epilepsy in children and to optimize interpretation using a streamlined, automated solution for analysis and quantification of PET FDG - Cortex ID Suite. Over the past 4 years despite the epidemic and the war in our country surgical treatment of drug-resistant epilepsy continues to develop. One of the factors contributing to this was the use of an $^{18}$F-FDG PET/CT scan. ***Materials and Methods:*** Our study included 100 children (1-17 years old, 55 female, 45 male) with normal or doubtful MRI that underwent an interictal 18F-FDG PET

as a part of a presurgical assessment. 18F-FDG PET was performed according to EANM procedure guidelines for brain PET imaging. Every patient received a dose of tracer injection according to the EANM Pediatric Dose calculator. Report of PET brain scans performed in two ways: the first -using only visual assessment and the second - reporting brain scans in Cortex ID. Among them, eight patients were excluded from the study because of short-term seizures after administration of FDG or 1 or 2 hours before scans appeared. Unfortunately, the parents hid this information. Among them, in 30 patients, we already have the pathohistological results after surgical treatment that revealed in 17 patients FCD, eight patients - hippocampal sclerosis, 3 with FCD in the combination of hippocampal sclerosis, 1 - pyloric gliosis, and one cavernous angioma. ***Results:*** Application of Cortex ID for patient reports showed that 65% of it helps to evaluate the epileptogenic focus in more detail even though the control Z - score database for adults, the correlation of visual assessment with 3D SSP methods for uptake ratio and Z-score data allows more focused detection of signs of hypometabolism caused by an epileptogenic focus, rather than distant consequences. ***Conclusion:*** Using 18 F- FDG PET CT brain scan in pediatric practice in presurgical diagnostic of drug-resistant epilepsy with negative or doubtful MRI results helps to select candidates for neurosurgical treatment. A combination of a visual and quantitative assessment of PET brain, using 3D SSP methods for uptake ratio and Z-score images helps more carefully and in detail to assess the interictal glucose metabolism of the brain to find the source of epilepsy.

## EPS-033

### Age variations in the normal physiological distribution of 18F-FDG

***J. Hagerman***[1], *D. Minarik*[2], *E. Trädgårdh*[1], *J. Oddstig*[2];
[1]*Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund/Malmö, SWEDEN,* [2]*Radiation Physics, Skåne University Hospital, Lund/Malmö, SWEDEN.*

***Aim/Introduction:*** The biodistribution of fluorine-18-fluorodeoxyglucose (18F-FDG) mimics the rate of tissue glucose utilization and is distributed in healthy/diseased tissue to varying degrees. Knowledge of the physiological accumulation of the tracer is central when interpreting positron emission tomography (PET) images. Clinical observations recognize differences in the physiological accumulation of 18F-FDG between adults and children - potentially associated with changes in glucose metabolism and/or body composition during a child´s development. Weight is recognized to influence biodistribution in adults, as white adipose tissue contributes to weight but is usually metabolically inactive. We aimed to investigate age-related quantitative differences in the normal distribution of 18F-FDG in children and adults. ***Materials and Methods:*** 18F-FDG PET images from 208 clinical patients (164 children), 0-76 years, were retrospectively included. Only presumed healthy tissue (according to PET) from the aorta, liver, spleen, lung, gluteus maximus, and pelvis skeleton were segmented in the PET images (assistance of corresponding computer tomography (CT) images), using a convolutional neural network with manual correction, generating a diversity of volumes-of-interest. Biodistribution was measured as the mean standardized uptake value (SUVmean). Patients were stratified into children (<20 years), adults (>20 years), and 0-8, 9-15, 16-19, and >20 years and analyzed in relation to their body composition. ***Results:*** Children had lower SUVmean than adults in the aorta (1.32 ±0.30, 1.64 ±0.34, p<0.001) (mean ±standard deviation), liver (1.66 ±0.42, 2.10 ±0.44, p<0.001), and gluteus maximus (0.51 ±0.10, 0.61 ±0.12, p<0.001), higher in the pelvic skeleton (1.13 ±0.20, 0.93 ±0.14, p<0.001), but similar in the lung (0.59 ±0.13, 0.61 ±0.14, p=0.396) and spleen (1.51 ±0.39, 1.58 ±0.33, p=0.258). Body composition was equivalent to normal weight for all adults, while obesity (6%), pre-obesity (16%), and underweight (10%) were present among the children. With a variation in significance level, the SUVmean among children for the aorta, liver, and spleen increased with age. In contrast, an initial increase, followed by a plateau, was observed for the lung, gluteus maximus, and pelvic skeleton. Regression analysis exposed SUVmean differences between adults and each younger group that remained significantly lower after adjusting for body mass index for the aorta, liver, and gluteus maximus. ***Conclusion:*** Our study confirms that SUVmeans generally increase, or remain constant, with age. Significantly lower accumulation of 18F-FDG was observed in children´s aorta, liver, and gluteus maximus compared to adults, which remained after adjusting for body composition. The result is important to recognize when reviewing/interpreting children´s 18F-FDG PET images.

## EPS-034

### The impact of the COVID-19 pandemic on oncological disease extent in children at FDG PET/MR staging

***Y. Xu****;*
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To evaluate the impact of coronavirus disease 2019 (COVID-19) pandemic on tumor staging and treatment of 18F-FDG PET/MR in children. ***Materials and Methods:*** Retrospective observational study including biopsy-proven, newly diagnosed Malignant tumor in children using whole-body FDG PET/MR staging in two selected intervals: May 1, 2017 to January 31, 2020 (Group A), and February 1, 2020 to June 30, 2022 (Group B). Data regarding primary tumour, regional lymph nodal (N) status and number of involved regional lymph nodal stations, and presence and number of distant metastases (M) were collected. ***Results:*** 1415 children(398 neuroblastomas, 104 blastomas, 73 hepatoblastomas, 394 lymphomas, 119 Langerhans histiocytosis, 98 rhabdomyosarcomas, 21 osteosarcomas, 24 malignant teratomas, 31 endodermal sinus tumors, 40 germ cell tumors, 19 Ewing's sarcoma, 15 hyaline cell sarcoma, and 79 other types of tumors) were included (672 in Group A vs 743 in Group B, respectively). The median intervals to PET/MR from the initial symptom in group A and group B were 7.3 (1.0-28.6) and 8.5(1.2-30.4) days, respectively (p<0.05). The median intervals to treatment from the initial symptom in group A and group B were 15.2 (5.6-30.5) and 16.4 (6.3-28.3) days, respectively (p>0.05). There was no statistically significant difference between the two groups in the staging of various types of tumors(p>0.05). ***Conclusion:*** For children with malignant tumors in Zhejiang Province, China, after the start of isolation restriction, although the median interval from initial symptoms to PET/MR was extended, there was no significant delay in PET/MR staging and treatment.

## EPS-035

### $^{18}$F-FDG PET/MR Imaging findings of pediatric neuroblastoma with different MYCN amplification status

***J. Liang****;*
*CHINA.*

***Aim/Introduction:*** To observe the $^{18}$F-FDG PET/MR imaging features of pediatric neuroblastoma (NB) with different MYCN gene amplification status. ***Materials and Methods:*** 140 pediatric neuroblastoma patients were enrolled and divided into MYCN group (n=62) and

unamplified group (n=78) according to MYCN gene copy number. The lesion location, size, morphology, shape, calcification, cystic degeneration and necrosis of tumors were compared between the two groups. The SUVmax and mean ADC values of tumor parenchyma were both compared between groups. ***Results:*** There were significant differences in tumor size, calcification, cystic degeneration and necrosis among groups (P <0.05), but there were no significant differences in tumor location, morphology and growth across the median line (P>0.05). The relationship between tumor and blood vessels and the invasion of neighboring organs were statistically different among the groups (P <0.05). There were statistically significant differences in SUVmax and mean ADC values of tumor parenchyma between groups (P <0.05). The SUVmax value of tumor parenchyma in MYCN group was significantly higher than that in unamplified group (P <0.05), while the mean ADC value in MYCN group was significantly lower than that in unamplified group (P <0.05). ***Conclusion:*** $^{18}$F-FDG PET/MR imaging features of pediatric neuroblastoma patients with different MYCN gene amplification status are different.

## EPS-036

### Value of qPET in Pediatric Patients With Hodgkin Lymphoma

***M. Mehesen***[1,2], *E. Moussa*[3,2], *M. S. Zaghloul*[1,2], *M. Elwakeel*[1,2], *W. Elsayed*[1,2], *N. Ali*[1,2];
[1]*National Cancer Institute., Cairo, EGYPT,*
[2]*Children's Cancer Hospital Egypt, Cairo, EGYPT,*
[3]*Menoufya University, Menoufya, EGYPT.*

***Aim/Introduction:*** qPET is a semi-automatic quantitative measurement used to assess the FDG-PET response in lymphoma. 898 scans of children with Hodgkin lymphoma from the EuroNetPHL-C1 (C1) trial were used to develop qPET. The aim of this study was to compare qPET and the Deauville score, then find their concordance in childhood HL patients treated at an Egyptian children's cancer hospital. ***Materials and Methods:*** qPET is computed by dividing the peakSUV of the hottest residual uptake by the meanSUV of the liver. Interim PET (after two cycles of chemotherapy) will be evaluated in accordance with qPET and DS, and the degree of concordance between the two will be determined. ***Results:*** We retrospectively analyzed 424 pediatric patients with newly diagnosed Hodgkin lymphoma (122 females and 302 males, with a mean age of 10.1 (2-18) years). In terms of pathologic subtypes, lymphocyte depletion was observed in 9 patients, mixed cellularity in 143 patients, NLPHL in 2 patients, lymphocytic rich in 15 patients, and nodular sclerosis in 255 patients. In 51 patients, stage IA was identified, then stage IB in 12 patients, stage IIA in 104 patients, stage IIB in 40 patients, stage IIIA in 61 patients, stage IIIB in 59 patients, stage IV A in 35 patients, and stage IVB in 62 patients. Based on PETCT measurements, DS was identified as DS1 in 24 patients, DS2 in 106 patients, DS3 in 187 patients, DS4 in 77 patients, and DS5 in 30 patients. 317 patients were negative (DS 1-3) and had an adequate response, while 107 were positive (DS 4-5) and had an inadequate response. qPET revealed that 341 patients were negative (less than 1.3) and 83 were positive.We found that 25 patients had a DS 4 (positive) and a qPET 3 (negative), while one patient had a DS 3 (negative) and a qPET 4 (positive). Two patients out of twenty-five (2/25) who were positive by DS and negative by qPET experienced a relapse, while the remaining twenty-three patients were in complete remission. EFS was 90.4% for negative DS and 80.1% for positive DS at 2 years (P = 0.004).EFS at 2 years was 88.3% for negative qPET and 83.9% for positive qPET (P = 0.03). ***Conclusion:*** Our qPET results indicate that it is a suitable semi-automatic quantitative method for evaluating response in pediatric HL patients. qPET thresholds from childhood HL in CCHE gave 73 % concordance for vDS and qPET.

## EPS-037

### Role of semi-quantitative assessment of $^{123}$I-MIBG uptake in pediatric neuroblastoma.Does semiquantitative evaluation of uptake improve the diagnostic accuracy of$^{123}$I-MIBG scintigraphy in pediatric neuroblastoma ?

***C. Altini***[1], *M. Villani*[1], *M. Pizzoferro*[1], *A. Castellano*[2], *A. Serra*[2], *M. De Ioris*[2], *D. Ciucci*[3], *C. Polito*[3], *E. Solfaroli Camillocci*[3], *V. Cannatà*[3], *E. Villanucci*[1], *V. Nicoloso*[1], *G. Marchetti*[1], *M. Garganese*[1];
[1]*IRCCS Bambino Gesù Children's Hospital, Nuclear Medicine Unit, Imaging Department, Rome, ITALY,*
[2]*IRCCS Bambino Gesù Children's Hospital, Department of Oncohematology, Rome, ITALY,* [3]*IRCCS Bambino Gesù Children's Hospital, Medical Physics Unit, Rome, ITALY.*

***Aim/Introduction:*** $^{123}$I-MIBG scintigraphy is indispensable in neuroblastoma staging and in the evaluation of response to treatment. Qualitative scoring systems are a known and reliable method of evaluation to assess response to therapy in bone and bone marrow metastatic sites but the determination of response in primary tumour is challenging, as qualitative evaluation of images is often not sufficient. Aim of our study is to evaluate the usefulness of semiquantitative assessment of tracer uptake in $^{123}$I-MIBG scintigraphies in the estimation of response to treatment in pediatric patients affected by neuroblastoma. ***Materials and Methods:*** we retrospectively evaluated staging scintigraphy and after induction chemotherapy scintigraphy of 33 patients affected by neuroblastoma (age range: 4 months - 17 years), for a total of 66 scintigraphies. All the studies (planar images and xSPECT/TC acquisitions) were performed from April 2021 to April 2023 in Our Center with an hybrid gamma camera (Symbia Intevo BoldTM, Siemens Healthineer). Treatment response after every treatment was classified as progressive disease or stable disease (PD and SD), partial and complete response (PR and CR) based on a comprehensive evaluation (CT data, qualitative evaluation of $^{123}$I-MIBG scan, trephines data) and correlated to the variation of the ratio of SUVmax lesion (SUVmaxLE)/SUVaverage liver (SUVavgLI). ***Results:*** we found in 29/33 cases (89,5%) a concordance between the overall classification of the response and the variation of the SUVmaxLe/SUVavgLI ratio; only in 4 cases we found a mismatch. Despite the classification of the response in stable disease, $^{123}$I-MIBG scintigraphy showed an increase of the SUVmax LE/SUVavgLI ratio in primary tumor above 50%. Among these patients, 3/4 presented metastatic disease at diagnosis, while 1/4 had localized disease, but segmental chromosome aberrations. ***Conclusion:*** in our experience, semiquantitative assessment of tracer uptake in primary tumor can improve the diagnostic accuracy of 123I-MIBG scintigraphy in Patients affected by neuroblastoma. Further studies with long term follow up are required in order to understand how semi-quantification of metabolic activity in primary tumor affects clinical management and outcome of these patients.

## EPS-038

### Dynamic Renal Scintigraphy In Pediatric Hydronephrosis: Imapct In Therapeutic Decision

***L. Zaabar***[1,2], *M. ElOuni*[3], *T. Ben Ghachem*[1,2], *D. Ben Sellem*[1,2], *B. Letaief*[1,2], *A. Mhiri*[1,2];
[1]*Salah Azaeiz Institute, Tunis, TUNISIA,* [2]*Faculté de Médecine de Tunis, Tunis, TUNISIA,* [3]*Health Ministery, Tunis, TUNISIA.*

***Aim/Introduction:*** Pyeloureteral junction syndrome is an urodynamic disorder responsible for ureteropelvic dilation upstream of an organic or functional obstruction. Its imaging modalities and therapeutic choices are controversial.The aim of this study was to evaluate the contribution of dynamic renal scintigraphy (DRS) using $^{99m}$Tc-MAG3 in initial and postoperative management of pediatric hydronephrosis. ***Materials and Methods:*** It was a five-year retrospective and descriptive study, conducted in the Nuclear Medicine Department of Salah Azaiez Institute, involving 89 children referred for exploration of their non-congenital hydronephrosis. All patients performed DRS using $^{99m}$Tc-MAG3 with hyperdiuresis provocation test, then they were defined as renal unit (RU), giving us a total number of 176 RU. ***Results:*** The average age was 6.47± 3.34 years. Sex ratio M/F was 1.17. Among the 107 RU with ureteropelvic dilation, 98 RU (91.6%) had non-obstructive isotopic nephrogram (IN). Only nine percent of the RU with ultrasound-documented UPD had obstructive type of IN. We noticed a non progression towards aggravation in 40 DRS (85%) among the 47 control DRS. We identified the change in Tmax between the initial and the 1$^{st}$ DRS control as the most significant parameter of the follow-up (p=0.026), and found statistically significant difference in the separate relative function between each two successive DRS throughout the follow-up (p=0.02). The comparison of postoperative status of IN did not show any adverse evolution in 12 of the 13 cases. We calculated NORA (NOrmalized Residuel Activity) for 39 RU on all performed DRS (initial, control and postoperative DRS), and we noticed 27 favorable results (69%) including 12 displacements all to a better result, and in particular the cancellation of five obstructive IN and therefore the eventual surgery. ***Conclusion:*** DRS with $^{99m}$Tc-MAG3 allows to identify kidneys at risk of damage and, consequently, to guide the most appropriate therapeutic management. Based on our findings, we present recommendations involving DRS as a cornerstone for initial management and monitoring of non-congenital hydronephrosis in children.

## EPS-039

### Predicting the clinical outcome of antenatally detected unilateral pelvi-ureteric junction obstuction.

***R. Belakroum***;
*Central Military Hospital, Algiers, ALGERIA.*

***Aim/Introduction:*** To determine, in children with antenatally detected pelviureteric junction (PUJ) stenosis, which factors may be predictive for deterioration of differential renal function (DRF) in case of initially conservative attitude. Initial level of hydronephrosis, quality of renal drainage and cortical transit were analyzed and compared to the late DRF outcome. ***Materials and Methods:*** We have followed the 80 consecutive children with antenatally diagnosed PUJ stenosis during a 5-year period (between 2016 and 2020). From this cohort, we retained 80 children with unilateral PUJ and strictly normal contralateral kidney with a median follow up of 42 months. Repeated ultrasounds, voiding cystourethrography, and Tc-99m-ethylene-dicysteine (EC) renograms were performed in all children. ***Results:*** Among the 80 patients of the study, 51 patients did not underwent a surgical intervention (64%), while surgical repair (Anderson-Hynes dismembered pyeloplasty) was performed in 29 (36 %). Early pyeloplasty was performed in 19 patients at a median age of 6 months and late pyeloplasty in 10 cases at a median age of 33 months. During conservative follow-up, DRF deterioration was observed in 11,5% of cases. When analyzing the DRF evolution in function of the initial antero-posterior renal pelvic diameter, the quality of renal drainage, and abnormal cortical transit, only renal pelvic APD≥40mm and abnormal cortical transit were predictive of DRF deterioration in case of conservative approach. ***Conclusion:*** Conservative management of children with unilateral PUJ stenosis is a safe procedure. Impaired cortical transit in renogram seems the best scnitigraphic criterion for identifying children for whom pyeloplasty is mandatory. ***References:*** [1]- Koff SA, Campbell KD. ### A Classic Never Goes Out of Style: Fusion Kidney Malformations, a 10 Years Retrospective Analysis

***I. Grierosu***[1,2], *R. Tibu*[2], *I. Starcea*[1,3], *A. Mocanu*[3], *R. Bogos*[3], *T. Lazaruc*[3], *R. Stamate*[2], *L. Rau*[2], *D. Raileanu*[2], *V. Cernov*[2], *A. Iacoban*[1], *W. Jalloul*[1], *T. Ionescu*[1], *C. Stolniceanu*[1], *A. Statescu*[2], *C. Stefanescu*[1,2];
[1]*UMF, Iasi, ROMANIA,* [2]*County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA,* [3]*Emergency Children Hospital „Sf. Maria", Iasi, ROMANIA.*

***Aim/Introduction:*** The most notorious renal malformation is the horseshoe kidney (HK). HK is a congenital anomaly in which the kidneys are usually united, forming an U-shape, hence the name horseshoe kidney. The incidence of HK is estimated at 0.25 % of the general population and occurs twice as often in men comparing to women. Most of the time it is incidentally discovered during abdominal ultrasonography but nevertheless, there are also many other types of fused kidney malformations. ***Materials and Methods:*** In this retrospective analysis, we aim to share our 10 years of experience regarding fusion kidney malformations in pediatric nuclear medicine from the North-Eastern Region of Romania. The retrospective group of patients is represented by 540 patients with one of these ultrasonographical diagnoses: renal hypoplasia, renal dysplasia, renal ectopia, renal agenesia, renal malformation, renal malrotation, pyeloureteral duplication, vesicoureteral reflux and HK. All patients underwent a $^{99m}$Tc-DMSA renal scan, static images and SPECT, using a Siemens DIACAM double headed Gamma camera. ***Results:*** From all the cases, 38 were diagnosed with a type of kidney malformation after a $^{99m}$Tc-DMSA renal scan. They were aged between 1 and 17 years old. We noticed a higher incidence in males (65.78 %) and also

a higher incidence of parenchymal isthmus fusion malformation (28.94 %). The others types of malformations were: fibrous isthmus (15.78 %), L-shaped left ectopia (18.42 %), L-shaped right ectopia (10.52 %), supernumerary kidney (15.78 %), sigmoid kidney (2.6 %), lump kidney (2.6 %), infero-superior left fusion (2.6 %), infero-superior right fusion (2.6 %). ***Conclusion:*** $^{99m}$Tc-DMSA has a major role in the diagnostic algorithm of renal malformations for the pediatric patients, with very low radiation exposure and essentially minimally invasive. It is certain that in the PET-CT and PET-MRI era, there is still an important place for classic scintigraphy.

## EPS-041

**Risk of renal damage in children with VUR grade III according to $^{99m}$Tc-DMSA scan grading**

***D. Chroustova***[1], *J. Trnka*[1], *J. Langer*[1], *I. Urbanova*[2], *L. Cerna*[1], *R. Kocvara*[1];
[1]*Charles University, 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC,* [2]*University Hospital Bulovka, Prague, CZECH REPUBLIC.*

***Aim/Introduction:*** Renal changes can have long-term consequences, and their prevention is the main goal of vesicoureteral reflux (VUR) treatment. Renal scintigraphy using $^{99m}$Tc-DMSA scan is considered as the gold standard to prove the presence and extent of renal parenchymal changes and to determine split renal function. The aim of this study was to determine the risk of renal damage in children diagnosed with VUR grade III, which is generally considered (along with VUR I and II) as a low-grade VUR, according to the occurrence of renal changes using the $^{99m}$Tc-DMSA scan grading. ***Materials and Methods:*** A total of 132 patients were examined (56 boys, 76 girls aged 6 months -11 years) 6 months after acute pyelonephritis with a diagnosis of VUR. Planar static scintigraphy of the kidneys was performed using GE Infinia gamma camera 2 h after i.v. administration of 18-80 MBq $^{99m}$Tc-DMSA according to EANM paediatric dosage card. Determination of the degree of kidney involvement according to the $^{99m}$Tc-DMSA grading G0-G4 (Mattoo et al) with our modification of the G4 grade was based on the number of affected segments (0-12) as follows: Grade G0: no involvement G1: 1-2 segments, G2: 2-4 segments G3: more than 4 segments, G4 smaller kidney (A without focal changes, B with marginal changes). For purpose of statistical analysis, the number of pathological segments/scars was assessed in each involved kidney. For G0-G3, the numbers were counted exactly, whereas for G4 the numbers were estimated based on expected count in this group. Mean values within each VUR grade were calculated and evaluated using Student´s t-test. ***Results:*** A total of 201 kidneys were evaluated: VUR I in 19 kidneys, VUR II in 32 kidneys, VUR III in 63 kidneys, IV in 62 kidneys, VUR V in 25 kidneys regardless of unilateral or bilateral occurrence. VUR III demonstrated significantly higher value of expected scars (3.11 vs 1.67, p=0.001) than the remaining low-risk grades I and II. On the other hand, when compared with high-risk grade IV, the value was not significantly lower (3.11 vs 3.77, p = 0.08). ***Conclusion:*** VUR III is linked to a higher incidence of high-grade $^{99m}$Tc-DMSA changes, especially grade G3, G4B which can be considered a risk factor leading to permanent renal damage. Therefore, we recommend excluding VUR III from the low-grade group and considering it as a standalone grade of moderate risk.

[1]*RayzeBio, San Diego, CA, UNITED STATES OF AMERICA,* [2]*PeptiDream, Kawasaki-Shi, JAPAN.*

***Aim/Introduction:*** Ephrin type-A receptor 2 (EphA2) is a type I transmembrane glycoprotein which belongs to the ephrin receptor subfamily. EphA2 is primarily expressed during embryonic development, and its expression levels are low or absent in normal adult tissues. EphA2 overexpression has been observed in multiple tumors such as bladder, cervical, ovarian, colorectal, lung and esophageal cancers. The broad overexpression in solid tumors and relatively low expression in normal adult tissues make EphA2 attractive for targeted radiopharmaceutical therapy (RPT). ***Materials and Methods:*** RAYZ-6114 is comprised of a macrocyclic peptide binder to EphA2, a linker, and DOTA chelator which can be complexed with different radiometals. RAYZ-6283 shares the same peptide binder and chelator with RAYZ-6114 but differs in the linker. The binding affinity, selectivity and cross-species reactivity to EphA2 and other Ephrin proteins were determined by surface plasma resonance (SPR). Target-mediated internalization was measured using flow cytometry. In vivo biodistribution and anti-tumor efficacy studies were performed in tumor-bearing athymic nude mice. A coagulopathy study was performed in Sprague Dawley rats. For tumor type identification, EphA2 immunohistochemistry (IHC) was performed on tumor microarrays (TMA) representing diverse tumor types. ***Results:*** IHC analyses of TMAs confirmed the expression of EphA2 in a multitude of solid tumors, with the highest positivity rates in cervical, pancreatic, bladder, colorectal, esophageal and non-small cell lung cancers. RAYZ-6114 showed high binding affinity to human EphA2 with a $K_D$ of 0.03 nM. High-affinity binding was conserved across mouse, cynomolgus monkey and human EphA2. No binding to other Ephrin type-A or Ephrin type-B proteins was detected, nor to EphA2-knockout cells. The binder rapidly and efficiently internalized in EphA2-positive H1299 cells upon target engagement, with ~75% internalized by 1 hour. In PC3 xenograft mice, $^{177}$Lu-RAYZ-6283 showed sustained tumor uptake (~25% ID/g) for up to 48 hours and tumor/kidney ratios of 2.7, 3.3 and 5.9 at 24h, 48h and day 7, respectively. Low uptake was seen in other normal tissues. Both $^{177}$Lu- and $^{225}$Ac- labelled RAYZ-6114 significantly inhibited tumor growth. Particularly, durable tumor regression and survival benefit were achieved by a single dose of $^{225}$Ac-RAYZ-6114 (3 uCi), out-performing $^{177}$Lu-RAYZ-6114 dosed at 3 mCi. No adverse clinical signs or changes in coagulation parameters were observed in Sprague Dawley rats. ***Conclusion:*** RAYZ-6114 and RAYZ-6283 are first-in-class, highly potent and selective macrocyclic peptide binders. Preclinical pharmacodynamic, pharmacokinetic, biodistribution and efficacy data demonstrated their potential for treatment of patients with EphA2-positive tumors.

### OP-138

**Preclinical Characterization of a Novel Peptide Binder to Glypican-3 for Targeted Radiopharmaceutical Therapy of Hepatocellular Carcinoma**

***G. Li***[1], *F. Lin*[1], *R. Clift*[1], *T. Ehara*[2], *H. Yanagida*[2], *S. Horton*[1], *K. Salvador*[1], *S. Richardson*[1], *M. Guest*[1], *A. Noncovich*[1], *A. Bhat*[1], *G. Han*[1];
[1]*RayzeBio, San Diego, CA, UNITED STATES OF AMERICA,* [2]*PeptiDream, Kawasaki, JAPAN.*

***Aim/Introduction:*** Glypican-3 (GPC3) is a membrane-associated heparan sulfate proteoglycan with no or minimal expression in normal adult tissues. Significant upregulation of GPC3 protein in hepatocellular carcinomas (HCC) has been observed in up to 75% cases, whereas no expression is seen in cirrhotic liver or intrahepatic cholangiocarcinoma. The differential expression of GPC3 between tumor and normal tissues provides an opportunity for GPC3-targeted radiopharmaceutical therapy (RPT) to treat HCC, a leading cause of cancer-related deaths worldwide. ***Materials and Methods:*** RAYZ-8009 is comprised of a novel macrocyclic peptide binder to GPC3, a linker, and chelator DOTA that can be complexed with different radioisotopes. The affinity of peptide binders to GPC3 was determined by surface plasma resonance (SPR), as well as a radioligand binding assay in human HCC cell line HepG2. The cross-species binding was assessed by radioligand binding using recombinant mouse, cynomolgus monkey, and human GPC3 proteins. Target-mediated internalization in HepG2 cells was measured using Microbeta at various time points. Circulating GPC3 levels were measured using plasma collected from athymic nude mice harboring HepG2 tumors of different sizes. In vivo biodistribution and anti-tumor efficacy studies were performed in GPC3+ tumor-bearing athymic nude mice. ***Results:*** RAYZ-8009 showed high binding affinity to human GPC3 with a $K_D$ of 0.7 nM as determined by SPR. Binding affinity was maintained across mouse, cynomolgus monkey and human GPC3. Potent cellular binding was confirmed in GPC3+ HepG2 cells, and was independent of choice of isotope. $^{177}$Lu-RAYZ-8009 showed fast and efficient internalization with 42% internalized by 20 minutes in HepG2 cells. In vivo biodistribution of $^{177}$Lu-RAYZ-8009 showed tumor uptake of 19.8, 16.6, 16.4, and 8.8 %ID/g at 2, 24, 48, and 96 hours, respectively. Renal uptake was 16.1, 4.7, 1.6, and 0.7 %ID/g at the same timepoints, with tumor/kidney ratios of 1.3, 3.7, 11.3, and 15.0, respectively. Minimal uptake was observed in other normal tissues. Tumor-specific uptake and retention were also observed when tumors were implanted orthotopically with no uptake in non-malignant liver tissue. Circulating GPC3 was detectable in mouse plasma but had no impact on biodistribution or clearance. Furthermore, significant tumor growth inhibition and survival benefit were achieved with $^{225}$Ac- or $^{177}$Lu-labelled RAYZ-8009 in GPC3+ HCC xenografts. ***Conclusion:*** Preclinical pharmacodynamic, pharmacokinetic, biodistribution and efficacy data demonstrate the potential of RAYZ-8009 as a RPT agent for the treatment of patients with GPC3-positive HCC.

## OP-139

### A Novel Anti-L1CAM Antibody-Radionuclide-Conjugate (ARC) as New Treatment Option for Ovarian Cancer

***C. Geraths***[1], *M. Behe*[2], *D. Winkler*[1], *M. Hackebeil*[1], *A. Blanc*[2], *T. Chiorazzo*[2], *S. Imobersteg*[2], *R. van der Kant*[3,4], *J. Schymkowitz*[3,4], *F. Rousseau*[3,4];
[1]*CIS Pharma AG, Bubendorf, SWITZERLAND,* [2]*Paul-Scherrer-Institut, Villigen, SWITZERLAND,* [3]*Switch Laboratory - VIB KU Leuven Center for Brain and Disease Research, Leuven, BELGIUM,* [4]*KU Leuven - Department of Cellular and Molecular Medicine, Leuven, BELGIUM.*

***Aim/Introduction:*** We present a novel ARC against the human cell adhesion molecule L1CAM which is upregulated in different cancers. Since it is related to a poor prognosis, L1CAM is a highly interesting target for an ARC. Our aim was to develop an improved humanised antibody targeting L1CAM, radiolabel it with Lu-177 and test it in vitro as well as in vivo. ***Materials and Methods:*** A humanisation of chimeric antibody chCE7[(1)] using latest in-silico modelling tools was performed thereby optimising physicochemical properties like affinity, stability, immunogenicity and aggregation behaviour. Further the antibody was a-glycosylated to be compatible with site specific coupling with transglutaminase. We generated DOTA and polymer-$(DOTA)_x$ (x = 2-5). We attached two DOTAs or two polymers to the functionalised antibody via click chemistry resulting in ARCs with drug (here chelator) to antibody ratios (DAR) 2-10. We tested the Lu-177 labelled ACR in vitro as well as in vivo. ***Results:*** The humanised huCE7 shows high binding affinity ($K_D$ = 64 pM). In-silico modelling for identification of aggregation prone regions compensated the negative effect of a-glycosylation leading to a robust and stable antibody. Melting temperatures (Tm1 = 64.6 °C; Tm2 = 79.0 °C) characterised by dynamic scanning fluorometry showed higher stability compared to the chimeric de-glycosylated chCE7 (Tm1 = 60.3 °C; Tm2 = 73.6 °C). These DOTA-coupled constructs were labelled with Lu-177 with high radiochemical purity (>99 %) in less than 10 min (37 °C) and subsequently tested for tumour-cell interaction and in a mouse xenograft model (SKOViP3, ovarian cancer). The lead ARC (DOTA coupled to the humanised Ab) showed a favourable biodistribution with low uptake in healthy tissue (e.g., liver after 96 h 4.7 ± 0.7 % iA/g) and a constant accumulation in the tumour tissue (maximum after 96 h = 67.5 ± 15.1 % iA/g). The overall survival (OS) in the treatment group (4 MBq Lu-177-huCE7, day 13 after tumour implantation, 10 mice per group) was 64 days (control group = 35 days). ***Conclusion:*** Here we present the first results of a novel ARC against L1CAM positive tumours, which showed a good in vivo efficacy in an aggressive ovarian cancer model. In the next steps the linker as well as dosing regime will be optimised to generate a candidate for investigative new drug enabling. ***References:*** [(1)]Amstutz et al. - Production and characterization of a mousehuman chimeric antibody directed against human neuroblastomaInt. J. Cancer: 53,147-152 (1993)

## OP-140

### In vitro evaluation of [$^{225}$Ac]Ac-DOTA-C595 for pancreatic ductal adenocarcinoma

***A. Hull***[1], *W. Hsieh*[2], *W. Tieu*[3], *A. Borysenko*[4], *D. Bartholomeusz*[2], *E. Bezak*[1];
[1]*University of South Australia, Adelaide, AUSTRALIA,* [2]*SA Medical Imaging, Adelaide, AUSTRALIA,* [3]*The University of Adelaide, Adelaide, AUSTRALIA,* [4]*Environment Protection Authority, Adelaide, AUSTRALIA.*

***Aim/Introduction:*** Pancreatic ductal adenocarcinoma (PDAC) continues to have a poor prognosis with limited curative treatments available. Targeted alpha therapy (TAT) using monoclonal antibodies (mAb) conjugated to alpha-emitting radionuclides such as Actinium-225 (Ac-225) may hold promise in treating PDAC. Cancer-specific mucin 1 (MUC1-CE) is a promising therapeutic target for PDAC TAT. MUC1-CE is overexpressed on over 90% of PDAC with minimal normal tissue expression. The C595 mAb effectively binds to MUC1-CE. The aim of this study was to develop a novel radioimmunoconjugate, [$^{225}$Ac]Ac-DOTA-C595, and characterise its in vitro ability to target PDAC cells via MUC1-CE. ***Materials and Methods:*** C595 was conjugated to p-SCN-Bn-DOTA chelator. The resulting conjugate was labelled to Ac-225. Cell binding with 0 - 500nM of [$^{225}$Ac]Ac-DOTA-C595 at 1 h was assessed in a series of four pancreatic cancer cell lines with varying MUC1-CE expression: PANC-1 (high expression), CAPAN-1 (moderate expression), BxPC-3 (low expression), AsPC-1 (low expression). An internalisation assay was performed in the cell lines to evaluate the rate of internalisation over 48h. The ability of [$^{225}$Ac]Ac-DOTA-C595 to induce double-strand DNA breaks (DSBs) was assessed in PANC-1 and AsPC-1 cells using γH2AX staining detected via flow cytometry. Clonogenic assays were performed in PANC-1 and AsPC-1 cells to establish the in vitro cytotoxicity of [$^{225}$Ac]Ac-DOTA-C595. ***Results:*** [$^{225}$Ac]Ac-DOTA-C595 had significantly greater binding to PANC-1 cells compared to CAPAN-1, BxPC-3 and AsPC-1 cells at concentrations of 50 nM and above. All cell lines showed rapid internalisation ranging from 15% of internalised activity within 1 h to 49% internalisation at 48 h. PANC-1 cells exhibited significantly more γH2AX foci than AsPC-1 cells within 1 h of [$^{225}$Ac]Ac-DOTA-C595 exposure ($p = 0.0069$). At 48 h post-[$^{225}$Ac]Ac-DOTA-C595 exposure, PANC-1 cells had significantly less γH2AX foci than that observed at 1 h ($p = 0.0083$), suggesting cell death or DSB resolution. The clonogenic survival of AsPC-1 and PANC-1 cells decreased as the concentration of [$^{225}$Ac]Ac-DOTA-C595 increased. The survival of PANC-1 cells was significantly lower than AsPC-1 cells at 1 and 5 nM of [$^{225}$Ac]Ac-DOTA-C595 ($p < 0.0001$), although cell survival was similar at higher concentrations. ***Conclusion:*** At an in vitro level, [$^{225}$Ac]Ac-DOTA-C595 efficiently binds to MUC1-CE positive PDAC cells and is rapidly internalised. The cytotoxic effects of [$^{225}$Ac]Ac-DOTA-C595 are heightened in cells with high MUC1-CE expression, although a therapeutic effect is evident in weakly expressing cells. Future work will include in vivo studies to further assess [$^{225}$Ac]Ac-DOTA-C595 as a therapeutic radioimmunoconjugate against PDAC.

## OP-141

### Preclinical Comparison of the GRPR Antagonists AMTG and RM2 Labelled With Terbium-161 and Lutetium-177 - A PRISMAP Project

***T. Günther***[1], *N. Holzleitner*[1], *T. Cwojdzinski*[1], *R. Beck*[1], *N. Urtz-Urban*[1], *C. C. Hillhouse*[2], *P. V. Grundler*[2], *N. P. van der Meulen*[2], *Z. Talip*[2], *S. Ramaekers*[3], *M. Van de Voorde*[3], *B. Ponsard*[3], *A. Casini*[1];
[1]*Technical University of Munich, Garching, GERMANY,*
[2]*Paul Scherrer Institute, Villingen, SWITZERLAND,*
[3]*Belgian Nuclear Research Centre, Mol, BELGIUM.*

***Aim/Introduction:*** To improve the metabolic stability of gastrin-releasing peptide receptor (GRPR) ligands, we recently substituted $Trp^8$ by α-methyl tryptophan (α-Me-$Trp^8$) in RM2 (DOTA-$Pip^5$-D-$Phe^6$-$Gln^7$-$Trp^8$-$Ala^9$-$Val^{10}$-$Gly^{11}$-$His^{12}$-$Sta^{13}$-$Leu^{14}$-$NH_2$) to achieve AMTG (α-Me-$Trp^8$-RM2). Other than retaining the favourable pharmacokinetics of RM2 irrespective of the radiometal used (copper-64, gallium-68, lutetium-177), a distinctly higher in vivo stability was observed for [$^{177}$Lu]Lu-AMTG (as compared to [$^{177}$Lu]Lu-RM2), which led to a significantly enhanced activity retention in the tumour over time. In this study, we labelled AMTG and RM2 with terbium-161 and carried out a

preclinical comparison by state-of-the-art experiments including their $^{177}$Lu-labelled analogues. ***Materials and Methods:*** $^{161}$Tb- and $^{177}$Lu-labelling was carried out at 90°C within 5 min (1.0 M NaOAc buffer, pH=5.5). GRPR affinity ($IC_{50}$, n=3) and internalisation (37 °C, 1 h, n=6) were evaluated on PC-3 cells. Metabolic stability was investigated in vivo at 30 min post-injection (p.i.) in CB17-SCID mice (n=3). Biodistribution studies were carried out at 1, 4, 24 and 72 h p.i. in PC-3 tumour-bearing CB17-SCID mice (n=4, 100 pmol each). ***Results:*** $^{161}$Tb- and $^{177}$Lu-labelling proceeded nearly quantitatively (>98%). The Tb-labelled compounds showed a slightly higher GRPR affinity than their Lu-labelled analogues ($IC_{50}$ (nM) of Tb-RM2: 2.46±0.16, Tb-AMTG: 2.16±0.09, Lu-RM2: 3.45±0.18, Lu-AMTG: 3.04±0.08). Internalisation studies revealed that 75-84% of the cell-associated activity was receptor-bound for both [$^{161}$Tb]Tb-/[$^{177}$Lu]Lu-RM2 and [$^{161}$Tb]Tb-/[$^{177}$Lu]Lu-AMTG. Lipophilicity (expressed as n-octanol/PBS distribution coefficient, $logD_{7.4}$, n=8) of the $^{161}$Tb-labelled analogues was slightly lower as compared to their $^{177}$Lu-labelled derivatives ([$^{161}$Tb]Tb-/[$^{177}$Lu]Lu-RM2: −2.63±0.05/−2.51±0.02, [$^{161}$Tb]Tb-/[$^{177}$Lu]Lu-AMTG: −2.48±0.07/−2.28±0.06). In vivo, both [$^{161}$Tb]Tb- and [$^{177}$Lu]Lu-AMTG displayed a distinctly higher stability (91-93% intact in serum, 68-74% in urine) than [$^{161}$Tb]Tb- and [$^{177}$Lu]Lu-RM2 (11-23% intact in serum, 0-1% in urine) at 30 min p.i. In vivo, all four compounds revealed a similar biodistribution profile at all time points, showing a rapid activity clearance from the pancreas and further off-target tissues. [$^{161}$Tb]Tb-AMTG exhibited the highest activity levels in the tumour as compared to the other three derivatives at 4 (16.0 versus 10.4-12.2 %ID/g), 24 (12.0 versus 9.1-11.5 %ID/g) and 72 h p.i. (5.3 versus 3.0-4.3 %ID/g). ***Conclusion:*** [$^{161}$Tb]Tb-AMTG demonstrated attractive in vitro (GRPR affinity, lipophilicity, receptor-bound fraction) and in vivo (metabolic stability, pharmacokinetics, activity retention in the tumour) characteristics. Due to its high in vivo stability and the higher number of Auger electron emissions per decay of terbium-161 as compared to lutetium-177, an enhanced therapeutic efficacy is anticipated for [$^{161}$Tb]Tb-AMTG over [$^{177}$Lu]Lu-AMTG and [$^{161}$Tb]Tb-/[$^{177}$Lu]Lu-RM2, which will be further evaluated in future studies.

## OP-142

### Preclinical Evaluation of a $^{68}$Ga/$^{177}$Lu-based CXCR4 Radioligand: A Theranostic Tool Against Advanced Prostate Cancer

***I. Astiazaran-Rascon***[1,2], *H. Kuo*[1], *H. Merkens*[1], *N. Colpo*[1], *P. Ng*[1], *C. Ong*[2,3], *Y. Wang*[1,2,3], *K. Lin*[1,2], *F. Bénard*[1,2];
[1]*BC Cancer, Vancouver, BC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA,* [3]*Vancouver Prostate Center, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Neuroendocrine prostate cancer (NEPC) is an aggressive subtype of advanced prostate cancer with poor prognosis and limited treatment options, necessitating the development of novel diagnostic and therapeutic approaches. CXCR4 radioligands have been evaluated against haematologic malignancies; however, their application in advanced prostate cancer has not been explored yet. Our group has developed a series of macrocyclic peptide-based radioligands with high affinity to CXCR4 for the targeted delivery of radionuclides. The theranostic pair [$^{68}$Ga]Ga/[$^{177}$Lu]Lu-BL34 was chosen as the lead candidate for preclinical evaluation as an imaging and therapeutic agent in NEPC patient-derived xenograft (NEPC PDX) models. ***Materials and Methods:*** The preclinical evaluation of [$^{68}$Ga]Ga/[$^{177}$Lu]Lu-BL34 was conducted in three different NEPC PDX models (LTL331R, LTL352 and LTL545). Protein expression of CXCR4 was confirmed ex vivo in tumour-bearing mice by molecular techniques. Also, expression levels of CXCR4 mRNA were analyzed from a publicly available dataset of advanced prostate cancer patients and PDX models. The in vivo tumour uptake of [$^{68}$Ga]Ga/[$^{177}$Lu]Lu-BL34 was evaluated by PET/SPECT imaging and biodistribution studies at 1h (n=6) or at 1, 4, 24 and 72h post-injection (n=5), respectively. ***Results:*** The relative CXCR4 protein expression levels are shown to be higher in LTL331R and LTL352 models in comparison to LTL545. This is in line with the documented mRNA levels for each model. Elevated expression of CXCR4 relative to SSTR2 mRNA was observed in a cohort of advanced prostate cancer clinical samples and PDX supporting its clinical relevance. We showed high and specific accumulation of [$^{68}$Ga]Ga-BL34 in LTL331R (13.48±3.48 %ID/g), LTL352 (12.37±3.95 %ID/g) and LTL545 (3.80±0.59 %ID/g) tumour-bearing mice 1h after injection. The LTL331R model was selected for further studies as it showed the highest tumour uptake of our radioligand. Time course biodistribution studies showed that [$^{177}$Lu]Lu-BL34 reaches maximum tumour uptake 1h after intravenous administration in LTL331R tumour-bearing mice (11.97±1.76 %ID/g), with a significant decrease observed after 4h (5.96±2.1 %ID/g). High tumour-to-blood (37:1), tumour-to-kidney (4:1) and tumour-to-liver ratio (16:1) were observed 1h after injection indicating its fast clearance from circulation. ***Conclusion:*** The results presented show that both [$^{68}$Ga]Ga-BL34 and [$^{177}$Lu]Lu-BL34 accumulate at high levels in the tumour site with minimal uptake in major organs. Currently, dose-escalation studies are being performed to evaluate the therapeutic response. The blood clearance of [$^{68}$Ga]Ga-BL34 is optimal for non-invasive imaging of NEPC and future work may increase the tumour retention time of [$^{177}$Lu]Lu-BL34 to improve the dose delivery for therapy.

## OP-143

### Albumin Binder-modified Radiolabeled Heterodimer Probe for Cancer Imaging and Therapy

***B. Yang****, Y. Gai, X. Song, X. Lv, Y. Long, Y. Wang, Y. Feng, R. An, X. Lan;*
*Dept of Nuclear Medicine and PET center,Union Hospital, Tongji Medical College,HUST, Wuhan, CHINA.*

***Aim/Introduction:*** Integrin $\alpha_v\beta_3$ and CD13 (aminopeptidase N, APN) are two important biomarkers involved in tumor angiogenesis, overexpressed by tumor neovascular endothelial cells and tumor cells, promoting angiogenesis, tumor growth and metastasis. RGD (Arg-Gly-Asp) and NGR (Asp-Gly-Arg) are two extensively investigated peptides targeting integrin $\alpha_v\beta_3$ and CD13, respectively. On the basis of heterodimer probe RGD-NGR, RGD-NGR-Ab-01, 02, 03 was synthesized by modifying the molecular structure and adding albumin binder. The study aimed to explore the feasibility of using $^{177}$Lu-RGD-NGR-Ab for in vivo radioligand therapy by single-dose administration in a BxPC-3 tumor bearing nude mouse model. ***Materials and Methods:*** $^{177}$Lu-RGD-NGR-Ab-01, 02, 03 were synthesized, and labelling efficiency and radiochemical purity were determined. The in vitro stability of the probes was investigated by measuring its radiochemical purity at different time points, and the protein binding rate and lipid water partition coefficient of the probes were measured separately. Preclinical pharmacokinetics were determined in BxPC-3 tumor bearing nude mouse model using SPECT/CT and biodistribution experiments. In the radioligand therapy study, mice were randomized into 4 groups: 37 MBq $^{177}$Lu-NGR-RGD, 18.5 MBq $^{177}$Lu-RGD-NGR-Ab-03, 37 MBq $^{177}$Lu-RGD-NGR-Ab-03, and PBS (control). A single-dose administration was applied at

the beginning of therapy studies. Tumor volume, body weight were monitored every 2 days. After the end of therapy, mice were euthanized. Tumors were then weighed, and systemic toxicity was evaluated via blood testing and histological examination of healthy organs. ***Results:*** All probes were successfully prepared with high purity and stability. $^{177}$Lu-RGD-NGR-Ab-01, 02, 03 were stable in PBS (pH 7.4) and saline for at least 72h. They exhibit excellent stability in vitro, with high protein binding rate and good water solubility. SPECT imaging and biodistribution studies of $^{177}$Lu-RGD-NGR-Ab-01, 02, 03 have proved their prominently improved tumor accumulation and retention at 96 h post-injection, especially for $^{177}$Lu-RGD-NGR-Ab-03, high tumor uptake and low background signal make it the optimal compound. In radioligand therapy studies, tumor growth was significantly suppressed in the 37 MBq $^{177}$Lu-RGD-NGR-Ab-03 group compared to other groups. ***Conclusion:*** Radioligand therapy using $^{177}$Lu-RGD-NGR-Ab-03 significantly suppressed tumor growth and prolonged survival time in BxPC-3 tumor bearing nude mice without obvious toxicity, indicating that $^{177}$Lu-RGD-NGR-Ab-03 is promising for clinical application and transformation.

## OP-144

### Preclinical Evaluation of [$^{212}$Pb]VMT-α-NET Targeted Alpha Therapy for High-Risk Metastatic Neuroblastoma

***D. Liu***[1], *J. T. Ewald*[1], *Z. Dai*[2], *C. Robels-Plannels*[3], *B. S. Cagle*[1], *S. N. Rodman III*[1], *M. Li*[1], *R. Rastogi*[2], *E. Sagastume*[1], *F. L. Johnson*[1], *D. Zepeda-Orozco*[3], *M. K. Schultz*[1,2];
[1]*Perspective Therapeutics Inc, Coralville, IA, UNITED STATES OF AMERICA,* [2]*University of Iowa, Iowa City, IA, UNITED STATES OF AMERICA,* [3]*Nationwide Children's Hospital, Columbus, OH, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** High-risk neuroblastoma (NB) in pediatric patients is an aggressive disease often accompanied by liver and bone marrow metastases, which leads to treatment failure and relapse (4-year survival <10%). NB tumors almost universally express SSTR2, suggesting a potential for improvements using peptide-receptor radionuclide therapy (PRRT). Here, we evaluate preclinically the use of theranostic pair $^{203/212}$Pb for PRRT using SSTR2-targeted agonist PSC-PEG2-TOC (VMT-α-NET) for NB image-guided therapy. In this study, we established a robust metastatic mouse model of NB and evaluated the efficacy of [$^{203/212}$Pb]VMT-α-NET for image-guided treatment of metastatic disease. ***Materials and Methods:*** VMT-α-NET was radiolabeled with $^{203}$Pb as SPECT imaging diagnostic radiotracer and $^{212}$Pb as targeted alpha therapeutic radiopharmaceutical. Maximum tolerated dose (MTD) was determined by administrating escalating levels of [$^{212}$Pb]VMT-α-NET (0 - 4.44 MBq) via tail vein to tumor-free SCID mice for a 32-day observation window. Two million IMR32-luc cells were implanted systemically via intracardiac injection into immunocompromised NSG mice and bioluminescence imaging was used to monitor tumor progression. For the efficacy study, 3 weeks post-inoculation, tumor-bearing mice (n=6-7/group) were administered a total of 2.22 MBq [$^{212}$Pb]VMT-α-NET by single, 2 or 3 fractionated dosing regimens, with vehicle mice receiving 8 mg of DL-Lysine/saline only. Endpoints include total tumor burden (bioluminenscence > 1000 times of the initial level), body weight changes >20%, overt toxicity. Hematological and renal responses were evaluated by periodic complete blood counts , urine and kidney biomarkers, serum chemistry and pathological read out of major organs. ***Results:*** A robust metastatic NB mouse model was established by intracardiac injection of IMR32-luc cells. Within two weeks, lesions were found mostly in liver, bone marrow and lung - and occasionally in brain, heart, mesentery as observed via bioluminescence imaging. Sequential SPECT imaging and biodistribution analysis using [$^{203}$Pb]VMT-α-NET confirmed metastases as well as highly tumor-specific targeting to metastatic lesions. The MTD of [$^{212}$Pb]VMT-α-NET in SCID mice was determined as 2.22 MBq without acute toxicity. For the 90-day efficacy study, median survival days for vehicle control, single and 2 fractionated dose groups were 37, 66.5 and 84, respectively. Three fractionated doses of 740 kBq of [$^{212}$Pb]VMT-α-NET produced 100% overall survival, with partial response and stable disease, while a single high dose of 2.22 MBq produced less benefit. More evaluation data will be updated. ***Conclusion:*** Multiple fractionated doses of [$^{212}$Pb]VMT-α-NET demonstrated effective tumor control and were well tolerated. Future studies will include combination therapy and optimizing the fractionation dose regimen.

## OP-145

### Preclinical Evaluation of $^{225}$Ac-rhPSMA-10.1, a Novel Radiohybrid PSMA Compound for Targeted Alpha Therapy of Prostate Cancer

*V. Vassileva*[1], *B. Waldron*[1], *A. Wurzer*[2], *C. D'Alessandria*[2], *R. Veggerby Grønlund*[3], *M. Wikke Hallund*[3], *D. Gauden*[1], *D. Stevens*[1], ***C. Foxton***[1];
[1]*Blue Earth Therapeutics, Oxford, UNITED KINGDOM,* [2]*Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY,* [3]*Minerva Imaging, Ølstykke, DENMARK.*

***Aim/Introduction:*** Theranostic "radiohybrid" prostate-specific membrane antigen (rhPSMA) ligands can be radiolabelled with $^{18}$F for diagnostic imaging or alpha or beta-emitting radiometals for therapeutic use in prostate cancer. Significant preclinical efficacy has been previously demonstrated with novel rhPSMA radiopharmaceutical, $^{177}$Lu-rhPSMA-10.1, now under evaluation in a Phase 1/2 trial (NCT05413850). Here, we present data on the preclinical evaluation of $^{225}$Ac-labelled rhPSMA-10.1, as a potential alpha-targeted therapy for prostate cancer, compared to $^{177}$Lu-rhPSMA-10.1. ***Materials and Methods:*** Binding affinity and cellular internalization assays were conducted in LNCaP cells, using $^{177}$Lu-PSMA-I&T as a reference compound. PSMA binding affinity ($IC_{50}$) was evaluated in a competitive binding assay using rhPSMA-10.1 complexed with natural Lanthanum ($^{nat}$La), serving as a cold surrogate for $^{225}$Ac, or natural Lutetium ($^{nat}$Lu). Cellular internalization was assessed by measuring free, surface-bound, and internalized activity after 1-hour incubation with $^{225}$Ac-rhPSMA-10.1 or $^{177}$Lu-rhPSMA-10.1 using γ-counting, and normalized to $^{177}$Lu-PSMA-I&T (% internalization). The lipophilicity of $^{225}$Ac-rhPSMA-10.1 and $^{177}$Lu-rhPSMA-10.1 was determined by the shake-flask method, measuring the distribution coefficient in n-octanol and PBS at pH 7.4 (log $D_{7.4}$). Therapeutic response to single-administration of $^{225}$Ac-rhPSMA-10.1 (30 kBq) or $^{177}$Lu-rhPSMA-10.1 (30 MBq) was evaluated in 22Rv1 tumour-bearing mice (n=8 per group). Efficacy was assessed based on relative tumour growth (change in tumour volume from treatment administration day/baseline) and survival of mice versus untreated controls ≤49 days post-treatment initiation. Body weights were monitored throughout for toxicity assessment. Two-way ANOVA and Tukey's multiple comparisons test (data analyzed until n=3 remained per group), and Kaplan-Meier, Log-rank survival analyses were performed ($p \leq 0.05$ considered significant). ***Results:*** Both $^{nat}$La-rhPSMA-10.1 and $^{nat}$Lu-rhPSMA-10.1 showed excellent PSMA binding affinity ($IC_{50}$ = 3.6±0.6 nM and 1.6±0.1 nM, respectively). High cellular internalization and similar lipophilicity were observed for both $^{225}$Ac-rhPSMA10.1 and

$^{177}$Lu-rhPSMA-10.1 (% internalization = 99±14 and 108±5; log$D_{7.4}$ = -3.4±0.2 and -3.8±0.1; respectively). $^{225}$Ac-rhPSMA-10.1 treatment significantly reduced tumour growth in vivo versus controls (from day 14 to 31, p<0.05), and prolonged survival of mice (median survival: 27, 43.5, and 42 days for untreated, $^{225}$Ac-rhPSMA-10.1, and $^{177}$Lu-rhPSMA-10.1 groups, respectively). There were no significant differences in tumour growth suppression or survival between the $^{225}$AcrhPSMA-10.1 and $^{177}$Lu-rhPSMA-10.1 groups, and both treatments were well-tolerated. ***Conclusion:*** These preclinical analyses demonstrate a promising therapeutic profile for $^{225}$Ac-rhPSMA10.1, using a 1000-fold lower activity than $^{177}$Lu-rhPSMA-10.1. Similar in vitro characteristics and in vivo therapeutic efficacy were observed for both $^{225}$Ac-rhPSMA-10.1 and $^{177}$LurhPSMA-10.1. $^{225}$Ac-rhPSMA-10.1 represents a novel alpha-targeted therapy with planned clinical trial application submission in 2023.

**Radiosensitivity of neuroendocrine cancer cells to $^{177}$Lu-DOTATATE and radiobiological implications for peptide radionuclide therapy**

***G. Tamborino***[1,2], *P. Engbers*[2,1], *T. de Wolf*[2,1], *T. Reuvers*[2,1], *M. Konijnenberg*[1], *J. Nonnekens*[2,1];
[1]*Department of Radiology and Nuclear Medicine, Erasmus University Medical Center, Rotterdam, NETHERLANDS,*
[2]*Department of Molecular Genetics, Erasmus University Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Despite the efficacy of peptide receptor radionuclide therapy (PRRT) for treatment of metastatic tumours, the radiobiology underlying the dose-response is poorly understood.This work aims to determine the relative biological effectiveness (RBE) of PRRT in comparison to external beam radiotherapy (EBRT) for cell death in a relevant neuroendocrine tumour cell-line (GOT1), while establishing a framework for realistic cellular dosimetry calculations in a cluster-forming scenario. ***Materials and Methods:*** $^{177}$Lu-DOTATATE uptake (membrane-bound and internalized fractions) was measured over a 4-hour incubation period and excretion into the medium was subsequently measured. Time-integrated activities were calculated for source regions up to 14 days(d). Viability was assessed at 7d (CellTiterGlo assay) and cell-death (flow cytometry) at 4,7,11 and 14d of exposure for 0.1-2.5MBq/mL of $^{177}$Lu-DOTATATE. For comparison, response to 0.5-2Gy x-ray irradiation was measured.Geant4/GATE was used to simulate the absorbed dose per decay (S-value) of lutetium-177 during in vitro cell irradiation.The absorbed dose calculations (MIRD-formalism) during the 4h-uptake (floating) and follow-up (plated) phase account for single cells and clusters of variable size, derived from microscopic image, assuming homogeneous or heterogeneous activity distribution (receptor: μ=log(1), σ=0.05 and/or cellular placement within cluster). Cross-absorbed dose is calculated either by weighting in-cluster S-values using a closed packing algorithm for cluster-size frequency, neglecting cross-cluster contribution, or by simulating the set-up from 8 microscopic images of plated cells. ***Results:*** Cross-cluster absorbed dose (from single cells and cluster) during 4h-uptake phase was negligible (<1%). The in-cluster S-value for 3D cellular clusters up to n=100 cells followed a saturation profile (cross S-value=$B_{max}$*n/($k_d$+n), $B_{max}$=4.69E-03±2.11E-04 Gy/Bq s, 1.77E-03±7.87E-05 Gy/Bq s and $k_d$=30±3, 13±5 for centre- and edge-cell, respectively). Self-, in-cluster, and medium (10mL) absorbed doses contributed 8%, 8-10%, and 83% of the 4h-absorbed dose, respectively. During the plated phase, the cross-cluster absorbed dose formed a substantial contribution to the total cross-absorbed dose per decay. Hence, the perfect packing approach underestimated it substantially (66% for membrane and 90% for cytoplasm sources). Assuming homogenous uptake, the average absorbed dose (1 MBq/mL) after 7d ranged between 2.9±1.0 Gy and 3.8±1.2 Gy, depending on the intra- and inter- set-up variability. Assuming a gradually reducing uptake in the cluster centre can reduce the absorbed dose per set of 0.5-1.1 Gy. Preliminary calculations indicate RBE=0.34±0.12 using as biological end-point the loss of viability at 7d and homogeneous uptake. ***Conclusion:*** According to our results, PRRT requires an absorbed dose three times higher than EBRT to achieve an equivalent effect.

### OP-147

**Stochastic microscale dosimetry in breast cancer micrometastasis model for alpha-emitter radiopharmaceutical therapy**

***R. Bastiaannet***, *M. Hasan, I. Liatsou, R. F. Hobbs, G. Sgouros; Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The alpha particles in alpha-emitter radiopharmaceutical therapy (αRPT) are very cytotoxic. But αRPT uptake is typically non-uniform, which combined with the short range of alphas in tissue (<100μm), necessitates dosimetry on a near-cellular spatial scale. We have previously developed a framework to perform in vitro dosimetry on a single-cell level. Using high-resolution confocal microscopy, we performed Monte Carlo-based dosimetry for >550 measured -rather than modeled- individual live cells. This allowed for a statistical approach to cell survival modelling, which fit the measured data significantly better [1]. The purpose of this work was to build on these results and apply our empirical approach to a clinically more relevant model: micrometastases. ***Materials and Methods:*** Micrometastasis-like 3D spheroids were grown using the NT2.5 cell line, which is a HER2+ breast cancer cell line. After 5 days, the spheroids reached a diameter of ~400 μm and were harvested. The spheroids were incubated with an anti-HER2 antibody (7.16.4; fluorescently labelled AF488) for 1-72 hours. Nuclei were stained using DRAQ5. Spheroids were imaged in 3D on a high-resolution confocal microscope, using a water-emersion objective with a long working distance. Attenuation and photobleaching were corrected for. Antibody penetration was measured as a function of time and a diffusion-binding/internalization pharmacokinetic model was fit to the data. Cell nuclei were segmented. This data was imported into our GEANT4-based Monte Carlo framework and the microdosimetric absorbed dose distributions to cell nuclei were calculated for a total of 18 spheroids, collectively consisting of thousands of cells. ***Results:*** Antibody penetration remained limited(<~5-8cell diameters), even after 3 days of incubation (binding site barrier problem). This results in a large fraction of the spheroid not receiving significant amounts of absorbed dose. In our previous work on cell monolayers, we found that over 50%

of cells do not receive any dose in most experimental conditions. But that was due to the random nature of the direction of the particle emissions. We found that this number is approaching zero in the 3D case of spheroids. ***Conclusion:*** Careful assessment of antibody penetration and stochastic microscale dosimetry allows for a better understanding of radiobiology in micrometastases. Work on relating this dosimetry to growth after treatment is currently ongoing. ***References:*** 1. ## OP-148

### Nephron Morphology Influences the Dosimetry of Microscopic Renal Tissues of Non-Uniform Activity Distributions of Alpha Particle and Low Energy Electron Emitters

***M. Andersson***[1,2], *N. Goudin*[3], *M. Pontoglio*[4], *H. Levillain*[2], *N. Reynaert*[2], *C. Saldarriaga Vargas*[1];
[1]*Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM,* [2]*Faculté de Médecine, Université Libre de Bruxelles (ULB), Brussels, BELGIUM,* [3]*Necker Bioimage Analysis platform SFR Necker US24/UAR 3633, Paris, FRANCE,* [4]*Institut National de la Santé et de la Recherche Médicale, Centre National de la Recherche Scientifique, Université de Paris, Paris, FRANCE.*

***Aim/Introduction:*** Mouse renal dosimetry at the level of nephron substructures is of interest for preclinical investigations of nephrotoxicity in radiopharmaceutical therapy with alpha-particle and electron emitters. As the distribution of radiopharmaceutical can be heterogeneous across different nephron substructures of kidney tissues, and even between different nephron types [1]. This study investigated the influence of nephron morphology on mouse kidney dosimetry. ***Materials and Methods:*** A realistic computational model of murine nephrons was developed based on 3D multiphoton microscopy images of mouse kidney tissues [2]. Three nephrons with distinctive morphology were modelled: a superficial (glomerulus in the outermost renal cortex), a juxtamedullary (glomerulus near the renal medulla) and a mid-cortical (intermediate) nephron. The shape and size (length) of the different nephron sub-compartments (glomerulus, proximal tubule (PT), loop of Henle and distal tubule) differ between each nephron type. S-values and energy absorbed fractions (AF) were calculated (GATE v9.2) for the different nephron sub-compartments for various Auger-electron, beta- and alpha emitting radionuclides ($^{177}$Lu, $^{161}$Tb, $^{211}$At), assuming a uniform radionuclide source in each nephron PT (or glomerulus). ***Results:*** For a source in the PT, the AF for self-irradiation is significantly higher for the juxtamedullary nephron than for the superficial nephron for all radionuclides (40% and 20% higher, respectively for $^{177}$Lu and $^{161}$Tb Auger and internal conversion electrons). The PT self-irradiation AF of beta particles are similar ($0.03 \leq AF \leq 0.06$) for all nephrons. The difference in AF between the mid-cortical nephron was within 20% higher for all particles of both radionuclides. For $^{211}$At, the AF for alpha particle PT self-irradiation is 70% and 20% higher for the juxtamedullary nephron than for the superficial and mid-cortical nephron, respectively. However, for all radionuclides, the S-values are substantially higher for the superficial nephron than for the mid-cortical (approximately 50% higher) and juxtamedullary (90% higher) nephron, as the PT mass of the superficial nephron is respectively 66% and 51% lower than the mass of the mid-cortical and juxtamedullary PTs. ***Conclusion:*** Differences in the morphology and substructure sizes of different nephrons significantly influences microscopic renal tissue dosimetry of low energy electron and alpha particle emitters with a heterogeneous activity distribution in murine kidneys. Therefore, consideration of nephron morphology and size characteristics in dosimetry calculations might be needed in cases of differential radioligand distributions across different nephron types to effectively support the preclinical investigation of nephrotoxicity in radiopharmaceutical therapy. ***References:*** [1] EJNMMI 2005;32(10):1136-43. https://doi.org/10.1007/s00259-005-1793-0 [2] Kidney International 2021;99(3):632-45. https://doi.org/10.1016/j.kint.2020.09.032

## OP-149

### Small-scale anatomical modeling of the salivary gland for alpha-particle and beta-article radiopharmaceutical therapy

***R. Hobbs****, I. Marsh, R. Bastiaannet, I. Liatsou, C. Brayton, K. Gabrielson, T. Yusufaly;*
*Johns Hopkins, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Salivary gland toxicity is a serious quality of life issue from both beta-particle ($^{131}$I or $^{177}$Lu-PSMA) and alpha-particle ($^{211}$At or $^{225}$Ac-PSMA) radiopharmaceutical therapy (RPT). Clinical sequelae include xerostomia, sialedenitis and tooth decay. These clinical observations do not correlate well with whole organ dosimetry as the uptake of the radioisotope or radiopharmaceutical is confined to a small sub-set of cells within the salivary glands, resulting in a higher absorbed dose to a whole category of cells (ductal cells) as compared to the average whole organ absorbed dose. We present an anatomically representative model of ductal branching inside the salivary gland to model the relative absorbed dose to the different cell types. ***Materials and Methods:*** The salivary gland, which produces and secretes saliva, is modeled as a sphere containing acinar cells, with varying radius to represent SG size distributions. Embedded within the bulk is a branched network of intra- and interlobular ducts, with tunable branching angles, number of levels, and segment lengths. Occupancy of the ductal cells and spacing of the branches are derived from ex vivo murine histopathology. Monte Carlo simulations for the relevant isotopes were run and the S values for the model obtained. Dose coefficients were obtained for the different compartments assuming activity uptake in the ductal cells, and compared to the whole organ dose coefficient as a function of salivary gland size. ***Results:*** Dose coefficients to the ductal cells are markedly higher than the average salivary gland dose coefficient. For $^{131}$I, this value is about 4 (depends on the organ size), while for most alpha-emitters it is closer to 14, with less variation as a function of size and with narrower distributions of absorbed dose per cell. ***Conclusion:*** A simple branching model with stylized parameters allows us to relate the average organ absorbed dose to cell-specific dosimetry, to which bio-kinetic modeling can then be applied (BED or EQD2). Experiments are ongoing to provide the measured apportionment factors (small scale activity distribution in the different ductal cell sub-types)and in vivo RBE determination, each specific to each SG type for model refinement. The human model will be supplemented with data from human cadaver studies. For RPT, the ductal cells are expected to be the dose-limiting sub-compartment of the salivary glands.

## OP-150

### Zebrafish embryos as experimental model to advance pre-clinical research in nuclear medicine

***C. Morgat***[1,2], *G. Siefried*[3,4], *S. Bodin*[1,2], *F. Cavelier*[5], *E. Hindié*[1,2,6], *M. Khatib*[3];
[1]*Nuclear Medicine Department - University Hospital of Bordeaux, Bordeaux, FRANCE,* [2]*INCIA, University of Bordeaux, CNRS, EPHE, UMR 5287, Bordeaux, FRANCE,* [3]*RyTME, Bordeaux Institute of Oncology (BRIC)-UMR1312 Inserm, Pessac, FRANCE,* [4]*Xenofish, Pessac, FRANCE,* [5]*Institut des Biomolécules Max Mousseron IBMM, UMR 5247 Pôle Chimie Balard, Montpellier, FRANCE,* [6]*Institut Universitaire de France, Paris, FRANCE.*

***Aim/Introduction:*** The current xenografted mice model has limitations to evaluate the efficacy of novel therapeutic radionuclides emitting short-range particles due to difficulties in identifying and following tumor cell clusters and micrometastases. Zebrafish allows the implantation of human tumor cells that can next metastasize ***Materials and Methods:*** The triple negative breast cancer cell line MDA-MB-231, overexpressing neurotensin receptor-1 was stably transfected with the pIRES2-EGFP empty vector. Following incubation with the neurotensin analogue [$^{111}$In]In-JMV 6659 at 1 or 2MBq/mL, cells were microinjected in zebrafish embryo perivitelline space. Embryos were then imaged under fluorescence imaging and the relative primary tumor area and the number of metastases were determined at several time points ***Results:*** [$^{111}$In]In-JMV 6659 at 2MBq/mL was able to eliminate almost all metastases, whilst its effect on the primary tumors was limited. ***Conclusion:*** Zebrafish embryos stand as a novel model to better evaluate the efficacy of short-range emitters on tumor cell clusters and micrometastases.

## OP-151

### Biodistribution and dosimetry of lipiodol with various beta emitters: a preclinical study

***A. Dieudonne***[1], *R. Santus*[2], *P. Vera*[1], *S. Becker*[1], *X. Violas*[2];
[1]*LITIS-Quantif, Centre Henri Becquerel, Rouen, Rouen, FRANCE,* [2]*Research and Development Division, Laboratoire Guerbet, Aulnay-sous-Bois, FRANCE.*

***Aim/Introduction:*** Radioembolization is one therapeutic options for the treatment of early-intermediate stage hepatocellular carcinoma. Lipiodol based agents were developed and used in research (1). The aim of this study was to compare lipiodol with several beta emitters. ***Materials and Methods:*** VX2 tumours were implanted on New Zealand rabbits, that further received an injection of lipiodol in the left hepatic artery. Tumours were explanted and imaged with X-ray micro computerized tomography (µCT) at 15 min, 1, 2, 6, 9 and 12 days. The voxel size was 141 µm or 172 µm depending on the field-of-view. Tumours were frozen and cut into 12 µm for histologic analysis. Absorbed dose distributions were simulated for $^{32}$P, $^{90}$Y, $^{131}$I, $^{177}$Lu and $^{188}$Re from the µCT biodistributions of lipiodol and using a dose-point kernel approach in water. Average absorbed dose per administered activity in the tumour (S/λ) were reported. Equivalent uniform biological effective dose (EUBED) were calculated for an average absorbed dose of 100 Gy, using α and β values of respectively 0.037 Gy$^{-1}$ and 0.0028 Gy$^{-2}$ (2). ***Results:*** Over the 19 rabbits included, 14 had exploitable data. The histologic analysis showed that the lipiodol distributes homogeneously in the tumour up to 12 days after injection. Average tumour S/λ value was statistically higher for $^{32}$P with 62.8 ± 94 Gy.MBq$^{-1}$, followed by $^{90}$Y (14.9 ± 22 Gy.MBq$^{-1}$), $^{131}$I (10.8 ± 16 Gy.MBq$^{-1}$), $^{177}$Lu (6.9 ± 11 Gy.MBq$^{-1}$), $^{166}$Ho (4.92 ± 7.4 Gy.MBq$^{-1}$) and $^{188}$Re (3.43 ± 5.1 Gy.MBq$^{-1}$). EUBED values for a tumour absorbed dose of 100 Gy for $^{90}$Y with 45.3 ± 20 Gy, followed by $^{188}$Re (39.8 ± 18 Gy), $^{32}$P (36.5 ± 16 Gy), $^{166}$Ho (36.1 ± 16 Gy), were statistically higher than $^{131}$I (17.5 ± 9 Gy) and $^{177}$Lu (12.0 ± 7 Gy). ***Conclusion:*** This study showed the ability of lipiodol to penetrate into the tumour and to remain in the compartment. It showed also the better dosimetry efficacy of $^{90}$Y and $^{188}$Re, thus confirming that they are the best candidates for radioembolisation. ***References:*** 1. ## OP-152

### DNA damage repair in PBMCs after internal ex vivo irradiation with $^{177}$Lu

***I. Strobel***[1], *H. Scherthan*[2], *J. Hahn*[1], *J. Müller*[2], *S. Schumann*[1], *A. K. Buck*[1], *M. Port*[2], *M. Lassmann*[1], *U. Eberlein*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.*

***Aim/Introduction:*** The aim of this study was to investigate DNA damage induction and repair in peripheral blood mononuclear cells (PBMCs) after internal ex vivo irradiation of whole blood with the β-emitter $^{177}$Lu. ***Materials and Methods:*** Blood samples of seven healthy volunteers were collected and divided in five aliquots each, of which one served as non-irradiated baseline. The remaining blood samples were incubated for 1h with varying $^{177}$Lu activities to achieve total absorbed doses to the blood between 3mGy to 100mGy, followed by PBMCs isolation. The PBMCs were divided in three subsamples to study the time course of the DNA damage repair and either fixed directly with 70% ethanol or 4h and 24h after culture in RPMI. Immunostaining of DNA double-strand break (DSB) markers γ-H2AX and 53BP1 revealed co-localised DSB foci in the PBMCs' nuclei that were counted microscopically in 100 nuclei per sample. To quantify the repair rates, a monoexponential model was used. ***Results:*** Mean absorbed doses to the blood of (3.4±1.5)mGy, (23.0±1.4)mGy, (47.3±2.0)mGy and (89.7±4.6)mGy were achieved. Directly after 1h internal irradiation, the mean of the average number of radiation-induced foci (RIF) per cell were 0.13±0.09 (3mGy), 0.30±0.09 (25mGy), 0.65±0.25 (50mGy) and 1.23±0.09 (100mGy). The average number of RIF showed a linear correlation to the absorbed dose ($r^2$= 0.96). After 4h the RIF per cell decreased significantly ($p<0.05$) to 0.30±0.08 (50mGy) and 0.41±0.18 (100mGy). Repair was complete within uncertainties after 24h, with RIF values of -0.01±0.12 (50mGy) and 0.13±0.14 (100mGy). The decrease in RIF at 3mGy and 25mGy was not significant due to large scatter of RIF values in the low dose range. The repair rate of the RIF were (0.15±0.12)h$^{-1}$ (25mGy; $r^2$=0.44), (0.21±0.03)h$^{-1}$ (50mGy; $r^2$=0.89) and (0.36±0.06)h$^{-1}$ (100mGy; $r^2$=0.90). The repair rate induced by 50mGy Lu-177 irradiation is in agreement with the value of (0.28±0.03)h$^{-1}$ obtained for $^{131}$I at an absorbed dose of 50mGy [1]. ***Conclusion:*** This study shows a linear increase of RIF for total absorbed doses between 3mGy and 100mGy directly after internal irradiation with $^{177}$Lu. A significant reduction of RIF to baseline values after 50 and 100mGy β-irradiation over 24h of culture indicates successful DSB repair. In addition, our data suggest a repair rate of DNA DSBs after low-dose internal irradiation that increases with the absorbed dose. ***References:*** [1] Schumann et al, EJNMMI, 49, 2022, 1447-1455

## OP-153

### From bench to bedside: $^{64}$Cu/$^{177}$Lu 1C1m-Fc anti TEM-1: mice-to-human dosimetry extrapolations for future theranostic applications

***J. Delage***[1], *N. Chouin*[2], *M. Cherel*[3], *S. M. Dunn*[4], *N. Schaefer*[5], *A. Faivre-Chauvet*[3], *J. O. Prior*[5], *S. Gnesin*[6];
[1]*Radiopharmacy Unit, Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*University of Nantes, Inserm, CNRS, University of Angers, Oniris, CRCI2NA, Nantes, FRANCE,* [3]*University of Nantes, CHU Nantes, CNRS, Inserm, CRCINA, Nantes, FRANCE,* [4]*LAbCore, Ludwig Institute for Cancer Research, Lausanne University Hospital and University of Lausanne, Epalinges, SWITZERLAND,* [5]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [6]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** The development of diagnostic and therapeutic radiopharmaceuticals is a hot topic in nuclear medicine. Several radiolabeled antibodies are under development necessitating both biokinetic and dosimetry extrapolations for effective human translation. The validation of different animal-to-human dosimetry extrapolation methods still is an open issue. We previously developed and tested preclinically a fully human single-chain variable fragment (scFv) Fc fusion, 1C1m-Fc, cross-reacting with both murine and human TEM-1. This fusion protein antibody was conjugated with DOTA and radiolabeled with $^{64}$Cu for PET imaging and with $^{177}$Lu for therapeutic purposes. ***Materials and Methods:*** This study reports the mice-to-human dosimetry extrapolation of $^{64}$Cu/$^{177}$Lu 1C1m-Fc anti-TEM-1 for theranostic application in soft-tissue sarcomas. We applied four different dosimetry methods; direct mice-to-human extrapolation (M1); extrapolation considering a relative organ-specific mass scaling factor (M2), application of a metabolic scaling factor (M3) and combination of M2 and M3 (M4). Furthermore, we evaluated the viability of using [$^{177}$Lu]Lu-1C1m-Fc as therapeutic agent in treating soft-tissue sarcomas (STS) investigating the administered activity that would results in reaching safety limits (in kidneys, red marrow, liver, spleen and gonads) and expected efficacy (in STS). ***Results:*** For the four dosimetry methods described above (M1-M4), we reported the average values of source organ TIACs extrapolated to the human from previously published mice data. Predicted in-human dosimetry for the [$^{64}$Cu]Cu-1C1m-Fc resulted in an effective dose of 0.05 mSv/MBq, favorable for diagnosis use. Absorbed dose (AD) extrapolation for the [$^{177}$Lu]Lu-1C1m-Fc indicated that the AD of 2 Gy and 4 Gy to the red-marrow and total-body can be reached with 5-10 GBq and 25-30 GBq of therapeutic activity administration respectively depending on applied dosimetry method. ***Conclusion:*** Dose estimation based on animal data is a mandatory requirement, providing important insights and guidance for predicting safety and efficacy of any radiolabeled compound prior to its diagnostic and/or therapeutic in-human translation. Different methods for animal-to-human dosimetry extrapolations have been reported in the literature but no consensus presently exists on the appropriate approach to apply for any specific radiolabeled compound. For our theranostic couple $^{64}$Cu/$^{177}$Lu 1C1m-Fc anti TEM-1, dosimetry extrapolation methods provided significantly different absorbed doses in organs. Even if dosimetry properties for the [$^{64}$Cu]Cu-1C1m-Fc are suitable for a diagnostic in-human use, the therapeutic application of [$^{177}$Lu]Lu-1C1m-Fc presents challenges and would benefit from further assessments in animals' models such as dogs before moving into the clinic.

## OP-154

### Simulations of the relative effectiveness of tumor stroma and cancer cell targeting radiopharmaceuticals

***Y. Song***[1,2], *J. Brosch-Lenz*[1], *C. D'Alessandria*[1], *K. Shi*[3], *W. Weber*[1];
[1]*Department of Nuclear Medicine, Klinikum rechts der Isar, Technische Universität München, Munich, GERMANY,* [2]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [3]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is a promising target for radiopharmaceutical therapy (RPT) because it is expressed in the stroma of many malignant tumors while its expression in normal tissues is highly restricted. However, there is a potentially higher heterogeneity of radiation dose to the cancer cells than for RPT directed against targets expressed by the cancer cells. The aim of this study was to explore the magnitude of this effect for Y-90 and Lu-177 labeled FAP ligands. ***Materials and Methods:*** The effects for RPT were modelled for spherical aggregates of cells (diameter: 20 µm) ranging from 400 µm to 2 mm in MIRDcell. The radioactivity was either distributed homogenously in all cells (scenario for RPT directed against targets expressed by cancer cells) or accumulated in only 50% or 25% of the cells, randomly distributed within the sphere (scenario for FAP ligands targeting fibroblasts in the tumor stroma). The biological half-life of the FAP radioligand was assumed to 10.1 h as previously published by Ferdinandus et al. (JNM 2022). Surviving tumor cell fractions were calculated using the alpha/beta parameters provided by MIRDcell. ***Results:*** When all the cells accumulated the same amount of radioactivity, the activity per cell required to kill 90% of the cells in spheres with diameters from 400 µm to 2 mm ranged between 0.98 Bq and 0.93 Bq for Lu-177, and between 1.5 Bq and 3.1 Bq for Y-90. When these amounts of radioactivity were accumulated by only 50% and 25% of the cells, the fractional cell kill of the unlabeled cells ranged between 30% and 60% for Lu-177 and 38% and 78% for Y-90. The loss of efficacy diminished for both isotopes with increasing lesion size. ***Conclusion:*** For the same total tumor uptake of radioactivity, radiopharmaceuticals targeting the tumor stroma deliver lower doses to the tumor cells than radiopharmaceuticals targeting the cancer cells. This effect is more pronounced for smaller lesions and only slightly improved by a high energy beta emitter such as Y-90. ***References:*** Ferdinandus J, Costa PF, Kessler L, et al. ***Aim/Introduction:*** Neoadjuvant radiochemotherapy is the standard treatment for locally advanced rectal cancers with variable anatomopathological responses on the surgical specimen with known treatment resistance factors including tumor hypoxia. This study aims to evaluate interest of [64Cu] Cu-ATSM (Cu-ATSM) PET-CT to predict neoadjuvant treatment response for locally advanced rectal cancers. ***Materials and Methods:*** T3 or T4 rectal adenocarcinoma patients with or without regional lymph node involvement on conventional imaging were included in this multicenter pilot study (NCT03951337). Before any neoadjuvant treatment, all patients performed [18F] FDG PET-CT (FDG1) and Cu-ATSM PET-CT and most patients performed preoperative FDG2. Acquisitions were performed on the pelvic region, 1- and 24-hours post-injection of 3 MBq/kg Cu-ATSM. Semi-quantitative image analyses were conducted. Rectal tumor and gluteal VOIs were respectively delineated with a 70% threshold and a manual delineation on 64Cu-ATSM images whereas a varying threshold was used for rectal tumor delineation on FDG examinations. SUVmax, SUVmean, tumor-to-muscle-ratio, Hypoxic-Tumor-Volume (HTV), and Hypoxic-Burden (HB: HTV x SUVmean) were calculated on Cu-ATSM images. ΔMTV and ΔTLG (FDG1-FDG2/FDG1) were calculated with 30% decrease considered as response. Anatomopathological Rödel score defined on the surgical specimen was used to classify patients as responders (R score=3-4), and non-responders (NR score=0-2). Progression-free survival was followed for 2 years. ***Results:*** Of 24 patients included in this study, only 14 had surgical intervention (sex ratio1/1, median age 67 years [49-77], MRI median rectal tumor height 44mm [33-105], 12 and 2 patients classified respectively as T3 and T4): 10 had a positive histological response to neoadjuvant therapy. Progression-free survival at 12 months was 81.8%; IC 95% [44.7-95.1]. Cu-ATSM quantitative analysis revealed an uptake increase between 1h and 24h for any SUV features as well as the tumor-to-muscle ratio. Indeed, median SUVmax, SUVmean, and tumor-to-muscle ratio increased from 3.81 [2.74-6.65] to 6.34 [2.81-11.69], 3.07 [2.23-5.10] to 5.25 [2.29-9.05], and 4.38 [2.63-7.25] and 6.7 [1.75-21.03] respectively. Conversely, median HTV and HB decreased respectively from 4.67cm$^3$ [1-18.74] to 0.95 cm$^3$ [0.34-9.27] and 14.88 cm$^3$ [5.12-58.32] to 4.05 cm$^3$ [1.03-44.05]. Population analysis (R vs NR) was not significant (p: 0.32-1.00). Additionally, early and late Cu-ATSM uptake did not correlate with FDG1 (p: 0.26-0.91). FDG ΔTLG was correlated to HB at 24h on Cu-ATSM (r =-0.68; p=0.02). ***Conclusion:*** These preliminary results showed that a greater tumor hypoxic volume (HB) at 24 hours was correlated with a poorer metabolic response (ΔTLG). Supplementary data will be presented during the congress for this ongoing study.

### OP-156

**The effect of free thyroxine on glucose metabolic activity in primary hepatic neoplasm: A study of PET-CT scans**

***Z. Zhao***[1], *X. Wang*[2], *J. Xiao*[1], *D. Wang*[1], *Z. Luo*[1];
[1]*Affiliated Hospital of Guangdong Medical University, Zhanjiang, CHINA,* [2]*Children's Hospital Affiliated to Zhengzhou University, Zhengzhou, CHINA.*

***Aim/Introduction:*** The glucose metabolic activity was an important characteristic in many malignant tumors, including the primary hepatic neoplasm. The standard uptake value (SUV) was a useful indicator in the 18F-FDG positron emission tomography (PET) examination, which could reflect the glucose metabolic activity. Some early research showed that the thyroid hormones, including the free thyroxine (FT4), also had effects on the malignant tumors. While the relationship of the FT4 and the glucose metabolic activity of primary hepatic neoplasm is largely unknown. In this study, we tried to explore this relationship using 18F-FDG PET examination. ***Materials and Methods:*** 18 patients with primary hepatic neoplasm were enrolled in this study. All of them received the 18F-FDG PET scanning. Hand-painted measurement was used to get the SUV. In this study, the SUVmax was used only. All of the patients received the thyroid hormones level measurement, including the FT4 level. The average of the FT4 level was 15.7 pmol/L. The FT4 levels in 10 patients (group 1) were higher than 15.7 pmol/L. The FT4 levels in 8 patients (group 2) were lower than 15.7 pmol/L. Differences between groups were estimated using the students t test. Nominal P values of less than 0.05 were considered to demonstrate statistically significant differences. ***Results:*** The media SUVmax was 8.92±3.74 in group 1 and 4.55±4.05 in group 2. The highest SUVmax was 13.4 in group 1 and 11.0 in group 2. The lowest SUVmax was 0.8 in group 1 and 0.7 in group 2. The SUVmax were higher in the group 1 than that in group 2. The difference was significant (P = 0.033). ***Conclusion:*** This study demonstrated the significant difference of SUVmax between the primary hepatic neoplasm patients with the higher level of FT4 and the lower level of FT4. The SUVmax were higher in the patients with the higher level of FT4 than those with the lower level of FT4. The results showed that the FT4 may effect the glucose metabolic activity of primary hepatic neoplasm. This maybe one of the reason why the thyroid hormones affect tumor growth, as some of the early research had studied.

## OP-157

### Assesment of biological parameters of esophageal cancer in pre-, and post-treatment 18F-FDG-PET/CT in patient with early relapse.

***A. Filipczuk***[1], *A. Lewandowska*[1], *A. Pietrzak*[1], *W. Cholewiński*[2];
[1]*Greater Poland Cancer Center, Poznan, POLAND,*
[2]*Medical University of Poznan, Poznan, POLAND.*

***Aim/Introduction:*** Esophageal cancer is one of the most agressive gastrointestinals tumor, and it is characterised with early relapse after radical treatment.PET/CT with the glukose analog 18F-FDG in esophageal cancer, is frequently used for staging, and evaluation of treatment response.After radical radiochemotherapy, heterogeneous and persistent FDG uptake in esophagus, may be cause by various reasons, including inflammation after treatment, or residual cancer process.The aim of the study, is to evaluate the link, between biological parameters of esophageal cancer before, or after radical treatment, and early relapse. ***Materials and Methods:*** Forty patients (64±9 years, 30M, 10F), with histologically confirmed esophageal cancer (35 with squamos cell carcinoma, and 5 with adenocarcinoma), underwent 18F-FDG-PET/CT scan 60min after tracer injection. All patients had first PET/CT scan before any treatment, and second scan 10 weeks after radiochemotherapy. According to pre treatment diagnosis - 32 patients were in stage II, 6 in III, and 2 in IV.Tumor's maximal and mean standarized uptake value (SUVmax, SUVmean), total lesion glycolysis (TLG), and metabolic tumor volume (MTV), before and after treatment were included in the analysis. ***Results:*** Average values of SUVmax, SUVmean, MTV and TLG before radiochemotherapy in patients with squamos cell carcinoma were: 14,0±5,5; 7,6±2,9; 25±26; 155±224, respectively. In patients with adenocarcinoma evaluated values were: 6,4±2,7; 3,3±1,0; 10,0±5,5; 43,1±31,7, respectively.In two patients, SUVmax after treatment was higher than before.In the remaining patients, SUVmax decreased after treatment to 5,7±3,6 (range 2,5-8,9).36 patients had relapse within 1 year, and 4pts in 2 years after radiochemotherapy.Average relative decrease of glucose metabolism after radiochemotherapy was 58% (±27%, range 2%-86%), and was associated in all patients, with an early relapse. ***Conclusion:*** Combination of biological parameters, delivered from pre-and post-treatment PET/CT, may be useful in the prediction of early relapse, in patients with esophageal cancer.

## OP-158

### Comparison of $^{18}$F-FDG PET/CT and $^{18}$F-FDG PET/MRI in Detection of Liver Lesions in Hepatocellular Carcinoma for Staging and Restaging

***B. Demir***[1], *C. Soydal*[1], *E. Dursun*[1], *M. Araz*[1], *D. Kuru Oz*[2], *N. O. Kucuk*[1];
[1]*Ankara University School of Medicine Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara University School of Medicine Department of Radiology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT is a widely accepted and useful imaging modality in staging and re-staging of various malignant solid tumours. However, in hepatocellular carcinoma(HCC) patients its ability to detect lesions is significantly affected due to the variable affinity and uptake patterns seen in HCC lesions. In this study we aimed to investigate additive value of liver-specific PET/MRI compared to routine whole-body PET/CT imaging. ***Materials and Methods:*** A total number of 77 patients and 99 pairs of PET/CT and dedicated respiratory gated contrast-enhanced PET/MRI acquired in same session that was performed between September 2018-December 2022, were included in this retrospective study. Total FDG-avid lesion numbers, affected liver segment numbers, SUVpeak, SUVmean, metabolic tumour volume(MTV), total lesion glycolysis(TLG) and tumour-background ratio(TBR) were assessed in each study. Lesion numbers were grouped as no lesion, 1 lesion, 2-4 lesions, 5-10 lesions and >10 lesions. Detected lesion and affected segment numbers compared between PET/CT and PET/MRI with Chi-Square test. ***Results:*** Indications of molecular imaging were for staging in 37 studies and for re-staging in 62 studies. Median AFP level of patients was 11.7ng/mL (min-max:1-33477). Whole-body PET/CT was positive for lymph node metastasis in 36 studies, lung metastasis in 15 studies, bone metastasis in 5 studies and adrenal metastasis in 5 patients. In PET/CT and PET/MRI studies median SUVpeak, SUVmean, MTV, TLG and TBR values were 6.9 vs. 7.9, 4.3 vs. 4.6, 168 vs. 160.98 $cm^3$, 1021.5 vs 1040 gr/mLx$cm^3$ and 2.1 vs. 2.1, respectively. Both PET/CT and PET/MR studies were negative for FDG-avid lesions in liver for 29 studies (29%). In 41 studies(41%) PET/CT and PET/MRI detected similar numbers of lesions. However, in the remaining 29 studies(29%) PET/MRI detected significantly higher numbers of lesions(p=0.001). Also, in 9 studies (9%) PET/MRI detected FDG-avid lesions in liver, while there was no pathological uptake in liver on PET/CT images. The number of affected segments was same in 43 studies(43%) on both modalities. But in 27 studies (27%) PET/MR detected higher number of affected segments than PET/CT (p=0.001). Average affected segment numbers on PET/CT and PET/MRI were 2.13 and 2.52 respectively. ***Conclusion:*** Certain variable biological features of HCC could complicate the detection of liver lesions. In order to overcome this setback imaging with a dedicated liver PET/MRI protocol can enhance diagnostic ability of PET imaging. In this study we have demonstrated superiority of PET/MRI against standard whole-body PET/CT imaging in the detection of HCC liver lesions.

## OP-159

### A proposed first-line treatment regime for Lenvitinib or Nivolumab based on dual-tracer PET/CT may improve progression free survival for advanced stage HCC patients

***S. Chen***, *S. Cheung, K. Cheng, Y. Yip, W. Leung, C. Ho;*
*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

***Aim/Introduction:*** HCC is known to be a highly heterogeneous malignant tumor with poor prognosis. Lenvatinib (a multi-TKI) and Nivolumab (a PD-1 blocker) are both first-line anti-cancer drugs approved for advanced/inoperable HCC. In our preliminary study, we showed that Lenvatinib could have significant difference in treating $^{11}$C-acetate (ACT)-avid HCC versus $^{18}$F-FDG (FDG)-avid HCC. On the other hand, literature data reported on PD-1/PD-L1 blockade effects for advanced HCC were also highly heterogeneous. We aim to evaluate if advanced HCC patients randomized into 2 treatment arms, Lenvatinib or Nivolumab, could have different progression-free survival (PFS) outcomes using dual-tracer PET as metabolic differentiators. ***Materials and Methods:*** This is a prospective study between year 2017 and 2020. All patients with advanced stage HCC (BCLC stage C) underwent baseline ACT and FDG (dual-tracer) PET/CT. They were then randomized into systemic treatment by either Lenvatinib or Nivolumab. Follow-up dual-tracer PET/CT were performed every 2-3 months after initiation of Lenvatinib or Nivolumab treatment until disease progression, death or to a maximum of 36 months. Patients were classified into 4 groups: (1) ACT-avid HCC treated by Lenvatinib (ACT-LVN), (2) FDG-avid HCC by Lenvatinib (FDG-LVN), (3) ACT-avid HCC by Nivolumab (ACT-NVM), (4) FDG-avid HCC

by Nivolumab (FDG-NVM), with PFS as endpoint. PFS time was calculated using the KaplanMeier method and analyzed using a logrank test. ***Results:*** Study recruited 75 patients (male:66, female:9 ; HBV:70, HCV:2; mean age=54.5±12.0 years, range:33-82 years): 42 treated by Lenvatinib and 33 by Nivolumab, with no significant difference in patient age, sex, hepatitis status, AFP level, and presence of extrahepatic metastases between the 2 treatment arms. Lenvatinib arm (ACT-LVN+FDG-LVN) and Nivolumab arm (ACT-NVM+FDG-NVM) had similar median PFS (6.0 vs 7.0 months). However, within the Lenvatinib arm, ACT-LVN group had a significantly longer PFS than FDG-LVN (8.0 vs 4.0 months); while in the Nivolumab arm, FDG-NVM group had a significantly longer PFS than ACT-NVM group (9.0 vs 3.0 months). These results suggest that if patients with ACT-avid HCC were treated by Lenvatinib and FDG-avid HCC by Nivolumab, differential PFS could be significantly improved at 6-month (71.1 vs 47.6%), 9-month (35.6 vs 23.8%), 1-year (24.4 vs 11.9%), 2-year (8.9 vs 2.4%) and 3-year (8.9 vs 2.4%), when compared with all patients treated by Lenvatinib first-line. ***Conclusion:*** With dual-tracer PET as metabolic differentiators, our proposed treatment regime for advanced stage HCC was to treat ACT-avid HCC first-line with Lenvatinib, and FDG-avid HCC first-line with Nivolumab.

## OP-160

### 18F-Fluorodeoxyglucose (FDG) and 18F-Fluorocholine (FCH) Positron Emission Tomography (PET) as Early Predictive Factorsof Overall Survival in Patients With Advanced Hepatocellular Carcinoma Treated WithSorafenib: a prospectivemulticentricstudy

***V. BESSON***[1], *C. Tabouret-Viaud*[1], *A. Fouquier*[2], *J. Bronowicki*[3], *E. Chevalier*[4], *A. Heurgue*[5], *D. Papathanassiou*[6], *J. Blanc*[7], *J. Pinaquy*[8], *L. Bengrine*[9], *X. Palard*[10], *H. Bourien*[11], *A. Bertaut*[2], *S. Manfredi*[12], *A. Cochet*[13];
[1]*Department of Nuclear Medicine, Centre Georges François Leclerc, Dijon, FRANCE,* [2]*Department of Statistics, Centre Georges-François Leclerc, Dijon, FRANCE,* [3]*Department of Gastro-Enterology and Hepatology, University Hospital of Nancy, Nancy, FRANCE,* [4]*Department of Nuclear Medicine, University Hospital of Nancy, Nancy, FRANCE,* [5]*Department of Hepato-Gastro-Enterology, University Hospital of Reims, Reims, FRANCE,* [6]*Department of Nuclear Medicine, Institut Jean Godinot, Reims, FRANCE,* [7]*Department of Hepato-Gastro-Enterology, University Hospital of Bordeaux, Bordeaux, FRANCE,* [8]*Department of Nuclear Medicine, University Hospital of Bordeaux, Bordeaux, FRANCE,* [9]*Department of Medical Oncology, Centre Georges-François Leclerc, Dijon, FRANCE,* [10]*Department of Nuclear Medicine, Centre Eugene-Marquis, Rennes, FRANCE,* [11]*Department of Medical Oncology, Centre Eugene-Marquis, Rennes, FRANCE,* [12]*Department of Hepato-Gastro-Enterology, Dijon, FRANCE,* [13]*ICMUB, UMR CNRS 6302, University of Burgundy, Dijon, FRANCE.*

***Aim/Introduction:*** Hepatocellular Carcinoma (HCC) is the third cause of cancer-related death and is most often diagnosed at an advanced stage. Sorafenib remains one of the recommended treatments for advanced HCC; however, its efficacy remains inconstant and the incidence of treatment-related adverse events is high. Thus, our aim was to evaluate the clinical significance of dual radiotracers studies, $^{18}$F-Fluorodesoxyglucose (FDG) and $^{18}$F-Fluorocholine (FCH) performed before and after one month of Sorafenib therapy, in patients with advanced HCC for the prediction of one-year survival. ***Materials and Methods:*** Patients with advanced HCC and eligible for Sorafenib therapy were recruited in the prospective open-label non-randomized multicentric PREMETHEP trial (NCT02847468; 6 recruiting centres). Patients were assessed to perform FDG and FCH PET/CT before treatment initiation and one month after in order to evaluate baseline and residual tumor metabolism. The following parameters were extracted from each scan: $SUV_{max}$ , $SUV_{avg}$ and Tumor to Normal liver Ratio (TNR= $SUV_{max}$ of the tumor/ $SUV_{avg}$ of normal liver) for the most significant lesion, volumetric parameters of the intra-hepatic tumor burden: Metabolic Tumor Volume (MTV), Total Lesion Glycolysis (TLG) for FDG, Total Lesion Choline Kinase activity (TLCK) for FCH. The tumor metabolic response ($\Delta SUV_{max}$, $\Delta SUV_{avg}$, $\Delta SUV_{mean}$, ΔTNR, ΔMTV, ΔTLG and ΔTLCK) was also calculated. Patients were followed during one year after treatment initiation. Logistic regressions with ROC curves were used to determine parameters associated with 1-year survival status (binary outcome). Optimal thresholds for quantitative parameters were determined using the Youden index method. Univariate and bivariate Cox analysis were performed to determine predictors of death. ***Results:*** Sixty-two patients (age 70±7 years) were included. All patients received Sorafenib therapy during at least one month. Median follow-up was 12 months. Twenty-two patients died during follow-up. In univariate analysis, only parameters reflecting high FDG tumor burden at baseline were significantly associated with death: TNR>1.5 (Hazard Ratio [HR]:7.1, 95% Confidence Interval [95%CI]:2.1-24.5, p=0.002), MTV>18 mL (HR:8.4, 95%CI:2.5-28.-, p<0.001; Sensitivity=86%, Specificity=71%), TLG>53g (HR:10.6, 95%CI:2.4-45.9, p=0.002) and presence of extra-hepatic lesions (HR:2.5, 95%CI:1.1-6.0, p=0.04). In contrast, neither follow-up FDG parameters, FCH parameters (baseline or follow-up), clinical and biological data had a prognostic significance. After adjustment on age, MTV>18 mL on baseline FDG PET/CT remained an independent predictor of death (HR:9.6, 95%CI:2.7-33.8, p<0.001). ***Conclusion:*** Baseline metabolic tumor burden determined with FDG PET/CT is a strong prognostic factor in patients with advanced HCC receiving Sorafenib therapy. FCH PET/CT does not seems to provide additional prognostic information.

## OP-161

### Assessing the performance of $^{68}$Ga-Fibroblast activating protein inhibitor-04 (FAPI) PET/CT in the diagnosis of cholangiocarcinoma - A prospective pilot study.

***D. Halanaik***, *V. Rajaraman, L. Aridhasan Meenakshi, A. Jeba Selvaraj, B. Pottakkat;
Jawaharlal Institute of postgraduate medical education and Research, Puducherry, INDIA.*

***Aim/Introduction:*** Initial studies have indicated favourable levels of FAPI expression in cholangiocarcinoma (CC). Even though F18-Fluorodeoxyglucose (FDG) positron emission tomography/ Computed tomography (PET/CT) is a frequently utilized method for assessing various malignancies, its application in cholangiocarcinoma was restricted. Therefore, our objective was to investigate the effectiveness of Ga-68 FAPI PET/CT in detecting cholangiocarcinoma and to evaluate its performance against that of F-18 FDG PET/CT. ***Materials and Methods:*** Patients suspected to have CC were recruited prospectively from January 2021 to March 2023. FDG and FAPI PET/CT studies were completed within 1 week. The final diagnosis of malignancy was achieved by tissue diagnosis (Either histopathological examination or fine needle aspiration cytology), radiological correlation from conventional modalities and serological correlation of Alpha-fetoprotein (AFP), Carcinoembryonic antigen (CEA) & Cancer antigen 19-9 (CA 19-9). Results were compared with the final diagnosis and expressed as sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy (DA).

***Results:*** 28 patients with suspected cholangiocarcinoma were included. Out of 28, 9 were metastatic and 17 were non-metastatic. For diagnosis of primary CC, FAPI PET/CT showed a sensitivity of 95.65% (CI:78-99.89%), specificity of 100% (CI:29.24-100%) & DA of 96.15% (CI:80.36-99.9%), whereas FDG PET/CT showed a sensitivity of 47.83% (CI:26.82-69.41%), specificity of 100% (CI:29.24-100%), and DA of 53.85% (CI:33.37-73.41%). Out of the 9 metastatic diseases, FDG and FAPI PET/CT detected 5 and 8 metastatic diseases, respectively. While the sensitivity of FAPI PET/CT was satisfactory, its effectiveness in identifying lesions was impeded by diffuse FAPI uptake in the liver (50%) and pancreas caused by pre-existing cirrhosis and periductal inflammation. ***Conclusion:*** In the diagnosis of primary and metastatic cholangiocarcinoma, FAPI PET/CT has demonstrated significant advantages over FDG PET/CT. Additional studies are necessary to assess the predictive value of FAPI PET/CT in the prognosis of cholangiocarcinoma.

***References:*** Kratochwil C, Flechsig P, Lindner T, Abderrahim L, Altmann A, Mier W, et al. 68 Ga-FAPI PET/CT: Tracer Uptake in 28 Different Kinds of Cancer. J Nucl Med. 2019 Jun;60(6):801-5.

## OP-162

### Static and Dynamic$^{68}$Ga-FAPI PET/CT in Mass Forming Pancreatitis and Pancreatic Ductal Adenocarcinomas (PDAC)

***M. Preussig***[1], *M. Lang*[2], *C. Schroeter*[1], *E. Gutjahr*[3], *U. Haberkorn*[1], *M. Röhrich*[1];
[1]*Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY,* [2]*Department of General, Visceral, and Transplantation Surgery, University Hospital Heidelberg, Heidelberg, GERMANY,* [3]*Department of Pathology, University Hospital Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** The differentiation between mass forming pancreatitis and pancreatic ductal adenocarcinomas (PDAC) based on conventional imaging methods like ultrasound, CT and MRI is frequently not possible. Here, we applied static (60 minutes post injection) and dynamic PET/CT with $^{68}$Gallium-labelled Fibroblast Activated Protein Inhibitors ($^{68}$Ga-FAPI-PET/CT) in 17 preoperative, treatment-naive patients with unclear pancreatic masses to evaluate the potential diagnostic value of this new imaging method for the differentiation between mass forming pancreatitis and PDAC. ***Materials and Methods:*** 17 Patient with unclear pancreatic masses underwent static and dynamic $^{68}$Ga-FAPI-PET/CT before surgical resection or biopsy of the pancreas and subsequent histological diagnoses. Static parameters (SUVmax and SUVmean) were generated from VOIs of pancreatic masses. Time activity curves and dynamic parameters including kinetic modeling were extracted from dynamic PET data using PMOD software. ***Results:*** Histology revealed PDAC in 10 patients and inflammation in 7 patients. We observed a markedly higher $^{68}$Ga-FAPI-uptake in PDACs than in inflammatory lesions (SUVmax: 17,93+/-4,95 versus 10,87+/-3,18 SUVmean: 10,76+/-2,96 versus 6,42+/-1,92). In dynamic PET-imaging, PDAC and inflammatory lesions showed distinctive and characteristic time activity curves: Whereas PDAC increased for 15+/-5 minutes followed by a plateau phase after the perfusion peak, the inflammatory lesions showed a steady and slow decrease after a perfusion peak. The average time to peak was markedly longer for PDAC (19 minutes) than for inflammatory lesions (4 minutes). PDAC showed higher K1and K2 values than the inflammations (K1:0,64+/-0,25 versus 0,33 +/-0,1, K2:0,77+/-0,63 versus 0,26+/-0,13). ***Conclusion:*** $^{68}$Ga-FAPI-PET/CT should be considered for patients where other imaging methods are not able to distinguish between malignant and inflammatory pancreatic masses. Overall, PDAC show higher $^{68}$Ga-FAPI-uptake than mass forming pancreatitis. However, an overlap of PDAC and pancreatitis-related uptake is possible. Dynamic time activity curves are distinctive for both PDAC and inflammation, which underlines the additional value of dynamic $^{68}$Ga-FAPI-PET acquisition.

## OP-163

### The Role of [$^{68}$Ga]Ga-DOTA-FAPI-04 PET/CT on Detecting Lesions and Altering Stage in Patients With Digestive System Malignencies With Non-FDG-avid Lesions

***G. Beydagi***[1], *N. Alan-Selcuk*[1], *K. Akcay*[1], *E. Demirci*[1], *O. Sonmez*[2], *M. Ocak*[3], *T. Toklu*[1], *S. Celik*[4], *B. B. Oven*[4], *L. Kabasakal*[1,5];
[1]*Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Yeditepe University, Faculty of Medicine, Istanbul, TÜRKIYE,* [3]*Istanbul University, Faculty of Pharmacy, Department of Pharmaceutical Technology, Istanbul, TÜRKIYE,* [4]*Yeditepe University, Department of Medical Oncology, Istanbul, TÜRKIYE,* [5]*Istanbul Unıversity-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** $^{68}$Ga-labeled FAP ligands ($^{68}$Ga-FAPI) have emerged as a promising alternative for cancer patients presenting with FDG-negative lesions. The objective of this study is to assess the potential efficacy of $^{68}$Ga-FAPI PET/CT in the detection, staging, and restaging of digestive system malignancies characterized by low FDG uptake or FDG-negativity. ***Materials and Methods:*** Obtaining approval from the Clinical Research Ethics Committee, we prospectively enrolled patients with pathologically confirmed primary tumors or metastases. All participants underwent $^{68}$Ga-FAPI-04 and $^{18}$F-FDG PET/CT within one week, either for initial assessment (detection, staging) or for recurrence detection (restaging). Two senior nuclear medicine physicians reviewed all studies by consensus. ***Results:*** $^{68}$Ga-FAPI PET/CT imaging was conducted in 69 patients diagnosed with digestive system malignancies, who presented with suspicious lesions on FDG PET/CT. Among the 69 patients, 43 had gastric cancer, 13 had colorectal cancer, 7 had pancreatic cancer, 4 had hepatocellular carcinoma, and 2 had appendix cancer. Twenty cases with gastric cancer and two cases with colon cancer were diagnosed with signet ring cell carcinoma. In comparison to FDG PET/CT, the primary malignancy stage increased in 31 patients (45%) on FAPi PET/CT. Moreover, the primary malignancy stage increased in 64% of patients diagnosed with signet ring cell cancer. Peritoneal metastases were observed in 47 patients (68%). Although peritoneal metastases were FDG-negative in 27 patients, peritoneal metastases could not be demonstrated in just one case with a colon cancer diagnosis on FAPi PET/CT. Consequently, in the entire patient cohort, major changes were implemented in the treatment approach for 27 patients (39%), while minor changes were made for 4 patients (6%). ***Conclusion:*** $^{68}$Ga-FAPI PET/CT demonstrates superiority in the detection, staging, and restaging of low FDG-avid tumors, particularly in gastro-entero-pancreatic cancers or in regions with an unfavorable tumor-to-background ratio on FDG-PET/CT. In accordance with our findings, 68Ga-FAPI PET/CT alters the disease stage in 45% of gastrointestinal malignancies.

**The value of chemokine receptor type 4 targeted PET imaging in primary aldosteronism preoperative localization diagnosis compared with adrenal venous sampling**

***N. Lu***[1], *C. Li*[1], *Y. Tian*[1], *Z. Xiao*[1], *D. Xing*[1], *J. Zhong*[1], *W. Li*[1], *D. Zeng*[1], *W. Luo*[1], *H. Guo*[1], *Z. Meng*[2], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Urology, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** Primary aldosteronism (PA) is the most common cause for secondary hypertension, some of which are curable by resecting the dominant aldosterone-producing lesions. However, how to accurately recognize the functional adenoma or differentiate the dominant side in bilateral lesions by CT scans are still challenging. Chemokine receptor type 4 is found highly expressed in aldosterone-producing tissues. We aimed to evaluate the preoperative localization diagnostic efficiency of $^{68}$Ga-PentixaFor PET imaging targeting CXCR4 in PA patients, compared with adrenal venous sampling (AVS), the current gold standard for PA differentiation. ***Materials and Methods:*** We prospectively recruited 19 PA patients (13 males and 6 females, 45±11 years old). All patients underwent PET/CT imaging of adrenal region 30 min (early scan) and 2 h (delayed scan) after injection of $^{68}$Ga-PentixaFor, as well as AVS before surgery, with 2-5 months following-up. The SUVmax of adrenal lesions in both scans were measured. The correlations of above data with AVS and pathological results were then analyzed. The threshold of SUVmax to differentiate the dominant side in PA was determined by receiver operating characteristic (ROC) analysis. ***Results:*** 8(42%) patients with unilateral lesion and 7(37%) patients with bilateral lesions performing dominant avid $^{68}$Ga-PentixaFor uptake, consistent with AVS results, turned out to be aldosterone-producing adenoma (APA), aldosterone-producing nodules (APNs), or aldosterone-producing micronodules (APMs) by pathological immunohistochemistry staining. 4(21%) patients with bilateral lesions showed weak $^{68}$Ga-PentixaFor uptake but had dominant side by AVS. These lesions were APNs/APMs according to pathological results. All of these patients were cured of hypertension post adrenalectomy. A total of 36 adrenal lesions in 19 patients were analyzed. The mean SUVmax of 24.8±11.0 and 19.3 ±11.5 at early and delayed phases separately of APA, the most common type of aldosterone-producing tissues, was significantly elevated than that of APNs/APMs (7.5±5.4 and 5.3 ±3.9, separately), (P<0.005). To differentiate dominant side in PA patients, the optimal cut-off level of early SUVmax=7.9 and delayed SUVmax=7 was associated with sensitivity of 94%, specificity of 100%, and Youden's index of 94%. ***Conclusion:*** $^{68}$Ga-PentixaFor PET imaging, as a non-invasive method compared with AVS, performed excellent ability in detecting APA and differentiating dominant lesions in PA patients. However, for some APNs or APMs patients with weak $^{68}$Ga-PentixaFor uptake, AVS should be supplied to distinguish the lesions need surgery.

### OP-165

**Incidental Findings on $^{18}$F-Fluorocholine PET for Parathyroid Imaging**

***A. Namazova***[1], *A. NAZARI*[1], *B. Ince*[2], *S. Sağer*[1], *K. Sonmezoğlu*[1];
[1]*Istanbul University-Cerrahpaşa, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University-Cerrahpaşa, Department of Nucleer Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The aim of our study is to investigate the etiology of incidentally detected choline accumulation in non-parathyroid tissues in patients who underwent FCH-PET scan for the purpose of investigating parathyroid adenoma in our center ***Materials and Methods:*** We retrospectively analyzed 235 patients who underwent FCH-PET for the purpose of investigating parathyroid adenoma in our center between 2017 and2022. After the patients were injected with 0.1mci/kg intravenous 18F-fluorocholine, PET/MR images of the neck and upper mediastinum were taken at the 15th minute, and PET/CT images of the vertex-upper thigh were taken at the 45th minute. Images were interpreted by competent readers in the field, and areas showing abnormal choline uptake were recorded. SUVmax values of abnormal choline uptake were obtained. Each finding was correlated with follow-up data from the electronic medical records. ***Results:*** Incidental findings were observed in 23 (9.79%) of the 235 patients examined. The median age of the patients was 61 (29-84). Focal FCH accumulation was detected in the prostate gland of 8 male patients (80%), the median age of these patients was 69 (38-71) and the median serum PSA value was 1.05 (0.2-3.03). The patients were found to be clinically and radiologically compatible with BPH in the urological examinations. Focal FCH uptake in the breast was observed in 4 female (30.7%) patients. The mammography and clinical examinations of these patients were evaluated in benign processes. In 4 patients (3 M, 1 F), focal FCH uptake was observed in the thyroid nodules, and FNAB result of 1 female patient was reported as benign and 3 male patients as malignant. Total thyroidectomy operation was performed on patients whose FNAB results were interpreted as malignant, and the pathology result of the patients was papillary thyroid carcinoma. In addition, adrenal uptake (adenoma) in 1 patient, pituitary uptake in 1 patient (physiological), bone marrow uptake in 1 patient (aplastic anemia), focal liver uptake in 1 patient (FNH), uptake in the left nasopharynx in 1 patient (scc carcinoma in situ?), 1 patient meningioma and axillary lymph node uptake were observed in 1 patient, and it was thought to be secondary to the covid-19 vaccination. There was no significant correlation between the SUVmax values of benign and malignant lesions and the nature of the lesions. ***Conclusion:*** Although FCH-PET imaging is routinely used for imaging parathyroid adenoma and prostate cancer, FCH accumulation can be seen incidentally in some other malignant and benign conditions.

### OP-166

**Correlation between kidney $^{18}$F-FDG uptake and renal function in patients with chronic kidney disease.**

***F. Dondi***[1], *A. Talin*[2], *D. Albano*[2], *A. Calabrò*[2], *M. T. Volpe*[2], *P. Furtuna*[2], *F. Bertagna*[2];
[1]*Spedali Civili di Brescia, Brescia, ITALY,* [2]*Università degli Studi di Brescia, Brescia, ITALY.*

***Aim/Introduction:*** The aim of the study was to underline a possible correlation between kidney uptake at $^{18}$F-fluorodeoxyglucose ($^{18}$F-FDG) positron emission tomography/computed tomography (PET/CT) and creatinine (Cr) values in patients with chronic kidney disease (CKD). ***Materials and Methods:*** Patients

were retrospectively enrolled. Cr levels, estimated glomerular filtration rate (eGFR) and class of renal impairment at the time of the scan were collected. Kidney uptake (Ku), expressed as the average standardized uptake value (SUVmax) of 5 region of interest (ROIs) for each kidney, was sampled and ratios with liver (Ku-L) and blood-pool (Ku-BP) uptakes were calculated. T-test and Anova test were used to compare renal uptakes between the different classes of renal impairment. Pearson's correlation coefficient was used to evaluate the correlation between Cr levels, eGFR levels and PET/CT results. Moreover, in the case of patients with multiple scans, the temporal evolution of Cr levels (dCr) and eGFR (deGFR) were calculated and compared to the evolution of $^{18}$F-FDG PET/CT parameters. ***Results:*** A total of 126 patients (81 male, mean age 71) who performed a total of 167 $^{18}$F-FDG PET/CT scans were enrolled. Seventeen patients were functionally monokidney, 90 had two functioning kidneys and 19 subjects were transplanted: 17 had a functioning transplanted kidney while 2 had uptake on both native kidneys and transplanted one. In the total cohort of patients, significant negative correlations for Cr with Ku, Ku-L and Ku-BP were reported; positive correlations for eGFR were demonstrated with the same parameters. In evolutional terms, negative correlation for dCr with Ku and Ku-BP and for deGFR with Ku, Ku-L and Ku-BP were reported. In the group of patients with two functioning kidneys, negative correlations for Cr with Ku, Ku-L and Ku-BP and positive correlation for eGFR with the same parameters were confirmed. In the same group, dCr had a significant negative correlation with Ku and Ku-BP as also deGFR did. In the cohort of transplanted subjects, no significant correlations between the aforementioned parameters were reported. Significantly different Ku-L and Ku-BP dichotomizing the patients based on a value of Cr of 1.2 mg/dL were reported. Significantly different Ku, Ku-L and Ku-BP between the different classes of CKD were demonstrated. ***Conclusion:*** Correlation between kidney $^{18}$F-FDG uptake with Cr and eGRF levels were reported, with the exception of transplanted patients. These insights were also confirmed between the temporal evolution of tracer uptake and renal functional parameters.

## OP-167

### Renal blood flow quantification for the evaluation of stress induced kidney imaging using Rubidium-82 PET/CT

***A. van de Burgt***[1,2], *F. H. P. van velden*[2], *F. Smit*[1,2], *L. F. de Geus-Oei*[2,3,4], *I. A. Dekkers*[2];
[1]*Alrijne hospital, Leiderdorp, NETHERLANDS,*
[2]*Leiden University Medical Center, Leiden, NETHERLANDS,*
[3]*University of Twente, Enschede, NETHERLANDS,*
[4]*Delft University of Technology, Delft, NETHERLANDS.*

***Aim/Introduction:*** Chronic kidney disease (CKD) is a worldwide health problem. There is a need for novel quantifiable (image) biomarkers to define the underlying mechanisms of early-stage CDK. Renal blood flow (RBF) and renovascular reserve (RVR), defined as the ratio between RBF during stress and rest, might enable evaluation of disease activity and treatment response monitoring. The aim of this study is to develop a compartment model using dynamic Rubidium-82 ($^{82}$Rb) PET/CT imaging and to evaluate RVR by using stress induced kidney $^{82}$Rb PET/CT imaging. ***Materials and Methods:*** Compartment models were developed based on the linkage and number of compartments and the delineation of the volume of interest (VOI). Image-derived input functions (IDIF) were derived from kidney, left-ventricular blood pool (LVBP), ascending thoracic aorta (ATA) and abdominal aorta (AA) VOIs. Subsequently, retrospective data were collected from 10 patients (5 impaired kidney function and 5 controls) undergoing dynamic myocardial $^{82}$Rb PET/CT imaging. Finally, obtained $K_1$ values were converted to RBF in rest and pharmacological stress, and the RVR was composed to evaluate the potential of stress induced kidney $^{82}$Rb PET/CT imaging. ***Results:*** A three-tissue compartment model was developed to distinct between cortex and medulla in three layers. No significant differences were found between the three layers ($p>0.05$). Subsequently, a one-tissue compartment model was developed based on myocardial blood flow models and showed a decrease in $K_1$ values in stress compared to rest for controls and patients with impaired kidney function of 20.6% and 7.9% (median in %) respectively when ISO-contouring and AA as IDIF were applied. The RVR for the controls were overall significantly lower compared to the impaired kidney function group, with the smallest median(IQR) of 0.40(0.28-0.66) and 0.96(0.62-1.15), respectively ($p<0.05$). ***Conclusion:*** In this proof-of-concept study, it was demonstrated that obtaining RBF in rest and stress using $^{82}$Rb PET/CT is feasible for a one-tissue and a three-tissue compartment model. As the three-tissue compartment model cannot distinguish between the cortex and medulla, the one-tissue compartment model is preferred. In the impaired kidney function group, response to adenosine was absent and might be explained by the inability of the diseased kidney to respond with increased RBF after adenosine administration. However, further research is necessary to assess the use of adenosine for stress induced kidney imaging. To show sufficient evidence for the use of stress induced kidney $^{82}$Rb PET/CT imaging in clinical practice, validation should take place in a future clinical study.

## OP-168

### Segmentation and Volumetric Analysis of Pulmonary Reperfusion after Pulmonary Thromboembolism using Lung Perfusion SPECT/CT

***N. Alvarez Mena***, *F. Sebastián Palacid, M. García Aragón, R. Zambrano Infantino, A. Hurtado Romero, R. Ruano Pérez;*
*Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** To assess pulmonary reperfusion in patients under follow-up for pulmonary thromboembolism (PTE) by segmental and volumetric analysis in lung perfusion SPECT/CT. ***Materials and Methods:*** Prospective study from November 2020 to December 2022, in which we included 40 patients with PTE diagnosed by lung perfusion scintigraphy (planar images associated with SPECT/CT), who underwent a scintigraphic control 6 months later. Variables such as age, sex and degree of reperfusion were analysed. For reperfusion assessment, 3D visual and quantification analysis was performed using SPECT/CT segmentation (Q.Volumetrix software, GE). In volumetric analysis, the mean volumes and counts of the defect at baseline and at scintigraphic control were assessed to calculate the relative evolution (%). It was considered as no reperfusion ≤ 15%, minor partial reperfusion > 15-50%, major partial reperfusion > 50-80% and complete reperfusion > 80%. In addition, concordance between visual and quantitative analysis was assessed ($\chi 2$ test). ***Results:*** Mean age 71 years (36-89). 70% female. In scintigraphic control assessed by visual analysis was objectified 55% of patients no reperfusion, 20% partial reperfusion and 25% complete reperfusion. In quantitative analysis, 17% of patients no reperfusion, 33% minor partial reperfusion, 39% major partial reperfusion and 11% complete reperfusion were observed. In the 29 patients with partial reperfusion, 21 patients

had, on average, a relative decrease in defect volume (RDV) of 39% (16-79%), 4 patients with relative increase in mean defect counts (RImC) of 34% (17-64%) and 4 patients with RDV and RImC > 15%. When statistically comparing both methods, no significant concordance was noted between the scintigraphic results of the visual and quantitative analysis (p=0.05). Fifty-two per cent of patients with partial reperfusion on volumetric analysis (15/29) were considered non-reperfused by visual analysis. ***Conclusion:*** In the follow-up of pulmonary thromboembolic disease, volumetric analysis by lung perfusion SPECT/CT is superior to visual analysis. Furthermore, it is a tool that facilitates the assessment of reperfusion in patients in whom no significant improvement is observed in visual analysis as it may avoid unnecessary and prolonged treatment if reperfusion is noted by quantification.

## OP-169

### Could FAPI and MIBI scans help in diagnostic dilemmas in interstitial lung disease (ILD) for distinguishing fibroinflammatory process? Ongoing translational exploratory study

***M. Assadi***[1], *M. Bahtouee*[2], *E. Jafari*[1], *R. Mazarei*[2], *M. Khazaei*[3];
[1]*Department of Nuclear Medicine, Molecular Imaging, and Theranostics, Bushehr Medical University Hospital, School of Medicine, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Internal Medicine (Division of Pulmonary Medicine), Bushehr Medical Center Hospital, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [3]*Department of Radiology, Bushehr Medical Center Hospital, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The distinction of active fibroinflammatory process from an inactive form of the disease is of great value in the management of interstitial lung disease (ILD). There is no specific non-invasive method for this purpose, we aim to evaluate the diagnostic values of FAPI and MIBI scanning for fibrosis and inflammation in patients suspected to ILD. ***Materials and Methods:*** In this prospective exploratory study, 8 ILD patients suspected to ILD according to the high-resolution CT and their symptoms underwent FAPI and MIBI studies till now. The imaging assessed to determine where and to which degree the FAPI tracer and MIBI accumulate in lung tissues of patients with interstitial lung disease. Positive FAPI scan was considered as active fibrotic process and also positive MIBI scan considered as active inflammation. ***Results:*** Of eight patients, five patients showed positive FAPI scan but negative MIBI scan. One patient showed mild uptake of MIBI and also positive FAPI scan. Both scans were negative for two patients. ***Conclusion:*** FAPI scan might be considered as a promising procedure for diagnosis and monitoring of progression and therapeutic effect in ILD patients. Subsequent to the continuing evidence on the many-sided pathophysiology of ILD, there is a need for a precise approach for the management of ILD patients, especially in intractable patients using the existing treatment.

## OP-170

### The Role Of [$^{99m}$Tc] Sodium Pertechnetate Pulmonary Ventilation Single Photon Emission Computed Tomography/Computed Tomography (Spect/Ct) In The Early Location Of Prolonged Pulmonary Air Lack In Adults. Our Experience.

***A. Peñaherrera Cepeda****, F. Gómez Caminero, J. Villanueva Curto, J. Badell Martínez, E. Campaña Díaz, P. García Talavera, E. Martín Gómez, S. Rama Alonso, M. Fuentes Gago., P. Tamayo Alonso;*
*Complejo asistencial universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** To evaluate the role of [99mtc] sodium pertechnetate pulmonary ventilation single photon emission computed tomography/computed tomography (SPECT/CT) in the early location of prolonged pulmonary air lack in adults to guide de surgical approach. ***Materials and Methods:*** Twenty two patients referred from the Thoracic Surgery Department (5 females; 17 males), mean age 64 +/- 13 years, with prolonged pulmonary air leak (greater than 5 days) were evaluated during February 2021 to March 2023. They were studied by pulmonary ventilation SPECT/CT for pre-surgical localisation of the air leak. All of them underwent a mixed morphofunctional tomographic study after a mean dose of 571.10 MBq with [$^{99m}$Tc] sodium pertechnetate, administered thanks to the Technegas® system. ***Results:*** Nineteen of the 22 SPECT/CT studies were positive and useful for the exact anatomical localisation of the peripheral air leak, 68% of which were in the upper lobes. Eighteen of these 19 patients underwent surgery, most of them with atypical segmentectomy of the lobe indicated by this technique, with immediate resolution of the pneumothorax in 100% of the operated patients. These patients were discharged 24 hours after surgery, compared to the patients who could not be operated (4 patients, 3 because the leakage point could not be located by this technique and 1 because it was not surgically accessible), who had prolonged hospital stays of up to 21 days in one of them. ***Conclusion:*** The [99mTc] sodium pertechnetate pulmonary ventilation SPECT/CT hybrid imaging, allows a very efficient localisation of pulmonary air leaks, thus allowing the correct surgical approach, minimising possible risks, guiding the surgeon to the exact location of the leak and reducing operating room time and hospital stay.

## OP-171

### Oropharyngoesophageal scintigraphy (OPES) in Systemic Sclerosis Patients: A Valuable Tool for Evaluating Dysphagia

***A. Marciano***[1], *M. Di Battista*[2], *M. Scarpuzza*[1], *A. Ambrogio*[1], *G. Nonne*[1], *A. Leo*[1], *E. Esposito*[1], *A. Valevich*[2], *M. Grosso*[1], *D. Volterrani*[1];
[1]*Nuclear Medicine, Department of Translational Research and New Technology in Medicine, University of Pisa, Pisa, ITALY,* [2]*Rheumatology Unit, University of Pisa, Pisa, ITALY.*

***Aim/Introduction:*** Evaluate the performance of oropharyngoesophageal scintigraphy (OPES) in assessing oropharyngeal and esophageal motility in patients with systemic sclerosis (SSc), both with and without dysphagia. ***Materials and Methods:*** The study enrolled adult SSc patients (129 patients, 87.7% female, mean age 57±16 years, median time from diagnosis 4.65 years) who underwent OPES. OPES was performed with both liquid and semisolid boluses (6 boluses) labelled with of $^{99m}$Tc nanocolloid and provided information on oropharyngeal transit time (OPTT), esophageal transit time (ETT), oropharyngeal retention index (OPRI), esophageal retention index (ERI), and site of bolus retention. ***Results:*** OPES identified at least one anomaly in 98%

of patients, and the results were generally worse for the semisolid bolus. Esophageal motility was widely impaired, with 78.9% of patients showing an increased ERI for the semisolid bolus, and the middle-lower esophagus was the most frequent site of bolus retention (57.3%). Although not statistically significant, there were increased retention indices in the male population. Oropharyngeal impairment was highlighted by widespread increased OPRI, especially for the semisolid bolus (96.1%). Considering only patients without a history of dysphagia at the examination (48 patients, 79.1% female, mean age 56±18 years, mean time from diagnosis 3 years), OPES identified at least one anomaly in 95.8% of patients, showing a similar distribution of anomalies to the whole population examined. Although dysphagic patients showed a higher median ERI (for the semisolid boluses) than those without a history of dysphagia, the difference is not statistically significant (p=0.061). ***Conclusion:*** In SSc patients OPES revealed similar alterations of the oropharingoesophageal motility in patients with and without history of dysphagia showing a marked SSc esophageal impairment, with slowed transit time and increased bolus retention. These findings suggest that OPES can provide valuable insights into dysphagia in systemic sclerosis patients and may aid in the early diagnosis and management of this pathology.

## OP-172

**Correlation Between Lymphoscintigraphy And Clinical Staging In Diagnosis Of Lymphedema**

***A. Kilicaslan***, *B. Okudan Tekin;*
*Ankara City Hospital, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Appropriate diagnosis, staging, and selection of the best treatment of patients with extremity lymphedema are essential for patient management. Lymphoscintigraphy is still accepted as the gold standard imaging method for the diagnosis of lymphedema (1-3). In this study, we aimed to retrospectively evaluate the staging of Lymphedema with lymphoscintigraphy findings and their compatibility with clinical practice. ***Materials and Methods:*** 131 patients who underwent lymphoscintigraphy imaging in our clinic between 2021 and 2023 with a preliminary diagnosis of lymphedema were included. Lymphoscintigraphies were re-evaluated retrospectively by two different physicians without clinical knowledge. For lymphoscintigraphy staging, normal lymphatic flow, the number of multi and/or dilated channels, transition to proximal lymph nodes, presence of deep lymph nodes and dermal-backflow were evaluated. Lymphoscintigraphies were classified between normal and Grade I-IV according to the criteria of "An Atlas of Clinical Nuclear Medicine". Statistical analysis was performed using Chi-Square and Kendalls tau tests in the IBM SPSS 26 program. ***Results:*** 59 of the patients were male and 72 were female. The median age was 62 years. In the clinical staging, 41 (31.2%) of the patients were stage 1, 66 (50.4%) stage 2, and 24 (8.4%) stage 3. In the lymphoscintigraphy evaluation, 41 (31%) of the patients were found to be scintigraphically normal. In the clinical staging of the patients who were evaluated as normal scintigraphically, 36 (87.8%) were stage 1, 6 (14.6%) were stage 2 and 3 (7.3%) were stage 3. In lymphoscintigraphy staging, a positive correlation was found between both readers (correlation coefficient for right and left: 0.87; 0.89, respectively). A positive correlation was found between the staging of both readers and the clinical staging ($P<0.05$). Among the readers, a positive correlation was found between reduced transition to proximal lymph nodes, multichannel lymphatic flow, dermal-backflow and clinical staging ($p<0.05$). However, no positive correlation was found between deep lymph nodes and clinical staging ($p>0.05$). ***Conclusion:*** There is a clinical correlation with the presence of decreased passage to proximal lymph nodes, multichannel and/or dilated lymphatic duct, and dermal-backflow. According to the results of our study, we think that lymphoscintigraphy, which is accepted as the gold standard in the literature in the diagnosis and follow-up of lymphedema, is an important auxiliary technique in patient management, as a reproducible and objective evaluation criterion.

**Role of scintigraphy in the staging of necrotizing otitis externa in diabetics**

***T. Ben Ghachem***, *R. Ghodhbane, L. Zaabar, I. Slim, A. Mhiri;*
*Salah Azaiez Institute, Tunis, TUNISIA.*

***Aim/Introduction:*** Malignant external otitis (MEO) is a rare but serious infectious pathology which develops from the external auditory canal, and which occurs mainly in diabetic subjects. The aim of our study is to determine the interest of bone scintigraphy with 99mTc-MDP in the diagnosis and assessment of extension of MEO.

***Materials and Methods:*** We report a retrospective study of 21 diabetic patients, collected over a 10-year period (2009-2019), referred for extension assessment of a confirmed MEO. The average age is 66.5 years with extremes ranging from 52 to 87 years. All subjects underwent a 99mTc-MDP bone scan with early and late skull-centered static image acquisition, a whole-body scan at 120 minutes, and a skull-centered tomoscintigraphy coupled with CT scan (SPECT/CT) scan. ***Results:*** Among the 21 diabetic subjects, 18 were insulin-requiring (71.4%). The diabetes was relatively unbalanced with an HbA1C between 8 and 10%. Bone scintigraphy with 99mTc-MDP was positive in 15 cases and negative in 6 cases. Extension to surrounding bony structures was found in 12 patients. This extension was present at the level of the temporomandibular joint in 1 case, of the petrous bone in 3 cases, of the mastoid in 3 cases and extended to the mastoid and the petrous bone in 5 cases. ***Conclusion:*** Bone scintigraphy with 99mTc-MDP is considered the examination of choice for the early diagnosis of MEO. It allows to make the initial assessment to know the degree of extension to the neighboring bone structures. SPECT/CT significantly improved its specificity.

## EPS-043

### A promising tool for excluding knee and hip prosthetic infection with a novel semiquantitative index in double-phase bone scintigraphy

***R. Zambrano Infantino****, J. Piñerúa-Gonsálves, F. Sebastian Palacid, N. Álvarez Mena, M. Alonso Rodríguez, M. García Aragón, B. Pérez López, C. Gamazo Laherran, M. González Soto, R. Ruano Pérez;*
*Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** Pain following hip and knee arthroplasty is a frequent issue, with aseptic loosening and prosthetic joint infection as the leading causes. Distinguishing between these conditions promptly is essential, as their treatment approaches differ significantly. This study aims to assess the accuracy of the Blood Pool Ratio-Delayed Ratio variation index in semiquantitative analysis of double-phase bone scintigraphy as a tool for the diagnosis of prosthetic joint infection in the hip and knee. ***Materials and Methods:*** A retrospective study was performed, including patients who underwent surgical intervention for suspected knee and hip prosthetic infection. A semiquantitative analysis was performed on planar images obtained from double-phase bone scintigraphy (blood pool and delayed phase) following the administration of 99mTc-hydroxymethylene-diphosphonate (99mTc-HMDP). In the blood pool phase, a region of interest (ROI) was placed on the affected area, and a corresponding position in the contralateral joint was selected as the control area. The Blood Pool ratio (BPr) was obtained by calculating the ratio between the two areas. Subsequently, the ROI was applied to the same areas in the delayed phase to determine the Delayed Ratio (Dr). The BPr-Dr variation index was calculated as [(Dr - BPr) / BPr] x 100. The results were compared with the culture and/or presence of intraoperative purulent joint fluid, and the accuracy of the semi-quantitative analysis was evaluated using ROC analysis. The Youden index was used to determine the optimal cut-off point of the BPr-Dr variation index for predicting infection. ***Results:*** Forty-seven patients with suspected prosthetic joint infection were included in the study. The semiquantitative analysis showed moderate model performance, with an area under the curve of 0.76 (95% CI 0.58-0.94). The optimal cut-off point for predicting prosthetic joint infection was an increase of 20.6% of the BPr-Dr index, with a sensitivity of 75.0%, specificity of 71.4%, negative predictive value of 89.9%, and positive predictive value of 47.3%. ***Conclusion:*** The proposed semiquantitative method appears to be a useful tool for excluding knee and hip prosthetic infection due to its high negative predictive value, which could potentially reduce the need for other tests such as scintigraphy with labeled autologous leukocytes. ***References:*** 1. Quartuccio N, Panareo S, Urso L, Sturiale L, et al. Initial results of the use of a novel semiquantitative parameter in three-phase bone scan to predict 99mTc-HMPAO-labeled leukocyte scintigraphy in patients with unilateral total knee replacement. ## EPS-044

### Assessment of disease severity in Sjögren's syndrome using semi- quantitative parameters on salivary gland scintigraphy.

***T. Singhal****, P. Singh, A. Rehman, K. Kandula, G. Parida, P. Kumar, K. Bishnoi, R. Emerson, S. Patro, K. Agrawal;*
*AIIMS Bhubaneswar, Bhubaneswar, INDIA.*

***Aim/Introduction:*** Sjögren's syndrome(SS) is a chronic autoimmune disease characterized by lymphocytic infiltration and destruction of exocrine glands. SS characteristically involves salivary glands with presence of xerostomia in majority (>93%) of patients. Severity of xerostomia can vary from mild to severe and debilitating. Labial histopathology and ANA are commonly used in diagnosis of SS but do not corelate well with disease severity. Tests available for objective assessment of disease severity include sialometry and salivary gland scintigraphy (SGS) (1). This study aims to correlate severity of xerostomia with semi-quantitative parameters on SGS. ***Materials and Methods:*** Sixty-one patients with diagnosis of SS who underwent SGS were analyzed. Based on clinical symptoms, the severity of xerostomia was graded into mild, moderate and severe. Semi-quantitative parameters (maximum uptake and excretion fractions(EFs)) for all salivary glands were calculated on SGS. Pearson's correlation coefficients were calculated to assess correlation with clinical disease severity. Also, correlation between ANA and disease severity was evaluated, when available(n=38). ***Results:*** Sixty-one patients (47 females and 14 males) with median age of 41 years (Range: 4-85y) were included. Of these, 38 had mild, 17 had moderate, while only 6 had severe disease. Mean values of SGS parameters are described in Table1 which were highest in mild and lowest in severe disease group ($p<0.05$). Pearson's correlation coefficient for left and right parotids & left and right submandibular glands EFs with disease severity were -.304, -.331, -.360 and -.365, respectively ($p<0.05$). Correlation coefficient for maximum uptake with disease severity were -.361, -.385, -.258 and -.221, respectively. The EFs showed significant negative correlation with disease severity while maximum uptake showed significant negative correlation for bilateral parotid and left submandibular gland. No significant correlation of ANA with disease severity was noted. ***Conclusion:*** Semi-quantitative parameters on SGS show reduction with increase in severity of xerostomia. Additionally, maximum uptake and EFs correlated well with severity of xerostomia of SS, whereas ANA levels showed no significant correlation with disease severity. SGS can serve as an objective parameter of clinical severity of xerostomia, which is otherwise difficult to determine clinically. ***References:*** 1. Chen YC, Chen HY, Hsu CH. Recent Advances in Salivary Scintigraphic Evaluation of Salivary Gland Function. Diagnostics (Basel). 2021 Jun 28;11(7):1173.

## EPS-045

### Oral Gallium -67 citrate Scintigraphy as a new highlighter for guided biopsiescolonoscopy in Inflammatory bowel disease.

***J. Calegaro***[1], *J. Tajra*[1,2], *J. Tajra*[3];
[1]*Secretaria de Estado de Saúde, Brasília, BRAZIL,*
[2]*Hospital de Base do Distrito Federal, Brasilia, BRAZIL,*
[3]*Centro Universitário UNIEURO, Brasília, BRAZIL.*

***Aim/Introduction:*** Histologic remission has been added prognostic information in Crohn´s disease, however colonoscopy randomized biopsies had a doubt results. AIM: this study analyzes the useful of oral gallium as a new highlighter for hot spot activity at guided biopsies by colonoscopy. ***Materials and Methods:*** This is a prospective study with 41 Crohn's disease treated patients in follow up treatment from 2016 to 2022. The patients underwent digestive transit studies with 67-Gallium Citrate (300uCi) after oral ingestion of 10 ml of water. The radionuclide protocols were performed at 1, 6, 12, 24, 48 and 72 h. A total of 20 patients were submitted to colonoscopy with randomized biopsies and 21 patients were underwent to colonoscopy guided biopsies with oral 67-gallium scintigraphy. The sample was evaluated by yearly SES-CD endoscopic score (mucosal healing for SES-CD<2). GHAS histologic score was used as referent test (remission for GHAS<4). Values of receiver operating characteristic (ROC) curve were obtained and compared. Significance test level was 0,05. ***Results:*** The population included 41 patients (13 men; 28 women); average age was 37,9; illness time was 4,48 years. In patients with mucosal healing (39%), there were 68% of histological activity identifiedwith sensitivity of 57% and specificity of 45% by oral $^{67}$Ga scintigraphy group. In the randomized biopsies group, there were 27% with mucosal healing and 45% of histological activity. Biopsies guided by oral $^{67}$Ga has a Mann-Whitney test with p =0,03. ***Conclusion:*** Oral $^{67}$Ga scintigraphy may be a useful and inexpensive test for guided biopsies in Crohn´s disease patients particularly in colonoscopies with mucosal healing. ***References:***

### Evolving Nuclear Imaging of Infection - The South African Initiative for Novel Radiopharmaceuticals

***T. Ebenhan***[1,2], *A. H. Mdlophane*[3,4], *J. Duvenhage*[1], *C. A. Grouws*[5,1], *M. Kaths-Lundie*[6], *O. Gheysens*[7], *T. Govender*[8,3], *T. Naicker*[5,3], *H. G. Kruger*[5], *J. Zeevaart*[4,2,3], *M. M. Sathekge*[3,9];
[1]*Preclinical Imaging Facility, Nuclear Medicine Reseach Infrastructure NPC, Pretoria, SOUTH AFRICA,* [2]*Nuclear Medicine, University of Pretoria, Pretoria, SOUTH AFRICA,* [3]*Nuclear Medicine Reseach Infrastructure NPC, Pretoria, SOUTH AFRICA,* [4]*Radiochemistry, Necsa, Pelindaba, SOUTH AFRICA,* [5]*Catalysis and Peptide Research Unit, University of KwaZulu Natal, Durban, SOUTH AFRICA,* [6]*Radiochemistry, Sefako Makgatho Health Science University, Pretoria, SOUTH AFRICA,* [7]*Department of Nuclear Medicine, Cliniques Universitaires Saint- Luc, and Institute of Clinical and Experimental Research, Université Catholique de Louvain, Leuven, BELGIUM,* [8]*Department of Chemistry, University of Zululand, KwaDlangezwa, SOUTH AFRICA,* [9]*Nuclear Medicine and Steve Biko Academic Hospital, University of Pretoria, Pretoria, SOUTH AFRICA.*

***Aim/Introduction:*** Positron emission tomography/computed tomography imaging has made remarkable inroads as a technique to advance diagnostics and monitoring of infectious diseases. Currently, the diagnostic toolbox of routine tracers includes metabolic imaging using [$^{18}$F]FDG or [$^{67/68}$Ga]citrate, imaging host response to infection using radiolabeled blood elements / radiolabeled antibodies. However, the initial diagnosis or specific therapy monitoring can be elaborate due to limited capabilities of available radiopharmaceuticals to decipher sterile inflammatory processes from active infection. With South Africa tracking an almost 20-year record of clinical research in utilizing [$^{18}$F]FDG-/[$^{68}$Ga]Ga-citrate-PET/CT imaging to battle various infection, a preclinical research program to develop more pathogen-specific PET-imaging agents has been in focus since 2014. This work will highlight the different strategies to advance novel radiopharmaceuticals for PET-imaging of infectious diseases. ***Materials and Methods:*** Better understanding of the more intricate infectious diseases, such as tuberculosis, MRSA, or malaria sparked an emergence of innovative, more-selective ligands with known targeting mechanism. Small molecules (A-EK, DnL, TB-Sid), antibiotics (DBI1-16, Purm) and peptide derivatives (UBI29-41, TBAI101, LL-37, CP1-3, Ph1, a-H8, PD-P1/-C1) were labelled with either copper-64 or gallium-68. The antibody (Ab) Pf-BII-6, the Ab-fragment Pf-McG45 and specific blood-derived elements (LE, PISC) were labelled with zirconium-89. Radiochemical synthesis and characterization as well as a preclinical assessment addresses tracer selectivity, accuracy and sensitivity to pursue with more disease-specific in vivo investigations. ***Results:*** A radiolabeling strategy developed for [$^{68}$Ga]Ga-UBI29-41 was further tailored for subsequent peptide-based molecules (or small molecules) thereby achieving >95% radiochemical purity and now undergoing full characterization during their preclinical assessment (except for LL-37). Promising results from radio-characterization suggesting [$^{68}$Ga]Ga-CDPx, -DnL, -Ph1, -a-H8 as candidates for more disease-specific in vivo imaging investigations. Facile radiolabeling, tracer inertness and favorable PET/CT imaging-guided pharmacokinetics motivates for [$^{89}$Zr] Pf-McG45 to become relevant for preclinical, malaria-specific applications. ***Conclusion:*** The stages of radiopharmaceutical research for various potential infection PET-imaging agents are presented. By meeting the requirement for infection imaging, Ga-68-labeled UBI29-41, -Purm and -CDPx are suited for potential translation to the clinical nuclear medicine setting whereas [$^{89}$Zr] Zr-Pf-McG45 based PET/CT imaging can become a preclinical biomarker tool to support antimalarial drug development. Using radiolabeled molecules with known predetermined functionalities, e.g., a bacteria-specific mechanism of action or targets may better facilitate diagnosis of infection or allow fast-tracking current antimicrobial drug development. However, based on this experience, future radiopharmaceutical development should give better attention to specific molecule design that meets the rather unique requirements of an infection imaging agent.

## EPS-047

### The Importance of FDG PET/CT in the Diagnosis of Left Ventricular Asist Device Infection

***Y. Okar***, *I. Sezgin, R. Horal, M. Urhan, B. Akkas;*
*Sultan Abdulhamid Han Training and Research Hospital, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Pre-transplant LVAD (left ventricular assist device) is a very important treatment approach in patients with end-stage heart failure. However, infection of the LVAD device is a condition that can result in high morbidity and mortality. In the presence of suspected infection, laboratory tests, blood culture and thorax X-ray, thorax CT, USG can be performed. These methods are insufficient in imaging LVAD device infections. Gram staining and culture of the LVAD device are recommended for the definitive

diagnosis of the presence of infection. In this study, our aim is to evaluate the success of FDG PET/CT in imaging the presence and extent of infection in patients with suspected LVAD infection. ***Materials and Methods:*** Twelve male patients(age:30-60) who applied to our clinic with the suspicion of LVAD infection between 2019-2023 were evaluated retrospectively. The pump part of the LVAD located in the intrathoracic area and the circumference of the intrathoracic and abdominal parts of the drive line were evaluated visually and semiquantitatively on PET/CT images. Areas with increased FDG uptake were confirmed with NAC (non attenuation correction) images and recorded as positive uptake. The definitive diagnosis of LVAD infection was decided based on the results of microbiological analysis (Table 1). ***Results:*** In PET/CT, 9/12(75%) patients were true positive, 2/12(17%) patients were true negative, 1/12(8%) patients were false positive was detected (table 1).Staphylococcus aureus and Pseudomonas aeuroginosa pathogens were grown in the microbiological evaluation of drive line exit site. Clinical and laboratory results of patients (9/12) who were found to be true positive in PET/CT strongly suggested the presence of LVAD infection. In true negative patients (2/12) laboratory values were normal and there was no growth in the culture. Laboratory results of the patient(1/12), whose result was false positive, were normal and there was no growth in the culture. All components of the device were replaced in 2 patients with involvement in the pump parts of the LVAD. Seven patients who showed involvement in favor of drive line infection on PET/CT were considered responsive to treatment because their clinical and laboratory values returned to normal after antibiotic treatment and there was no growth in the control culture. Sensitivity:100%, specificity:66%, PPV:90%, NPV:100% were calculated. ***Conclusion:*** In the presence of high clinical and laboratory suspicion of infection in LVAD device infection, PET/CT has a high advantage in demonstrating the presence and extent of infection.

## EPS-048

### Clinical Value and Utility of the $^{18}$F-FDG PET/CT in Detecting Prosthetic Infection After the Aortic Valve and Thoracic Aorta Reconstruction.

***V. Carrero-Vásquez***[1], *I. Sánchez-Rodríguez*[1], *F. Escrihuela-Vidal*[2], *L. Gracia-Sánchez*[1], *P. Notta*[1], *M. Pudis*[1], *S. Bondia-Bescós*[1], *A. Blasco*[3], *B. Hervas-Sanz*[1], *C. Martínez-Ramos*[1], *P. Perlaza-Jiménez*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine Department, Bellvitge University Hospital, Barcelona, SPAIN,* [2]*Infectious Diseases Department. Bellvitge University Hospital., Barcelona, SPAIN,* [3]*Cardiovascular Surgery Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** To assess the utility of 18F-FDG PET/CT in detecting infection in aortic vascular prostheses. Identify the morphometabolic characteristics that allow discerning between post-surgical inflammatory changes and the infectious process. Correlate PET/CT findings with clinical data. ***Materials and Methods:*** A retrospective descriptive study in patients undergoing reconstruction of the aortic valve and thoracic aortic artery with prosthetic devices who presented clinical suspicion of prosthetic infection and underwent an examination with 18F-FDG PET/CT for diagnostic purposes. Twelve patients were reviewed from March 2016 to December 2021. Demographic data, vascular devices, symptoms, clinical analysis, and the characteristics of the PET/CT study were studied, contrasting with the final diagnosis. ***Results:*** 12 patients (8 men) with a mean of 71 years old (53-82) were analyzed. The 2 patients that PET/CT classified as positive were true positives; 3 were classified as doubtful: 1 was positive, and the other 2 were negative. Two of those positive for endocarditis presented heterogeneous uptake; the other showed a focal uptake on the PET image. The positive patients showed a higher semiquantitative uptake index (SUVmax) in the suspicious images and a slight elevation of leukocytes compared to the negative patients. The CT identified abscesses in 2 of the 3 positive patients. The 7 patients that PET/CT classified as negative were true negatives. ***Conclusion:*** $^{18}$F-FDG PET/CT allowed us to reject all negative patients, avoiding unnecessary surgeries and prolonged courses of antibiotic therapy. It demonstrated excellent performance in the detection and localization of infectious processes. The focal uptake pattern and the abscess were the PET/CT image findings that were most associated with the diagnosis of infection.

## EPS-049

### Role of [18F]FDG PET/CT in patients with suspected ventricular assist device infection. Experience in a PET/CT dedicated cardio center.

***B. Hervás Sanz***[1], *L. M. Gràcia-Sánchez*[1], *I. E. Sánchez-Rodríguez*[1], *P. C. Notta*[1], *V. A. Carrero-Vásquez*[1], *C. Martínez-Ramos*[1], *A. Palomar-Muñoz*[1], *M. Pudis*[1], *S. Bondia-Bescós*[1], *J. L. Díaz-Moreno*[1], *C. Díez-López*[2], *J. González-Costello*[2], *L. Herrador-Galindo*[2], *F. Escrihuela-Vidal*[3], *N. Sabé-Fernández*[3], *D. Ortiz-Berbel*[4], *K. ***Aim/Introduction:*** Ventricular assist devices (VAD) are used in patients with heart failure either as bridge therapy to cardiac transplantation or as destination therapy.The aim of this study is to evaluate the usefulness and diagnostic capability of [18F]FDG PET/CT in patients carrying VADs with suspected underlying infectious processes. ***Materials and Methods:*** Retrospective descriptive study of patients (p) carrying VAD, with performance of [18F]FDG PET/CT for suspected infection between July 2018 and January 2023. Demographic data, baseline pathology, VA purpose and PET/CT findings were studied. ***Results:*** 11p (5 female, 5 male, 1 transgender female) with a mean age of 55.4 years [31-76], affected by dilated cardiomyopathy (8 ischaemic, 2 toxic secondary to chemotherapeutic treatment, 1 idiopathic) were analysed. 7p were VAD carriers as bridging therapy and 4p as destination. The reasons for requesting PET/CT were in 10p clinical suspicion of device infection and in 1p suspicion of interstitial nephritis. 5p presented PET/CT suggestive of infection (4 on driveline entry and subcutaneous tract; 1 on ventricular device and mediastinal cannulae). Microbiological analysis was performed in all of them and was positive in only 3p. Despite this, all 5p received antibiotic treatment with beta-lactams (4p with resolution of the infectious condition and 1p requiring cardiac transplantation). 1p presented a discrete increase in metabolism at the level of the subcutaneous driveline tract attributable to an inflammatory process. 5p showed no findings suggestive of infection by PET/CT and the final diagnosis was unrelated to the VAD (2p without infection and 3p with infection in locations other than the VAD). The median SUVmax of patients with extrathoracic infection (driveline entry and subcutaneous tract) was 2.5 g/ml vs. 1.36 g/ml in relation to the rest of the patients without infection.The median SUVmax of patients with intrathoracic infection was 4.99 g/ml vs. 3.6 g/ml for

the rest of the patients without infection. ***Conclusion:*** 18F]FDG PET/CT has been able to detect in our sample, in a non-invasive way, infection related to ventricular assist devices, presenting higher diagnostic yield and a high negative predictive value with respect to microbiological analysis.

## EPS-050

### Asesessment Of Splenic And Bone Hypermetabolism As Indirect Signs Of Infection/Inflammation In Patients With Suspected Infective Endocarditis Or Implantable Cardiac Device Infection.

***A. Padilla Bermejo***[1], *F. J. Pena Pardo*[1], *M. Amo Salas*[2], *M. N. Sicilia Pozo*[1], *C. Lucas Lucas*[1], *M. Contreras Ameduri*[1], *L. García Zoghby*[3], *M. Cruz Montijano*[3], *E. Noriega Álvarez*[1], *A. M. García Vicente*[3], *Á. Soriano Castrejón*[3], *M. P. Talavera Rubio*[1], *V. M. Poblete García*[1]; [1]*Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN,* [2]*Mathematics Department, Castilla la Mancha University of Ciudad Real, Ciudad Real, SPAIN,* [3]*Nuclear Medicine Department, University General Hospital of Toledo, Toledo, SPAIN.*

***Aim/Introduction:*** To determine the association of indirect signs of infection/inflammation on 18F-FDG PET/CT, such as spleen and bone marrow (BM) hypermetabolism with the diagnosis of infective endocarditis (IE), when assessed in patients with suspected IE in native valves (NV), prosthetic valves (PV) or implantable cardiac electronic device endocarditis/infection (ICEDI). ***Materials and Methods:*** Patients with suspected IE undergoing 18F-FDG PET/CT from April/2019 to January/2022 (60 min of FDG incorporation, all patients under myocardial suppression) were retrospectively included. SUVmax was determined in spleen and vertebral body of L2 for BM assessment, classifying as positive those values higher than hepatic SUVmax. The diagnosis of IE was established by a multidisciplinary team. The association of BM and/or splenic positivity with the final diagnosis of endocarditis and myocardial uptake was assessed on the overall patient group and the analysis by subgroups using Pearson's Chi-square test and exact two-tailed and asymptotic, respectively. ***Results:*** 85 patients were analysed, 34 with suspected IE in NV, 33 with IE in PV and 18 with ICEDI. IE was finally considered definite in 27 patients and 9 patients were diagnosed with device infection. In the overall patient group, the prevalence of BM hypermetabolism was 25.5% (30/85), 22.1% (26/85) in case of splenic hypermetabolism, 12.5% (15/85) of both simultaneously and 48.2% (41/85) in case of splenic and/or BM hypermetabolism. There was a statistically significant relationship between the final diagnosis of IE and increased splenic (P=0.004), BM (P=0.015) and splenic and/or BM (P=0.020) metabolism. There was no statistically significant relationship between myocardial uptake and splenic and/or BM hypermetabolism. In the subgroup analysis, the prevalence of splenic hypermetabolism was 43.75% (7/16) in definite IE and 15% (7/44) in probable IE. The prevalence of splenic hypermetabolism and BM hypermetabolism in definite IE was 37.5% (6/16). A statistically significant association was found between definite IE and splenic hypermetabolism (P=0.034) and between definite IE and BM and splenic hypermetabolism (P=0.037). ***Conclusion:*** In this cohort the presence of splenic, with or without bone marrow hypermetabolism, was related to the diagnosis of IE and may be useful as an additional indirect sign to support the suspicion of IE.

## EPS-051

### Assessment in clinical practice of the valvular uptake index with [18F]FDG-PET/CT in patients with prosthetic valve endocarditis

***S. Guzmán Ortiz****, B. Rodriguez Alfonso, K. Velásquez Díaz, I. Obedkova, M. Grajeda Gallardo;*
*Puerta de Hierro University Hospital, Madrid, SPAIN.*

***Aim/Introduction:*** The uptake pattern of infective prosthetic endocarditis (PVE) with [18F]FDG-PET/CT can be visually complex and subjective. The valvular uptake index (VUI) has been proposed to improve the diagnostic performance of qualitative analysis. Our aim was to assess the outcome of its application in clinical practice. ***Materials and Methods:*** Retrospective analysis of patients with suspected PVE with [18F]FDG-PET/cardiac CT and optimal myocardial suppression from 05/2017 to 12/2018. Quantification was performed on a VOI manually adjusted over the entire 10 mm thick valvular area, and drawn on morphometabolic fusion images in a cross-sectional projection. The VUI was calculated with the formula (SUVmax-SUVmean)/SUVmax. Cut point VUI ≥ 0.45 was suggestive of PVE. Sensitivity, specificity, PPV, NPV, accuracy, precision of visual analysis and SUV was calculated. The clinical decision of the multidisciplinary endocarditis team was considered as the reference standard. ***Results:*** Sixteen patients with suspected PVE were included. In 9 patients a definitive diagnosis of PVE was made and in 7 it was ruled out. Visual PET/CT analysis showed a sensitivity of 89%, specificity 71%, PPV 80%, NPV 83%, accuracy 81% and precision 80%. Visual PET/CT analysis in the aortic valve showed sensitivity 75%, specificity 100%, PPV 100%, NPV 71%, accuracy 85% and precision 100%. In mitral valve, sensitivity 100%, specificity 75%, PPV 80%, NPV 100%, accuracy 88% and accuracy 80%.In relation to the VUI, it presented sensitivity 100%, specificity 57%, PPV 75%, NPV 100%, accuracy 81% and precision 75%. The VUI analysis in the aortic valve showed sensitivity 88%, specificity 100%, PPV 100%, NPV 83%, accuracy 92% and precision 100%. In the mitral valve sensitivity 100%, specificity 25%, PPV 60%, NPV 100%, accurancy 63% and precision 60%.Of the 9 patients with PVE, 4 had positive PET/CT (positive VUI); 1 negative PET/CT (positive VUI) and 4 doubtful PET/CT (3 had positive VUI and 1 negative VUI). Of the 7 patients without PVE, 3 had negative PET/CT (negative VUI) and 1 doubtful PET/CT (negative VUI); 2 negative PET/CT (positive VUI) and 1 positive PET/CT (positive VUI). ***Conclusion:*** The VUI showed good performance and diagnostic accuracy, especially in the aortic prosthetic valve, and clarified the doubtful cases of visual analysis. ***References:*** 1. Roque A, Pizzi MN, Fernández-Hidalgo N, et al. The valve uptake index: improving assessment of prosthetic valve endocarditis and updating [18F]FDG PET/CT(A) imaging criteria. Eur Heart J Cardiovasc Imaging. 2022;23(9):1260-1271. doi:10.1093/ehjci/jeab279.

## EPS-052

### Utility of PET/CT with $^{18}$F-FDG for the localization of malignant and pre-malignant colorectal disease and its correlation with different microorganisms in patients studied for suspected prosthetic infective endocarditis and/or intracardiac devices.

***J. Badell****, F. Gómez-Caminero López, P. García-Talavera San Miguel, J. C. Cañadas Salazar, E. Campaña Díaz, S. López Puche, S. Rama Alonso, E. Casillas Sagrado, P. Tamayo Alonso;*
*Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** To establish the relationship between pathological $^{18}$F-FDG uptake in colon and malignant/pre-malignant colorectal disease and its association with microorganisms (enteropathogenic/non-enteropathogenic) in patients studied for suspected prosthetic infective endocarditis (IE) and/or intracardiac devices (ICD). ***Materials and Methods:*** We included 122 patients with suspected IE/DIC who were referred to our service. A PET/CT study was performed with $^{18}$F-FDG from the base of the skull to the thighs 60 minutes after intravenous administration of

$^{18}$F-FDG after myocardial suppression (diet 48-72 hours + fasting 12-18 hours + fractionated heparin at 50IU/kg). Pathological valvular foci, possible colorectal deposits and their correlation with morphological images were identified. PET/CT findings were evaluated with anatomopathological and microbiological results. ***Results:*** 84 men and 38 women (67.6 years ± 14.05 years). PET/CT detected 11 pathological deposits of $^{18}$F-FDG in colorectal location. Thirty-nine underwent colonoscopy for other indications. Of these, 8 had a normal study, 14 had benign macroscopic lesions and 17 had suspicious lesions histologically studied as benign lesions (3), pre-malignant lesions (13) and malignant lesions (1). Of the 14 pre-malignant/malignant lesions, microorganisms were detected in 8, predominantly streptococci: viridans (1), gallolyticus (1), gordonii (1), staphylococci: aureus (2), haemolyticus (1) and enterobacteria: E. coli (2). Of the 11 patients with colonic deposition on PET/CT, 6 corresponded to malignant/premalignant lesions, associated with the enterococci subgroup. ***Conclusion:*** PET/CT with $^{18}$F-FDG for IE/ICD study can identify, incidentally, colorectal uptake that correlates with malignant/premalignant lesions, especially in patients with streptococcal and enterobacterial bacteremia, so any hypermetabolic focus seen on PET/CT should be studied with colonoscopy and histologically.

## EPS-053

### The Role of [18F]FDG-PET/MRI in Patients with Large-Vessel Vasculitis

***G. Argalia***[1], *M. Fogante*[2], *G. Biscontini*[1], *F. M. Fringuelli*[1], *A. Palucci*[1], *C. Romagnolo*[1], *C. Cottignoli*[1], *N. Schicchi*[2], *P. Esposto Pirani*[2], *P. Fraticelli*[3], *L. Burroni*[1];
[1]*Nuclear Medicine, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY,* [2]*Radiology, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY,* [3]*Internal Medicine, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY.*

***Aim/Introduction:*** Investigate the role of [18F]FDG-PET/MRI in the management of patients with large vessel vasculitis (LVV), at different stages of the disease. ***Materials and Methods:*** We retrospectively enrolled all consecutive patients with LVV who underwent [18F]FDG-PET/MRI at our department from July 2022 to February 2023. Inclusion criteria were: 1) clinical diagnosis of LVV: Takayasu's arteritis, giant cell arteritis, aortitis and periaortitis and IgG4-related vasculitis; 2) [18F]FDG-PET/MRI performed at any time during the disease course (pre-therapy, during therapy and follow-up). [18F]FDG-PET/MRI scans were performed with a hybrid PET/MRI tomograph enabling simultaneous acquisition of PET and 3Tesla-MRI images. Contrast-agent was injected intravenously. Four PET/MRI patterns were defined: 1) Positive [18F]FDG-PET/MRI (vessel wall uptake equal-to or greater-than hepatic uptake) and positive contrast-agent-MRI (stenosis/wall thickening): active inflammation; 2) Negative [18F]FDG-PET/MRI and negative contrast-agent-MRI: normal; 3) Negative [18F]FDG-PET/MRI and positive contrast-agent-MRI: fibrous; 4) Positive [18F]FDG-PET/MRI and negative contrast-agent-MRI: metabolic. ***Results:*** Overall, 23 patients were included; 7 females and 16 males with a median age of 69 yrs. The sample was divided and analysed into three groups: 1) Pre-therapy (7 patients); 2) During therapy (15 patients); 3) Follow-up (1 patient). The four PET/MRI patterns are distributed as follows: pre-therapy: 3/7 active inflammation, 1/7 normal, 3/7 metabolic; during therapy: 8/15 active inflammation, 1/15 normal, 4/15 fibrous, 2/15 metabolic; follow-up: 1/1 fibrous. PET/MRI was able to evaluate the anatomical alterations of the vessel wall and the metabolic ones allowing, pre-therapy, an early assessment (often the metabolic alteration precedes the anatomical one); during therapy an accurate evaluation of its effectiveness (and its possible modification) distinguishing between active inflammation and fibrosis and in follow-up a possible relapse of the disease in patients with vessel walls' alterations. ***Conclusion:*** [18F]FDG-PET/MRI with contrast-agent can be useful in different phases of the clinical history of LVV. The two most important purposes of the examination were the metabolic evaluation of the disease and the exact localization of the anatomical vascular damage. The multidisciplinary approach and the fact that the two most important exams for LVV assessment are performed synchronously makes the [18F]FDG-PET/MRI with contrast-agent a very accurate exam. According to our preliminary results the [18F]FDG-PET/MRI could play a role in the management of patients with LVV.

## EPS-054

### Role of 18F-FDG PET/CT in patients with Hemophagocytic lymphohistiocytosis (HLH)

***R. Goel***, *K. Chandekar, N. A. Damle, Y. Dharmashaktu, C. Bal, R. Kumar, M. Tripathi, P. Kumar;*
*All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.*

***Aim/Introduction:*** Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening, multi-organ disorder caused by immune system dysregulation and characterized by fever, hepatosplenomegaly, cytopenias, and progressive multiple-organ failure. HLH is often secondary to autoimmune diseases, cancers (most commonly lymphoid cancers and leukemias), or infections in contrast to familial HLH[1]. This study aims to evaluate the role of 18F-FDG PET/CT in patients with a clinical suspicion of HLH ***Materials and Methods:*** We retrospectively reviewed data of 12 patients(2 female, 10 males; age 4-52 years) with a clinical suspicion of HLH by HLH-2004 criteria[2] referred from the medicine department of our tertiary care hospital between January 2018 to April 2023. All patients underwent 18F-FDG PET/CT to identify the possible trigger for HLH and were correlated with histopathology. ***Results:*** 10/12 (83.4%) patients were found to have anemia, 11/12(91.6%) had thrombocytopenia, 6/12(54.5%) had hypertriglyceridemia. Elevated levels of ferritin were found in 10/12 (83.4%) patients. On PET/CT images, splenomegaly was found in 6 (50%) patients, out of which 5 (83.4%) had diffusely increased FDG uptake and 1(16.6 %) showed focal splenic lesions. Hepatomegaly was observed in 4/12(33.4%) patients. Diffuse bone marrow uptake in the visualized skeleton was seen in 5/12(41.6 %) patients and 2/12 (16.6%) patients showed focal increased FDG uptake in marrow. Lymphadenopathy with increased FDG uptake was seen in 7(58.3 %) patients and all had involvement of two or more nodal groups. Based on scan findings suspicious for lymphoma/leukemia, histopathological correlation was advised for 8/12 (66.7 %) patients. Of these, histopathological reports of 5/8 (62.5%) patients were positive for malignancy [HL:3 (60%), Leukemia:1 (20%), B cell lymphoma:1 (20%)] whereas histopathological reports of 3/8 (37.5%) patients did not reveal any malignancy. PET/CT images of 4/12 (33.3%) patients did not reveal any findings suggestive of underlying malignancy. ***Conclusion:*** 18F FDG PET/CT was able to correctly detect haematolymphoid malignancy in 5/12 (41.6%) patients and accurately rule it out in 4/12 (33.3%) patients, thereby benefitting 9/12 (75%) patients with clinical suspicion of HLH. Thus, it is helpful for identifying the possible trigger (particularly malignant disease), extent of disease in secondary HLH and aids in guiding site for biopsy. However, more studies on a larger patient population are required to

validate the same. ***References:*** 1.Fisman DN. Hemophagocytic syndromes and infection. Emerg Infect Dis. 2000;6(6):601-8. 2.Henter J-I, Horne A, Aricó M, Egeler RM, Filipovich AH, Imashuku S, et al. HLH-2004: Diagnostic and therapeutic guidelines for hemophagocytic lymphohistiocytosis. ## EPS-055

### Establishing The Ideal Time Point In Imaging Patients With $^{99m}$Tc-Ethambutol Scintigraphy In Extrapulmonary Tuberculosis

***D. Khan***, *N. A. Damle, S. Sagar, A. Ghazal, V. Tiwari, C. Bal, M. Tripathi, S. Sikdar, P. Ranjan, V. Manhas, P. Kumar;*
*AIIMS Delhi, Delhi, INDIA.*

***Aim/Introduction:*** Tc99m labelled ethambutol (EMB) is a non-invasive modality to image tuberculosis, however there is scarce literature to suggest optimal scan time, resulting in few serial images till 6-24 hours. We aimed to identify ideal time point for imaging of tubercular lesions in Tc99m ethambutolscintigraphy in order to reduce number of scans acquired to single time point. ***Materials and Methods:*** We prospectively studied 24 tuberculosis (20 confirmed, 4 suspected) over 1 year in our center. Patients were injected with 10mCi of radiolabelled 99mTc-ethambutol and serial whole-body scans were acquired on SPECT/CT gamma camera. Scans were acquired as 5 min dynamic and static images over 15, 30 and 45 min and 1,2,4 ,6,12 and 24 hrs. We attempted to acquire atleast 4 sets ofimages. SPECT/CT scan was acquired at time of peak uptake in known pathologic lesion. Any abnormal focus of uptake outside known normal biodistribution of the drug was considered positive. ***Results:*** Mean age of patients was 39.7±13.2 with 11 male and 13 female patients. Ethambutol (EMB) was successfully labelled with 99mTc with a mean labelling efficiency of 95±1.5%(n=24) with optimal QC. In 20 clinically diagnosed patients, 16 had bone (80%), 2 lymph nodal(10%) and 2 had abdominal TB(10%) .Out of 16 patients with bone TB, 6 patients had spinal TB, 1 had sternal TB, 5 had Knee TB, 1 had elbow, 2 had hip TB and 1 had femoral TB. Ideal time points for imaging of tubercular lesions using EMB scan were assessed visually and quantitively. On visual analysis, 9 out of 20 (45%) patients showed ideal time point at 45 min post injection of 99mTc-EMB. Rest of the patients showed optimal uptake with adequate background clearance at 1 hr(5/20,25%), 2hr (4/20,20%) and 4 hr (2/20, 10%) post injection. Quantitative analysis was done by calculating lesion to background ratios (LBR) over serial time point images. Region of interests (ROI) were drawn over lesion and liver (background). We found that in 20 positive cases, highest mean LBR ratios was 3.3±2.8 obtained at 1 hr image post injection with significant p value of 0.008($p<0.05$) using Kruskal Wallis Test. ***Conclusion:*** Ideal time point for 99mTc-EMB scintigraphy evaluated through qualitative and quantitative analysis for visualization of bone lesions in tuberculosis is 45-60 minutes after injection of 99mTc-Ethambutol and a single whole body image acquired at this time point appears sufficient for evaluation of tubercular lesions.

## EPS-056

### $^{18}$F-FDG PET/CT metabolic parameters as predictors of immune status and disease severity in the patients with non-tuberculous mycobacteria

***D. Chen***[1], *Y. Chen*[2], *S. Yang*[1], *T. Li*[1], *K. Liu*[1], *Z. Wang*[1], *T. Zhang*[1], *G. Wang*[1], *K. Zhao*[1], *X. Su*[1];
[1]*Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA,* [2]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, CHINA.*

***Aim/Introduction:*** Non-tuberculous mycobacteria (NTM) infection is an increasing health problem due to delaying an effective treatment. The decision of therapy strategy relies strongly on the immune status, extent of lesion involvement, and disease severity in NTM patients. However, there is very little data on the use of imaging methods including $^{18}$F-FDG PET/CT for predicting these risk factors of NTM treatment. Herein, the aim of the present study was to investigate predictive value of $^{18}$F-FDG PET/CT for evaluating immune status, extent of lesion involvement and disease severity in NTM patients. ***Materials and Methods:*** A total of 23 patients with confirmed diagnosis of NTM infection who underwent $^{18}$F-FDG PET/CT imaging were analyzed retrospectively. The clinical data, including the patients' immune status, lesion distribution, severity of NTM pulmonary disease (NTM-PD), clinical manifestation, and laboratory examination, and $^{18}$F-FDG PET/CT imaging characteristics were reviewed. $^{18}$F-FDG PET/CT images were analyzed visually and semi-quantitatively by measuring maximum standardized uptake value ($SUV_{max}$), $SUV_{max}$ of the most FDG-avid lesion ($SUV_{Top}$), the most FDG-avid lesion-to-liver $SUV_{max}$ ratio ($SUR_{Liver}$) , the most FDG-avid lesion-to-blood pool $SUV_{max}$ ratio ($SUR_{Blood}$), metabolic lesion volume (MLV) and total lesion glycolysis (TLG).The optimal cut-off of $^{18}$F-FDG was determined using receiver operating characteristic curve (ROC). ***Results:*** Of the 23 patients with NTM infection, there were 6 patients (26.09%) with localized pulmonary diseases and 17 patients (73.91%) with disseminated diseases. Moreover, among these patients, there were a total of 22 cases with lung involvement, 17 cases with extra-pulmonary involvement. These involved lesions had high or moderate $^{18}$F-FDG uptake (median $SUV_{Top}$: 8.2±5.7). For the patients' immune status, the median $SUV_{Top}$ in immunocompromised and immunocompetent patients was 10.0 and 5.2, and the difference was significant (P=0.038). As for the distribution of NTM lesions, $SUR_{Liver}$ and $SUR_{Blood}$ in localized pulmonary and disseminated diseases were 1.9 vs.3.8, and 2.7 vs. 5.5, respectively, with significant difference (P=0.016 and 0.026). Moreover, For the severity of NTM-PD, $SUV_{max}$ of lung lesion ($SUV_{l\text{-}lung}$), $SUV_{max}$ of marrow ($SUV_{Marrow}$), platelet count in the severe group were 7.7, 4.4, and 314.0±119.3×$10^9$/L, respectively, and significantly higher than those in the non-severe group (4.3, 2.4 and 194.3±73.1×$10^9$/L) (P= 0.027, 0.036 and 0.003). ***Conclusion:*** $^{18}$F-FDG PET/CT is a unique and powerful tool in the diagnosis, evaluation of lesion activity, immune status and extent of lesion involvement in the NTM patients and can contribute to planning the appropriate treatment of NTM.

## EPS-057

### Correlation of Total Lesion Glycolysis with Inflammatory and Immune Biomarkers in Talaromyces Marneffei Infection Patients: A Cross-sectional and Longitudinal FDG PET/CT Study

***W. Bao***[1], *X. Zhang*[1], *Q. Huang*[1], *S. Ren*[1], *F. Hua*[2], *C. Zuo*[1], *F. Xie*[1], *Y. Guan*[1];
[1]*Huashan Hospital, Shanghai, CHINA,*
[2]*Longhua Hospital, Shanghai, CHINA.*

***Aim/Introduction:*** Talaromyces marneffei (T. marneffei) is an emerging opportunistic fungal infection, particularly affecting immunocompromised patients. Accurate evaluation of disease activity and response to treatment is essential for optimal patient management. This study aims to investigate the correlation between total lesion glycolysis (TLG) derived from FDG PET/CT and inflammatory and immune biomarkers in patients with T. marneffei infection. Additionally, the study provides a longitudinal assessment of these parameters, including three post-treatment follow-ups, to evaluate the potential of TLG as a non-invasive imaging biomarker for disease monitoring and treatment response evaluation. ***Materials and Methods:*** Eighteen patients diagnosed with T. marneffei infection underwent a baseline FDG PET/CT scan, out of which three had follow-up scans after the initiation of treatment. Quantitative PET parameters, including TLG, were obtained from each lesion group. Inflammatory and immune biomarkers, such as CRP, ESR, and IgG level, were collected concurrently with imaging. Pearson correlation coefficients were calculated to assess the relationship between TLG and biomarkers at baseline and follow-up time points. Paired t-tests were performed to evaluate the changes in TLG and biomarkers between the baseline and follow-up scans for the three patients with follow-up data. ***Results:*** At baseline, significant correlations were observed between TLG and inflammatory and immune biomarkers (CRP, ESR, and CD4+ T-cell counts) in the 18 patients (CRP: r=0.66, p=0.001; ESR: r=0.83, p<0.001; IgG level: r=0.80, p<0.001). In the three patients with follow-up data, paired t-tests demonstrated significant changes in TLG ($t(2) = 4.92$, p<0.001) and biomarker levels between the baseline and post-treatment scans (CRP: $t(2) = 5.41$, p<0.001; ESR: $t(2) = 6.23$, p<0.001; IgG level: $t(2) = 4.87$, p<0.001). These changes suggest a strong association between TLG and the patients' response to treatment, as evidenced by the alterations in inflammatory and immune biomarker levels. ***Conclusion:*** This study demonstrates a significant correlation between TLG derived from FDG PET/CT and inflammatory and immune biomarkers in patients with Talaromyces marneffei infection. The results also suggest that TLG may serve as a potential non-invasive imaging biomarker for disease monitoring and treatment response evaluation in these patients. The findings, however, are limited by the small number of patients with follow-up data. Further studies with larger cohorts and multiple follow-up time points are needed to confirm the utility of TLG in evaluating disease progression and response to therapy in Talaromyces marneffei infection.

## EPS-058

### Head-to-head comparison of $^{18}$F-FDG PET and labelled leucocyte scintigraphy for the monitoring of treatment response in malignant external otitis

***S. Melki***[1], *M. Hurstel*[1], *A. Vasseur*[2], *D. Nguyen*[2], *C. Rumeau*[2], *A. Verger*[1,3];
[1]*Department of Nuclear Medicine and Nancyclotep, University Hospital of Nancy, Nancy, FRANCE,* [2]*Department of ENT, University Hospital of Nancy, Nancy, FRANCE,* [3]*IADI, INSERM, UMR 1254, Université de Lorraine, 54000, Nancy, FRANCE.*

***Aim/Introduction:*** Malignant external otitis (MEO) is a rare disease associated with high morbidity-mortality, with no currently available consensus concerning the imaging modality to apply to assess the treatment response. The aim of this study is to directly compare the diagnostic performances of $^{18}$F-FDG PET and labelled leucocyte scintigraphy (LS) for the monitoring of treatment response in MEO ***Materials and Methods:*** Consecutive patients with MEO performed a $^{18}$F-FDG PET scan, at least one week after the end of antibiotic therapy, as well as planar and SPECT labelled leucocyte scintigraphy within one month of delay. Semi-quantitative analyses were performed with calculation of ratios of affected/non-affected sides for PET, 4h and 24h LS time acquisitions as well as kinetic of ratios in PET (at diagnosis and after treatment) and LS (4h-24h). The final treatment response was assessed by two experimented ENT physicians gathering clinical, otoscopic and biological information. ***Results:*** Seventeen patients (74.0 ±10.6 years old, 5 women) were included in this longitudinal study. The best diagnostic performances were obtained with $SUV_{max}$-lesion-to-background ratio in PET and lesion-to-background ratio in 4h time acquisitions in LS (respective thresholds of 4.1, 1.05 in planar and 1.11 in SPECT with 94%, 94% and 88% of accuracies). In multivariate analysis, $SUV_{max}$-lesion-to-background ratio in PET was the only predictive factor of non-treatment response when associated to all clinical parameters (p=0.003). ***Conclusion:*** $^{18}$F-FDG PET is a widely accessible imaging modality for evaluating the treatment response in MEO, with high diagnostic performances, equivalent to those of LS. 4h time acquisitions with LS seem to be sufficient to evaluate the treatment response in MEO.

## EPS-059

### Dynamic [$^{18}$F]FDG PET/CT imaging with a LAFOV PET/CT camera system to differentiate between infection and inflammation.

***N. D. van Rijsewijk***, *J. H. van Snick, F. F. A. Ijpma, M. Wouthuyzen-Bakker, J. van Sluis, A. W. J. M. Glaudemans;*
*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** [$^{18}$F]FDG PET/CT is commonly used for imaging infection and inflammation in nuclear medicine. However, distinguishing infection from inflammation on static images after 1 hour post injection can be challenging. In this study, we aim to differentiate between infection and inflammation by leveraging dynamic imaging. ***Materials and Methods:*** Patients referred to the nuclear medicine department with suspected infection or inflammatory disease were dynamically scanned on a long axial field of view (106 cm) PET/CT system for 65 minutes immediately following [$^{18}$F]FDG injection. PET data were reconstructed using 31 frames as follows: 6x10 sec, 3x20 sec, 6x30 sec, 5x1 min, 11x5 min. Additionally, static images were reconstructed from the last 3 min. All images were reconstructed using both clinically optimized settings (CLIN) and European Association of Nuclear Medicine Research Ltd. (EARL) standard 2 settings (EARL2). Volumes of interest were drawn at various locations: infection and inflammation sites, spleen, liver, aorta, bone marrow in L5 and/or iliac crest, femoral artery, gluteus muscle and caput femoris. Time activity curves (TACs) were generated based on the dynamic reconstruction, and standardized uptake values (SUVs) were calculated at CLIN and EARL2 reconstructions after correction for blood glucose, following EANM guidelines. ***Results:*** To date, a total of three infection sites (2 fracture related infections and 1 lead infection of a left ventricular assist device) and four inflammation sites were identified in four patients. For EARL2 reconstructed images, $SUV_{peak}$ for infection sites was 2.94, 6.50 and 6.89, and 3.19, 7.01 and 8.22 for CLIN reconstructed images. For inflammation sites, $SUV_{peak}$ ranged between 1.56 - 4.02 (EARL2) and 1.73 - 3.45 (CLIN). The increase in $SUV_{peak}$ from 30 - 65 minutes post-injection was at least 10% (10%, 26%, and 31%, absolute:

0.41, 2.05, and 1.96 SUV, respectively) for EARL2 reconstructed images and at least 18% (18%, 28%, and 37%, absolute: 0.81, 2.30, and 2.65 SUV, respectively) for CLIN reconstructed images for infection sites, both with a clear increasing slope. In contrast, for inflammation sites, the percentual increase or decrease in $SUV_{peak}$ during the same time frame showed a more stagnating curve and a more erratic pattern: from -1% to 5% (absolute: -0.04 - 0.17 SUV) on EARL2 images and from -5% to 3% (absolute: -0.10 - 0.11 SUV) on CLIN images. ***Conclusion:*** Preliminary results show that TACs might be helpful to differentiate infection from inflammation using the increase of [$^{18}$F]FDG uptake in time.

## EPS-060

### Exploring the clinical ambit of $^{68}$Ga-NOTA-UBI PET/CT as an infection imaging technique

***N. Damle***, *Y. Dharmashaktu, A. Singhal, S. Ballal, R. Goel, S. D. Maurya, V. Tiwari, A. Gawande, S. Sagar, J. Jaleel, C. Bal, M. Ansari, V. Kumar;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Ubiquicidin (UBI) is a cationic antimicrobial peptide with tremendous potential for imaging of infectious diseases as it helps in differentiating between sterile inflammation and various infections. Here we have labelled UBI with chelator NOTA complexed with Ga-68 and used the radiolabelled compound to look for infective etiology in clinically challenging scenarios. ***Materials and Methods:*** Labelling of UBI conjugated with NOTA and Ga-68 was optimized at 95°C, pH of 4-5 with the radiochemical purity of at least 95% and higher. We retrospectively reviewed the $^{68}$Ga-NOTA-UBI scans of 22 patients (5 female, 17 male; age range 23-65 years) between January 2022 to March 2023 done at our institution. Patients were injected with 3-5 mCi of $^{68}$Ga-NOTA-UBI intravenously and early whole body and delayed regional PET/CT images were acquired at 45-60 mins and 90 mins post injection respectively. Lesions were graded as positive, suspicious and negative for infection by three independent Nuclear Medicine physicians. ***Results:*** Normal tracer biodistribution was visualized in cardiac blood pool, liver, kidneys, bladder and occasionally in spleen & rarely in marrow. Out of 22 patients, 9/22 were referred with a suspicion of orthopedic implant associated infection, 6/22 to differentiate between malignancy & infection, 1/22 for pyrexia of unknown origin (PUO), 1/22 for suspected aspergilloma and 5/22 for miscellaneous infections. 7/9 (77.7%) patients with implant associated infection suspicion showed significant increased soft tissue tracer uptake around the implant and were interpreted as positive for infection while 2/9 were reported suspicious. Of the 6 scans done for differentiating infection from malignancy, 2/6 were reported as positive for infection, 3/6 as negative and 1 patient was reported equivocal. 1 patient who was referred for PUO evaluation had multiple focal marrow lesions with increased tracer uptake suggestive of infection. 1 patient with clinical suspicion of aspergillosis was reported positive for infection involving right orbit and right lung. Out of 5 scans done for miscellaneous infections 3/5 were positive while 2/5 were suspicious and negative for infection respectively. ***Conclusion:*** $^{68}$Ga-NOTA-UBI is a promising PET/CT imaging agent for detecting orthopedic implant associated infection with a strong evolving role in distinguishing infective and non-infective pathology. However, studies on a larger patient cohort are required to validate the same and establish its definitive role.

## EPS-061

### Correlation Between Emotional and Psychological Symptoms and Brain Glucose Metabolism on PET/CT in Patients with Long Covid

***L. Wichert-Ana***, *D. L. Ferreira, L. E. Lopes-Santos, A. C. Trevisan, G. D. Angelis, J. S. Sakamoto, B. G. Coretti, L. Alexandre-Santos, M. P. Foss, O. Y. Fukumori, M. Kato, F. A. Pitella, V. Tumas, F. B. Rodrigues;*
*Ribeirão Preto Medical School - University of São Paulo, Ribeirao Preto, BRAZIL.*

***Aim/Introduction:*** The SARS-CoV-2 pandemic is a global health problem characterized by multiple variants, different levels of severity and high morbidity. Persistent symptoms after the acute phase of COVID-19 have been reported, including post-traumatic stress disorder, mood and anxiety disorders, fibromyalgia, and chronic fatigue syndrome. Most of these symptoms may be related to the infection itself, the way of coping with the disease or the stress generated by the pandemic. However, the topography and pathophysiology of post-COVID brain involvement, whether due to the neuro-infection or clinical and therapeutic factors, are still not entirely known. This study correlated psychological and emotional symptoms with brain glucose metabolism changes in PET/CT in long COVID patients. ***Materials and Methods:*** Twenty-two patients with persistent cognitive complaints after mild COVID and 20 healthy controls underwent psychological assessment and [18F]FDG brain PET/CT. The psychological evaluation measured levels of executive dysfunction, anxiety and depression symptoms, and physical and mental fatigue. PET/CT data were modelled by CortexID software. ***Results:*** Mann-Whitney U test revealed significant differences between groups in all psychological variables, with greater severity of self-reported symptoms in the mild COVID group compared to healthy controls. We observed negative correlations between left anterior cingulate cortex (ACC) metabolism and symptoms of anxiety ($\rho$ = -0.305, p = 0.049), physical fatigue ($\rho$ = -0.351, p = 0.023), and executive dysfunction ($\rho$ = -0.304, p = 0.050). Our results support the hypothesis of different patterns of ACC activation in response to threat and anticipatory anxiety, in which hypervigilance to external stimuli was associated with ventral ACC deactivation. ***Conclusion:*** The anatomoclinical correlations evidenced by brain PET/CT may help understand the pathophysiology of neuropsychiatric disorders and contribute to therapeutic strategies for the psychological symptoms associated with Long COVID. ***References:*** Straube, T., Schmidt, S., Weiss, T., Mentzel, H. J., & Miltner, W. H. (2009). Dynamic activation of the anterior cingulate cortex during anticipatory anxiety. Neuroimage, 44(3), 975-981.

## EPS-062

### Brain Perfusion SPECT, DAT SPECT, and [18F]FDG PET/CT and PET/MRI Findings in Patients with Long COVID

***L. Wichert-Ana***[1], *L. S. C. Wellingta*[1], *L. E. Lopes-Santos*[1], *K. J. C. C. Lacerda*[1], *V. R. Sá*[2], *F. E. Padovan-Neto*[2];
[1]*Ribeirão Preto Medical School - University of São Paulo, Ribeirao Preto, BRAZIL,* [2]*Department of Psychology, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, University of São Paulo, Ribeirao Preto, BRAZIL.*

***Aim/Introduction:*** Prolonged COVID-19 affects patients after the acute phase of infection, beyond 12 weeks, with persistent symptoms such as fatigue, cognitive dysfunction, and respiratory difficulties. In addition, the virus demonstrates neurotropism, causing neurological and psychiatric disorders. This study aims to review the main findings of perfusion

SPECT, DAT SPECT, and [18F]FDG PET/CT brain in patients with neuropsychiatric manifestations of long COVID. ***Materials and Methods:*** A systematic literature review was conducted in the PUBMED, SCOPUS, and EMBASE databases, searching for articles published on brain findings post-COVID-19 and up to 02/12/2022. The keywords "COVID-19 And PET/CT And BRAIN" and "COVID-19 And SPECT And BRAIN" were entered in the search fields. After excluding publications relating to non-brain studies, the search resulted in 05 articles on cerebral SPECT and 15 articles on cerebral PET/CT in Long COVID. ***Results:*** Perfusion SPECT findings in patients with Long COVID showed hyperperfusion in the cerebellum and diffuse hypoperfusion, especially in the frontal lobes, which recovered after a few months. Studies with tracers for dopaminergic transporters demonstrated reduced DAT density in the striatum, worse in the putamen and on the left side. In addition, the [18F]FDG PET/CT and PET/MRI findings demonstrated areas of glycolytic hypometabolism in various brain regions (frontal lobes, temporal lobes, left insula, and diffuse areas in the parietal and occipital lobes). Moreover, brain regions with glycolytic hypermetabolism were also observed, mainly in the cerebellum, subthalamic nucleus, and right thalamus. ***Conclusion:*** Perfusion SPECT, DAT SPECT, and cerebral PET/CT contribute to the evaluation of brain changes associated with prolonged COVID-19, allowing quantification of regional cerebral blood flow and regional cerebral glucose metabolic rate. Changes in cerebral SPECT are milder than those described in PET/CT and PET/MRI, possibly due to the lower spatial resolution of the technique. These findings help understand the pathophysiology of neuropsychiatric manifestations of Long COVID and guide future therapeutic strategies.

**Deep learning-based abnormality classification in $^{123}$I-ioflupane SPECT imaging**

***T. Yamao***, *R. Yamakuni, N. Takahashi, K. Miwa, Y. Kaneko, N. Miyaji, H. Ito;*
*Fukushima Medical University, Fukushima, JAPAN.*

***Aim/Introduction:*** Diagnosis of dopamine transporter (DAT) single-photon emission computed tomography (SPECT) imaging is based on visual interpretation combined with quantitative analysis. Quantitative analysis evaluates the specific binding to DAT in the striatum. However, quantitative assessment of the spatial distribution of striatal accumulation remains to be established. The present study aimed to develop a deep learning system to discriminate abnormalities in striatal accumulation on DAT SPECT. ***Materials and Methods:*** The subjects were 60 DAT SPECT images (normal; 23, abnormal; 37). All images were anatomically standardized by $^{123}$I-ioflupane template [1]. The area surrounding of the striatum was cropped from the whole brain. Seven continuous images were used as input to a convolutional neural network. The network was based on pre-trained VGG19 model, and fine-tuning was performed on 840 images from 60 subjects with data augmentation by horizontal flipping. An ensemble of seven axial slices of VGG19 was used to determine normal and abnormal. Classification performance was evaluated using five-fold cross-validation. Receiver operating characteristic (ROC) analysis was performed to compare the area under the curve (AUC), VGG19, specific binding ratio (SBR) and asymmetry index (AI). A heat map based on the gradient-class activation map (Grad-CAM) was generated to demonstrate how the VGG19 model classified the DAT SPECT image. ***Results:*** The proposed method exhibited an accuracy of 91.9%, sensitivity of 91.1%, and specificity of 94.1%, as determined by the five-fold cross-validation method. The AUC values for VGG19, SBR, and AI were 0.898, 0.919, and 0.872, respectively. In the normal subject, the heat map displayed activation in only a narrow region of the striatum, whereas in the abnormal subject, activation was observed in a broader region around the striatum. ***Conclusion:*** The proposed method allowed to discriminate normal and abnormal images in DAT SPECT images with high accuracy. Our current system might provide reliable support for diagnosing patients with parkinsonism. ***References:***

### OP-178

**Quantitative evaluation of SPECT/CT performance for therapeutic Lu177 radionuclide with NEMA standards**

***P. Dwivedi***[1], *V. Sawant*[1], *A. Jha*[2], *V. Rangarajan*[2];
[1]*Advanced Centre for Treatment Research and Education In Cancer, Mumbai, INDIA,* [2]*Tata Memorial Hospital, Mumbai, INDIA.*

***Aim/Introduction:*** The use of quantitative SPECT/CT imaging for targeted radionuclide therapy with 177Lu holds excellent potential for developing imaging based personalized dose assessment. The study aims to evaluate the quantitative performance of SPECT/CT and its effect on image quality parameters for 177Lu by utilising standard NEMA image quality phantom and PET/CT quality assurance methodology. ***Materials and Methods:*** The study was performed on a dedicated SPECT/CT system using a NEMA standard image quality phantom having 6 sphere inserts (inner diameter 10, 13, 17, 22, 28, and 37 mm) and a lung insert. Except for the largest 37 mm sphere (filled with water), all other spheres were filled with an activity 177Lu concentration of 440 kBq/mLmL.At minimum three degree angle and for minimum of 30 seconds per projection, the phantom images were collected with a four spheres to background activity concentration ratio (no background,1:4, 1:8, 1:16). Also, the accuracy of attenuation correction was determined using lung insert. The attenuation corrected images reconstructed with OSEM iterative reconstruction method were analysed. The region of interest (ROI) was drawn in a transverse image slice containing the sphere's center and adjacent slices, calculating average counts in the sphere. Percent contrast recovery was calculated for each sphere to background ratio. A total of 12 ROI for each sphere diameter were drawn in central and adjacent slices for background variability assessment for each hot sphere to background ratio. ***Results:*** The highest percent contrast recovery in hot sphere was observed in the 28 mm sphere for a 16:1 hot sphere to background ratio, whereas the 10 mm sphere shows the least per cent recovery ranges in all sphere to background ratios. The background variability was maximum for the 10 mm sphere diameter and the least was noted for the 28 mm sphere. The 37 mm cold spheres show highest contrast recovery in all sphere volumes. The highest lung error was seen in no background concentration ratio images. The

maximum lung error was seen in the 16:1 sphere to background concentration ratio. ***Conclusion:*** The study results show that percent contrast increases with an increase in the sphere size where there is significant effect of background concentration on percent contrast recovery and background variability.The results indicates overall good quantitative performance of SPECT CT for therapeutic radionuclide 177Lu when experimented with NEMA standards. This also concludes that NEMA methodology for PET/CT can be applied to SPECT/CT for quality assurance tests.

## OP-179

### Broad quantification calibration of various isotopes for quantitative analysis and the assessment of their SUVs in a SPECT/CT scanner

***H. Ko***, *J. Choi, S. Park;*
*Asan Medical Center, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Broad Quantification Calibration(B.Q.C) is used for the quantitative analysis of the Standard Uptake Value(SUV) in a SPECT/CT scanner. B.Q.C was performed for Tc-99m, I-123, I-131 and Lu-177, then we acquired the phantom images to ascertain whether the SUVs were measured accurately. Because there is no standard method for assessing SUV in SPECT, we used the ACR Esser PET phantom alternatively. The purpose of this study was to lay the groundwork for the quantitative analysis with various isotopes in a SPECT/CT scanner. ***Materials and Methods:*** Symbia Intevo 16 and Intevo Bold SPECT/CT scanners were used for this study. The B.Q.C procedure has two steps: the first is point source sensitivity cal. and the second is volume sensitivity cal. to calculate the volume sensitivity factor(VSF) using a cylinder phantom. To verify the SUVs, we acquired the images using the ACR Esser PET phantom, then we measured the $SUV_{mean}$ on background and $SUV_{max}$ on hot vials(25, 16, 12 and 8 mm). The SPSS software was used to perform Mann-Whitney test to analyze the difference in the SUVs obtained using the Intevo 16 and Intevo Bold. ***Results:*** The results of sensitivity(CPS/MBq) for Detector 1, 2 and VSF were as follows(Intevo 16 D1 sensitivity/D2 sensitivity/VSF and Intevo Bold); 87.7/88.6/1.08 and 91.9/91.2/1.07 for Tc-99m, 79.9/81.9/0.98 and 89.4/89.4/0.98 for I-123, 124.8/128.9/0.69 and 130.9/126.8/0.71 for I-131, 8.7/8.9/1.02 and 9.1/8.9/1.00 for Lu-177, respectively. The results of the SUV assessment using the ACR PET phantom were as follows(Intevo 16 BKG $SUV_{mean}$/25mm $SUV_{max}$ /16mm/12mm/8mm and Intevo Bold); 1.03/2.95/2.41/1.96/1.84 and 1.03/2.91/2.38/1.87/1.82 for Tc-99m, 0.97/2.91/2.33/1.68/1.45 and 1.00/2.80/2.23/1.57/1.32 for I-123, 0.96/1.61/1.13/1.02/0.69 and 0.94/1.54/1.08/0.98/0.66 for I-131, 1.00/6.34/4.67/2.96/2.28 and 1.01/6.21/4.49/2.86/2.21 for Lu-177, respectively. The SUVs obtained using the Intevo 16 and Intevo Bold showed no statistically significant difference($p>0.05$). ***Conclusion:*** In the past, only qualitative analysis was possible using a gamma camera. On the other hand, it is possible to not only acquire anatomic localization, 3D tomography, but also achieve the quantitative analysis of the SUVs in SPECT/CT scanners. We could lay the groundwork for quantitative analysis of various isotopes, such as Tc-99m, I-123, I-131 and Lu-177 by B.Q.C and verify the accuracy of SUV measurements using the ACR phantom. Moreover, periodic calibration is necessary to maintain the precision of the quantitative evaluation. Thus, we can perform the quantitative analysis of isotopes in follow-up scans obtained using the SPECT/CT examinations and evaluate therapeutic responses in theranostics.

## OP-180

### Differential Diagnosis of Lewy Body Dementia andAlzheimer's Disease in ECD SPECT Images Using 2D and 3D CNN Methods

***Y. Ni***[1], *Z. Lin*[1], *S. Tsen*[1], *M. Pai*[2], *P. Chiu*[3], *G. Hung*[4], *K. Lin*[5], *I. Hsiao*[6], *C. Chang*[7], *Y. Chang*[8];
[1]*Health Physics Division, Institute of Nuclear Energy Research, Atomic Energy Council, Taoyuan, TAIWAN,* [2]*Alzheimer's Disease Research Center, National Cheng Kung University Hospital, Taiwan, TAIWAN,* [3]*Department of Neurology, Show Chwan Memorial Hospital, Changhua, TAIWAN,* [4]*Department of Nuclear Medicine, Chang Bing Show Chwan Memorial Hospital, Changhua, TAIWAN,* [5]*Department of Nuclear Medicine and Molecular Imaging Center, Linkou Chang Gung Memorial Hospi-tal, Taoyuan, TAIWAN,* [6]*Department of Medical Imaging and Radiological Sciences & Healthy Aging Center, Chang Gung University, Taoyuan, TAIWAN,* [7]*Department of Neurology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, TAIWAN,* [8]*Department of Neurology, Institute of translational research in biomedicine, Kaohsiung Chang Gung Memorial Hospital, Chang Gung University College of Medicine, Kaohsiung, TAIWAN.*

***Aim/Introduction:*** The purpose of this study was to evaluate the differential diagnostic performance of 2D and 3D CNN deep learning models on Tc-99m ECD SPECT images of Alzheimer's disease (AD) and Lewy Body Dementia (LBD). ***Materials and Methods:*** Since Taiwan's insurance pays Tc-99m ECD SPECT for the diagnosis of dementia, in order to facilitate future clinical application scenarios, this study was conducted using the brain nuclear medicine imaging database established in Taiwan, which includes 4 hospitals. In order to balance the amount of training data, Tc-99m ECD SPECT images of 112 AD patients and 127 LBD patients were selected. The method of image standardization was to perform spatial normalization through SPM5 software and use the whole cerebellum as a reference region for intensity normalization. We used 2D and 3D convolutional neural networks for the AD/DLB classification task, where the 2D model used the InceptionV3 pre-trained model for transfer learning, and the 3D model used composed of 4 layers of 3D convolutional layer architecture. 90% of all the data was used as a training set, and the other 10% was used as an independent test set. And used 5-fold cross-validation to reduce the issues of overfitting and selection bias. During the training process, the t-SNE method was used to visualize the data distribution of the classification. The performances of the models were analyzed by indicators such as sensitivity, specificity, precision, accuracy, and F1 score. ***Results:*** As shown in Table 1, the performances of the AD/LBD classification task on the independent test set using the 2D and 3D CNN models. In the 2D CNN model, the sensitivity for detecting LBD was 1.0, the specificity was 0.77, the precision was 0.79, the accuracy was 0.88, and the F1 score was 0.88; in the 3D CNN model, the above indicators were 1.0, 0.85, 0.85, 0.92, and 0.92, respectively. ***Conclusion:*** In this study, using Tc-99m ECD SPECT images, both 2D and 3D CNN deep learning models can distinguish the two most common neurodegenerative diseases AD and LBD. The research results show that the performance of the 3D CNN model is better than that of the 2D CNN model, which might due to the relatively complete preservation of the spatial relationship of the 3D image.

## OP-181

### Validation of dramatic CT topogram dose reduction with use of tin filter

***K. Christensen***[1], *P. C. Holdgaard*[1], *L. L. Østergård*[1], *N. A. Bebbington*[2];
[1]*Lillebaelt University Hospital, Vejle, Vejle, DENMARK,*
[2]*Siemens Healthcare A/S, Aarhus, DENMARK.*

***Aim/Introduction:*** The CT tin (Sn) filter reduces unnecessary dose compared with conventional filtration. Saltybaeva et al. (1) found optimal Sn-topogram settings of Sn100kV/75mA in abdominal phantoms, providing large dose savings compared to non-Sn topograms. However, scan ranges outside the abdomen are often performed in PET-CT and SPECT-CT. The aim was to find the optimal Sn-topogram settings for ranges outside the abdomen. ***Materials and Methods:*** The Kyoto Kagaku adult whole-body phantom was scanned on a PET-CT system with standard and obese habitus, with several Sn-topogram (Sn140kV/Sn100kV and 75mA/20mA) and non-Sn topogram settings (20mA with 100kV/120kV (conventional reference)/140kV). Dose Length Product (DLP) was recorded for each topogram. To evaluate effect on tube current modulation, CT scans were made after each topogram, and mAs-profiles plotted (Z-direction). To determine effect on visual identification of anatomical landmarks for planning scan ranges, 16 landmarks were scored for visibility on a scale of 1-3. 4 metal objects were placed on the phantom (1 abdominal, 2 thoracic, 1 mandibular), to determine visibility for applying Metal Artefact Reduction. Landmarks and metal artifacts were evaluated by one trained observer. All findings were compared to the conventional reference. ***Results:*** DLP (mGy.cm) for the conventional reference (120kV/20mA) was 4.8. DLP was reduced with settings of 100kV/20mA (2.6mGy.cm), Sn140kV/20mA (1.6mGy.cm), Sn100kV/75mA (1.1mGy.cm) and Sn100kV/20mA (0.3mGy.cm), representing dose savings of 46%, 67%, 77% and 94% respectively. For standard and obese patients, all mAs profiles were comparable to the conventional reference, apart from in the abdominal scan range at Sn100kV/20mA for the obese patient, showing mAs reduction of up to 10%. Similarly, Sn100kV/20mA did not allow visualization of the abdominal metal object in standard and obese modifications. All other ranges and settings showed all metal objects. At Sn100kV/20mA for the standard patient, visibility of 14/16 landmarks were comparable with the conventional reference, whilst visibility of the scapulae and the bottom of the liver were reduced, and for the obese patient, visibility of the lumbar spine and iliac crests were reduced in addition. ***Conclusion:*** Sn100kV/75mA should be used for scan ranges which include the abdomen, providing 77% topogram dose saving compared with the conventional reference. However, if the scan range does not include the abdomen, Sn100kV/20mA appears to be adequate, and saves an additional 73% topogram dose compared with Sn100kV/75mA. ***References:*** 1.Saltybaeva N,Krauss A,Alkadhi H. Technical note: radiation dose reduction from computed tomography localizer radiographs using a tin spectral shaping filter. Med Phys. 2019;46(2):544-549.

## OP-182

### Clinical Application of SPECT Phantoms Created Using Paper Phantoms

***T. Nagahara***[1], *T. Katafuchi*[2], *T. Inagaki*[1], *R. Isobe*[1], *K. Kato*[1];
[1]*Nagoya University Graduate School of Medicine, Nagoya, JAPAN,* [2]*Gifu University, Gifu, JAPAN.*

***Aim/Introduction:*** In recent years, single-photon emission computed tomography (SPECT) research has become mainstream in nuclear medicine, with increasing use of three-dimensional phantoms. In contrast, two-dimensional paper phantoms are restricted for evaluating planar images because they lack thickness and cannot be easily applied to three-dimensional SPECT images. However, previous studies have shown that paper phantoms can be applied in SPECT evaluation and that 3D images can be delineated from 2D images. This study examined the optimal conditions for evaluating SPECT images using a SPECT phantom created from paper phantoms and discussed the possibility of its clinical application. ***Materials and Methods:*** Paper phantoms were designed using PowerPoint based on Burger's phantom and were created by mixing $^{99m}TcO_4$-prepartation and black ink, loading it into an ink cartridge, and printing it using an inkjet printer. Subsequently, a SPECT phantom was fabricated by alternately overlapping the paper phantoms with polystyrene foams or acrylic plates to determine its thickness. This was used for the SPECT collection with a gamma camera, and the differences in the images obtained were compared. To determine the optimal conditions, the pixel size was divided into two classes: one in which the pixel size was smaller than the distance between the paper phantoms, and the other in which the pixel size was approximately the same as the distance between the paper phantoms. In addition, another SPECT phantom was created using clinical images as the design for the paper phantoms, and the images of SPECT and static acquisition were compared. ***Results:*** Under clinical conditions, a pixel size smaller than the phantom spacing was appropriate for evaluating SPECT images using a SPECT phantom created from paper phantoms. The counts obtained using acrylic plates decreased by >50% compared to those obtained using polystyrene foams, resulting in a smaller visible area. Furthermore, the SPECT images had indistinct edges, whereas the static images showed an overall clearer image. ***Conclusion:*** A study with a view to clinical applications, such as creating a SPECT phantom using acrylic plates and clinical images and evaluating the images, suggests that this phantom can be applied in clinical practice.

## OP-183

### SPECT/CT-ONLY Imaging for Sentinel Lymph Node Biopsy in Breast Cancer: Efficient and Effective

***B. Bosveld***[1], *R. A. Valdés Olmos*[2], *W. van der Bruggen*[1], *C. D. Bavelaar-Croon*[3], *B. F. Bulten*[1];
[1]*Slingeland Hospital, Doetinchem, NETHERLANDS,*
[2]*Leiden University Medical Center, Leiden, NETHERLANDS,*
[3]*Alexander Monro Hospital, Bilthoven, NETHERLANDS.*

***Aim/Introduction:*** For nuclear imaging prior to sentinel lymph node biopsy in breast cancer (SLNB), current international guidelines propose flexible directives. A previous survey of 57 nuclear medicine departments in the Netherlands showed wide variation in interpretation of those directives. Nearly all scanning protocols (98%) were based on planar scintigraphy, with Single Photon Emission Computed Tomography combined with Computed Tomography (SPECT/CT) used exclusively in cases of inadequate sentinel lymph node (SLN) visualisation. One hospital skipped planar imaging and directly applied SPECT/CT to identify SLNs, which is an efficient protocol in terms of capacity planning for staff and gamma cameras. We therefore investigated whether SPECT/CT-ONLY could safely replace our standard planar scintigraphy protocol. ***Materials and Methods:*** We conducted a randomised non-inferiority trial comparing SLNB operation time after SPECT/CT versus planar scintigraphy. Enrolled patients were assigned 1:1 to a control group (planar protocol, i.e. multidirectional static images plus skin marking) and an intervention group (SPECT/CT protocol, i.e. SPECT/CT-ONLY without skin marking).

Informed consent was obtained. Participants received two periareolar intracutaneous injections into the affected breast. Two hours later they underwent the scanning protocol they were assigned to. Surgery was performed three to four hours post injection. To answer our primary research question, we calculated the 95% confidence interval for difference in SLNB operation time between the two groups. A 95% confidence interval entirely below 5 minutes additional operation time after SPECT/CT would demonstrate significant non-inferiority. Secondary outcomes were SLNs identified by nuclear medicine physicians and SLNs removed by surgeons. ***Results:*** Between April 1 and December 31, 2022, 79 adult women were enrolled. For 65 of these 79 participants (82%) SLNB operation time could be analysed. Mean difference in operation time between SPECT/CT and planar group was -1.83 minutes, i.e. shorter operation time in the SPECT/CT group. The 95% confidence interval (-4.73;+1.08min) was entirely below +5 minutes. In all 79 participants one (85%), two (13%) or three (2%) SLNs were preoperatively identified. In 8 participants (10%) not all preoperatively identified SLNs were removed. This occurred 7 times in the planar group and 1 time in the SPECT/CT group. ***Conclusion:*** SPECT/CT-ONLY seems to be not only an efficient, but also an effective preoperative nuclear medicine imaging protocol for SLNB in breast cancer. Operation time was significantly non-inferior after SPECT/CT compared to planar scintigraphy, and we reported lower incidence of non-removed SLNs in the SPECT/CT group.

## OP-184

### Contamination of the Isolation Room After Iodine-131 Ablation Treatment

***K. Levänen****, N. Miettinen, H. Leskinen, J. Heikkinen;*
*Department of Radiology and Nuclear Medicine, The wellbeing services county of South Savo, Mikkeli, FINLAND.*

***Aim/Introduction:*** Orally ingested iodine-131 is used for the treatment thyroid grand cancers. Due to the radiation hazard that the high energy radiation (max. energy 364 keV) of I-131 induces, isolation of the treated patients is a necessary procedure. The Finnish Radiation and Nuclear Safety Authority requires that the residual activity inside the patient is under 800 MBq (a measured dose rate of <40 µSv/h) before ending the isolation. During the isolation, patients contaminates the room with their excretion. Therefore, conducting a thorough decontamination as part of the room cleaning is a vital part of the radiation safety procedures in the hospital. A dose rate exceeding 5 µSv/h measured from an item is considered a radiation hazard and the item in question needs to be stored in a decay-in-storage before wash or disposal. This study aims to determine the frequency of contamination in different locations in the isolation room. ***Materials and Methods:*** The contamination level of ten selected locations of the isolation room was measured after 30 patients treated with 1110, 1850 or 3700 MBq of iodine-131. The measurements were conducted using handheld dose rate meter after the patient left the isolation room. The measured locations were: both sides of the pillow, bed linen, patient clothing, patient slippers, toilet seat, toilet bowl, floor drain and waste containers in bathroom and patient room. ***Results:*** The isolation room was found contamined (dose rate >5 µSv/h) frequently at least in one location. However, the contamined locations were mostly the patient room and bathroom waste containers (50% and 33% of the times respectively). Patient clothing was found contamined two times (max 147µSv/h), pillow and bed linen both a single time. The dose rates of the toilet bowl and the floor drain did not exeed the threshold of contamination. The contamination of these locations was found to be caused by saliva, sweat or urine. ***Conclusion:*** The results indicate that the contamination in the isolation room after iodine-131 treatment is minimal. Since the contamination was mostly found from the waste containers where contamination can be expected, we can conclude that the patients have been well-informed of the radiation hazards of the treatment. The results of this study helps to keep the personell, who clean the room after isolation, better informed of the radiation safety of their work furhermore preventing the contamination spread from the isolation room. ***References:*** Finnish Radiation and Nuclear Safety Regulation stuklex (2013)

## OP-185

### Dose rate evaluation of patients performing diagnostic Nuclear Medicine procedures

***A. Santos****, P. Colarinha;*
*Hospital Cuf Descobertas, Lisbon, PORTUGAL.*

***Aim/Introduction:*** Patients submitted to Nuclear Medicine (NM) procedures are non-sealed sources of radiation. Diagnostic NM is considered to involve small amounts of radiation to both the patient and the public. The aim of this study is to answer three of the most common questions asked by patients, regarding public exposure, with the use of a quantitative method and relate the results with legal dose limits and international recommendations. ***Materials and Methods:*** Dose-rate (microsievert/hour) was measured at 1m distance, at the end of three diagnostic procedures (Geiger-muller counter): 1) Bone Scintigraphy (BS) with $^{99m}$Tc-HDP (N=48), 2) Myocardial Perfusion Scintigraphy (MPI) with $^{99m}$Tc-Tetrofosmine (N=31) and 3) PET with $^{18}$F-FDG (FDG) (N=50). The average dose was used to calculate the cumulative dose on 3 hypothetical scenarios, corresponding to three of the most common questions asked, in regard to public irradiation: A) I will travel for 2h in a private car, is the dose to my driver within legal limits? B) Will we be within public dose limits if I sleep tonight with my spouse? C) Can I go to work tomorrow? ***Results:*** Dose-rate was measured and its average determined (table 1). The cumulative dose for each scenario was calculated (table 1). ***Conclusion:*** Public legal annual limit of 1mSv was not reached in any of the studied scenarios. Only in Scenario B) for MPI group was reached the cumulative dose of 0,3mSv. This study allowed our group to communicate with patients about the public exposure in an informed and evidence-based manner. ***References:*** • Radiation Protection Nº 180 - Medical Radiation Exposure of the European Population. **Predictive value of [18F]F-Choline and PSMA-based quantitative parameters for response to [177Lu] Lu-PSMA-617 therapy in mCRPC: The added value of dynamic FDG acquisition using Patlak method**

***S. Miet***[1], *B. Maucherat*[1], *P. Baumgartner*[1], *E. Picot-Dilly*[1], *P. Lalire*[1], *A. Morel-Thierry*[1], *D. Rusu*[1], *M. Le Thiec*[1], *V. Nicolas*[2], *F. Rolland*[1], *C. Rousseau*[2], *L. Ferrer*[2];
[1]*ICO René Gauducheau, F-44800 Saint-Herblain, Nantes, FRANCE,* [2]*ICO René Gauducheau, F-44800 Saint-Herblain, Nantes Université, Univ Angers, INSERM, CNRS, CRCI2NA, F-44000, Nantes, FRANCE.*

***Aim/Introduction:*** [177Lu]Lu-PSMA-617 (Lu-PSMA) is a promising therapy for metastatic castration-resistant prostate cancer (mCRPC), but there is still a need for reliable predictive tools to balance risk and benefit. Recent studies suggest that FDG PET/CT (FDG) may have added value in predicting response to therapy compared to [68Ga]Ga-PSMA-11 PET/CT (PSMA)[1]. This study compared the predictive value of [18F]F-Choline (FCH), PSMA and FDG-based quantitative parameters and assesses the added value of dynamic FDG acquisition using the Patlak method[2]. ***Materials and Methods:*** We retrospectively enrolled 26 patients with mCRPC, of which 10 had complete pre-therapeutic data (FCH, PSMA, and FDG and FDG dynamic PET/CT) and sufficient clinical follow-up (2023-059). Tumour volumes were delineated using semi-automatic segmentation (3DSLICER), and PSA changes were recorded according to the Prostate Cancer Working Group Criteria (PCWGC3) after three cycles of Lu-PSMA. PET/CT quantitative parameters were compared with PSA early change response. For all acquisition types, patient global scores were defined as the maximum and median of SUVmax, SUVmean, SUVmedian, and TLG. ***Results:*** In total, 1099, 625, 681 and 993 segmentations were respectively delineated on FCH, FDG,FDG dynamic PET/CT and PSMA images. Lesion volumes defined on FCH and PSMA examinations were not different (p-value=0.06) as opposed to those compared on FDG/FCH and FDG/PSMA examinations (p-value<0.005). Lesion volumes defined on Patlak's Ki images were not different to volumes defined on the other modalities (p-values>0.10) except for FDG (p-value=0.005). Regarding PSA change, 7 patients had a positive response defined as a drop-off superior to 30%. The three non-responders exhibited the lowest maximum SUVmax values on PSMA examinations (p-value=0.01). ***Conclusion:*** This study aimed to provide insights into the predictive value of FDG, FCH and PSMA-based quantitative parameters for response to Lu-PSMA therapy in mCRPC. Preliminary results showed that patients with the highest PSMA SUVmax better respond to 177Lu-PSMA therapy. The dynamic FDG acquisition benefit using Patlak method still needs to be addressed. These findings may help improve patient selection for Lu-PSMA therapy. ***References:*** 1. Jadvar H. ### OP-188

**FAP-Targeted Radiopeptide Therapy using$^{177}$Lu-, $^{225}$Ac-and90Y-labeled 3BP-3940 in Diverse Advanced Solid Tumors: First-in-Humans Results**

***J. Zhang***[1], *V. Jakobsson*[1], *A. Mishra*[2], *A. Eismant*[2], *L. Greifenstein*[2], *C. Kramer*[2], *A. Klega*[2], *C. Landvogt*[2], *C. Mueller*[2], *R. P. Baum*[2];
[1]*National University of Singapore, Singapore, SINGAPORE,* [2]*Curanosticum Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

***Aim/Introduction:*** The purpose of this study was to determine the feasibility of using a novel FAP-targeted cyclic peptide 3BP-3940 for peptide targeted radionuclide therapy (PTRT) and present first-in-humans results using $^{177}$Lu, $^{90}$Y and $^{225}$Ac labeled 3BP-3940 in end-stage cancer patients. ***Materials and Methods:*** 40 patients (23 men and 17 women; mean age 60.8±10.2 years) with advanced metastatic cancers of the pancreas, breast, lung, esophagus, hepatocellular, appendix, ovary, prostate and bowel presented with disease progression after previous treatments and were treated with $^{177}$Lu-, $^{225}$Ac- and $^{90}$Y- PTRT between March 2021 and October 2022. Pre-treatment PET/CT imaging was done with $^{68}$Ga-3BP-3940 to determine tumor uptake. Treatment response was evaluated according to RECIST and EORTC. Kaplan-Meier survival analysis was performed to calculate overall survival (OS), defined from the start of PTRT. ***Results:*** Cumulative activity was for $^{177}$Lu 7.0 ± 2.0 GBq; range 2 - 12 GBq (n, patients=33, 82.5%), $^{90}$Y 5.3 ± 2.0 GBq; range 1.9- 7.6 GBq (n, patients = 10, 25%) and $^{225}$Ac 8.9 ± 3.4 MBq; range 5.0 - 18 MBq (n, patients = 28, 70 %). Visual analysis of posttherapy whole-body scans and SPET/CT scans demonstrated significant uptake and retention of 3BP-3940 in tumor lesions on delayed imaging in all patients, with very high tumor-to-background ratio. Dosimetry was calculated for one pancreas cancer patient who received 9.73 GBq 177Lu, uptake was for the brain 37 mGy, for the lungs 161 mGy, for healthy liver tissue 86 mGy, for the pancreas 142 mGy, for the kidneys 265 mGy, and for the primary pancreas lesion 2200 mGy. 6-8 weeks after the first cycle, responses were progressive disease (n=7, 27 %), partial remission (n=13, 50 %), mixed pattern (n=2, 8 %), and stable disease (n=4, 15 %). Patient 17 is after two cycles 3BP-3940 PTRT in complete remission. For the entire cohort from the start of PTRT (n = 40), the median OS was 10.0 months. In the subgroup of patients with advanced pancreatic adenocarcinoma (n = 10), the median OS was 7.5 months. ***Conclusion:*** 3BP-3940 PTRT is feasible with $^{177}$Lu/$^{90}$Y/$^{225}$Ac either alone or as TAndEM treatment of end-stage cancer patients. Treatments were well-tolerated without significant adverse effects. 3BP-3940 PTRT demonstrated a favorable biodistribution, significant uptake and retention in tumor lesions with very high tumor-to-background ratio, and should objective responses in advanced metastatic adenocarcinomas and sarcomas. The survival benefit for pancreatic adenocarcinoma patients seems to be very promising.

## OP-189

### Static and dynamic 68Ga-FAPI-46 PET in 18F-FDG-negative pulmonary lesions - target validation and imaging properties

***M. Roehrich***, *J. Daum, J. Hoppner, F. Eichhorn, K. Schlamp, E. Gutjahr, H. Winter, U. Haberkorn;*
*University Hospital Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) expressing Cancer associated fibroblasts (CAFs) are crucial for the progression of malignant tumors, among them lung cancer (LC). In particular, CAFs are present in lepidic LCs. This subtype of LC is frequently 18F-FDG-negative, but also other LC subtypes can exhibit variable glucose metabolism. Given the strong expression of FAP in the stroma of LC, 68Ga-FAPI-PET is a promising imaging modality for LC in general and particularly for primary FDG-negative pulmonary lesions as 18F-FDG-negativity cannot exclude malignancy in these cases. Here, we have confirmed FAP-expression of CAFs in lepidic LCs and evalauted the diagnostic potential of 68Ga-FAPI-PET for 18F-FDG-negative pulmonary lesions. ***Materials and Methods:*** HE staining and FAP-immunohistochmistry of paraffin embedded sections of 24 lepidic LC was performed. Static (60 minutes p.i.) and dynamic 68Ga-FAPI-46 PET was applied in 20 patients with 18F-FDG negative pulmonary lesions. After PET imaging, all patients underwent lung biopsy and histological diagnosis. Pulmonary lesions and healthy appearing lung tissue were contured manually and SUVmax, SUVmean and corrresponding target to background ratios of 68Ga-GAPI-46-PET and 18F-FDG imaging were calculated. Dynamic 68Ga-FAPI-46 PET data was analzyed qualitatively and quantitatively (time to peak and kinetic modeling). ***Results:*** Immonohistochemistry showed strong FAP-expression in lepidic LC. Histology revealed LC in 6/15 patients and benign results in 9/15. LCs showed markedly higher 68Ga-FAPI-46 uptake than 18F-FDG uptake (average SUVmax 3,93 +/- 0,89 versus 1,54 +/- 0,52, average SUVmean 2,47 +/- 0,54 versus 1,08 +/- 0,38). In particular, a lepidic LC was well decernable in 68GA-FAPI-46-PET (SUVmax 3,80, SUVmean 1,75 versus 0,60), but not in 18F-FDG (SUVmax 0,94). Benign lesions also showed higher 68Ga-GAPI-46-uptake than 18F-FDG-uptake (SUVmax 3,12 +/- 1,95 versus 2,16 +/- 1,24, SUVmean 1,89 +/- 1,34 versus 1,26 +/- 0,81), but the average 68Ga-FAPI-46/18-FDG average ratio was higher in LC than in benign lesions (3,64 +/- 1,59 versus 1,89 +/- 0,32). In dynamic imaging, LC and benign lesions showed different time activity curves with increasing uptake for 15-20 minutes followed by slow washout for LC and constant washout for benign lesions, which was reflected by prolonged time to peak of (815 +/- 330 seconds versus 410 +/- 440 seconds). ***Conclusion:*** Static and dynamic 68Ga-FAPI-46 PET is a promising approach for the characterization of 18F-FDG-negative pulmonary lesions. As 68Ga-FAPI-46 PET reflects the presence of CAFs in LC, it provides tumor biology-based imaging information and may impact future clinical decision making in this challenging setting.

## OP-190

### $^{68}$Ga-FAPI-46 vs $^{18}$F-FDG PET/CT and contrast-enhanced CT in patients with advanced gastrointestinal stroma tumors (GIST)

***T. Bartel***[1], *K. M. Pabst*[1], *A. Milosevic*[2], *S. Bauer*[3], *J. Falkenhorst*[3], *H. Lanzafame*[1], *I. A. Mavroeidi*[3], *M. Nader*[1], *J. T. Siveke*[3,4,5], *K. Herrmann*[1], *R. Hamacher*[3], *W. P. Fendler*[1];
[1]*Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [2]*Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY,* [3]*Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany, Essen, GERMANY,* [4]*Bridge Institute of Experimental Tumor Therapy, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [5]*Division of Solid Tumor Translational Oncology, German Cancer Consortium (DKTK, Partner Site Essen) and German Cancer Research Center, DKFZ, Heidelberg, GERMANY.*

***Aim/Introduction:*** GISTs are the most common mesenchymal tumors of the gastrointestinal tract. Contrast-enhanced CT is current clinical standard diagnostic, however lacks detection of small lesions and peritoneal deposits. $^{68}$Ga-FAPI-46 PET images tumor-associated fibroblast in a wide range of tumor entities with high accuracy. Our aim was to investigate tracer uptake and detection efficacy of $^{68}$Ga-FAPI-46 PET compared to $^{18}$F-FDG PET/CT and contrast-enhanced CT in patients with GIST. In addition, we aimed to assess the impact on treatment management. ***Materials and Methods:*** All patients with GIST in our prospective database of 899 patients who underwent $^{68}$Ga-FAPI-46 PET/CT between June 2020 and March 2023 were retrospectively reviewed. Clinical data, histo- and molecular pathology including mutation status (c-KIT, PDGFRA) were collected. Lesion- and region-based detection efficacy was assessed compared to $^{18}$F-FDG PET/CT and contrast-enhanced CT, subdivided into true-/false-positive and true-/false-negative findings. Histopathology/follow-up were standard of reference. $SUV_{max}$/$SUV_{mean}$/$SUV_{peak}$ and Tumor-to-Background Ratios (TBR) of both tracers were compared using Wilcoxon test. Impact on management was assessed by pre- and post-imaging questionnaire sent to the treating physicians. ***Results:*** A total of n=10 patients with a median age of 61 years (range: 55-84 years) and advanced GIST were analyzed. C-KIT/PDGFRA mutation was present in n=7/1 patients. Overall, n=56 tumor lesions were detected (local: n=35 (62%), lymph node: n=1 (2%), distant (soft tissue/organ): n=20 (36%)). Detection rates for contrast-enhanced CT/$^{18}$F-FDG PET /$^{68}$Ga-FAPI-46 PET were n=34/32/11 (local tumor), n=1/1/1 (lymph node), n=20/13/13 (distant)). N=14 lesions (19.7%; lymph nodes in one patient (histopathology available: n=4)) were false-positive on contrast-enhanced CT/$^{18}$F-FDG PET and true-negative on $^{68}$Ga-FAPI-46 PET. N=1 lesion (1.4%; distant metastasis) was false-positive on $^{68}$Ga-FAPI-46 PET and true-negative on both other imaging modalities. In a patient-based analysis, interpatient heterogeneity was observed for both tracers with average $SUV_{peak}$ values ranging from 1.0 to 12.7 for $^{68}$Ga-FAPI-46 PET and from 1.6 to 6.3 for $^{18}$F-FDG PET. $SUV_{max}$/$SUV_{mean}$ showed no significant difference between both tracers ($^{18}$F-FDG vs. $^{68}$Ga-FAPI-46: 5.0 (±2.1) vs. 4.9 (±4.3); p=0.23/3.1 (±1.3) vs. 3.0 (±2.6); p=0.28). $TBR_{muscle}$ (p=0.028) was significantly higher for $^{18}$F-FDG PET and $TBR_{bloodpool/liver}$ showed no difference (p=0.75/p=0.48). Biopsy was prevented (n=1)/performed additionally (n=2) due to $^{68}$Ga-FAPI-46 PET. ***Conclusion:*** Tracer uptake was heterogeneous for $^{18}$F-FDG and $^{68}$Ga-FAPI-46 PET resulting in highest detection rate for contrast-enhanced CT alone. Due to additional detection

of distant metastases on $^{68}$Ga-FAPI-46 PET, management changed in one third of patients. Accuracy will be further evaluated in an ongoing prospective trial (NCT05160051).

## OP-191

### Radiolabeled Somatostatin Receptor Antagonist versus Agonist for Peptide Receptor Radionuclide Therapy in Patients with Therapy-resistant Meningiomas - Phase 0 Part of the Promenade Study

***C. Eigler***[1], *L. McDougall*[1], *A. Bauman*[1], *P. Bernhardt*[2], *M. Hentschel*[1], *K. A. Blackham*[1], *G. Nicolas*[1], *M. Fani*[1], *D. Cordier*[1], *D. Wild*[1];
[1]*University Hospital Basel, Basel, SWITZERLAND,*
[2]*University of Gothenburg, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Our aim was to compare the meningioma and organ absorbed doses of the new radiolabeled somatostatin receptor antagonist [$^{177}$Lu]Lu-DOTA-JR11 with the established radiolabeled somatostatin receptor agonist [$^{177}$Lu]Lu-DOTATOC in the same patients with progressive meningiomas that are refractory to standard treatment. ***Materials and Methods:*** In this prospective, single-center, open label phase 0 study (NCT04997317), 6 patients were included: 3 men and 3 women (mean age 63.5 years, age range from 39 to 83 years). Patients received 6.9-7.3 GBq (standard activity) [$^{177}$Lu]Lu-DOTATOC followed by 3.3-4.9 GBq (2 GBq/m$^2$ x body surface area) [$^{177}$Lu]Lu-DOTA-JR11 in an interval of 10±1 weeks. In total one [$^{177}$Lu]Lu-DOTATOC and 2-3 [$^{177}$Lu]Lu-DOTA-JR11 treatment cycles were performed. Quantitative SPECT/CT was done at ~24, ~48 and ~168 h after injection of both radiopharmaceuticals in order to calculate meningioma and organ doses (3D segmentation approach). Disease control rate (DCR) was calculated. ***Results:*** The median (range) of the mean meningioma absorbed dose of one treatment cycle was 11.5 (4.7-22.7) Gy for [$^{177}$Lu]Lu-DOTA-JR11 and 3.4 (0.8-10.2) Gy for [$^{177}$Lu]Lu-DOTATOC, (P=0.03). The mean bone marrow and kidney absorbed doses after one treatment cycle were 0.28 (0.16-0.39) and 3.6 (1.6-5.9) Gy for [$^{177}$Lu]Lu-DOTA-JR11 as well as 0.11 (0.05-0.17) and 3.0 (1.3-5.3) Gy for [$^{177}$Lu]Lu-DOTATOC, respectively. According to the CTCAE v5.0 two patients developed reversible grade 2 lymphopenia after one cycle [$^{177}$Lu]Lu-DOTATOC. Afterwards, two patients developed reversible grade 3 lymphopenia and one patient developed reversible grade 3 lymphopenia and neutropenia after 2-3 cycles [$^{177}$Lu]Lu-DOTA-JR11. No grade 4 or 5 adverse events were observed ≥15 months after therapy start. DCR (all stable disease) was 83% (95% CI, 53-100%) at ≥12 months after inclusion. ***Conclusion:*** [$^{177}$Lu]Lu-DOTA-JR11 shows 2.2-5.7 times higher meningioma and 1.7-3.1 times higher bone marrow absorbed doses compared to [$^{177}$Lu]Lu-DOTATOC despite 1.4-2.1 times lower injected activities. First efficacy results indicate a high DCR with an acceptable safety profile in this conventional treatment-resistant meningioma patients. Therefore, larger studies with [$^{177}$Lu]Lu-DOTA-JR11 are warranted.

## OP-192

### Inter-institutional differences and common ground in $^{177}$Lu-PSMA radionuclide therapy: International survey in 95 theranostic centers

***Aim/Introduction:*** $^{177}$Lutetium-labeled prostate-specific membrane antigen (Lu-PSMA) radionuclide therapy has proven its effectiveness in prospective randomized clinical trials and received FDA and EMA approval in 2022. Patient numbers and number of theranostic centers are expected to significantly increase, requiring standardization/harmonization of patient selection, therapy protocols, therapy response assessment and treatment discontinuation criteria. The aim of this international questionnaire study was to assess operational differences and similarities between Lu-PSMA treatment centers. ***Materials and Methods:*** The web-based questionnaire comprised 62 questions. The survey was designed by a core team of 5 physicians and externally reviewed by international experts before an e-mail invitation for study participation was sent in June 2022. E-mail recipients included 1) all centers involved in patient recruitment for the TheraP and VISION trials 2) PubMed search for corresponding authors on clinical Lu-PSMA publications, and 3) international key contacts. Duplicates were removed. The survey was closed in late September 2022. ***Results:*** 95 out of 211 (45%) contacted centers completed the questionnaire. Most participating centers were located in Europe (51%), followed by north- and south-America (22%), Asia (22%), Oceania (3%), and Africa (2%). During the 12 months prior to this study, a total of 5906 patients received Lu-PSMA therapy in the 95 participating centers. Most patients in these last 12 months were treated in Europe (2840/5906; 48%), followed by Asia (1313/5906; 22%) and Oceania (1225/5906; 21%). To assess patient eligibility, PSMA-ligand PET or SPECT was performed in all centers and $^{68}$Ga-PSMA-11 was the most frequently injected radiotracer (77%). Mean standard injected activity per cycle was 7.3 GBq (range 5.5-11.1 GBq). Additional pre-therapy imaging included FDG-PET/CT, contrast enhanced CT, renal and bone scintigraphy in 49%, 32%, 30%, and 15% of centers for clinical standard of care/compassionate care/local research protocols, and 26%, 60%, 21%, and 67% respectively for industry sponsored trials. PSMA-PET eligibility criteria included subjective qualitative assessment of PSMA positivity in 33%, VISION criteria in 23%, and TheraP criteria in 13% of centers. 33/95 (35%) centers did not apply standardized response assessment criteria. Of the remaining centers, PSMA PET Progression Criteria (PPP) for treatment response were applied by 37%, RECIST by 24%, PCWG3 by 22%, RECIP by 11%, and PERCIST by 7%. ***Conclusion:*** Results revealed inter-institutional differences in Lu-PSMA radionuclide therapy. Standardization/harmonization of protocols and criteria is desirable in anticipation of increasing number of patients and theranostic centers.

## OP-193

### Safety and dosimetry evaluation of personalized dose I131-apamistamab prior to HCT in the phase 3 SIERRA trial for patients with relapsed/refractory acute myeloid leukemia (R/R AML)

***N. Pandit-Taskar***[1], *M. Natwa*[2], *M. Chen*[3], *W. Yap*[4], *G. Wiseman*[5], *E. Leung*[6], *A. Desai*[7], *P. Brodin*[7], *E. Haeuber*[7], *A. Nahar*[7], *R. L. Wahl*[8];
[1]*Molecular Imaging and Therapy, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Ohio State University, Columbus, OH, UNITED STATES OF AMERICA,* [3]*Yale New Haven Hospital, New Haven, CT, UNITED STATES OF AMERICA,* [4]*University of Kansas Medical Center, Kansas City, KS, UNITED STATES OF AMERICA,* [5]*Mayo Clinic Rochester, Rochester, MN, UNITED STATES OF AMERICA,* [6]*The Ottawa Hospital, Ottawa, ON, CANADA,* [7]*Actinium Pharmaceuticals, Inc., New York, NY, UNITED STATES OF AMERICA,* [8]*Washington University St. Louis, St. Louis, MO, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** I131-apamistamab is a radioimmunoconjugate to CD45 that delivers high-dose targeted radiation to hematopoietic cells, allowing for myeloablation prior to allogeneic hematopoietic cell transplant (aHCT) in patients with active R/R AML. Here we present a safety and dose-response evaluation of targeted high-dose I131-apamistamab from the SIERRA randomized controlled Phase 3 trial, compared to physician's choice of conventional care (CC). ***Materials and Methods:*** Patients with active R/R AML were randomized to I131-apamistamab vs. CC. Patients on the I131-apamistamab arm received study drug with fludarabine and total body irradiation (2 Gy) followed by aHCT. Pts on CC arm received physician's choice of salvage therapy. Organ-specific uptake and dosimetry estimates based on gamma camera imaging following tracer dose administration was used to individually tailor the prescribed activity of the therapeutic dose of I131-apamistamab. Estimated total integrated activity coefficients (TIACs) and organ-specific absorbed dose estimates were calculated for each patient. The estimated absorbed doses to organs-at-risk were tabulated along with the rates of relevant non-hematological grade ≥3 adverse events in this heavily pre-treated patient population. ***Results:*** Out of the 153 patients enrolled in the SIERRA trial, 76 were in the I131-apamistamab arm and 77 in the CC arm. All 66 patients that received the therapeutic dose of I131-apamistamab went on to receive an aHCT vs. only 14 patients (18.2%) on the CC arm using standard conditioning regimens, and the 66 patients treated with I131-apamistamab form the subset for this analysis. I131-apamistamab prior to aHCT was well tolerated with low rates of non-hematological grade≥3 adverse events in the form of sepsis (4/66, 6.1%), mucositis (10/66, 15.2%), pneumonitis (2/66, 3.0%), acute kidney injury (3/66, 4.5%), acute GVHD (4/66, 6.1%) and acute liver injury (2/66, 3.0%). Median estimated absorbed dose to bone marrow was 16 Gy (range: 5 to 45 Gy), with median dose to relevant organs-at-risk being generally low at 2.5 Gy to lungs, 2.4 Gy to small intestine, 4.1 Gy to kidneys and 3.6 Gy to stomach. Liver was considered the dose limiting organ-at-risk in this trial with maximum tolerated dose of 24 Gy, and median received dose of 21.6 Gy, with very few grade ≥3 liver toxicities observed. ***Conclusion:*** I131-apamistamab conditioning followed by aHCT proved safe and tolerable in this population of heavily pre-treated patients with active R/R AML. This treatment delivered high-dose targeted radiation to leukemic cells, while doses to organs-at-risk were well below safety limits established from external beam radiation.

## OP-194

### $^{89}$Zr-DFO-girentuximab PET/CT imaging for clear cell renal cell carcinoma - ZIRCON study results of diagnostic performance, including in very small lesions

***Aim/Introduction:*** Accurate noninvasive techniques to risk stratify patients with renal mass remains an unmet need. Girentuximab is a chimeric monoclonal antibody with high affinity for carbonic anhydrase IX (CAIX), which is highly expressed in clear cell renal carcinoma (ccRCC); thus, $^{89}$Zr-DFO-girentuximab may aid diagnosis, characterization, and differentiation of ccRCC and other renal lesions. ZIRCON was an open label, multicenter clinical trial evaluating the performance of $^{89}$Zr-DFO-girentuximab PET/CT for detection of ccRCC. We present data on diagnostic performance of in very small renal lesions, and inter-/intrareader consistency. ***Materials and Methods:*** 300 patients with an IDRM (≤7 cm; cT1) scheduled for partial or radical nephrectomy within 90 days from planned $^{89}$Zr-DFO-girentuximab administration received a single dose of $^{89}$Zr-DFO-girentuximab IV (37 MBq±10%; 10mg girentuximab) on Day 0 and underwent abdominal PET/CT imaging on Day 5 (±2days). Blinded central histology review determined ccRCC status. PET positivity was assessed by 3 independent blinded central readers. The coprimary objectives were to evaluate both the sensitivity and specificity of $^{89}$Zr-DFO-girentuximab PET/CT imaging in detecting ccRCC, using histology as the standard of truth. Key secondary objectives included both sensitivity and specificity in the subgroup of patients with IDRM ≤4cm (cT1a). Other secondary objectives included safety and tolerability. Fleiss' kappa statistics determined agreement between qualitative visual assessment of $^{89}$Zr-DFO-girentuximab tumour targeting (tracer uptake in target lesion: yes/no); an intra-class kappa of ≥0.70 was considered acceptable. Cohen's kappa statistics determined intra-reader reproducibility. ***Results:*** 300 patients received $^{89}$Zr-DFO-girentuximab (mean age 62±12 y; 71% Male). The primary analysis included 284 evaluable patients (central histology and readable PET). Across all 3 readers, the average [95% CI] sensitivity and specificity was 86% [80%, 90%] and 87% [79%, 92%] respectively for coprimary endpoints, and 85% [77%, 91%] and 90% [79%, 95%] resp. for key secondary. Sensitivity and specificity in lesions ≤2cm ranged from 90-100% . Inter- and

Intra-reader consistency was 91% and 100%, respectively. Of 263 adverse events (AEs) in 124 patients, 2 AEs of mild intensity were treatment related. ***Conclusion:*** $^{89}$Zr-DFO-girentuximab PET/CT is a well-tolerated, accurate, noninvasive modality for imaging of renal masses for detection and characterization of ccRCC, supporting patient treatment/management decision making. ***References***: ClinicalTrials.gov Identifier: NCT03849118. ***Aim/Introduction:*** Trophoblast cell-surface antigen 2 (Trop-2) is involved in the proliferation and progression of various solid tumors. Trop-2 targeted antibody drug conjugates have showed good efficacy and safety profile in patients with many cancer types. Thus, a noninvasive method for fast delineation of Trop-2 can significantly benefit cancer diagnosis and therapy monitoring. The goal of this study is to develop peptide ligands with strong affinity to Trop-2 was and labeled them with different radiometals for positron emission tomography (PET) imaging and targeted radiotherapy of pancreatic cancer. ***Materials and Methods:*** With the analysis of crystal structure from human Trop-2, molecular docking strategies (e.g. SiteMap and FT Map) was used to find

five potential binding pockets inside Trop-2, and determined the critical amino acids inside. We identified five peptide sequences with strong binding affinity against Trop-2. One candidate (named TP1) was conjugated with p-SCN-Bn-NOTA and subsequently radiolabeled with gallium-68. Flow cytometry, microscopy studies, cell internalization assay, and competitive binding assay were conducted to investigate the cellular interaction behavior of TP1 peptide in Trop-2 positive BxPC-3 pancreatic cancer cells. PET imaging with $^{68}$Ga-NOTA-TP1 was carried out in pancreatic tumors with different Trop-2 expression levels. Western blot of tumor lysate was conducted to correlate the uptake of $^{68}$Ga-NOTA-TP1 with Trop-2 expression level. Finally, lutetium-177 was also labeled with NOTA-TP1 to treat BxPC-3 tumors. ***Results:*** Both TP1 (Kd = 0.62 nM) and NOTA-TP1 (Kd = 15.1 nM) showed good binding affinity and specificity against uPA, confirmed by abovementioned assays. $^{68}$Ga-NOTA-TP1 had a fast internalization into Trop-2$^{+}$ BxPC-3 cells, significantly higher than that in AsPC-1 cells (Trop-2 low). Serial PET imaging revealed that $^{68}$Ga-NOTA-TP1 had a fast and strong accumulation in BxPC-3 tumors (6.8 ± 1.4 %ID/g at 1 h p.i., n = 4), significantly higher than those in AsPC-1 tumors at all time points examined. In vivo Trop-2 specificity was confirmed and the tumor uptakes obtained from PET correlated with Trop-2 expression in tumor measured by Western Blotting. $^{177}$Lu labeling of NOTA-TP1 was also achieved with a radiochemical yield of 34.2 ± 6.4% (n = 4) and good radiochemical purity, while $^{177}$Lu-NOTA-NP1 showed significant tumor growth inhibition for BxPC-3 in vivo, with no noticeable toxicity incurred. ***Conclusion:*** Quantitative PET imaging with $^{68}$Ga-labeled TP1 peptides can facilitate oncologists to adopt more relevant treatment planning, and $^{177}$Lu-labeled TP1 can kill pancreatic cancer selectively. Those radiolabeled peptides can serve as good radiotheranostic agents for pancreatic cancer.

## OP-213

### Glioblastoma and Pancreatic Adenocarcinoma - Versatile radiolabeled probe targeting Low Density Lipoprotein Receptors (LDLR)

***I. Tworowska***[1], *L. Flores*[1], *X. Qu*[1], *C. Malicet*[2], *R. Zielinski*[3], *P. Lecorche*[1], *E. Delpassand*[4], *J. Temsamani*[5];
[1]*RadioMedix Inc., Houston, TX, UNITED STATES OF AMERICA,* [2]*Vect-Horus, Marseille, FRANCE,* [3]*MDAnderson, Houston, TX, UNITED STATES OF AMERICA,* [4]*RadioMedix, Houston, TX, UNITED STATES OF AMERICA,* [5]*Vect-Horus, Marseille Cedex 15, FRANCE.*

***Aim/Introduction:*** RMX-VH is a proprietary chelator modified-peptide developed for radiotheranostic targeting the Low-Density Lipoprotein Receptors (LDLR)-overexpressing in solid tumors. The overexpression of LDLR has been reported in multiple solid tumors and correlated with disease prognosis. In addition, LDLRs are known to facilitate the transport of endogenous ligands through the blood-brain barrier (BBB). RMX-VH can serve as a delivery vector to pass the BBB and target LDLR-overexpressed GBM. Our goal was to synthesize and characterize $^{212}$Pb-RMX-VH, develop a protocol of SPECT $^{212}$Pb-imaging, and perform to complete in vitro/in vivo pre-clinical studies in relevant glioblastoma (GBM) and pancreatic-ductal adenocarcinoma (PDAC) models. In parallel, we evaluated the distribution and safety of $^{68}$Ga-RM-VH in eIND studies. ***Materials and Methods:*** The labeling of RMX-VH (25ug) with $^{212}$Pb chloride was done using a manual approach in acetate buffer pH=6.0 in the presence of 40mg/ml ascorbate used as a scavenger. The radio/chemical purity was analyzed using iTLC chromatography, radio/UV HPLC, and gamma counter normalized for $^{212}$Pb and $^{212}$Bi energy windows. The uptake studies were completed in multiple GBM cancer cell lines ( U87MG, A172, U373) and PDAC (HPAF-II, BxPC-3, and MiaPaCa2 ) showing various levels of LDLR expression. The SPECT images were acquired using a gamma-eye camera at 2h, 4h, and 24h post-injection with follow-up biodistribution studies. The organs and tumor were collected, weighed, and the tissue radioactivity was measured with a gamma counter. The percentage of injected dose-per-gram of tissue (%ID/g) was calculated and decay-corrected. ***Results:*** Our results showed that the radiopharmaceutical had a radiochemical purity of over 98% and no indication of radiolysis at 4 hours post-synthesis. The cellular uptake studies confirmed time-dependent accumulation of the agent reaching the highest uptake at 24h for HPAFII (13.7 %ID/g), BXPC3 (10.9 %ID/g) and lower for MiaPaca2 (3.6 %ID/g), and Colo357 (2.99 ID/g). The SPECT imaging studies showed selective accumulation of the agent in the orthotopic models of PDAC50 as early as 2h post-injection. The uptake correlated with bioluminescent data and PET/CT imaging studies using diagnostics analog, $^{68}$Ga-RMX-VH. The bioD studies have shown (7.05 %ID/g) retention of the agent in the orthotopic PDAC at 2h post-injection, slightly reduced at 4h (4.56 %ID/g) and 24h (5.44 %ID/g) with renal excretion from the bloodstream as the main route of elimination. ***Conclusion:*** Our findings suggest that RMX-VH has favorable LDLR-tumor targeting properties. Ongoing studies include the evaluation of the companion diagnostic $^{68}$Ga-RMX-VH in eIND clinical studies in the USA.

## OP-214

### Preparation and preclinical evaluation of ACE1 targeting molecular probe $^{68}$Ga-DOTA-BPP

***Q. Zhang***, *Z. Yang, Z. Hua;*
*Peking University Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Triple negative breast cancer (TNBC), is estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2) are all negative breast cancer by pathological examination, and the prognosis of this type of breast cancer is extremely poor. Angiotensin-converting enzyme 1 (ACE) is an important part of human renin-angiotensin-aldosterone system. Relevant literature has shown that ACE1 is highly expressed in the TNBC cell line MDA-MB-231. Therefore, ACE1 is expected to become a new target of TNBC. In this study, $^{68}$Ga-DOTA-BPP, a novel peptide nuclide molecular imaging probe targeting ACE1 was constructed. The tumor-specific molecular imaging ability of the probe was evaluated by MDA-MB-231 and MCF-7 tumor models using Micro-PET/CT equipment. ***Materials and Methods:*** The peptide DOTA-BPP was radiolabeled with positron nuclide 68Ga. The labeling rate and radiochemical purity of the peptide were determined by Radio-HPLC. The in vitro stability of the peptide in normal saline and 5% human serum albumin (5% HSA) was analyzed. Pharmacokinetics were used to investigate the metabolism of the probe in the blood of normal mice. Immunohistochemical methods were used to analyze the expression of ACE1 in clinical TNBC specimens, and then two breast cancer models of MDA-MB-231 and MCF-7 were constructed to verify the specificity of the probe. The mouse model was injected with 3.7 MBq $^{68}$Ga-DOTA-BPP in the tail vein, and Micro-PET/CT imaging was performed on the mouse model with tumor. To investigate the tumor imaging ability of $^{68}$Ga-DOTA-BPP ***Results:*** The radiochemical purity of the product was greater than 99% after purification by C18 column. The radiochemical purity of the product was greater than 95% after the probe was placed in normal saline and 5% HSA for 2 hours. The mean expression rate of ACE in 143 clinical TNBC specimens was about 27%. The half-life of $^{68}$Ga-DOTA-BPP in the blood of normal mice was 1.41 min and 14.18 min, respectively, indicating that the probe could be rapidly metabolized in the blood. Imaging results showed that

the probe was concentrated at the tumor site of MDA-MB-231 in ACE positive breast cancer model, but no significant uptake was observed at the tumor site of MCF-7 in ACE negative breast cancer model. ***Conclusion:*** Molecular probe $^{68}$Ga-DOTA-BPP has good stability in vitro, and preliminary studies have shown that this probe has good targeting to TNBC tumors. Therefore, this study is expected to provide a new strategy for the diagnosis and treatment of TNBC.

## OP-215

### Construction of a novel PET probe of Iodine-124 labeled ADC for Trop-2 targeting and Micro-PET imaging

***Z. Zeng***[1], *D. Li*[1], *X. Yan*[2], *L. Li*[1], *J. Ding*[1], *X. Sheng*[2], *H. Zhu*[1], *Z. Yang*[1];
[1]*Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Department of Genitourinary Oncology, Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** Trop-2 is closely associated with the development and progression of various tumors, and its high expression is indicative of poor prognosis. Non-invasive imaging of Trop-2 in vivo can be achieved with an iodine-124 ($^{124}$I) labeled antibody drug conjugates (ADC, IMMU-132) positron emission tomography (PET) probe, which offers an essential approach for diagnosing and monitoring tumors with anti-Trop-2 clinical practice. ***Materials and Methods:*** In this study, we stained Trop-2 in pancreatic cancer tissue samples from patients with varying survival rates and developed a novel Trop-2 targeting molecular probe, $^{124}$I-IMMU-132. We investigated the targeting and binding abilities of the probe to Trop-2 positive tumors in Capan-1/MDA-MB-468/Mcf-7 cells and their animal models. ***Results:*** Immunofluorescent staining revealed that Trop-2 is highly expressed in human pancreatic cancer and can predict the prognosis. The constructed $^{124}$I-IMMU-132 probe had reliable radio-chemical characteristics and maintained binding affinity (Kd = 2.200 nmol/L). The probe uptake by Trop-2 positive Capan-1/MDA-MB-468 cells increased in a time-dependent manner. The probe specifically bound to Capan-1/MDA-MB-468 tumors in vivo, and the T/muscle ratio of SUVmax gradually increased with time from 4.30 ± 0.55 to 10.78 ± 1.80 ($p<0.01$) in the Capan-1 model and from 8.84 ± 0.95 to 32.20 ± 2.9 ($p<0.001$) in the MDA-MB-468 model. The biodistribution and pharmacokinetics of $^{124}$I-IMMU-132 in the mouse model were consistent with the imaging, and the estimated dosimetry for humans was acceptable (the effective radiation dose was less than 4.2 mSv when 70 MBq probe was injected). ***Conclusion:*** $^{124}$I-IMMU-132 PET is a promising imaging technique for delineating Trop-2 positive tumors, with great potential in early diagnosis and targeted population selection of patients.

## OP-216

### Immuno-PET Imaging of Tumor Mesothelin Expression with Gallium-68 Radiolabeled Nanobody

***X. Lv***[1,2], *Z. Xu*[3], *X. Song*[1,2], *Y. Gai*[1,2], *D. Jiang*[1,2], *P. Lei*[3], *W. Wei*[4], *Y. Zhang*[1,2], *R. An*[1,2], *X. Lan*[1,2];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Department of Immunology, School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [4]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.*

***Aim/Introduction:*** Mesothelin (MSLN) overexpresses in various solid tumors especially in pancreatic cancer and ovarian cancer while limited in normal tissues, making it a promising candidate for molecular imaging and targeted therapy. Nanobodies, the smallest antibody derived fragment, are facile to modify for functional agent conjugation, together with ideal characteristics appropriate to aforementioned application. Then immuno-positron emission tomography (Immuno-PET) could provide valuable whole-body information for analysis of related target properties and potential lacks. The objective of this work was to evaluate the in vivo distribution property of the nanobody (MS3) as MSLN-overexpressing tumor-directing agent via immuno-PET study. ***Materials and Methods:*** By labeling a MSLN-specific nanobody with Gallium-68, we developed a MSLN-targeted immune-PET imaging probe [$^{68}$Ga]Ga-NOTA-MS3. The in vivo characteristics and specificity of the probe was estimated in preclinical tumor models bearing different level of MSLN. Then we strived to reduce renal uptake with premedication of sodium maleate, thereby improving visualization of intraperitoneal tumor lesions and protecting from radiation-induced nephrotoxicity. The mean percentage of injected dose per gram (%ID/g) for various tissues were obtained by drawing regions of interest. Human cancer cells lines BxPC-3 and HuH-7 were identified as respectively high and low MSLN-expressing, and the BxPC-3 MSLN knockout (BxPC-3 KO) cell line was successfully constructed for comparative study. ***Results:*** The non-decay corrected yield of $^{68}$Ga-NOTA-MS3 was around 47%, and the radiochemical purity exceeded 98% according to radio-high-performance liquid chromatography. Consistent with the results from western blot and immunohistochemistry, the tumor uptake of $^{68}$Ga-NOTA-MS3 was ranked from highest to lowest in BxPC-3, BxPC-3 KO and HuH-7. Apart from the half-hour point imaging greatly affected by blood-pool signal, the tumor uptakes, tumor-to-muscle (T/M) and tumor-to-blood (T/B) ratios of BxPC-3 on each time point were significantly higher than those in the other two groups. The highest tumor uptake, T/M and T/B of BxPC-3 come to 1.28%ID/g at 30 minutes post-injection, 22.2 and 8.18 at 4 h post-injection, respectively. Furthermore, the pre-administration of sodium maleate significantly reduced renal uptake of $^{68}$Ga-NOTA-MS3, from 32.2 to 7.52%ID/g at 30 minutes post-injection, without compromising tumor uptake, hence ameliorate the delineation of tumor in situ. ***Conclusion:*** We successfully validated one specific MSLN nanobody, MS3, and the derived immune-PET probe $^{68}$Ga-NOTA-MS3 showed precise visualization for accurate diagnosis of MSLN-expressing lesions.

## OP-217

### CD70-targeted immunoPET imaging of renal carcinomas

***X. Zhou***, *Q. Xia, J. Liu, W. Wei;*
*shanghai jiaotong university, Shanghai, CHINA.*

***Aim/Introduction:*** The diagnosis of primary and metastatic lesions in renal cell carcinoma (RCC) remains a clinical challenge. The cluster of differentiation (CD70) is specifically expressed in RCC making it a potential diagnostic and therapeutic target for RCC. This work aims to develop an immuno-positron emission tomography (immunoPET) imaging strategy targeting CD70 and to assess the diagnostic value of new molecular probes in preclinical RCC models. ***Materials and Methods:*** CD70 expression was detected in various types of RCCs and normal kidney tissues using immunohistochemical staining. Two novel CD70-specific single-domain antibodies (sdAbs) and their albumin-binding domain (ABD) variants were produced and labeled with gallium-68 ($^{68}$Ga, $T_{1/2}$ = 1.1 h) and zirconium-89 ($^{89}$Zr, $T_{1/2}$ = 78.4

h) to develop radiolabelled agents with different half-lives. The diagnostic properties of the developed tracers targeting CD70 ( [$^{68}$Ga]Ga-NOTA-B3, [$^{68}$Ga]Ga-NOTA-B6, and [$^{89}$Zr]Zr-DFO-ABDB6) were evaluated in subcutaneous RCC patient-derived xenograft (PDX) models. For clinical study, PET/CT images were acquired at 1 h after injection of [$^{68}$Ga]Ga-NOTA-B6 (1.85-3.7 MBq/kg) in 3 RCC patients with metastases. ***Results:*** Expression of CD70 was associated with gender, tumor differentiation, tumor thrombus, necrosis, distant metastasis, and overall survival. SdAbs targeting CD70 and ABD fusion proteins had high affinity for recombinant human CD70. ImmunoPET imaging with [$^{68}$Ga]Ga-NOTA-B3 and [$^{68}$Ga]Ga-NOTA-B6 visualized subcutaneous RCC with clarity. Tumor uptake of [$^{68}$Ga]Ga-NOTA-B6 was significantly reduced after the blockade of CD70. [$^{68}$Ga]Ga-NOTA-ABDB6 had significantly prolonged in vivo circulation time. Multi-time point immunoPET imaging with [$^{89}$Zr]Zr-DFO-ABDB6 showed that tumors were visible within 144 h after injection, with the best tumor-to-background ratio achieved at 72 h after injection. In 3 RCC cancer patients, there was no adverse reaction during study. The uptake of [$^{68}$Ga]Ga-NOTA-B6 had signifcantly high tumor uptake in CD70-positive metastatic lesions at 1h post-injection. ***Conclusion:*** CD70 is expressed in primary and metastatic lesions of most ccRCCs and is strongly associated with patient survival. We have successfully developed sdAb-derived CD70-targeted immunoPET tracers and characterized their superior diagnostic accuracies in preclinical RCC models.

## OP-218

### Screening, development and preliminary evaluation of CLDN18.2 specific peptide PET probes

***Z. Wang***[1], *C. Zhao*[2], *J. Ding*[1], *H. Zhu*[1];
[1]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Key Laboratory for Research Evaluation of Radiopharmaceuticals (National Medical Products Administration), Department of Nuclear Medicine, Peking University Cance, Beijing, CHINA,*
[2]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Biochemistry and Molecular Biology, Peking University Cancer Hospital and Institute, Beijing, Beijing, CHINA.*

***Aim/Introduction:*** Gastric cancer (GC) remains prevalent worldwide, especially in Asian countries. Recent global clinical trials have shown that CLDN18.2 is an ideal target for the treatment of gastric cancer and patients with high CLDN18.2 expression can benefit from targeted therapy. Therefore, accurate and comprehensive detection of CLDN18.2 expression is important to the effective use of this target. The objectives of this study are to screen and obtain CLDN18.2 specific targeted peptides, and construct $^{68}$Ga labeled molecular probes to achieve real-time and comprehensive evaluation of CLDN18.2 in vivo. ***Materials and Methods:*** Phage display technology was used to screen CLDN18.2 specific peptides from 100 billion libraries. 293T$^{CLDN18.1}$ cells were used to exclude non-specific binding and CLDN18.1 binding sequences while 293T$^{CLDN18.2}$ cells were used to screen CLDN18.2 specific binding peptides. The monoclonal clones obtained from phage screening were sequenced and peptides were synthesized based on the sequencing results. Binding specificity and affinity were assessed with FITC conjugated peptide using ELISA, flow cytometry and immunofluorescence experiments. DOTA conjugated peptide was also synthesized for $^{68}$Ga radio labeling. The in vitro stability, in vivo molecular imaging and biodistribution were also characterized. ***Results:*** Overall, 54 monoclonal clones were selected after phage display screening. Subsequently, based on cell ELISA results, CLDN18.2 preference monoclonal clones were selected for DNA sequencing, and four 7-peptide sequences were obtained after sequence comparison. Among them, a peptide named T37 was further validated in vitro and in vivo. The T37 peptide specifically recognized CLDN18.2 but not CLDN18.1 and bound strongly and specifically to CLDN18.2-positive cell membranes. The $^{68}$Ga-DOTA-T37 probe has good properties and high stability in vitro. It has high biological safety and PET/CT studies have shown that it can specifically target CLDN18.2 protein and CLDN18.2-positive tumors in mice. ***Conclusion:*** A CLDN18.2-specific peptide T37 was obtained. $^{68}$Ga-DOTA-T37 demonstrated the superiority and feasibility of being a CLDN18.2 specific probe in PCT/CT imaging that deserves further development and exploitation.

## OP-219

### Immuno-PET of Colorectal Cancer with A CEA-Targeted $^{68}$Ga-Nanobody: From Bench to Bedside

***L. Li***[1], *X. Lin*[1], *X. Ma*[1], *F. Liu*[1], *B. Jia*[2], *Z. Yang*[1];
[1]*Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Peking University, Beijing, CHINA.*

***Aim/Introduction:*** The accurate diagnosis of colorectal carcinoma (CRC) can assist physicians in developing reasonable therapeutic regimens, thereby significantly improving patient's prognosis. Carcinoembryonic antigen (CEA)-targeted PET imaging shows great potential for this purpose. Despite showing remarkable abilities to detect CRC, previously reported CEA-specific antibody radiotracers or pretargeted imaging are not suitable for clinical use due to poor pharmacokinetics and complicated imaging procedures. In contrast, nanobodies exhibit ideal characteristics for PET imaging, for instance, rapid clearance rates and excellent distribution profiles, allowing same-day imaging with sufficient contrast. In this study, we developed a novel CEA-targeted nanobody radiotracer, $^{68}$Ga-HNI01, and assessed its tumor imaging ability and biodistribution profile in preclinical xenografts and patients with primary and metastatic CRC. ***Materials and Methods:*** HNI01 was generated by immunizing lama with CEA proteins and site-specifically with $^{68}$Ga using the THP as chelator. Micro PET imaging and biodistribution studies were performed in CEA-positive LS174T and CEA-negative HT-29 xenografts. Following successful preclinical assessment, a phase I study was conducted in 9 patients with primary and metastatic CRC. Participants received 151.21 ± 25.25 MBq of intravenous $^{68}$Ga-HNI01 and underwent PET/CT scan at 1 h and 2 h post injection. Patients 01-03 also underwent whole-body dynamic PET imaging within 0-40 minutes p.i. All patients underwent $^{18}$F-FDG PET/CT imaging within 1 week after $^{68}$Ga-HNI01 imaging. Tracer distribution, pharmacokinetics and radiation dosimetry were calculated. ***Results:*** $^{68}$Ga-HNI01 was successfully synthesized within 10 minutes under mild conditions with radiochemical purity > 98% without purification. Miro PET imaging revealed clear visualization of LS174T tumors, while signals from HT-29 tumors were significantly lower. Biodistribution studies indicated that uptake of $^{68}$Ga-HNI01 in LS174T and HT-29 was 8.83 ± 3.02 %ID/g and 1.81 ± 0.87 %ID/g, respectively, at 2 h p.i. No adverse events occurred in all clinical participants after injection of $^{68}$Ga-HNI01. A fast blood clearance and low background uptake were observed, and CRC lesions could be visualized with high contrast as early as 30 minutes after injection. $^{68}$Ga-HNI01 PET could clearly detect metastatic lesions in the liver, lung and pancreas, and showed superior ability than $^{18}$F-FDG PET/CT in detecting small metastases. ***Conclusion:*** $^{68}$Ga-HNI01 is a novel CEA-targeted

PET imaging radiotracer with excellent pharmacokinetics and favorable dosimetry profiles. $^{68}$Ga-HNI01 PET is an effective and convenient imaging tool for detecting CRC lesions, particularly for identifying small metastases.

## OP-220

### Increasing the Tumor-to-Blood Ratio by Click-Cleavable Radioimmunoimaging with [$^{89}$Zr]Zr-DFO-Trans-Cyclooctene-Trastuzumab in Mice

***K. E. de Roode***[1,2], *M. Vlastara*[1], *R. Rossin*[1], *F. J. M. Hoeben*[3], *M. Boswinkel*[2], *L. H. J. Kleijn*[1], *J. Nagarajah*[2], *S. Heskamp*[2], *M. Rijpkema*[2], *M. S. Robillard*[1];
[1]*Tagworks Pharmaceuticals, Nijmegen, NETHERLANDS,* [2]*Department of Medical Imaging, Radboud University Medical Centre, Nijmegen, NETHERLANDS,* [3]*SyMO-Chem, Eindhoven, NETHERLANDS.*

***Aim/Introduction:*** Positron-emission tomography (PET) imaging using $^{89}$Zr-labeled monoclonal antibodies is limited by the long blood circulation time of these antibodies, resulting in low tumor-to-background ratios. To overcome this drawback, we developed a $^{89}$Zr-labeled Trastuzumab (Tmab) construct, [$^{89}$Zr]Zr-TCO-Tmab comprising a chemically cleavable trans-cyclooctene (TCO) linker [1, 2] between antibody and radiometal-chelate. Upon in vivo reaction with tetrazine (trigger) in blood, but not inside tumor cells, a bioorthogonal click-to-release reaction leads to liberation of rapidly clearing [$^{89}$Zr]Zr-DFO from the antibody construct. ***Materials and Methods:*** Several [$^{89}$Zr]Zr-TCO-Tmab construct variants were synthesised and their [$^{89}$Zr]Zr-DFO release upon reaction with trigger was evaluated in vitro. The best performing candidate was studied in vitro on BT-474 cancer cells to determine the rate of internalisation, and subsequently in healthy and BT-474 tumor-bearing mice to determine the biodistribution with and without trigger. In addition, PET imaging of tumour-bearing mice administered with [$^{89}$Zr]Zr-TCO-Tmab was performed before and after trigger administration. ***Results:*** The best performing [$^{89}$Zr]Zr-TCO-Tmab and trigger pair demonstrated 83% release of [$^{89}$Zr]Zr-DFO fragment in mouse plasma, and in line with predicted HER2 internalization over time, successful internalisation of [$^{89}$Zr]Zr-TCO-Tmab into BT-474 cells was observed in vitro. In tumor-bearing mice we observed a striking increase of the tumour-to-blood ratio from 1.0 ± 0.4 to 2.3 ± 0.6 (p=0.0057) and from 2.5 ± 0.7 to 6.6 ± 0.9 (p<0.0001) when the trigger was administered at 6 h and 24 h post-mAb, respectively. Same-day PET imaging confirmed a clear increase in tumor-to-background ratio after administration of trigger. ***Conclusion:*** We demonstrated successful enhancement of tumor-to-background ratios in mice using a click-cleavable [$^{89}$Zr]Zr-TCO-Tmab construct. The results presented here demonstrate the potential of click-cleavable strategies to reduce radiation doses and overcome inconvenient lengthy intervals in PET imaging with full-size antibodies. ***References:*** 1. ## Cutting Edge Science Track - TROP Session: Segmentation and Denoising

## OP-221

### Deep learning is a promising tool for fully automatic malignant lesions identification and segmentation in whole-body bone scans

***F. Oliveira***, *Â. Silva, J. Castanheira, M. Silva, C. Constantino, D. C. Costa;*
*Champalimaud Foundation, Lisboa, PORTUGAL.*

***Aim/Introduction:*** Automated identification of malignant lesions in whole-body bone scans (BS) as well as the delineation of those lesions for the computation of the bone scan index are important tasks for disease quantification. We aim to assess the feasibility of fully automatic malignant lesion detection and segmentation in BS using deep learning based on a U-Net architecture. ***Materials and Methods:*** We randomly selected, from our archives, 434 whole-body BS obtained with $^{99m}$Tc-HDP ($^{99m}$Tc-hydroxydiphosphonate), in anterior and posterior projections. Two nuclear medicine physicians reviewed the BS and all information contained in the patients' clinical records. Thereafter, they labeled all bone lesions suspected of malignancy. A self-adaptative Bayesian classifier was used for semiautomatic lesion segmentation [1]. For each malignant lesion, the segmentation was done in the projection displaying higher contrast to the background. In cases where two segmentations were obtained (one per projection), they were fused afterward. For fully automatic lesion detection and segmentation, we trained a two-channel 2D U-Net using the nnU-Net framework [2]. The dataset was randomly split into 384 BS for training and the remainder 50 for the test. The posterior projection of each BS was mirrored to match the anterior projection pixel-by-pixel and then used as a second channel in the 2D U-Net. The Dice coefficient was used to measure the pixelwise agreement between the semiautomatic and fully automatic segmentations. ***Results:*** In total, 155 BS were identified by the physicians as having at least one malignant lesion, 137 were included in the training, and 18 were in the test set. Most of the "non-malignant" BS were from oncological patients with only degenerative bone and joint disease. After applying the 2D U-Net model obtained in the training process to the test set, 16 out of 18 BS were correctly identified as having malignant lesions (sensitivity 89%), and 31 out of 32 without malignant lesions (specificity 97%). The BS classification predictive positive value (PPV) was 94%. Regarding the quality of the segmentation on the 18 BS of the test set with malignant lesions, the median Dice coefficient was 0.68 (interquartile range 0.48-0.77), with sensitivity of 54%, and PPV of 90%. ***Conclusion:*** The solution here implemented using deep learning is a promising tool for the automatic identification of BS with malignant lesions and their segmentation. Financial support: Project LISBOA/NORTE-01-0247-FEDER-017685, from PORTUGAL2020. ***References:*** [1] Constantino et al. J Digit Imaging. 2023. doi:10.1007/s10278-023-00823-y. [2] Isensee et al. ## OP-222

### Using a 3-D UNet artificial intelligence model to segment PSMA-avid lesions in $^{68}$Ga-PSMA-11 PET/CT images

***E. Greenblatt***[1], *M. Maker*[1], *A. Kadumberi*[1], *S. Wail*[2], *P. Kuo*[1];
[1]*Invicro, Needham, MA, UNITED STATES OF AMERICA,*
[2]*Telix Pharmaceuticals, North Melbourne, AUSTRALIA.*

***Aim/Introduction:*** $^{68}$Ga-PSMA-11, a PET imaging radiopharmaceutical, is utilized for staging and detection of biochemical recurrence of prostate cancer. PSMA-avid lesion segmentation enables assessment of quantitative volumetric and SUV metrics. Segmentation is resource demanding - particularly with extensive multi-system disease. The aim was to develop artificial intelligence segmentation of lesions trained with $^{68}$Ga-PSMA-11 image datasets. ***Materials and Methods:*** 660 PET/CT images were gathered from three sites. Images from two sites were divided into training (n=585) and benchmark (n=30) datasets; the third site's images (n=45) were test data. A standard was developed for disease below 3g/ml that may be clinically relevant in low disease burden patients. Semi-automated tools were utilized to label bone, lymph node, liver, prostate/prostate bed, peritoneal, pleura, and adrenal lesions. UNet models were trained to predict lesion classes at both high and low resolution; several included a physiological uptake segmentation class. Models were tested in cross-validated predictions of training data, and lead models were evaluated with benchmark and validation datasets. For each lesion class the average, median, and volume-weighted average dice ($Dice_{vw}$) scores described model performance. $R^2$ between predicted versus ground truth volume, SUV mean, SUV maximum, PSMA load, and the fraction of cases that were purely false-positive or false-negative characterized the model's stratification of disease burden across patients. ***Results:*** Bone segmentations matched experts in all datasets and models ($0.79<Dice_{vw}<0.92$). Lymph node performance was more varied ($0.44<Dice_{vw}<0.76$), as was the prostate class where cases were available ($0.06<Dice_{vw}<0.68$). $R^2$ across patients followed a similar pattern among classes with bone showing the strongest relationships ($0.83<R^2<1.00$), while these measures were highly varied for lymph node and prostate ($0<R^2<1.00$). Low disease, liver and other class performed poorly. One high-resolution model with the physiological uptake class was highest performing across datasets, although the high-resolution model without such segmentation had superior lymph node segmentation in the benchmark and test datasets. Clinical review of the segmentations found bone and lymph node segmentations to be valuable and beneficial in volumetric analysis of $^{68}$Ga-PSMA-11 images. ***Conclusion:*** High-resolution models trained on this population are advantageous for segmenting large bone lesions at resolutions twice the PET image. Lymph node and prostate segmentations also performed well but require review in the pelvic region. Segmentation of prostatic lesions are difficult to distinguish from the bladder. The models segment low disease, liver and other lesion classes poorly. The addition of more training data, including no lesion images, may improve future models.

## OP-223

### A Feature-Based Ensemble of 3D U-Nets for Computed Tomography (CT) Lung Lobe Segmentation

***E. Amini***[1,2], *R. Klein*[1,3,4];
[1]*Ottawa Hospital Research Institute, Ottawa, ON, CANADA,* [2]*Carleton University, Ottawa, ON, CANADA,* [3]*The Ottawa Hospital Department of Nuclear Medicine, Ottawa, ON, CANADA,* [4]*University of Ottawa Department of Medicine, Ottawa, ON, CANADA.*

***Aim/Introduction:*** Lung lobe segmentation is a critical step in the diagnosis, treatment, and monitoring of lung diseases. Recent advances in deep learning-based approaches have shown promising results for accurate and efficient lung lobe segmentation. However, the clinical applicability of these algorithms is challenging due to a wide variation in fissure anatomy, disease and imaging methods. We propose a novel segmentation method explicitly trained on a unique, heterogenous image set. ***Materials and Methods:*** The study used a dataset of 120 CT scans with annotations for lung lobes and trachea. Images were stratified by difficulty of lung lobe segmentation by visual score on a 3-level scale based on factors such as fissure perceptibility, completeness, and presence of disease patterns. Data were then split randomly into 80% for training and 20% for testing preserving stratification. To prepare the training data, eigenvalue analysis of the Hessian matrix at three different scales was performed on each scan to generate tubular structures (e.g., blood vessels and airways) in the image, at three levels of detail (coarse to fine). Consequently, each lobe presents as its own network of airways and blood vessels; revealing the fissures as gaps between these networks. Each CT scan was then masked with the filtered image and its associated trachea label, and a 3D U-Net architecture was separately trained for each detail level. A fourth model was trained on the unprocessed CT scans. As a final step, a random forest classifier was trained to combine the outputs from these models to segment each lobe. The performance of the proposed method is evaluated using the dice similarity coefficient (DSC) and the mean surface distance (MSD). ***Results:*** The proposed method DSC correlated with difficulty class (DSC = 0.93±0.01, 0.91±0.09 and 0.71±026 for easy, moderate, and hard, respectively). However, MSD (0.46±0.15, 0.44±0.09, and 0.48±0.14 mm) was consistent between difficulty classes. These results are consistent with visual impression of segmentation results in which erroneous segments tended to crisscross the fissures. ***Conclusion:*** In this study, we performed a lung lobe segmentation using a feature-based ensemble of 3D U-Net models using CT scans and tubular structure-filtered images. The segmentation performance correlates with visual impression of the task difficulty, achieving clinically useful results with good image quality and good fissure visibility. Future efforts must address difficult cases by improving automation and/or enabling manual tweaking of automatic segmentation results.

## OP-224

### Improving Automated Lesion Detection and Segmentation in PET/CT Scans: A Comparative Study of 3D UNet-Based Configurations

***M. Namías***, *Y. V. Rotstein Habarnau;*
*Fundación Centro Diagnóstico Nuclear, Buenos Aires, ARGENTINA.*

***Aim/Introduction:*** Fluorodeoxyglucose (FDG) positron emission tomography / computed tomography (PET/CT) scans are routinely used for oncologic staging and response assessment. In this context, automatic lesion detection and segmentation is still a challenging task, since lesions are not the only FDG-avid regions, with physiological uptake also present on healthy tissues. Moreover, lesions of different shapes, sizes and FDG uptake may be found in diverse body regions. In this work, we explore different deep learning strategies to improve the rate of both false positive and false negative results in automated lesion detection and segmentation. ***Materials and Methods:*** We compared the performance of different 3D UNet-based configurations that automatically segment the lesions in PET/CT images. We trained

a 3D UNet using different input channels: PET image, a denoised PET image, the fusion of PET and CT images, and the fusion of PET, CT and organ segmentations obtained from the CT images. We also trained a mirror-UNet: one path segments the organs from a CT image and the other one segments the lesions from the PET image, with both paths sharing the bottleneck and thus obtaining a multimodal representation of image features. We trained and validated our networks on the AutoPET MICCAI 2022 Challenge dataset [1], considering only the studies with lesions. We used the Dice score, false positive (FPV) and false negative (FNV) volumes as performance metrics, averaged over the studied test cases. ***Results:*** We found that combining the PET and CT reduces the FPV compared to the unimodal PET model (12.13 ml vs 25.27 ml), but slightly increases the FNV (8.67 ml vs 5.70 ml). They both have similar Dice coefficients (0.65 for PET/CT vs 0.64 for PET). Adding a tissue segmentation channel as an input reduces the FPV compared to unimodal PET (13.02 ml), at the expense of FNV and Dice performance (14.70 ml and 0.57 respectively). The denoised version of the PET model had a very similar performance to that of the original PET (Dice=0.64, FPV=26.51 ml, FNV=5.04 ml). The mirror-UNet configuration gave the best Dice and FNV and a better FPV than de unimodal PET: Dice=0.67, FPV=18.93 ml and FNV=4.13 ml. ***Conclusion:*** We successfully compared the performance of different 3D UNet-based configurations for automatic lesion detection and segmentation in PET/CT, of which the mirror-UNet variant is the best-performing one. ***References:*** [1] https://autopet.grand-challenge.org/

## OP-225

### A Hybrid Neural Network Architecture to improve low-dose PET Image Reconstruction

***S. Kaviani***[1], *A. Sanaat*[2], *M. Mokri*[1], *C. Cohalan*[3], *J. Carrier*[1,4]; *[1]Université de Montréal, Montréal, QC, CANADA, [2]University of Geneva, Geneva, SWITZERLAND, [3]CHUM - Centre hospitalier de l'Université de Montréal, Montréal, QC, CANADA, [4]CHUM - Centre hospitalier de l'Université de Montréal, Montreal, QC, CANADA.*

***Aim/Introduction:*** Positron emission tomography (PET) images are prone to noise, resulting in low contrast and reduced spatial resolution, particularly in low-count settings typical for dynamic acquisitions. The challenge of low-count PET data is a major concern in clinical practice, as it leads to difficulties in image interpretation and may compromise the accuracy of diagnosis. Therefore, developing an accurate and efficient image reconstruction method for low-count PET data is essential. In this work, we propose a novel deep-learning approach for low-dose PET image reconstruction. ***Materials and Methods:*** The novel deep learning approach for low-dose PET image reconstruction by combining two neural network architectures, the Transformer and UNet, and incorporating them into the unrolled maximum a posteriori estimation (MAPEM) algorithm. Our proposed approach was evaluated using both simulated and real patient data. The simulated dataset was generated using NiftyPET to simulate forward projection operators and noise models to generate ground truth images and simulated projection data, while the real patient dataset was acquired using a Siemens Biograph mMR PET scanner. We also implemented state-of-the-art methods for comparison purposes: OSEM, MAPEM, and unsupervised denoising. The reconstructed images are compared to ground truth images using metrics such as peak signal-to-noise ratio (PSNR), structural similarity index (SSIM), and relative root mean square error (rRMSE) to quantitatively evaluate the accuracy of the reconstructed images. ***Results:*** For the simulated data, our approach achieved an average PSNR of 38.91, an average SSIM of 0.976, and an average rRMSE of 0.077. These results outperformed 3 state-of-the-art methods, which had average PSNRs of 36.54, 37.15, and 37.88, average SSIMs of 0.969, 0.972, and 0.974, and average rRMSEs of 0.105, 0.093, and 0.089. For the real patient data, our approach achieved an average PSNR of 33.72, an average SSIM of 0.955, and an average rRMSE of 0.129. These results also outperformed other methods which had average PSNRs of 31.89, 32.12, and 32.87, average SSIMs of 0.944, 0.947, and 0.950, and average rRMSEs of 0.159, 0.149, and 0.145. ***Conclusion:*** These results demonstrate that our proposed approach can effectively reconstruct low-dose PET images with reduced noise levels and better edge preservation compared to other reconstruction and post-processing algorithms. Our method shows potential for clinical use as it can reconstruct smooth images while preserving edges.

## OP-226

### A deep learning method for the recovery of standard-dose imaging quality from ultra-low-dose PET on wavelet domain

***S. Xue***[1], *F. Liu*[1], *H. Wang*[2], *M. Viscione*[1], *R. Guo*[2], *A. Rominger*[1], *B. Li*[2], *K. Shi*[1]; *[1]University of Bern, Bern, SWITZERLAND, [2]Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Recent development in positron emission tomography (PET) dramatically increased the effective sensitivity by increasing the geometric coverage leading to total-body PET imaging. This encouraging breakthrough brings the hope of ultra-low dose PET imaging equivalent to transatlantic flight with the assistance of deep learning (DL)-based methods. A critical bottleneck for conventional DL-based methods is their limited capability in the application in the heterogeneous domain of PET imaging. We aim to develop a wavelet-based DL method that can recover high-quality imaging from ultra-low-dose PET. ***Materials and Methods:*** In contrast to traditional DL techniques that perform denoising on the image domain, we propose to feed the network with the wavelet-decomposed high frequency component of PET imaging, where the noise is mainly concentrated. The effectiveness and robustness of our proposed approach was verified in tests of different imaging tracers on different scanners. Total-body PET images of 550 patients using $^{18}$F-FDG, $^{18}$F-PSMA, $^{68}$Ga-DOTA-TOC, $^{68}$Ga-DOTA-TATE, acquired using total-body PET scanners, including Biograph Vision Quadra (Siemens Healthineers), uEXPLORER (United Imaging) in Shanghai and Bern, were included for the development and testing of the proposed method [1]. The generated image quality was evaluated with customized scoring system, using weighted global physical metrics and local clinical-relevant features. ***Results:*** Although the method was developed using data from one scanner, it achieved score of 2.16 on both Quadra and Explorer, which improved over conventional deep learning methods (2.09) and non-AI enhanced images (1.66). Our deep learning methodology showed advantages on all DRF ($p < 0.05$). ***Conclusion:*** The proposed wavelet-based DL method leads to fast computation and despeckling with well-preserved image details, which can improve the performance and robustness of image quality recovery on ultra-low-dose PET imaging. It may improve the trustworthiness and clinical acceptability of DL-based dose reduction. ***References:*** Xue, Song, et al. "A cross-scanner and cross-tracer deep learning method for the recovery of standard-dose imaging quality from low-dose PET." European journal of nuclear medicine and molecular imaging (2021): 1-14.

## OP-227

### Sequential Deep Learning Image Enhancement Models Improve Diagnostic Confidence, Lesion Detectability and Image Reconstruction Time in PET

***M. Dedja***[1], *A. Mehranian*[2], *K. M. Bradley*[3], *M. D. Walker*[1], *S. D. Wollenweber*[4], *R. Johnsen*[4], *D. R. McGowan*[1,5];
[1]*Oxford University Hospitals, Oxford, UNITED KINGDOM,* [2]*GE Healthcare, Oxford, UNITED KINGDOM,* [3]*Cardiff University, Cardiff, UNITED KINGDOM,* [4]*GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA,* [5]*University of Oxford, Oxford, UNITED KINGDOM.*

***Aim/Introduction:*** Investigate the potential benefits of sequential deployment of two deep learning (DL) algorithms namely DL Enhancement (DLE) and DL-based time-of-flight (ToF) (DLT). DLE aims to enhance the rapidly reconstructed ordered subset expectation maximisation algorithm (OSEM) images towards block-sequential-regularised-expectation-maximisation (BRSEM) images [1], whereas DLT aims to improve the quality of BRSEM images reconstructed without ToF [2]. As the algorithms differ in their purpose, the sequential application may allow the benefits from each to be combined. ***Materials and Methods:*** 20 FDG PET-CT scans were performed on a GE Healthcare PET-CT D710 scanner. List-mode data was reconstructed with four combinations of algorithms: 1.BRSEMToF, 2.BRSEMnonToF+DLT, 3.OSEMToF+DLE and 4.OSEMToF+DLE+DLT. To assess image noise, 30mm-diameter spheres were drawn in both lung and liver to measure standard deviation of voxels within the volume. In a blind clinical reading, an experienced reader rated the images in a five-point Likert scale (5 best) based on diagnostic confidence and lesion detectability. The reader also ranked the images based on the same metrics (1 best). Statistical differences were corrected for multiple comparisons using Bonferroni correction. ***Results:*** For reconstructions 1-4 noise in the liver was 0.24±0.04,0.23±0.06,0.19±0.04,0.19±0.04. There was a significant decrease in image noise for 3&4 compared to the reference reconstruction (1) (Bonferroni corrected p<0.02), demonstrating that reconstructions with DLE have lower liver noise. Conversely, for the lung 0.07±0.02,0.08±0.02,0.07±0.02,0.07±0.02 with no statistical difference across reconstructions (p>0.05). Clinical image reading scores showed a significant preference for OSEMToF+DLE+DLT over other reconstructions in both lesion detectability(p<0.05) and diagnostic confidence(p<0.05). The score for lesion detectability in reconstructions 1-4 was 3.85±0.48,3.75±0.54,3.6±0.66,4.8±0.40 and the ranking was 2.40±0.80,2.65±1.01,2.55±1.02,1.00±0.00. For diagnostic confidence the score was: 3.50±0.59,3.35±0.65,3.65±0.57,4.8±0.40, the ranking was: 2.65±0.91,2.85±1.01,2.30±0.84,1.00±0.00. ***Conclusion:*** The combination of DLE and DLT increases diagnostic confidence and lesion detectability compared to BRSEM images, and to each DL algorithm in isolation. As DLE+DLT uses input OSEM images, and because DL inferencing is fast, there is a significant decrease in overall reconstruction time. This could have applications to total body PET as reconstruction time increases with the axial field of view. Future work will include multiple blinded readers and additional test cases. ***References:*** [1]Mehranian, A. et al.(2021) "Image enhancement of whole-body oncology [18F]-FDG PET scans using deep neural networks to reduce noise,"European Journal of Nuclear Medicine and Molecular Imaging, 49(2), pp. 539-549. [2]Mehranian, A. et al.(2022) "Deep learning-based time-of-flight image enhancement of non-ToF PET scans," European Journal of Nuclear Medicine and Molecular Imaging, 49(11), pp. 3740-3749.

## OP-228

### The Effect of Multimodal Anatomical Images in Deep Learning-enhanced Low-dose Amyloid PET Imaging

***S. Kuo***[1], *M. Lee*[1], *C. Ko*[2], *K. T. Chen*[1];
[1]*National Taiwan University, Taipei, TAIWAN,* [2]*National Taiwan University Hospital, Taipei, TAIWAN.*

***Aim/Introduction:*** Amyloid PET has been commonly used in Alzheimer's disease diagnoses [1]. As the potential risk of radiation exposure remains a concern, deep learning methods have been proposed to generate full-dose PET images from simulated low-dose PET images [2, 3]. This study aims to investigate the contribution of multimodal anatomical images (CT and MRI) by leveraging all available imaging information. ***Materials and Methods:*** The images used in this study were obtained from 52 (mean±standard deviation [SD]: 65.4±12.2 years) participants and acquired separately on PET/CT and MR scanners; 410±102 MBq of the amyloid radiotracer 11C-Pittsburgh Compound-B were administered to the participant. The dynamic PET scan time was 70 minutes. In each PET dataset the last 3 frames (40-70 minutes post-injection) were averaged to create the full-dose ground truth image. The third last frame (40-50 minutes post-injection) was chosen as the simulated low-dose PET image (about 1/3 dose). U-nets [4] were trained in this work with the inputs being combinations of multimodal images (Case 1: low-dose PET image only, Case 2: low-dose PET and CT images, Case 3: low-dose PET and T2-weighted MR images, and Case 4: low-dose PET, CT, and T2-weighted MR images). 10-fold cross-validation was used to prevent testing on the same datasets. The metrics PSNR and SSIM were used to evaluate image quality. ***Results:*** The results generated from these networks all demonstrated significant improvements (p-value < 0.001) in terms of metrics when compared to the low-dose PET images and resembled the full-dose ground truth images. The incorporation of additional modalities into network training all yielded relatively higher SSIM and PSNR scores. Comparing SSIM in models incorporating other modalities, namely Case 2 (mean±SD: 0.9825±0.0099), Case 3 (0.9844±0.0087), and Case 4 (0.9837±0.0095), to Case 1 (0.9720±0.0349), statistically significant improvements in all 3 comparisons were observed (p-value < 0.05). The addition of MR images (Case 3 and Case 4) also showed significant improvement (p-value < 0.05) in PSNR compared to Case 1. ***Conclusion:*** This study demonstrated that incorporating CT and MR information into a deep learning network for predicting full-dose PET images from low-dose PET images significantly improved image quality. These findings also highlighted the value of utilizing anatomical imaging information for PET-related deep learning tasks. ***References:*** [1] GD Femminella et al. Int J Mol Sci. 2018.[2] KT Chen et al. Radiology. 2019.[3] KT Chen et al. Eur J Nucl Med Mol Imaging. 2020.[4] O Ronneberger et al. MICCAI. 2015.

## OP-229

### Iterative Deep-Learning Denoising in Bone SPECT-CT Reconstruction Based on Simulations from Clinical Data

***O. Ziv***, *B. Yuzefovich, J. Sachs, G. Kovalski;*
*GE Healthcare, Haifa, ISRAEL.*

***Aim/Introduction:*** In Single-Photon Emission Computed Tomography (SPECT) imaging, achieving adequate signal-to-noise ratio is often limited by high statistical photonic noise. A fundamental problem in applying noise reduction techniques, is that small findings are typically similar to the image noise characteristics. Therefore, suppressing noise without impairing clinical image features is challenging with conventional algorithms.

Deep-Learning (DL) techniques have shown great potential in improving image quality in medical imaging applications. However, for SPECT it can be impractical to acquire high quality clinical images for the model learning targets. This study proposes a simulation-based DL approach to improve image quality of bone SPECT scans. ***Materials and Methods:*** Data generation: total of 2184 simulations were generated for the model training directly from clinical data including SPECT projections and CT images from 55 whole-body Tc99m bone exams. Realizations generation contains 4 steps: (1)Noise-free objects generation using dedicated algorithms, (2)Insertion of lesions with known location and contrast, (3)Noise insertion to depict a given scan time, (4)Final image reconstruction for training. DL model: a supervised 3D residual U-Net model was trained with input noisy image data and the ideal target data, using mean squared error loss function. During inferencing, the DL model is applied iteratively within the reconstruction iterations for incremental denoising process towards convergence. Both attenuation-corrected (AC) and non-corrected (NC) exams were processed. ***Results:*** The DL model was evaluated using digital phantom (XCAT with inserted lesions, 100 realizations) and clinical data (80 SPECT-CT exams, 6 expert readers). Both image characteristics (Structural Similarity Index (SSIM), Peak Signal-to-Noise Ratio (PSNR)) and lesion characteristics (Contrast-to-Noise Ratio (CNR), Contrast Recovery Coefficient (CRC)) were calculated on the digital phantom images. The clinical images were evaluated using a 5-points Likert score for Image Quality (IQ), Image Resolution (IR) and Noise Level (NL). The results (including 3 systems, 5 contrast ratios) represent an average improvement as compared to a standard reconstruction protocol (AC, NC respectively). Image characteristics improvement in SSIM (+4.8%, +3.8%) and PSNR (+12.1%, +2.9%) and lesion characteristics improvement in CNR (+29.6%, +42.4%) and CRC (+9.1%, +1.8%) were obtained. The clinical review demonstrated an improvement in IQ (+17.9%, +16.5%), IR (+27.2%, +25.7%) and NL (+12.2%, +17.0%). ***Conclusion:*** This study demonstrates a simulation-based DL approach integrated within the image reconstruction process to improve SPECT image quality. This approach effectively reduces noise, enhances image resolution and contrast, which led to improved image quality and potentially enhanced diagnostic accuracy.

## Clinical Oncology Track - TROP Session: Neuroendocrine Tumors Treatment

### OP-230

**A phase I theranostic study evaluating the safety and tolerability of $^{177}$Lu-satoreotide tetraxetan with $^{68}$Ga-satoreotide trizoxetan companion imaging in participants with extensive-stage small-cell lung cancer (ES-SCLC) on atezolizumab maintenance therapy**

***L. Emmett***[1], *J. Cardaci*[2], *K. O'Byrne*[3], *S. Arulananda*[4], *A. Prawira*[5], *B. Pais*[6,7], *M. Crumbaker*[1], *N. Lenzo*[8];
[1]*St Vincent's Hospital, Sydney, AUSTRALIA,* [2]*Hollywood Private Hospital, Nedlands, AUSTRALIA,* [3]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [4]*Monash Health, Clayton, AUSTRALIA,* [5]*Obatica, Zetland, AUSTRALIA,* [6]*Ariceum Therapeutics, Berlin, GERMANY,* [7]*SRT-Biomedical, Soest, NETHERLANDS,* [8]*GenesisCare, Murdoch, AUSTRALIA.*

***Aim/Introduction:*** ES-SCLC is a neuroendocrine carcinoma with a dismal prognosis. Etoposide/platinum-based chemotherapy (E/P-CT) has been the standard of care for patients with ES-SCLC for decades. Recently, immune checkpoint inhibition (ICI) with atezolizumab or durvalumab added to E/P-CT, followed by ICI maintenance therapy, has resulted in survival benefit. However, the need for improved treatment options remains as the median progression free (mPFS) and overall survival (mOS) is still not more than 5-7 and 13-14 months, respectively. Somatostatin receptor 2 (SST2) is expressed in the majority of SCLC lesions and SST2 targeted radioligand therapy has proven safe and effective in other neuroendocrine tumors. We therefore hypothesise that adding the SST2-antagonist $^{177}$Lu-satoreotide tetraxetan ($^{177}$Lu-SSO110) to maintenance treatment with atezolizumab is safe and will result in efficacy benefits for patients with ES-SCLC eligible for maintenance treatment. ***Materials and Methods:*** The main objective of this study is to assess the safety and tolerability of $^{177}$Lu-SSO110 and the recommended phase 2 dose in combination with atezolizumab. The secondary objective is to assess the preliminary anti-tumour activity. The exploratory objectives include the assessment of the level of concordance of lesions visible on $^{68}$Ga-satoreotide trizoxetan ($^{68}$Ga-SSO120) PET/CT versus lesions visible on contrast-enhanced CT and/or FDG PET. Inclusion criteria include histologically or cytologically confirmed ES-SCLC, adequate organ and bone marrow function, a life expectancy >18 weeks, and ≥1 positive lesion on $^{68}$Ga-SSO120 PET/CT. The first dose of $^{177}$Lu-SSO110 will be administered after the 1$^{st}$ or 2$^{nd}$ cycle of atezolizumab maintenance therapy. Each patient will be treated with 4 doses of $^{177}$Lu-SSO110 6-9 weeks apart, which may be extended up to 7 in case of clinical benefit. The study will follow a BOIN design to determine the recommended phase 2 dose with a target dose-limiting toxicity (DLT) rate of 0.30. The $^{177}$LuSSO110 starting dose is 3.7 GBq which can be (de)escalated to 2.3, 3.0, 4.5, and 5.2 GBq, as required. ***Results:*** Preliminary results of this ongoing, open label study will be presented at the meeting. ***Conclusion:*** This study will support the selection of a recommended phase 2 dose and assess preliminary safety and efficacy of $^{177}$Lu-SSO110 in patients with ES-SCLC on atezolizumab maintenance therapy.

### OP-231

**Evaluation of Progression-Free Survival (PFS) in Patients with Advanced, Non-resectable, Progressive GEP-NET Treated Using Combine Radioligand and CAPTEM therapy.**

***J. Cwikla***[1], *A. Zrajkowska*[2], *G. Nowicka*[3], *J. Pałucki*[4], *N. Seklecka*[2], *A. Kolasińska-Ćwikła*[4];
[1]*University of Warmia and Mazury, Olsztyn, POLAND,* [2]*Diagnostic and Therapy Center – "Gammed" Warsaw, Poland, Warsaw, POLAND,* [3]*Warsaw Medical University, Warsaw, POLAND,* [4]*Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, POLAND.*

***Aim/Introduction:*** Prospective, single-arm, open-label, case series study with assessment efficacy and safety of combined radioligand therapy (RLT) and CAPTEM in, advanced, unresectable progressive GEP-NET (NCT04194125). Primary endpoint: locally assessed RECIST 1.1 progression-free survival (PFS). Secondary goals: objective response rate (ORR), disease control rate (DCR), clinical response based on performance status (PS), additional safety (AEs). ***Materials and Methods:*** Twenty-one patients in group of 23 screened subjects between 18 February 2019 to 01 May 2023 included into analysis. All patients with confirmation of GEP-NETs at advanced, progressive, non-resectable stage.

Combine RLT ($^{177}$Lu DOTATOC) and CAPTEM used in all subjects. Clinical follow-up at least 48 months. Mean age 58.6 +12.6, male to female ratio 8/13. Tumour characteristics: NETG1=9, G2=10, G3=2. Disease status and treatment efficiency were evaluated by clinical assessment including PS, ORR, also biochemical response and safety profile of combine therapy. ***Results:*** Pancreatic (panNET) n=14, midgut n=7. Cumulative activity $^{177}$Lu (GBq) of whole therapy; median=25.1GBq (20.4-27.0), per therapy median=6.5 GBq (5.8-6.8). Median PFS for all subjects (IQR) 31.5 months (16.0-n.r.), panNET PFS 28.0 m (14.0-n.r.), midgut PFS=31.5 months (24.5-n.r). After 6 weeks of follow-up 9 pts (42%) had partial response (PR) and 11 (52%) had stable disease (SD), after 3 m 9 had PR, 8 had SD, single had disease progression (DP). After 6 m 9 PR, 9 SD and 2 DP, after 12 m single 1 complete response, 10 PR, 5 SD and 2 DP. DCR after 6 weeks all patients, after 3 months 17 subjects (90%), 6 months 18 patients (85%) and after 12 months 16 subjects (89%). Clinical evaluation including PS=1 in 12 subjects improved at 6 to PS=0 in 2 cases PS=2 improve to PS=1, no change in 7 subjects. Treatment-emergent adverse events (TEAEs) were reported in most of them. The most common AEs was a transient lymphopenia G2 (44%) and G3 (8%); others AEs and their significant intensity (at least G3) were observed sporadically, no G4, during and after therapy. Persistent lymphopenia in treated subjects noted in 16% of cases. ***Conclusion:*** Combine therapy (RLT&CAPTEM) is effective in GEP-NET in terms of improvement of PFS in those who had documented DP. Clinical response, DCR of combine therapy seen in most of subjects during follow-up. Significant benefit in terms of ORR reported in panNET but not in midgut. In panNET who had PR four of them had primary tumor removal, single with CR for 4 years.

## OP-232

### Safety and organs-at-risk dosimetry in patients with gastroenteropancreatic neuroendocrine tumours (GEP-NETs) treated with $^{177}$Lu-DOTATATE peptide receptor radionuclide therapy (PRRT): data from prospective phase II clinical trial

***M. Mileva***[1], *C. Van Bogaert*[2], *G. Marin*[3], *H. Levillain*[3], *C. Artigas*[1], *C. Marin*[3], *R. Danieli*[3], *A. Deleporte*[4], *C. Jungels*[4], *B. Vanderlinden*[3], *Z. Wimana*[1,5], *A. Hendlisz*[4], *P. Flamen*[1], *I. Karfis*[1];
[1]*Nuclear Medicine Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [2]*Nuclear Medicine Department, Hôpital Erasme, H.U.B, Brussels, BELGIUM,* [3]*Medical Physics Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [4]*Medical Oncology Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [5]*Radiopharmacy Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM.*

***Aim/Introduction:*** Safety of PRRT through evaluation of adverse events (AEs) and glomerular filtration rate (GFR) changes in patients with GEP-NETs, and their association with organs-at-risk (OARs) dosimetry and patient progression-free-survival (PFS). ***Materials and Methods:*** Patients with progressive GEP-NETs were prospectively included and treated with four cycles of $^{177}$Lu-DOTATATE every 12 weeks, afterwards followed every 6mo until disease progression. AEs (CTCAEv4.03) occurring from the day of first treatment injection until 12 weeks after the last PRRT injection were collected and followed up until resolution (or patient end-of-study). GFR was calculated using plasma clearance of $^{51}$Cr-EDTA or $^{99m}$Tc-DTPA, at baseline, end-of-treatment and every 6mo during follow-up. Dosimetry of kidneys, bone marrow (BM) and spleen, was performed after each PRRT cycle, as previously published [1]. The %change of GFR at last available follow-up from baseline was correlated with the radiation dose received by the kidneys using Spearman correlation coefficient. Differences of BM and spleen dose between patients with high (2-4) and low grade (0-1) of haematological toxicity were assessed using Mann-Whitney U-Test. Kaplan-Meier method and log-rank test was used to estimate the PFS. ***Results:*** In 37pts included, median PFS was 28mo. Most patients (28/37) received four PRRT cycles. Most common AEs of any grade were anaemia and lymphopenia (65%), followed by thrombocytopenia and fatigue (51%), alopecia (46%) and nausea (41%). Most common grade ≥3 AEs were lymphopenia and increase in gamma-glutamyl transferase, in 43% and 14% of patients, respectively. After median of 23.4mo from the first cycle, median GFR decrease was 11% (95%CI:6%-18%). Median cumulative biological effective dose (BED) received by the kidneys and BM was 27.8Gy and 0.8Gy respectively. Median cumulative absorbed dose (AD) to the spleen was 40.9Gy. No correlation was found between GFR %decrease and kidneys' cumulative BED (Spearman ρ=-0.09; p=ns). BED of the BM was higher for patients developing high grade (n=6, median: 0.8Gy) versus low grade thrombocytopenia (n=31, median: 0.55Gy) (p=0.04). No association between BM BED and grades of lymphopenia and anaemia was demonstrated, as well as between the spleen AD and haematological toxicities. No statistical evidence was found for association between GFR decrease or the development of haematological toxicity and PFS. ***Conclusion:*** We confirm the global safety of PRRT. Apart from association between BM BED and thrombocytopenia, no other haematological toxicities were associated with dose to BM and spleen or with PFS, similarly to GFR decrease and dose to kidneys. ***References:*** 1.Marin G et al: Phys Med.2018;56:41-9.

[12]*HM Hospitales Madrid, Madrid, SPAIN,* [13]*Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN,* [14]*Hospital Ramón y Cajal, Madrid, SPAIN,* [15]*Hospital Universitario Morales Meseguer, Murcia, SPAIN,* [16]*Hospital Universitario Central de Asturias, Oviedo, SPAIN.*

***Aim/Introduction:*** Clinical trial evidence supporting the effectiveness of 177Lu-DOTATATE therapy (PRRT) is primarily focused on gastroenteropancreatic neuroendocrine neoplasms (NENs). Nevertheless, it is reasonable to consider that this therapy may also be effective in other NENs that express somatostatin receptors. This study aims to evaluate the efficacy and safety of PRRT in patients with advanced, non-resectable bronchopulmonary NENs. ***Materials and Methods:*** SEPTRALU represents a national, multicenter (23 hospitals) registry encompassing patients with advanced neuroendocrine neoplasms (NEN) who have undergone treatment with 177Lu-DOTATATE in clinical practice. This analysis includes patients with advanced bronchopulmonary

NENs treated between 2014 and 2022. The Kaplan-Meier method was utilized to analyze survival, the RECIST 1.1 criteria determined response rate, and the Common Terminology Criteria for Adverse Events (CTCAE) version 3.0 served as the basis for classifying toxicity. ***Results:*** Of the 706 patients registered with NEN, 9.35% (n=66) had bronchopulmonary NENs, with a median age of 62 years (range, 21-83) among these patients. 78% were male (n=51), and 84% had an ECOG performance status of 0-1 at diagnosis (n=55). The most common histological subtype was atypical carcinoid (53%, n=35), with neuroendocrine carcinomas accounting for 16% (n=11). The most frequent metastasis location was the liver (80%, n=53), followed by lymph nodes (53%, n=35), and bone (48%, n=32). Lutetium was administered as a second-line treatment in 31% of cases (n=20), as a third-line treatment in 58% (n=38), and in subsequent lines for the remaining patients (n=8). Prior to lutetium treatment, 54% of patients (n=36) had undergone primary cancer resection, 92% (n=61) had received somatostatin analogs, and 43% (n=28) had been treated with everolimus. The duration from diagnosis to the initiation of PRRT was 35 months (95% CI, 3-52). The response rate was 34% (n=22), with 52% (n=34) achieving stabilization. With 41/66 progression events and 26/66 deaths, progression-free survival was 18.4 (95% confidence interval (CI), 15.8-33.4) months, and overall survival was 47.9 (95% CI, 20-NA) months. The most common toxicity was neutropenia (44%, n=29), with 7% (n=5) of cases presenting as grade 3-4. ***Conclusion:*** 177Lu-DOTATATE is safe and active in patients with advanced bronchopulmonary NEN treatment in clinical practice. This study supports the development of phase III clinical trials to definitively determine the role of 177Lu-DOTATATE in bronchopulmonary NEN and the optimal treatment sequence. .

## OP-234

### Cylindrical TGR as Early Radiological Predictor of RLT Progression in GEPNETs. A Proof of Concept

***F. Scalorbi***[1], *E. Garanzini*[1], *G. Calareso*[1], *C. Marzi*[2], *S. Mazzaglia*[3], *G. Di Rocco*[1,4], *G. Argiroffi*[1], *L. Mascitti*[1,4], *M. Cuomo*[1,4], *S. Pusceddu*[1], *M. Milione*[1], *M. Baccini*[2], *E. Seregni*[1], *A. Marchianò*[1], *M. Maccauro*[1];
[1]*Istituto Nazionale Tumori Milano, Milan, ITALY,* [2]*Department of Statistics, Computer Science, Applications (DiSIA), University of Florence, Firenze, ITALY,* [3]*ASST Santi Paolo e Carlo, San Paolo University Hospital, Milan, ITALY,* [4]*University of Milan, Milan, ITALY.*

***Aim/Introduction:*** Tumor Growth Rate (TGR) allows for early and quantitative assessment of SSAs (somatostatin analogues) and systemic treatments in GEPNETs (gastro-entero-pancreatic neuroendocrine tumors). Recently, TGR application has been proposed in the prediction of radio ligand therapy (RLT) response too. The aim is to evaluate the accuracy of cylindrical TGR (cTGR, obtained modifying the TGR formula) in the prediction of early progression after RLT, compared with the conventional TGR. ***Materials and Methods:*** Progressive metastatic G1-G2 GEPNETs treated with RLT (177Lu-DOTATATE, 4 administrations, 7.4 GBq) from April 2019 to October 2022 were considered. Inclusion criteria were three contrast enhancement CT scans per patient: one within three months of RLT start (i.e. baseline CT), one after two RLT administrations (i.e. interim CT) and one within three months after RLT (i.e. follow-up CT). RLT response was assessed at follow-up, according to RECIST1.1, as percentage variation of lesion diameters over time (a continuous value), and as four different classes: complete response (CR), partial response (PR), stable disease (SD) or progressive disease (PD). TGR was computed by comparing baseline and interim CT, in two ways: by approximating lesion volume to (i) a sphere (i.e., conventional TGR) or (ii) an elliptical cylinder (cTGR). Multivariate linear regression was performed to model the relationship between the change in TGR (conventional or cylindrical) and the continuous response to RLT, including the following covariates: age, gender, primary tumor, grading, ECOGPS, lines of therapy, and WHO grading. Moreover, ROC curves and optimal TGR cut-off values were computed to predict the PD class. STATA v16 software was used. ***Results:*** 58 patients (34 females, mean age 62.8) were included, resulting in 58.6% midgut, 41.4% foregut, 55.2% G2. In accordance with RECIST, 8.6% had early progression (PD) after RLT. In the PD prediction task, cTGR showed the best AUROC (0.82), compared with TGR(0.78). The optimal cut-off points were 6.57%/month (80% sensitivity, 94.34% specificity) and 5.96%/month (80% sensitivity, 92.45% specificity) for cTGR and TGR, respectively. Results were confirmed by multivariate analysis where both the TGRs were independent predictors of PD, with a higher coefficient for cTGR (1.16) compared to the conventional one (1.11). ***Conclusion:*** Both the TGRs are good predictors of RLT response with a better performance of cTGR. This study is a proof of concept that paves the way for clinical trials on the purpose of introducing cTGR in clinical practice. ***References:*** Dromain C. ## OP-235

### Safety and Efficacy of Lu-177-DOTATATE in Metastatic or Inoperable Pheochromocytoma/Paraganglioma: An Interim Analysis

***F. Lin***[1], *J. Carrasquillo*[1], *J. del Rivero*[1], *I. Shami*[1], *Z. Joy*[1], *B. Turkbey*[1], *J. Klubo*[1], *Y. Teng*[2], *A. Jha*[1], *E. Mena*[1], *M. L. Lindenberg*[1], *C. Chen*[1], *P. Herscovitch*[1], *C. Millo*[1], *K. Pacak*[1];
[1]*National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA,* [2]*Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Pheochromocytoma/Paraganglioma (PPGL) are rare neuroendocrine tumors that express somatostatin receptors (SSTR) and can be treated with radiolabeled somatostatin analogues. We report on the safety and efficacy of Lu-177-DOTATATE in the treatment of metastatic or inoperable PPGL in a prospective phase 2 clinical trial. ***Materials and Methods:*** This is an open-label, single-arm phase 2 study to evaluate the efficacy and safety of Lu-177-DOTATATE in patients with PPGL (NCT03206060). Patients are divided into apparent sporadic and SDHx cohorts. The primary endpoint is progression free survival (PFS) at 6 months post initiation of treatment. Eligibility criteria include: SSTR+ tumor and progression by RECIST 1.1 within 12 months. Anatomic scans as well as F-18-FDG and Ga-68-DOTATATE PET scans are acquired at baseline, 4 weeks after the second cycle, and 8 weeks after the fourth cycle,. Lu-177-DOTATATE is administered at 200 mCi (7.4 GBq) every 8 weeks x 4 cycles with amino acid renal blocking. An interim analysis is built-in for both the sporadic and SDHx cohorts when each has reaches 18 participants. ***Results:*** 36 patients (18 per cohort) were evaluated. For the sporadic cohort, 16 (89%) patients achieved stable disease (SD) while 2 (11%) had partial response (PR). In the SDHx (SDHA=2, SDHB=15, SDHD=1) cohort, 10 (55%) patients had SD, 3 (17%) patients had PR, and 5 (28%) patients had progression. 31/36 (86%) met the primary study end point, and the mean PFS is 19.1 months. Patients in the sporadic cohort had longer average PFS of 22.7 months vs 15.4 months in the SDHx cohort. Adverse events unique to the PPGL population include increased catecholamine-related symptom starting as early as

during the Lu-177-DOTATATE infusion and persisting for days to weeks after treatment. Serum catecholamine levels often surged quickly, which likely accounts for the increase in symptoms, and on average peaked at 24 hours post-administration (median increase = 60%, maxincrease 10x baseline). Despite these acute increases and associated symptoms, catecholamine levels inmost patients returned approximately to baseline by Day 28. ***Conclusion:*** Lu-177-DOTATATE has high efficacy and a good safety profile for metastatic PPGL in both the sporadic and SDHx cohorts, although the PFS in the spordic group (24.6 months) is longer than in the SDHx (13.2 months) group. While catecholamine crisis related to surging serum catecholamine levels occurs, levels usually return to near baseline and patients can be safety treated, though ICU care is sometimes needed.

## OP-236

### Efficacy and safety of dosimetry-based, personalized $^{177}$Lu-DOTATATE PRRT of neuroendocrine tumours: an update from the P-PRRT trial

***M. Morin***, *F. A. Buteau, A. Beaulieu, F. Arsenault, G. Bouvet, A. Desy, N. Lafrenière, G. April, J. M. Beauregard; Department of Radiology and Nuclear Medicine, and Cancer Research Center, Université Laval, Quebec City, Canada; Department of Medical Imaging, and Research Center (Oncology Axis), CHU de Québec – Université Laval, Quebec City, QC, CANADA.*

***Aim/Introduction:*** Peptide receptor radionuclide therapy (PRRT) is widely administered using a fixed activity per cycle, despite the consequent high interpatient variability in healthy tissues dosimetry, and the growing evidence that such a one-size-fits-all approach may leave most patients undertreated. The P-PRRT clinical trial is a phase 2 study of a personalized PRRT regime in which the $^{177}$Lu-DOTATATE activity is tailored to deliver a prescribed renal absorbed dose (NCT02754297). The updated efficacy and safety results are presented. ***Materials and Methods:*** Patients with inoperable progressive and/or symptomatic neuroendocrine tumours (NETs) showing sufficient SSTR expression on scintigraphy or PET were eligible. They received up to four induction cycles of $^{177}$Lu-DOTATATE every two months, with a personalized activity to achieve a target cumulative renal absorbed dose of 26.5 Gy, assessed using quantitative SPECT/CT. RECIST v1.1 criteria were used to assess the best radiological response and the progression-free survival (PFS). Overall survival (OS) was recorded. PFS and OS were also assessed in the subgroup of participants with midgut NETs whose characteristics matched the eligibility criteria of the NETTER-1 trial. Blood counts and creatinine-based estimated glomerular filtration rate results were compiled to determine the frequency of grade 3 and 4 haematological and renal toxicities according to CTCAE v5.0. The incidence of secondary haematological malignancies was assessed. ***Results:*** 226 participants with NETs of various origins, functional statuses and grades were enrolled and treated with 813 induction cycles averaging 9.54 GBq (0.67-33.68 GBq) of $^{177}$Lu-DOTATATE. The overall response rate was 30.4% and the disease control rate was 95.9% (1.8% complete response, 28.6% partial response, 19.8% minor response, 45.6% stable disease and 4.1% progressive disease). Overall, the median PFS and OS were 26.0 and 44.0 months, respectively. In the NETTER-1 subgroup (n=53), the median PFS and OS were 36.0 and 42.3 months, respectively. 61 participants (27%) experienced at least one grade 3-4 non-lymphopenia haematological toxicity: thrombocytopenia in 14.6%, leucopoenia in 11.5%, anaemia in 11.1%, and neutropenia in 9.3%. In the vast majority of cases, the haematological toxicity was reversible and did not significantly interfere with patient care. Two participants (0.9%) developed a myelodysplastic syndrome. One patient developed grade 3 renal toxicity that could be attributable to PRRT. ***Conclusion:*** Personalized $^{177}$Lu-DOTATATE PRRT based on renal dosimetry is feasible and shows an acceptable toxicity profile. It allows to escalate the injected activity in most patients suffering from a wide range of SSTR-expressing NETs, with encouraging efficacy results. ***References:*** NEJM 2017;376:125-135. EJNMMI 2019;46:728-742.

## OP-237

### Extended Peptide Receptor Radionuclide Therapy: Evaluation of Nephrotoxicity and Therapeutic Effectiveness in Neuroendocrine Tumor Patients Receiving More Than Four Treatment Cycles

***X. Fan***[1], *T. Zhao*[2], *V. Jakobsson*[2], *X. Chen*[2], *R. P. Baum*[3], *J. Zhang*[2]; [1]*Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medici, Shanghai, CHINA,* [2]*Department of Diagnostic Radiology Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [3]*CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

***Aim/Introduction:*** To evaluate the nephrotoxicity and therapeutic effectiveness of peptide receptor radionuclide therapy (PRRT) with more than four treatment cycles. ***Materials and Methods:*** This retrospective study included 751 patients who underwent multiple PRRT treatments, with complete follow-up information available for 637 patients after four treatment cycles. The overall renal function indicators before and after multiple treatments were analyzed. Nephrotoxicity was compared between patients receiving four cycles and those receiving more than four cycles, considering creatinine levels and CTCAE creatinine grades. Treatment effectiveness was evaluated using survival analysis, focusing on overall survival and disease-specific survival (DSS). ***Results:*** The study included 281 patients in the four-cycle treatment group and 356 in the more-than-four-cycle treatment group. No significant differences in baseline characteristics and renal function were observed between the groups before treatment. Mean post-treatment creatinine levels were 89.30 ± 51.19 μmol/L in the four-cycle group and 93.20 ± 55.98 μmol/L in the >4-cycle group, with no significant differences between the groups ($P = 0.364$). CTCAE creatinine grading of renal function was not statistically significant between the groups ($P = 0.448$). Adverse renal events occurred in 1/281 (0.4%) patients in the four-cycle group and 4/356 (1.1%) in the >4-cycle group. The median follow-up time was 88.3 months (95% CI: 79.3-97.3). Median overall survival was 66.1 months (95% CI: 61.2-71.0) for the entire cohort, 52.8 months (95% CI: 45.5-60.2) for the four-cycle group, and 72.8 months (95% CI: 66.2-79.5) for the >4-cycle group. Cox regression analysis indicated a better prognosis for the >4-cycle group in terms of overall survival (HR: 0.580, $P < 0.001$) and DSS (HR: 0.599, $P < 0.001$). ***Conclusion:*** For neuroendocrine tumor patients undergoing PRRT, multiple treatments are feasible, effective, and safe. Patients experiencing disease recurrence or progression after the standard four-cycle treatment may benefit from additional treatment cycles.

## OP-238

### Outcome prediction in patients with gastroenteropancreatic neuroendocrine tumours (GEP-NETs) treated with $^{177}$Lu-DOTATATE peptide receptor radionuclide therapy (PRRT): results from a prospective phase II clinical trial

***M. Mileva***[1], *G. Marin*[2], *H. Levillain*[2], *C. Artigas*[1], *C. Van Bogaert*[3], *C. Marin*[2], *R. Danieli*[2], *A. Deleporte*[4], *C. Jungels*[4], *B. Vanderlinden*[2], *Z. Wimana*[1,5], *A. Hendlisz*[4], *P. Flamen*[1], *I. Karfis*[1];
[1]*Nuclear Medicine Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [2]*Medical Physics Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [3]*Nuclear Medicine Department, Hôpital Erasme, H.U.B, Brussels, BELGIUM,* [4]*Medical Oncology Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM,* [5]*Radiopharmacy Department, Institut Jules Bordet, H.U.B, Brussels, BELGIUM.*

***Aim/Introduction:*** To predict outcome of patients with gastroenteropancreatic neuroendocrine tumours (GEP-NETs) early during the course of treatment with $^{177}$Lu-DOTATATE peptide receptor radionuclide therapy (PRRT) using $^{68}$Ga-DOTATATE-PET/CT and tumour absorbed dose (AD). ***Materials and Methods:*** Patients with progressive GEP-NETs were prospectively included and treated with four cycles of 7.4GBq of $^{177}$Lu-DOTATATE (NCT01842165). $^{68}$Ga-DOTATATE-PET/CT was performed at baseline and ten to twelve weeks after the first injection. Specific uptake parameters ($SUV_{max/mean}$, tumour-to-blood, tumour-to-spleen ratio) and volumetric parameters (SSTR-tumour volume (TV), total-lesion SSTR expression) were measured in maximum five target lesions per patient. Dosimetry was performed using three timepoint SPECT/CTs after the $^{177}$Lu-DOTATATE injections to calculate tumour AD at cycle 1 (C1). Average values of the $^{68}$Ga-DOTATATE-PET/CT parameters (baseline and relative changes after the first PRRT cycle from baseline) and minimal, maximal and mean C1 tumour AD in each patient, were tested for association with progression-free survival (PFS). Kaplan-Meier method and log-rank test was used to estimate the PFS. Optimal cut-offs of continuous variables were determined with the Contal and O'Quigley method. ***Results:*** 37 patients were included, mean age at inclusion of 66y (±8.1). Most common primary NET was small-intestinal (23/37), followed by pancreatic (10/37) and colorectal (4/37). Most NETs were of grade 2 (22/37). All patients received at least one prior line of treatment (median: 2). Most patients (28/37) received four cycles of $^{177}$Lu-DOTATATE. Median PFS was 28mo. 11/37 (30%) patients achieved partial response (RECIST1.1). SSTR-TV decrease of more than 10% after the first PRRT cycle from baseline, discriminated patients with significantly longer median PFS of 51.3mo, compared to mPFS of 22.8mo in patients in which SSTR-TV increased or decreased less than 10% after one PRRT cycle from baseline (p=0.003; HR:0.35, 95% CI:0.16-0.75). Similarly, total-lesion SSTR expression decrease of more than 10% from baseline after the first PRRT cycle discriminated patients with a mPFS of 32.2mo compared to 26.2mo (p=0.05; HR:0.42,95%CI:0.17-1.0). Patients receiving minimal C1 AD of 35Gy in all target lesions exhibited significantly longer PFS (48.1mo vs 26.2mo, HR:0.37,95%CI:0.17-0.82; p=0.02). There was no statistical evidence of an association between the uptake $^{68}$Ga-DOTATATE-PET/CT parameters or the maximal and mean C1 AD and PFS. ***Conclusion:*** Changes of volumetric parameters on $^{68}$Ga-DOTATATE-PET/CT after the first treatment cycle could be used for early therapy response assessment in patients with GEP-NETs treated with $^{177}$Lu-DOTATATE. The association of the minimal tumour AD at C1 with the patient outcome, provides basis for personalised dosimetry-guided treatment strategies.

### Comparing left ventricular function derived from CMR and gated $^{13}$N-ammonia PET-MPI - An evaluation of reproducibility using hybrid PET/MR

***D. F. Sager***[1], *N. Manz*[2], *S. Manser*[2], *L. Laubscher*[3], *A. W. Stark*[4], *J. Schuetze*[4], *P. A. Kaufmann*[1], *C. Gräni*[4], *R. R. Buechel*[1];
[1]*Department of Nuclear Medicine, University Hospital Zurich, Zurich, SWITZERLAND,* [2]*Faculty of Medicine, University of Bern, Bern, SWITZERLAND,* [3]*Department of Health Science and Technology, ETH Zurich, Zurich, SWITZERLAND,* [4]*Department of Cardiology, University Hospital Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Cardiac magnetic resonance (CMR) and electrocardiogram gated $^{13}$N-ammonia positron emission tomography myocardial perfusion imaging (PET-MPI) provide accurate and highly comparable global left ventricular ejection fraction (LVEF) measurements. Beyond accuracy, however, reproducibility becomes vital when serial LVEF assessments are required. Avoiding variations caused by intra- or inter-reader variability is essential, as they could potentially negatively impact treatment decisions. The aim of this study was to compare reproducibility of LVEF measurements derived from simultaneously acquired CMR and PET-MPI. ***Materials and Methods:*** Ninety-three patients undergoing hybrid PET/MR imaging for evaluation of suspected or known coronary artery disease, or with history of myocarditis were retrospectively included. LVEF was derived from CMR and PET-MPI in a blinded fashion at two separate core labs with two expert readers each, using two state-of-the-art software packages for CMR (cvi42 version 5.13.8 and Medis Suite MR version 3.2.48.8) and PET-MPI (QPET version 2017.7 and CardIQ Physio version 2.06-3), respectively. Intra- and inter-reader reproducibility were assessed using correlation and Bland-Altman (BA) analyses. ***Results:*** BA analyses showed smaller biases for LVEF derived from PET-MPI (intra-reader bias -0.1% for QPET and 0.9% for CardIQ, inter-reader bias -0.4% for QPET and -0.8% for CardIQ) than those derived from CMR (intra-reader bias 0.7% for cvi42 and 2.8% for Medis, inter-reader bias -0.9% for cvi42 and -2.2% for Medis) with comparable results for limits of agreement. Intra- and inter-reader correlations of LVEF were high among both modalities and all four software packages ($r \geq 0.87$ and ICC $\geq 0.91$, all correlations significant at $p < 0.0001$). Notably, LVEF derived from PET-MPI and analyzed with QPET outperformed all other analyses, yielding near-perfect correlations ($r = 0.99$ and $r = 0.98$ for intra- and inter-reader reproducibility, respectively, QPET correlations significantly higher than other software packages at $p \leq 0.0001$). ***Conclusion:*** Electrocardiogram gated $^{13}$N-ammonia PET-MPI provides equivalent, if not better intra- and inter-reader reproducibility of LVEF than CMR. Hence, it may serve as a valid alternative to CMR for patients requiring serial LV functional assessments.

## OP-240

### Use of First-Pass Non-Gated $^{15}$O-water PET for Evaluation of Left Heart Remodelling and Cardiac Function in Severe Mitral Regurgitation

***J. Sigfridsson***, *H. J. Harms, J. Bergsten, M. Lubberink, T. Kero, T. Baron, F. A. Flachskampf, J. Sörensen;*
*Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** Patients with severe primary mitral valve regurgitation (MiR) are serially evaluated for signs of progression, and decisions on surgical intervention are based on symptoms and quantification of regurgitation severity, left ventricular and left atrial dilatation with echocardiography or gold standard cardiac magnetic resonance (CMR). PET has currently no role in MiR evaluation and regurgitant volume measurements require ECG-gated images, which are generally of insufficient quality on non-digital PET. However, the ratio of forward stroke volume (FSV) and LV end-diastolic volume (LVEDV) obtained from CMR corresponds to both mitral regurgitant fraction (RegFraction) and LV dilatation, and predicts future need of valvular surgery. This ratio, as well as left atrial volume (LAV), can be measured with $^{15}$O-water PET first-pass images analysed with indicator dilution techniques. Our aim was to study if $^{15}$O-water-PET with first-pass imaging can be used for assessing MiR severity. ***Materials and Methods:*** We included 45 asymptomatic patients with moderate-severe/severe MiR and 9 healthy volunteers (HV). LVEF was >60% in all MiR by CMR. Patients underwent same-day scanning with $^{15}$O-water-PET, echocardiography and CMR, and HV only PET. PET-scans were performed on an older BGO-based PET/CT (DST, n=28) or modern digital PET/CT (DMI, n=26). First-pass PET-analysis was conducted using in-house developed software, enabling fully automated quantitation of LAV, FSV and LVEDV, using previously validated methods. For comparison, echo-based LAV and CMR-based FSV, LVEDV, FSV/LVEDV and regurgitant fraction (RegFraction) were derived. PET-based prediction of time to surgery was evaluated using Cox regressions. ***Results:*** PET-based LAVi, LVEDVi in MiR were elevated, and FSV/LVEDV reduced, compared to HV (LAV: 58±21 vs 26±3ml/m$^2$; LVEDV: 108±25 vs 65±11 ml/m$^2$; FSV/LVEDV: 42±10 vs 71±11 %, all p<0.0001), but FSVi was preserved (43±6 vs 45±4 ml/m$^2$, p=0.32). PET-LAV correlated with echocardiographic LAV (r=0.73, p<0.0001) and PET-based FSV, LVEDV and FSV/LVEDV correlated with CMR (FSV: r=0.82; LVEDV: r=0.87; FSV/LVEDV: r=0.82, P<0.0001 for all). Both PET-based LAV and FSV/LVEDV correlated with CMR-based RegFraction (LAV: r=0.67; FSV/LVEDV: r=-0.81, both p<0.0001). Twenty-two patients progressed to surgery during follow-up (median 2.7y). PET-based LAV and FSV/LVEDV predicted time to surgery (p<0.02 for both). PET results were not significantly affected by PET/CT device (ST or DMI). ***Conclusion:*** Automated measurements of left heart morphology and function in MiR are feasible using non-gated $^{15}$O-water-PET even on older PET/CT devices. PET-based LAV and FSV/LVEDV correlated with gold standard regurgitation severity and were predictive of progression requiring surgery.

## OP-241

### Added value of automatic coronary artery calcium scoring from low dose CT $^{15}$O-water PET scans in MACE prediction in comparison to the reference, calcium scoring CT scans.

***M. Dobrolinska***[1], *R. Jukema*[2], *S. van Velzen*[3], *P. van Diemen*[3], *M. Greuter*[1], *N. Prakken*[1], *N. van der Werf*[4], *P. Raijmakers*[3], *R. Slart*[1], *P. Knaapen*[3], *I. Isgum*[3], *I. Danad*[4];
[1]*UMCG, Groningen, NETHERLANDS,* [2]*UMC Amsterdam, Amsterdam, NETHERLANDS,* [3]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [4]*UMC Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** We sought to assess the value of coronary artery calcium (CAC) scored automatically from LDCT scans acquired during MPI $^{15}$O-water-PET scanning and CAC scored from a reference, CSCT scans, in predicting long-term major adverse cardiac events (MACE). ***Materials and Methods:*** Between 2008 and 2014, 505 consecutive patients, with suspected CAD, who underwent myocardial perfusion $^{15}$O-water - PET with LDCT and dedicated CSCT scan, regardless of CSCT and CT angiography results, were included in this single centre study. For CAC scoring from CSCT scans, the reference Agatston method was applied. For automatic scoring in LDCT, a previously described method was applied. Briefly, to enable calcium quantification in LDCT scans with large slice thickness, low image resolution and cardiac motion artifacts, the automatic scoring does not apply the standardly used 130 HU threshold for calcium detection. Instead, it mimics visual scoring to quantify calcium on LDCT scans using a generative adversarial deep learning approach. Subsequently, each patient was assigned to one out of five point scale equivalent to Agatston risk groups (0; 1-100; 101-400; 401-1000; >1000 Agatston score). MACE was defined as a composite of all-cause death, myocardial infarction, late and urgent revascularization (PCI and CABG), and unstable angina. ***Results:*** During the median follow up of 6.8 (interquartile range 4.8-7.8) years, 16.8% of patients experienced an end-point event. The agreement in risk classification between reference CSCT manual scoring and automatic scoring from LDCT was 0.58 (95%CI: 0.53-0.62). Based on multivariable Cox regression analysis of associations with MACE between CAC scored from CSCT scans and myocardial perfusion defects, increasing CAC was associated with an increased risk of MACE, which was significant for patients with CAC 1-100 (hazard ratio (HR) 3.84, 95%CI 1.64-9.00, P=0.002), CAC 101-400 (HR 4.27, 95%CI 1.76-10.36, P=0.001), CAC 401-1000 (HR 8.87, 95%CI 3.50-22.47, P<0.001), CAC>1000 (HR 9.59, 95%CI 3.80-24.21, P<0.001) compared with patients with CAC 0. Based on automatic analysis, the risk of MACE was significantly higher only in patients with CAC>400 (CAC 401-1000: HR 2.30, 95%CI 1.23-4.29 P=0.009, CAC>1000: HR 3.77, 95%CI 1.81-7.84, P<0.001). ***Conclusion:*** Both, automatic CAC scoring from LDCT scans and CAC scoring from a reference CSCT scans, improved identification of patients at higher risk of long-term MACE, independently from the MPI $^{15}$O-water-PET results. Nevertheless, due to decreased detectability of CAC from LDCT scans, adding a CSCT scans to myocardial perfusion scans should be considered.

## OP-242

### Impact of data driven motion correction on accuracy of summed stress and rest scores measured with NH3 cardiac PET.

***S. Lazarenko***[1], *L. van Wunnik*[1], *F. M. van der Zant*[1], *T. S. Martinez-Lucio*[2], *O. I. Mendoza-Ibañez*[2], *C. Hayden*[3], *B. Spottiswoode*[3], *R. J. J. Knol*[1];
[1]*Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS,* [2]*University Medical Centre Groningen, Groningen, NETHERLANDS,* [3]*Siemens Medical Solutions United States Of America, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The summed stress score (SSS) is a powerful independent predictor of all ischemic cardiac events [1,2]. Abnormal SSS (>3) is associated with a significantly higher cardiac event rate in patients with an intermediate to high pretest probability of CAD. Normal SSS (≦3) is associated with a low event rate in patients with any pretest probability of CAD [1,2]. High respiratory motion during PET acquisition typically degrades image quality as this produces blurry images and possible underestimation of perfusion in some myocardial areas.

This may subsequently lead to an incorrect, overestimated SSS. The aim of this study was to investigate the impact of data driven motion correction (DDMC) software prototype on the accuracy of SSS and summed rest scores (SRS) measured with NH3 cardiac PET. ***Materials and Methods:*** 26 patients who underwent a PET/CT (Biograph Vision 600) examination from July 2020 to February 2021 in the Noordwest Ziekenhuisgroep Alkmaar (Netherlands) were retrospectively included. Inclusion criteria: no prior history of CAD, high MBF, normal LV-function, ongoing follow-up since the scan without major adverse cardiac events (MACEs) or recurrent chest pain. Datasets without motion correction and with DDMC were analyzed with Corridor 4DM, which was used to determine the SSS and SRS. Differences were analyzed using paired sample t-tests in SPSS. ***Results:*** For the selected group of patients SSS and SRS <4 were expected. SSS and SRS measured from DDMC datasets were significantly lower in compared to uncorrected, original datasets, 2.1±2.0 vs 5.5±5.0 p=0,001 for SSS and 1.4±2.1 vs 3.4±3.6 p=0,002 for SRS, respectively. Only 4 patients had SSS >3 following DDMC, whereas 16 patients had SSS >3 in the data without motion correction. ***Conclusion:*** Data driven motion correction improves image quality and the accuracy of summed stress and rest scores measured with NH3 cardiac PET ***References:*** [1] Brophey MD, Farukhi IM, Castanon R, DeLaPena R, Bradshaw L, Banerjee S. ## OP-243

### The role of motion correction tools in left ventricular function parameters as measured by gated $^{13}$N-NH$_3$ PET/CT

***T. Martinez-Lucio***[1], *R. J. J. Knol*[2], *O. I. Mendoza-Ibanez*[1], *L. van Wunnik*[2], *F. M. van der Zant*[2], *C. Tsoumpas*[1], *R. H. J. A. Slart*[1], *S. V. Lazarenko*[2];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Northwest Clinics Alkmaar, Alkmaar, NETHERLANDS.*

***Aim/Introduction:*** Gated cardiac positron emission tomography (PET) is an imaging technique that synchronizes acquired PET data to the heart cycle based on electrocardiogram (ECG) signal. Gated series provide quantitative functional parameters of the left ventricle (LV), namely LV ejection fraction, end-systolic volume (ESV) and end-diastolic volume (EDV), typically used for risk stratification and prognosis in coronary artery disease (CAD). However, cardiac PET often comprises artifacts related with cardiac, respiratory and/or patient motion, which can lead to misinterpretation of the results. Previous studies have suggested that LV function parameters, particularly ESV and EF could be under- and overestimated respectively, due to presence of motion artifacts. Motion correction (MC) tools have been developed to overcome this drawback, such as CardioFreeze with dual-gating technology and data driven motion correction (DDMC). This study aims to elucidate the effect of these tools in LV function assessment. ***Materials and Methods:*** Twenty-four patients with suspected CAD that underwent gated $^{13}$N-NH$_3$ PET/CT in the Northwest Clinics Alkmaar (Netherlands) from 28-07-2020 to 15-12-2020 were retrospectively included. Inclusion criteria: no history of CAD, normal perfusion and LV-function, follow-up since the time of study without major adverse cardiac events or recurrent symptomatology. Four reconstructions were performed: no motion correction (NMC), CardioFreeze, DDMC and DDMC & CardioFreeze. Analysis was done with Cedars-Sinai QPET software. Clinical data, LVEF and LV volumes in rest and stress were acquired for the final analysis. For statistical analysis paired T-tests were performed to compare the LV parameters with and without the MC tools. ***Results:*** Study population consisted of 24 patients (62.5% women), all patients older than 42 years old, and 22 (91.6%) vasodilated with adenosine. With regard to EDV rest and stress, significant differences were found only between the NMC and DDMC groups ($p<0.01$). Regarding ESV and EF in both rest and stress significant differences were found between NMC with CardioFreeze, DDMC and CardioFreeze & DDMC ($p<0.001$). Larger mean differences with NMC are measured after applying CardioFreeze & DDMC (ESV rest: -5.42, ESV stress: -6.54, LVEF rest: 5.13% and LVEF stress: 6.08%) Interestingly, of both individual MC tools, CardioFreeze demonstrated larger mean differences. ***Conclusion:*** The use of motion correction tools increase significantly ESV values and decrease significantly EF values, with larger differences after applying two combined tools of motion correction, CardioFreeze & DDMC. ***References:*** Tang et. al. Enhancing ejection fraction measurement through 4D respiratory motion compensation in cardiac PET imaging. Phys Med Biol. 2017 Jun 7;62(11):4496-4513

## OP-244

### The prognostic value of non-perfusion parameters on CZT SPECT in patients with normal myocardial perfusion imaging: a large scale single-center retrospective cohort study.

***K. Ko***[1], *C. Lin*[2], *L. Tang*[2], *C. Liu*[2], *D. Wang*[3];
[1]*National Taiwan University Cancer Center, Taipei, TAIWAN,* [2]*National Taiwan University Hospital, Taipei, TAIWAN,* [3]*Tri-Service General Hospital, Taipei, TAIWAN.*

***Aim/Introduction:*** The purpose of this study is to evaluate the clinical significance of non-perfusion variables derived from thallium-201 CZT SPECT in patients with normal myocardial perfusion. ***Materials and Methods:*** Data for 2017-2019 from an integrated health care information system of a single hospital were analyzed. A total of 1635 patients with normal myocardial perfusion (summed stress score of 3 or less) using vasodilator stress were identified. We collected non-perfusion variables from gated thallium-201 CZT SPECT imaging. Patients were followed up at least 2 years for major adverse cardiovascular events (MACEs), including cardiovascular death, nonfatal myocardial infarction, hospitalization due to stroke, heart failure, unstable angina or revascularization. ***Results:*** Out of 1634 patients, MACEs occurred in 96 (5.9%) patients and the mean follow-up period was 20.7±11.5 months. In these patients, 64 of them were diagnosed as significant coronary artery stenosis. After adjusted for potential clinical prognostic factors, multivariable Cox regression analysis revealed post-stress increased lung-to-heart (L/H) ratio (HR: 4.625; 95% CI: 2.022 to 10.578; $p = 0.008$), post-stress increased RV uptake (HR: 2.378; 95% CI: 1.152 to 4.907; $p = 0.021$) and post-stress ejection fraction (EF) worsening (HR: 2.196; 95% CI: 1.392 to 3.464; $p = 0.003$) as independent predictors of MACEs. Kaplan-Meier survival curve analysis for MACEs according the number of non-perfusion imaging predictors showed that patients with 2 or more factors as above mentioned had the higher incidence of MACEs.

***Conclusion:*** Normal myocardial perfusion might confer low risk of obstructive coronary artery disease. However, care must be taken for post-stress lung uptake, RV uptake and post-stress EF worsening, which were associated with higher adverse cardiac events.

## OP-245

### A machine-learning-based prediction model of lethal arrhythmic events by using the $^{123}$I-meta-iodobenzylguanidine derived late heart-to-mediastinum ratio: Application into separate Japanese and European cohorts

***K. Nakajima***[1], *T. Doi*[2], *T. Nakata*[3], *H. Tada*[1], *D. O. Verschure*[4], *V. Frantellizzi*[5], *H. J. Verberne*[6];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Teine Keijinkai Hospital, Sapporo, JAPAN,* [3]*Hokodate-Goryoukaku Hospital, Hokodate, JAPAN,* [4]*Zaans Medical Center, Zaans, NETHERLANDS,* [5]*Sapienza University of Rome, Rome, ITALY,* [6]*University of Amsterdam, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** A machine-learning (ML)-based prediction model for differentiating events in heart failure (HF) patients was created by using the $^{123}$I-meta-iodobenzylguanidine (mIBG) derived late heart-to-mediastinum (H/M) ratio in combination with clinical variables. This study focused on lethal arrhythmic events (ArE) using two retrospective cohorts; a Japanese cohort (Cohort-J) of non-specific chronic HF patients and a European cohort (Cohort-E) of HF patients mainly referred for cardiac device implantation (ICD/CRTD). ***Materials and Methods:*** The ML model was based on 13 variables (age, sex, left ventricular ejection fraction (LVEF), NYHA functional class, comorbidities, etc.) from 526 Japanese patients with chronic HF. The primary outcome parameters for this study were ArE (arrhythmic death, sudden cardiac death and appropriate ICD therapy) and HF death (HFD) after 2 years. The test group (Cohort-J) consisted of 581 Japanese patients with chronic HF who underwent mIBG scintigraphy (mean age 68±12y, LVEF 31±11%, mean follow-up 29 months, and 86% in NYHA I-II). The European test group (Cohort-E) included 246 patients (mean age 64±11y, LVEF 29±9 %, mean follow-up 31 months, and 91% in NYHA II-III). ICD/CRTD was implanted in 18% and 66% in Cohorts-J and E, respectively. ArE probability was calculated for each patient. The indication for ICD/CRTD therapy was predicted and actual outcomes were compared. ***Results:*** Based on the ML-based model, baseline risk for ArE+HFD was calculated as 19±20% and 35±25% in Cohort-J and E, respectively, and actual event rate was 22% and 34%, respectively (p=0.0006). When ArE risk of <3%, 3-9%, and >9% was respectively defined as low, intermediate and high ArE risk, ICD/CRTD was implanted in 7%/18%/25% for low/intermediate/high risk groups in Cohort-J (p<0.0001), and 56%/66%/78% for Cohort E (p=0.01) during 2-year follow-up. In the Cohort-J ArE was observed in 3%/8%/12% for low/intermediate/high risk groups (p=0.009). However, in the Cohort E ArE occurred in 36%/35%/30% in the three risk groups, respectively (p=ns). There was a "bell-shaped" relationship between ArE rate and H/M in the Cohort-E. ***Conclusion:*** Patients with higher ArE risk were more often indicated for ICD/CRTD in both cohorts. The subsequent ArE outcome was adequately predicted in the Japanese population, but not in the Cohort-E. This failure in prediction could be explained by differences in baseline characteristics between the Japanese and European cohorts; amongst others potentially high-risk ArE patients were more prominently included in the latter. ***References:*** (ML model) Nakajima K, et al. J Nucl Cardiol 2022;29:190-201

## OP-246

### Long-axial field-of-view PET/CT scanners improve the detection of inflamed coronary artery plaques with [$^{68}$Ga] Ga-DOTA-TOC imaging

*C. Mingels, C. Bregenzer, N. Gözlügöl, L. Knappe, I. Alberts, A. Rominger,* ***F. Caobelli****;*
*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Inflamed coronary artery plaques are major determinants of myocardial infarction and sudden cardiac death. Hence, it is crucial that prone-to-rupture coronary lesions are identified, to risk-stratify patients with coronary artery disease (CAD). While positron emission tomography (PET) with somatostatin receptor 2 ligands ($SST_2$) like [$^{68}$Ga]Ga-DOTA-TOC may reveal inflammation due to activated monocyte-derived macrophages, many reports in literature, featuring standard PET scanners, showed limited sensitivity and spatial resolution. Recently, a new generation of PET/CT scanners with a long-axial field of view (LAFOV) has been introduced, characterized by increased sensitivity over standard scanners. We therefore aimed to investigate, whether this gain in sensitivity also pertains to [$^{68}$Ga]Ga-DOTA-TOC LAFOV PET/CT. ***Materials and Methods:*** We retrospectively evaluated 113 patients with neuroendocrine tumors and without history nor symptoms of CAD, who underwent a [$^{68}$Ga]Ga-DOTA-TOC LAFOV PET/CT during their oncological workup. Images were acquired on a LAFOV Biograph Vision Quadra (Siemens Healthineers) PET scanner (FOV 106cm) 60 minutes after intravenous administration of 154±19.77 MBq [$^{68}$Ga]Ga-DOTA-TOC. If a high $^{68}$Ga-DOTA-TOC uptake of the coronary plaque was visually detected, standardized uptake values ($SUV_{max/mean/peak}$) and Hounsfield Units (HU) were measured by placing an isocontour VOI with 40% threshold. Lesion-to-background (LBR) ratios and lesion to mediastinal blood pool (LMR) ratios were calculated. Patients with coronary artery calcifications were divided into 3 Group according to the number of affected vessels (1= one-vessel disease, 2=two-vessel disease, 3=three-vessel disease). A linear regression model was used to correlate the semi-quantitative values with the degree of calcification (HU). ANOVA testing was performed to reveal differences in the [$^{68}$Ga]Ga-DOTA-TOC uptake according to the Likert scale of calcification. ***Results:*** 68.8% of our patients showed calcifications of any degree in the coronary arteries (Likert-score median: 1, IQR: 2.25). In 56.3% at least one calcified plaque was identified as [$^{68}$Ga]Ga-DOTA-TOC-avid ($SUV_{max}$: 1.26±0.42; HU: 75±49.05, LMB >1.0). [$^{68}$Ga]Ga-DOTA-TOC uptake within coronary plaques was significantly higher in Patients with 3-vessel disease compared to other groups (p= 0.02, Figure 1). There was only a weak correlation between plaque calcification density and $SUV_{maxc/mean/peak}$ ($R^2$: 0.159/0.139/0.185, p=0.23/0.26/0.21). ***Conclusion:*** [$^{68}$Ga]Ga-DOTA-TOC LAFOV PET/CT yields a high detection rate of inflamed coronary plaques, which is superior to what reported in literature for standard PET scanners. Patients with higher burden of calcified plaques showed significantly higher [$^{68}$Ga]Ga-DOTA-TOC uptake, indicating that the detected uptake is probably expression of prone-to-rupture lesions.

## OP-247

### Adequacy of whole-body parametric imaging of regional tissue perfusion using the recent total-body PET system and i.v. $^{15}$O-water

***H. Iida***[1], *H. Merisaari*[2], *N. Ono*[3], *N. Kudomi*[4], *T. Tolvanen*[5], *V. Saunavaara*[5], *H. Sari*[6], *J. Knuuti*[1], *L. Nummenmaa*[1], *P. Nuutila*[1]; [1]*Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND,* [2]*Department of Radiology, University of Turku, Turku, FINLAND,* [3]*Nara Institute of Science and Technology, Ikoma, JAPAN,* [4]*Kagawa University School of Medicine, Kagawa, JAPAN,* [5]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND,* [6]*Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** Total-Body PET (TBPET) is attractive for whole-body imaging with much higher sensitivity but could be restricted due to limited counting rate performance. We aim to evaluate the adequacy of simultaneous parametric imaging of whole-body tissue perfusion. ***Materials and Methods:*** Seven volunteers (3 males and 4 females with ages: 21-50 and 31-60 yo, body weight: 74-108 and 61-124 kg, BMI: 23.4-31.2 and 22.7-42.9, respectively) participated in the PET experiments involving 8 scans at 4 different i.v. bolus $^{15}$O-water doses ranging from 20 to 700 MBq. The administration was to the brachial vein with the arms on the side. True, random, and total prompt rates were obtained and the noise-equivalent count rates (NECR) (1) were calculated during all PET scan periods. Dynamic images were reconstructed for Maximum-Ring-Distance of 85 to which 40 volumes-of-interest (VOI) were selected to calculate quantitative tissue perfusion (TP) and distribution volume (DV) assuming a single tissue compartment model with a vascular component (1TCM). The arterial input function (AIF) was obtained from the aorta time-activity curve. Administration dose dependency in TP and DV was then evaluated. The pixel-by-pixel calculation of TP and DV was also evaluated in selected scans to identify potential sources of errors. ***Results:*** NECR and prompt rates decreased monotonically after the completion of $^{15}$O-water administration to the vein, suggesting that the coincidence slew rate was not saturated even at the maximum administration dose of 700MBq, though the breakdown was seen for a 20 cmφ cylinder phantom already at 400MBq, due to smaller attenuation. VOI analysis did not demonstrate a significant reduction or difference in TP or DV at 700MBq compared with other administration doses for VOIs of TP>0.3 ml/min/g. Significant intra-subject variation was seen if not corrected for inconsistent positioning of VOIs both for AIF and tissues due to movement, and inappropriate delay particularly in peripheral regions, e.g., the branchial/thigh muscle and intra-organ delay in the liver and also in the brain in some extent. The parametric images for TP and DV were visually superior with a larger administration dose, particularly in small TP regions. ***Conclusion:*** Despite the wide range of TP from 0.01 to 5 ml/min/g, $^{15}$O-water PET is feasible for providing whole-body TP and DV, and even parametric images. Further technical advances are required for organ-specific adaptation of the model including adequate corrections for intra-and inter-organ delay in AIF and the partial volume effect. ***References:*** (1) J Nucl Med 2005; 46:1825-1834

### $^{99m}$Tc-Ethambutol Single Photon Emission Computed Tomography/Computed Tomography (SPECT/CT) Scan in Pulmonary Tuberculosis: Correlation of $^{99m}$Tc-Ethambutol Avidity with CT Manifestations

***F. Aghahosseini***[1,2], *Y. Salehi*[1,2], *S. Farzanefar*[1,2], *M. Abbasi*[1,2], *F. Saboktakin*[1,2], *N. Vahidfar*[1,2], *P. Sheikhzadeh*[1]; [1]*Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Nuclear Medicine Department, Valiasr Hospital, Imam Khomeini Complex Hospital, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Technetium - 99m - ethambutol (99mTc-ethambutol) scintigraphy, as a molecular imaging modality, can be potentially used to identify the biological process of anatomical changes at cellular and subcellular levels. The present study aimed to investigate the correlation between 99mTc-ethambutol avidity and computed tomography (CT) manifestations of pulmonary TB. ***Materials and Methods:*** This study was conducted on 10 previously untreated patients with a culture-proven diagnosis of pulmonary TB, who underwent chest CT scan and 99mTc-ethambutol single photon emission computed tomography (SPECT)/CT scan within seven days. Each individual pulmonary lesion in the chest CT scans was investigated for 99mTc-ethambutol uptake on SPECT/CT images and further categorized as positive (if 99mTc-ethambutol uptake exceeded the background activity) and negative vice versa. For the purpose of semiquantitative analysis, a scoring system was developed on a per-subsegment basis, in which each segment was divided into three subsegments, based on the maximum number of lesion types counted in a single segment. The summation of scores for each individual lesion type was compared between the two 99mTc-ethambutol positive and negative groups. Moreover, CT manifestations were classified dichotomously as destructive (i.e., cavities, bronchiectasis, and fibro-destructive changes) and non-destructive (i.e., non-cavitary nodules, consolidation, centrilobular nodular infiltration, and miliary pattern) lesions and further assessed for any significant differences regarding 99mTc-ethambutol uptake. ***Results:*** Out of the 359 involved sub-segments, 57 were predominantly occupied by cavities (score=67, 18.7%), followed by bronchiectasis (score=56, 15.6%) and fibro-destructive changes (score=54, 15%). The 99mTc-ethambutol uptake occurred in 52/54 sub-segments with predominant feature of bronchiectasis (92.9%), 50/54 with fibro-destructive changes (92.6%), and 54/67 with cavities (80.6%), while no significant 99mTc-ethambutol uptake was found in 11/11 sub-segments with non-destructive fibrosis (100%), 37/41 with consolidation (90.2%), 44/49 with non-cavitary nodules (89.8%), 48/54 with miliary pattern (88.9%), and 21/25 with centrilobular nodular infiltration (84%) (P=0.000). Comparison of 99mTc-ethambutol uptake between the two groups of destructive and non-destructive lesions revealed a significantly higher rate of 99mTc-ethambutol positivity in the first group (156/177, 88.1% vs. 19/180, 10.6%; P=0.000). ***Conclusion:*** The current study

revealed that 99mTc-ethambutol uptake occurs significantly more frequent in destructive lesions such as bronchiectasis, fibro-destructive changes, and cavities, all of which contribute to the lung remodeling process, compared to non-destructive CT manifestation. It may be presumed that 99mTc-ethambutol scintigraphy may have the potential to provide prognostic information on the development of pulmonary impairment after tuberculosis (PIAT).

## OP-249

### Head to head comparison of ultrasound and Tc - 99m glucosamine SPECT/CT imaging of patients with rheumatoid arthritis of the knee.

***O. Evbuomwan***, *G. Engelbrecht;*
*University Of The Free State, Bloemfontein, SOUTH AFRICA.*

***Aim/Introduction:*** The evaluation of disease activity in rheumatoid arthritis (RA) is challenging and requires very sensitive, feasible and reliable investigations. Ultrasound (US) and MRI have been the forefront imaging modalities in the management of patients with RA. If properly used, US has been shown to offer a very high diagnostic accuracy, because of its ability to accurately measure blood flow to inflamed joints and detect early synovial changes. However, it is an operator dependent technique and could be cumbersome in imaging multiple joints in a single patient. These disadvantages are not associated with nuclear medicine functional imaging. In this prospective study we aimed at assessing RA synovitis of the knee, with SPECT/CT imaging using the SPECT glucose analogue $^{99m}$Tc glucosamine in comparison of US imaging. ***Materials and Methods:*** This was a prospective study, in which 10 patients with proven rheumatoid arthritis and active disease of the knee were recruited. Each participant was injected with 20-25mCi of $^{99m}$Tc labelled glucosamine. SPECT/CT (2 hours post injection) imaging of the knees were performed. Joints were qualitatively assessed for abnormal increased uptake of the radiotracer in the suprapatellar, lateral, medial, and popliteal regions. Ultrasound of the knees were performed on the same day during the waiting period between the blood pool and SPECT/CT imaging. An experienced radiologist assessed each US scan for suprapatellar, lateral, and medial synovitis and popliteal bursitis. ***Results:*** Eight sites in both knees of each participant were assessed for disease activity, making a total of 80 sites assessed. The median (interquartile range) age was 65 (53-68) years, and the majority (n = 7; 87.5%) were females. The overall calculated sensitivity and specificity of 99mTc glucosamine was 96% and 44% respectively. However, taking each knee as a single site, the specificity increased to 90%. ***Conclusion:*** This study revealed that 99mTc glucosamine imaging had a very high sensitivity in the imaging of patients with RA of the knee, and it compares very well with US. The overall low specificity might be as a result of associated osteoarthritis in these patients, the detection of subclinical disease not picked up by US imaging or a combination of both. Further studies are however warranted to establish its role in the management of patients with RA.

## OP-250

### SUV-Based Assessment of Known or Suspected Polyarthritis on Double-Phase Whole-Body Bone Tomoscintigraphies Provided by a High-Speed CZT Camera

***F. Rajadhas***[1], *C. Morizot*[2], *D. Loeuille*[2], *I. Chary-Valckenaere*[2], *V. Roch*[1], *P. Marie*[1,3], *L. Imbert*[1,3], *A. Bahloul*[1,3];
[1]*CHRU-Nancy, Department of Nuclear Medicine and Nancyclotep Imaging Platform, Nancy, FRANCE,* [2]*CHRU-Nancy, Department of Rheumatology, Nancy, FRANCE,* [3]*Université de Lorraine, INSERM U1254, IADI, Nancy, FRANCE.*

***Aim/Introduction:*** New whole-body high-speed CZT-cameras provide high-quality images with absolute quantification that is useful for monitoring 177Lu-based therapy. However, the usefulness of such quantification remains to be demonstrated for double-phase bone scintigraphy. This study, conducted in patients referred to bone scintigraphy for known or suspected poly-arthritis, aimed to determine whether the SUV maximal (SUVmax), observed within articular regions during the blood-pool (BP) and delayed (DP) phases, may predict the results achieved from a conventional visual analysis by experienced observers. ***Materials and Methods:*** We included 56 patients (48±15 years-old, 37 women), who had been referred to bone scintigraphy for a suspected or known polyarthritis. High-speed whole-body 3D recordings were started 5 min after the intravenous injection of 482 to 641 MBq of 99mTc-HMDP (BP phase with 9 minutes SPECT recording) and almost 3 hours later (DP phase with 18 minutes SPECT recording). Results of visual analysis of the SPECT and CT images, achieved by a consensus of two experienced observers, were regrouped into 26 different articular regions and further correlated with the SUVmax from the same regions. ***Results:*** Among the 1456 joint regions considered, 201 were visually judged abnormal at DP, of which 88 were additionally judged abnormal at BP. The SUVmax of the remaining 1255 normal articular regions were independently influenced by the joint locations and body mass index (both $p<0.001$), but not by age and sex, and they could be regrouped into 4 different joint groups with equivalent SUVmax levels: G1, ankles, feet and hands joints (95% confidence intervals: 1.28-1.37 at BP and 1.82-1.99 at DP); G2, wrists, knees and elbows (1.71-1.85 at BP and 2.68-2.98 at DP); G3, shoulders, hips and sterno-clavicular joints (2.21-2.33 at BP and 4.86-5.14 at DP); and G4, sacroiliac joints and thoracic and lumbar spine (3.03-3.24 at BP and 6.01-6.39 at DP). The criterion of a SUVmax setting above the upper limit of the 95% confidence interval, which had been determined for the corresponding normal articular group and scintigraphy phase, provided high specificities for the prediction of visually abnormal regions at BP (96% (1304/1360)) and DP 96% (1204/1250)). Whereas the corresponding sensitivities were lower (78% (69/88)) and (66% (132/201)), respectively). ***Conclusion:*** In patients referred to double-phase whole-body bone tomoscintigraphies using a high-speed 360° CZT-camera for a known or suspected polyarthritis, the BP and DP joint SUVmax are highly predictive of the results provided by a conventional visual analysis from experienced observers.

## OP-251

### Assessing the augmentive value of 18F-FDG PET/CT over 99mTc-MDP bone scan in distinguishing infection from aseptic loosening of prostheses.

***S. Shamim***, *H. Khairwa, S. Sagar, D. Khan, K. Sivashankar, N. Kundu, N. Kumar, G. Arora, R. Kumar;*
*AIIMS New Delhi, Delhi, INDIA.*

***Aim/Introduction:*** Methylene diphosphonate (MDP) bone scan is a valuable tool for distinguishing between infection and aseptic loosening of prostheses, but in cases where patients have already received antibiotics, the MDP uptake can persist for a prolonged period, making it challenging to differentiate between the two conditions. Our study aimed to assess the additional benefit of using Flurodeoxyglucose (18F-FDG)-PET/CT in conjunction with 99mTc-MDP bone scan to distinguish between infection and aseptic loosening in patients who are experiencing symptoms related to their prostheses. ***Materials and Methods:*** At a tertiary care centre in India, we conducted a prospective study that included all patients referred to our department with suspected infection or aseptic loosening of prostheses between January 2019 and March 2023 having doubtful finding on MDP scan. Patient underwent 99mTc-MDP planar imaging and SPECT/CT according to our department protocol. Patient having clear diagnosis on bone scan were excluded from the study. 18F-FDG PET/CT was performed if the MDP scan findings were inconclusive. Clinical follow-up and post operative findings were considered gold standard. Two experienced nuclear medicine physicians reviewed both types of scans, and their results were compared. ***Results:*** There were 16 patients fulfiling inclusive criteria and having inconclusive bone scan were included in the study, 11 were male and 5 were female, with an average age of 48.63±18.63 years. Out these 16 patients FDG-PET/CT showed increased metabolic activity in 11 patients (68.75%) and FDG-PET/CT showed negative results in 05 patients (31.25%). As a result, 18F-FDG PET/CT was able to exclude infection in 5 out of 16 (31.25%) patients and confirmed infection in 11 out of 16 (68.75%) patients. On clinical follow up, the 11 patients diagnosed as positive based on the scans responded to antibiotics while 5 patients who were negative on FDG PET/CT scan were operated for loosening with good post operative outcome and there was no evidence of infection found during surgery and post surgery culture. ***Conclusion:*** We concluded that patients with negative or clearly positive bone scan results, there is no need to undergo additional 18F-FDG PET/CT scans. However, in patient having inconclusive bone scan, 18F-FDG PET/CT may have a promising role for confirming or excluding infection.

## OP-252

### [$^{18}$F]FDG PET/CT identified infections and inflammation in persistent critical illness

***B. van Leer***, *K. M. Demenaga, M. W. N. Nijsten, J. H. van Snick, R. H. J. A. Slart, A. W. J. M. Glaudemans, J. Pillay;*
*UMCG, Groningen, NETHERLANDS.*

***Aim/Introduction:*** In patients with persistent critical illness (PerCI), prognosis after day 10 is no longer determined by the initial admission diagnosis, but by a cascade of events resulting in new and persistent organ failure.[1] Acquired immune paralysis, resulting in occult infections or persistent inflammation both play a role in PerCI.[2] [$^{18}$F]FDG PET/CT can be used as a method to image (low-grade) infection and inflammation.[3] Our aim is to investigate the value of [$^{18}$F]FDG PET/CT in patients with PerCI. ***Materials and Methods:*** Patients (≥18 years) admitted to the ICU of the University Medical Center Groningen between 2010 and 2023 by whom a [$^{18}$F]FDG PET/CT was performed ten days or more after ICU admission were retrospectively included. [$^{18}$F]FDG PET/CT report was evaluated for infection foci and in combination with clinical records therapy change was scored. Therapy change was defined as any therapeutic decision (e.g. starting, stopping, continuing or restricting) reported to be made directly after the [$^{18}$F]FDG PET/CT. In addition, we assessed whether presence of infection on the [$^{18}$F]FDG PET/CT was associated with length of ICU stay and all-cause mortality using Kaplan-Meier with Log-Rank test. ***Results:*** 18 patients were included. Clinical signs of Inflammation or infection was the main reason to perform a [$^{18}$F]FDG PET/CT scan. In 13 (72%) patients an infectious focus was found. [$^{18}$F]FDG PET/CT was followed by therapy change in 11 patients (61%). In 9 patients a decision was made regarding antibiotic therapy. Corticosteroids were started in 2. Furthermore, in 2 patients drainage of infected collections was performed and in one patient supportive therapy was limited. Two patients died. Mean ICU admission time was 47 days. No association between presence of infection on [$^{18}$F]FDG PET/CT and ICU stay and all-cause mortality was observed. ***Conclusion:*** In patients with PerCI and clinical suspicion of inflammation, [$^{18}$F]FDG PET-CT contributes to identification of an infectious or inflammatory focus and results in therapy change. Larger prospective studies are needed to determine the impact of [$^{18}$F]FDG PET/CT on length of stay and mortality in this patient category. ***References:*** 1. Iwashyna TJ, et al. ## OP-253

### Comparison of [$^{18}$F]FDG and [$^{18}$F]DPA714 for the visualization of the pathogenesis of pulmonary tuberculosis in rhesus monkeys (Macaca mulatta)

***M. Stammes***[1], *M. Vierboom*[1], *C. Sombroek*[1], *J. Bakker*[1], *R. Vervenne*[1], *S. Hofman*[1], *A. Windhorst*[2], *J. Langermans*[1,3], *F. Verreck*[1];
[1]*BPRC, Rijswijk, NETHERLANDS,* [2]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [3]*Utrecht University, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Tuberculosis (TB) remains a global threat with a mortality rate of 1.5 million people in 2020. To fight tuberculosis a better understanding of pathogenesis and the complex host-pathogen interactions at different disease stages is essential. Dedicated tracers to follow spatiotemporal changes by molecular imaging like PET would help providing such insight. The most extensively studied tracer in TB, used both in the clinic and in research, is [$^{18}$F]FDG which is highly sensitive but not specific. A more specific tracer that has been developed targets the mitochondrial translocator protein (TSPO), which is upregulated in activated microglia and mononuclear phagocytes. Since macrophages are the target cells of Mycobacterium tuberculosis (Mtb) infection playing a critical role in host immunity including the formation of TB granulomas, such tracers are interesting candidates to study in the context of TB. In this study we set out to pioneer the use of the TSPO tracer [$^{18}$F]DPA714 in the primate host, along with [$^{18}$F]FDG as

a control, to visualize the pathogenesis of pulmonary tuberculosis upon experimental infection of rhesus monkeys (Macaca mulatta). ***Materials and Methods:*** Three adult healthy male rhesus monkeys were challenged 8 times at one-week intervals by repeated limiting dose exposure to Mtb. Next to baseline scans, PET-CTs were recorded 4, 5, 6 and 7 weeks after the primary challenge, alternating the use of[$^{18}$F]DPA714 or [$^{18}$F] FDG, respectively. Eleven weeks after the primary challenge the animals were euthanized, and a full necropsy was performed. ***Results:*** While experimental infection was verified postmortem by pathological examination and by increasing immune diagnostic signals from the blood along the infection phase, also both tracers demonstrated spatiotemporal alterations in lungs and mediastinal lymph nodes from 4 weeks after the primary challenge onwards. Remarkably, as the [$^{18}$F]FDG tracer showed an elevating trend, the initial [$^{18}$F]DPA714 signals at week 4 appeared decreasing 2 weeks later. Histological assessment of TSPO showed a staining pattern that was in concordance with the expression of CD68, a marker of innate macrophages, more than CD3, which is specific to adaptive T lymphocytes. ***Conclusion:*** The results of this pilot study indicate that the TSPO tracer [$^{18}$F]DPA714 has the potential to detect experimental Mtb infection at early stages in the primate host through measurement of inflammatory responses. The disparate dynamics of [$^{18}$F] DPA714 versus [$^{18}$F]FDG signals warrant further investigation and suggest that, during the development of TB disease, increasing inflammatory metabolism is not correlated with macrophage recruitment and/or activation.

## OP-254

### 68Ga-triacetylfusarinine C (TAFC) Siderophore PET/CT for Detection of Invasive Aspergillus Infection: the SPECIFIC Clinical Trial Protocol

***S. M. Levy***[1,2,3], *B. Z. Sim*[4,2], *M. Haskali*[1,2], *C. Decristoforo*[5], *H. Haas*[6], *M. Slavin*[4,2], *M. Hofman*[1,2], *A. Douglas*[4,2];
[1]*Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [2]*Sir Peter MacCallum Department of Oncology, The University of Melbourne, Melbourne, AUSTRALIA,* [3]*Department of Nuclear Medicine, The Royal Melbourne Hospital, Melbourne, AUSTRALIA,* [4]*Department of Infectious Diseases, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [5]*Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA,* [6]*Institute of Molecular Biology, Biocenter, Medical University of Innsbruck, Innsbruck, AUSTRIA.*

***Aim/Introduction:*** Invasive Aspergillus infection (IAI) is a common infection in immunocompromised patients undergoing cancer therapies. Prompt diagnosis is paramount given high morbidity and mortality. Whilst 18F-fluorodeoxyglucose (FDG) PET/CT is useful in diagnosis, it remains non-specific. Siderophore-radiolabelled PET/CT may facilitate rapid and non-invasive diagnosis of IAI. Siderophores are natural scavengers of iron produced by pathogens, essential for pathogen function, and quite specific for certain pathogens. Aspergillus fumigatus secretes two siderophores - fusarinine C and TAFC. TAFC is relatively specific for acute IAI and not taken up by human cellular systems. 68Ga is an attractive radionuclide for TAFC radiolabelling, due to equal charge and comparable radius to ferric iron, allowing iron displacement by 68Ga. Preclinical studies demonstrate diagnostic potential of 68Ga-TAFC PET/CT with specific visualisation of Aspergillus fumigatus infection [1]. This study aims to evaluate whether these pre-clinical findings can be confirmed in humans with proven or probable IAI. ***Materials and Methods:*** This is a first-in-human pilot observational cohort imaging study of patients with probable or proven IAI. 10 patients satisfying inclusion and exclusion criteria will be recruited to undergo 68Ga-TAFC-PET/CT within two weeks of IAI diagnosis, in addition to standard of care (SOC) imaging. 68Ga-TAFC will be compounded on-site. Baseline and post-imaging clinical data, haematologic, renal and liver function will be collected. Whole body PET/CT will be performed at 15, 60 and optionally 180 minutes following intravenous injection of 1.8-2.2 MBq/kg 68Ga-TAFC. Findings pertinent to IAI and physiologic uptake will be qualitatively and quantitatively analysed, including scan classification as positive or negative, measurement of SUVmax, SUVmean and MTV, and safety. Findings will be compared to existing SOC imaging (18F-FDG-PET/CT or CT). ***Results:*** 68Ga labelling was optimised to yield 68Ga-TAFC quantitatively at 50 C (pH 4.0) in 7 minutes. Production was then automated on a radiochemistry module and validated to produce high purity and pyrogenic free formulation for clinical administration. Clinical trial is anticipated to commence mid-2023. ***Conclusion:*** This proof-of-concept clinical trial aims to evaluate suitability of 68Ga-TAFC PET/CT for imaging IAI. ***References:*** [1] Journal of Fungi 2021; doi: 10.3390/jof7070558

## OP-255

### FAPI PET/CT Imaging of Pulmonary Hypertension Caused by Fibrosing Mediastinitis and FAPI Radiotargeted Therapy

***L. Song****, Z. Wu, C. Zan;*
*First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** To propose an innovative strategy for the integration of diagnosis and treatment of fibrous mediastinitis (FM) through targeting fibroblast activation protein inhibitor (FAPI) for fibrosis rats, and provide a theoretical basis for patients with pulmonary hypertension caused by fibrosing mediastinitis (PH-FM) based on PET/CT imaging. ***Materials and Methods:*** By performing $^{18}$F-FAPI PET/CT scan on patients with PH-FM, we determined the presence of FAPI-avid in FM lesions. We then injected $^{177}$Lu-FAPI-46 into a fibrosis rat model for SPECT/CT scan, evaluated the therapeutic effect, and estimated the absorbed dose and effective dose for this agent in the treatment of patients with FM. ***Results:*** PET/CT imaging of patients with 349.13±46.39 MBq of $^{18}$F-FAPI showed high-level uptake (SUVmax=7.94±0.26) in FM lesions. $^{18}$F-FAPI PET/CT imaging of fibrosis rats (8.28±0.91 MBq) suggested significant uptake of $^{18}$F-FAPI in the fibrotic lesions (SUVmax=2.11±0.23). SPECT/CT imaging of fibrosis rats injected with 17.87±1.99 MBq of $^{177}$Lu-FAPI-46 showed that the fibrotic lesions displayed FAPI-avid up to 60 h. These fibrosis rats were set as the control group (n=6), not treated by $^{177}$Lu-FAPI-46, and other three treatment groups were the 30 MBq group (n=6, 33.32±1.28 MBq), the 100 MBq group (n=6, 112.07±11.64 MBq), and the 300 MBq group (n=4, 299.00±10.06 MBq). No spontaneous healing of lesions was observed during the treatment period in the control group, and there was complete healing on day 9, day 11 and day 14 in the 30 MBq, 100 MBq and 300 MBq groups, respectively. With a significant difference in the free of event rate in the Kaplan-Meier curve among these four groups (log-rank chi-squared value=25.593, P-value < 0.001), the dose of 300 MBq displayed the best therapeutic effect, and no damage was observed in the kidney. We further presumed organ-absorbed doses and an effective dose (ED=0.4320 mSv/MBq) of $^{177}$Lu-FAPI-46 for patients. ***Conclusion:*** $^{18}$F-FAPI PET/CT can be a potentially valuable tool for the clinical diagnosis of PH-FM. Using $^{177}$Lu-FAPI-46 may be a novel and safe strategy for the integration of diagnosis and treatment of FM.

## OP-256

### Increased Colonic TSPO Expression in Inflammatory Bowel Diseases by the Translocator Protein 18kDa Radioligand [18F]DPA-714

***Q. He***[1], *D. Jiang*[2], *Y. Guan*[2], *A. Fei*[1], *F. Xie*[2];
[1]*Department of General Medicine, Xinhua Hospital Affiliated to Shanghai Jiaotong University School of Medicine., Shanghai, CHINA,* [2]*Department of Nuclear Medicine & PET center, Huashan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** Currently specific means of non-invasive imaging examination for inflammatory bowel disease is still lacking. Considering that the Translocator Protein (TSPO) is widely expressed in intestine and participates in intestinal immune response, [18F]DPA-714 is used to explore the colitis degree of DSS-induced chronic colitis mice, so as to provide a new non-invasive examination method. ***Materials and Methods:*** Colon biopsies were obtained from IBD patients and HC, including patients with active CD (A-CD, n = 24), patients with CD in remission (R-CD, n = 10), patients with active UC (A-UC, n = 25), patients with UC in remission (R-UC, n = 7) and healthy controls (HC, n = 16). TSPO was determined by qRT-PCR. CD-SES/UCEIS was recorded at the same time. Correlation between TSPO and CD-SES/UCEIS was performed by Spearman rank correlation. Male C57BL/6 mice were administrated with 2% DSS in drinking water for 7 consecutive days, followed by 14 days for recovery. The cycle was repeated for 3 times before all mice were sacrificed. [18F]DPA-714 scans were performed in the end. Ten mins static PET imaging at 40 min post-injection of [18F]DPA-714 was involved in this study. ***Results:*** TSPO was significantly increased in the inflamed mucosa of active IBD patients compared with that in HC or IBD patients in remission. However, no difference was found between HC and patients with CD or UC in remission. Correlation between TSPO expression in colon mucosa and CD simple endoscopic score (CD-SES) of CD patients and UCEIS of UC patients, respectively. As a result, a positive association was observed between TSPO and CD-SES or UCEIS. Successful establishment of chronic colitis mice model was verified by intestinal immunohistochemical staining. [18F]DPA-714 scan was performed to evaluate the colitis degree. A remarkably higher uptake in intestinal was observed in colitis mice compared to controls. ***Conclusion:*** TSPO is significantly increased in active IBD patients and positively correlated with disease activity. The Translocator Protein 18kDa Radioligand [18F] DPA-714 could be used as a non-invasive evaluation examine method for IBD patients.

### Implementing a Clinical Pathway for Treatment with I 131 for Differentiated Thyroid Cancer: Evaluation of Quality Objectives

***J. Cruz Vasquez****, A. Alonso Echarte, I. Blanco Saiz, E. Anda Apiñaniz, A. Alomar Casanovas, I. Saura Lopez, A. Barrera Cerpa, N. Rudic Chipe, M. Ribelles Segura, E. Goñi Gironés, A. Camarero Salazar;*
*Hospital Universitario de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** A clinical pathway (CPW) is a healthcare plan applied to a clinical process with a predictable course, detailing a sequence of interventions carried out by healthcare professionals through a multidisciplinary perspective, with the objective of reducing the variability in care and aiding in decision-making. This clinical management tool allows for periodic evaluation of quality of care, improvement of the transmission of information to patients, patients' assessment of the process and safety, the optimization of resources, and maintaining updated training for professionals. After the planning, development, and implementation of a CPW for the metabolic therapy with I-131 in our hospital, the objective was to meet the quality objetives in ≥ 80% of patients and to identify areas for improvement. ***Materials and Methods:*** During the implementation (2019-2022), data from the CPW and satisfaction surveys from all patients with DTC and an indication for post-surgical therapy with I-131 was analyzed. We evaluated the following time interval objectives: surgery to I-131 administration < 4 months (T1); surgery to Endocrinology appointment <2 months (T2); NuclearMedicine appointment to I-131 administration <2 months (T3). Other objetives were median hospital stay 1-3 days and a global patient satisfaction index >8 (scale 1 to 10). ***Results:*** From 131 patients, 84 women (64.1%) had a median age of 51 years (IQR: 11-85). 118 (90.1%) had papillary carcinoma and 13 (9.9%) had follicular carcinoma. 96 patients (73.3%) had stage 1, 27 (20.6%) had stage 2, 5 (3.8%) had stage 3, and 2 (1.5%) had stage 4. The dose administered of the radiopharmaceutical was between 1.11-7.4 Gbq. The median T1 was 102.55 days (47-268), meeting the objective in 96 patients (77%). The median T2 was 58.58 days (24-206), meeting the objective in 71 patients (56.8%). The median T3 was 28.67 days (13-121), meeting the objective in 127 patients (96.9%). The median hospital stay was 2.03 days (1-5). There was a significant positive correlation between the hospital stay and the activity of administered I-131 (r=0.556, p=0.00). Satisfaction surveys were collected from a total of 51 patients. Overall, 90% of patients assessed their care with 8-10 points. ***Conclusion:*** The quality objectives met were time between Nuclear Medicine appointment and treatment, hospital stay, and patient satisfaction. There is room for improvement in time between surgery and treatment and time between Endocrinology appointment and treatment. There is a possibility these objectives were not met due to patient and/or hospital clinical variations.

## EPS-064

### FNA-Tg in Metastatic Lymph Node Predictions Local Recurrence Following Lateral Neck Dissection in Papillary Thyroid Carcinoma

***Y. Yang***[1], *X. Jia*[1], *J. Hui*[2], *A. Yang*[1], *R. Gao*[1];
[1]*the First Affiliated Hospital of Xi 'an Jiaotong University, Xi 'an, Shaanxi, CHINA,* [2]*Shaanxi Cancer Hospital, Xi 'an, Shaanxi, CHINA.*

***Aim/Introduction:*** Lateral lymph node metastasis (LLNM) is associated with distant metastasis and locoregional recurrence in papillary thyroid carcinoma (PTC). Still, the prognostic significance of LLNM, as well as that of concurrent predictors, remains unclear. Thyroglobulin through fine-needle aspiration (FNA-Tg) is frequently practiced in the preoperative diagnosis of LNM, and LNM with a high FNA-Tg level was related with a higher tumor load. The goal of this study was to evaluate the FNA-Tg as a risk factor to prediction of local recurrence following therapeutic lateral neck dissection (LND) for PTC. ***Materials and Methods:*** This cohort study reviewed medical records of patients with PTC suspected of having LLNM and underwent cytology through FNA+FNA-Tg

as well as therapeutic LND in our institution, between January 1, 2019, and January 1, 2021. The relationships between clinical outcomes and FNA-Tg in LLNM were analyzed using logistics regression analysis. Receiver operating characteristic (ROC) curve analysis was used to obtain the cut-off value for FNA-Tg. ***Results:*** The study cohort included 65 patients (34 male, 31 female; median age, 41.7 years) with a median follow-up of 31.5 months after surgery. Local recurrence (including persistent disease) and distant metastasis were revealed in 22 (33.85%) and 3 (13.64%) cases, respectively. The median FNA-Tg levels of metastatic LNs respectively were 500.00 ng/mL and 335.90 ng/mL in patients with and without recurrence. Comparing recurrence patients who required further attention or treatment with those who did not recur, no significant difference was found concerning sex, age, BRAF, tumor size, capsular invasion, histology and pT stage. In univariate analysis, FNA-Tg value, FNA-Tg beyond the measurement limit, number of primary lesions, multifocal, extraglandular invasion, lateral lymph nodes ratio (LLNR), and number of iodine treatments were risk factors for local recurrence/persistence in LLND ($P < 0.05$). Multivariate analysis revealed that above factors were independent risk factors ($P < 0.05$),except for number of primary lesions. Noteworthy, FNA-Tg greater than 460.00 ng/mL was predictive of recurrence, which combined LLNR had higher predictive value with 89.50% sensitivity and area under ROC curve of 0.814 (95%CI: 0.689-0.938). Combined with FNA-Tg exceeding the measurable upper limit (>500 ng/mL), FNA-Tg showed an advantage in predicting local recurrence/persistence. ***Conclusion:*** FNA-Tg is an independent risk factor to predict local recurrence/persistent disease before therapeutic LND. And FNA-Tg combined LLNR can potentially assist in guiding the extent of LLND and identifying at-risk patients who need aggressive treatment and intensive surveillance for postoperative recurrence.

## EPS-065

### Role of $^{18}$F-NaF PET/CT on bone evaluation in patients with differentiated thyroid cancer undergoing radioactive iodine therapy and $^{18}$F-FDG PET/CT: preliminary results

***F. Volpe***[1], *C. Nappi*[1], *E. Zampella*[1], *E. Nicolai*[2], *L. Piscopo*[1], *D. Bianco*[3], *C. Vallone*[1], *F. Volpicelli*[1], *M. Falzarano*[1], *L. Pace*[4], *A. Cuocolo*[1], *M. Klain*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Naples, Italy, Napoli, ITALY,* [2]*IRCCS SDN, Diagnostic Imaging, Naples, Napoli, ITALY,* [3]*CIRA - Italian Aerospace Research Centre, Capua, ITALY, Capua, ITALY,* [4]*Dipartimento di Medicina, Chirurgia e Odontoiatria "Scuola Medica Salernitana" /DIPMED, Salerno, ITALY.*

***Aim/Introduction:*** Differentiated thyroid cancer (DTC) is the most frequent endocrine malignancy. After surgery, DTC patients are referred to $^{131}$I radioactive (RAI) therapy and a post-therapeutic total-body scintigraphy (PT-WBS) to identify local and/or remote metastases. In presence of high levels of thyroglobulin and suspicion of no-iodine avid metastasis, PET/CT with $^{18}$F-FDG is also indicated. $^{18}$F-NaF PET/CT has been recently introduced for evaluation of bone metastases in oncological patients. However, no data are available regarding the comparison between $^{18}$F-FDG and $^{18}$F-NaF PET/CT in DTC patients with suspicion of bone metastasis at $^{131}$I-PT-WBS.We compared the role of $^{18}$F-NaF PET/CT with $^{131}$I-PT-WBS and $^{18}$FDG-PET/CT on bone evaluation in DTC patients. ***Materials and Methods:*** We enrolled consecutive DTC patients undergoing RAI therapy avid bone uptake on PT-WBS, referred to $^{18}$F-NaF PET/CT and $^{18}$F-FDG PET/CT from June 2020 to November 2022. Findings on the 3 scans were compared for detection rates and imaging concordance. ***Results:*** A total of 10 patients (3 men, 66±13 years) were included. Thyroglobulin levels at time of RAI therapy were 2441±4048 ng/dL (mean thyroid stimulating hormone: 66±36 mUI/mL). The administered $^{131}$I dose was 4748±1455 MBq. At $^{131}$I-PT WBS 2 patients showed residual thyroid bed uptake and latero-cervical avid nodes, 6 also demonstrated lung avid foci and all 10 patients had skeletal involvement with a total of 22 bone iodine avid lesions. At $^{18}$F-FDG PET/TC, 20 bone lesions (in 9 patients) demonstrated 18F-FDG uptake and densitometric alterations, and 2 lesions (in 1 patient) did not show any pathological finding. Five more pathological foci were observed on thyroid bed (2/2), latero-cervical nodes (2) and lung (1/6) taking into consideration that the other 5 lung lesions were <5 mm size on CT evaluation and hence not metabolically evaluable. Similarly, at $^{18}$F-NaF PET/CT the same 20 bone lesions also demonstrated abnormal uptake and the other 2 did not. Additionally, other 13 focal bone sites with benign densitometric pattern at CT were observed in 7 subjects. ***Conclusion:*** $^{18}$F-NaF PET/CT did not add information on metastatic skeletal involvement in DTC patients over $^{131}$I-PT-WBS and $^{18}$F-FDG PET/CT, with comparable specificity for bone evaluation but with a not negligible rate of nonspecific findings. Moreover, both $^{131}$I-PT-WBS and $^{18}$F-FDG PET/CT also allowed to evaluate other potential disease compartments such as thyroid bed, nodes and lungs confirming the highest disease detection rate for $^{131}$I-PT-WBS over other imaging modalities.

## EPS-066

### Correlation of thyroglobulin reduction index after $^{131}$I therapy with RECIST1.1 assessment results in DTC with microscopic pulmonary metastases

***T. Tian***, *R. Huang;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** This study analyzed the relationship between the stimulated thyroglobulin reduction index (TRI) and RECIST1.1 assessment results in DTC patients with microscopic pulmonary metastases (< 1 cm), aiming to provide a reliable evidence for the clinical decision of $^{131}$I therapy in such patients. ***Materials and Methods:*** The clinical data of patients with pulmonary metastatic DTC underwent $^{131}$I therapy in our department from 2009 to 2022 were retrospectively analyzed, and all pulmonary metastases in each patient were < 1 cm in diameter. Stimulated thyroglobulin (sTg) was measured before $^{131}$I treatment (interval > 6 months), TRI=100×(sTg1-sTg2)/sTg1. Response evaluation was performed 6-12 months after each $^{131}$I therapy according to RECIST criteria. ***Results:*** A total of 78 patients with DTC with lung metastases < 1 cm in diameter were included in the study. The median follow-up time was 5.8 years (range: 2-33 years), during which TRI was measured and response was evaluated 236 times, and the median number of $^{131}$I treatments was 4 (range: 2-11). The median s-Tg was 116.10 ng/mL (range: 2.8-5000 ng/mL) and the median TRI value was 35.2% (range: - 403.2% - 95.4%). According to RECIST version 1.1, no patients in the study cohort achieved CR, 13 patients with PD (5.5%), and 222 patients (94.5%) with non-CR non-PD. The ROC curve yielded an optimal cut-off value of -28% for TRI for predicting PD, and patients in the TRI < -28% group were more likely to have PD than those with higher TRI levels (23.8% vs. 3.7%. $P < 0.001$). In the non-CR non-PD group, 17.1% (38/222) showed a reduction in the number of pulmonary metastatic lesions after $^{131}$I therapy. ROC curve analysis showed that the best cut-off value for TRI to predict lesion reduction was 15.2 %, with

a sensitivity of 92.1%. There were far more patients with reduced lesions in the TRI > 15.2% group than in those with TRI ≤ 15.2% (21.9% vs. 4.8%, P=0.002). Multifactorial analysis showed that TRI was associated with reduced pulmonary metastatic lesions after $^{131}$I therapy (HR: 5.196, 95% CI: 1.159-17.774, P=0.009), whereas type of pathology, interval of $^{131}$I treatment, cumulative dose of $^{131}$I therapy were not associated with reduced pulmonary metastatic lesions. ***Conclusion:*** TRI can objectively indicate the efficacy of $^{131}$I therapy. In DTC patients with non-CR non-PD pulmonary metastases assessed by RECIST 1.1 criteria, TRI >15% can predict a better response and can be used to guide subsequent $^{131}$I therapy.

## EPS-067

### Towards clinical translation of a novel antibody-based $^{177}$Lu-labeled radiopharmaceutical for treatment of anaplastic thyroid cancer

***A. Mortensen***[1,2], *H. Berglund*[2], *T. Mohajer Shojai*[2], *H. Lotsholm Persson*[3], *A. Stenman*[1], *P. Jha*[2], *C. Juhlin*[1], *P. Bernhardt*[4], *J. Zedenius*[1], *F. Frejd*[2], *M. Nestor*[2,3,3];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Uppsala University, Uppsala, SWEDEN,* [3]*Science for Life Laboratory, Stockholm, SWEDEN,* [4]*University of Gothenburg, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Anaplastic thyroid cancer (ATC) is a rare but dire disease with few therapeutic options that offer more than simply palliative care. The cancer-associated cell-surface antigen CD44v6 is overexpressed in approximately 50% of all ATC and can be utilized for molecular radiotherapy. In collaboration with the Science for Life Laboratory, Drug Discovery and Development platform (SciLifeLab, DDD), we have developed a novel, antibody-based radiopharmaceutical targeting CD44v6. ***Materials and Methods:*** Phage selection and affinity screening was performed in an IP-free library created by DDD. Antibody candidates were assessed in vitro for specificity, affinity and off-target binding. The primary candidates were evaluated in vivo in mice bearing ATC xenografts using $^{125}$I and a final candidate was selected. A dual-nuclide study ($^{125}$I/$^{177}$Lu) provided dosimetry data and a pilot therapy study using $^{177}$Lu-labeled antibody was evaluated in an ATC xenograft model. Affinity maturation was performed and candidates were evaluated in vitro and in vivo in several xenograft models with varying CD44v6-expression levels. The lead drug candidate was evaluated for therapy in two ATC xenograft models and imaged using small-animal SPECT. A biodistribution study in rabbits was performed as a secondary toxicology species using $^{111}$In-labeled antibody. Further, $^{68}$Ga-PET/CT in cynomolgus was performed to confirm lack of unspecific binding. ***Results:*** Affinity, off-target binding and in vivo distribution studies resulted in the selection of Akir-1par as the primary lead candidate antibody. The dosimetry study indicated that $^{177}$Lu would significantly increase the tumor dose compared to $^{131}$I and the pilot therapy study resulted in 100% survival in the therapy group compared to controls in a high CD44v6-expressing xenograft model. Affinity-matured candidates demonstrated superior binding compared to the parental antibody and a final candidate was chosen, Akir-1. A dose-dependent therapeutic response to $^{177}$Lu-Akir-1 was demonstrated using a high CD44v6-expressing xenograft model. Surprisingly, even a moderate dose of $^{177}$Lu-Akir-1 resulted in complete remission of all treated animals in a low/moderate CD44v6-expressing xenograft model, cementing the superiority of Akir-1 compared to Akir-1par. The biodistribution of $^{111}$In-Akir-1 in rabbits confirmed the previous pattern of low or non-existent uptake in normal tissues and no active binding to bone marrow. PET/CT in cynomolgus using $^{68}$Ga confirmed low uptake in healthy tissues. ***Conclusion:*** The accumulated results from all animal studies cement the validity of $^{177}$Lu-Akir-1 as a promising, novel antibody-based radiopharmaceutical targeting CD44v6 in ATC and a clinical phase 1 study is planned for 2024.

## EPS-068

### Differentiating subcentometer pulmonary metastases in differentiated thyroid cancer patients by integration of machine learning and deep learning: a retrospective, multicenter study

***X. Gao****;*
*Department of Radiology, Zhejiang Cancer Hospital, Hangzhou, CHINA.*

***Aim/Introduction:*** Diagnosing subcentimeter pulmonary metastases in indeterminate pulmonary nodules is crucial for patients with differentiated thyroid cancer.We aim to develop and validate novel integration models combing machine learning and deep learning for diagnosing subcentimeter pulmonary metastases in differentiated thyroid cancer patients. ***Materials and Methods:*** Models were developed in a primary center included 1244 subcentimeter pulmonary metastases on CT. Lesions were randomly assigned (7:3) to training or internal validation. Integration models based on machine learning were built with selected radiomics features and deep learning features and compared with classic machine learning models or deep learning models to classify the indeterminate subcentimeter lung nodules as pulmonary metastases or benign nodules. External validation contained 161 subcentimeter differentiated thyroid cancer pulmonary metastases in two independent centers. Stepwise validation was further performed according to the nodule's largest diameter in order to test models' generalization ability for subcentimeter nodules of different sizes. ***Results:*** Among all the machine learning models, the support vector machine showed the best discrimination in external validation, with a 0.910 AUC and a 0.935 AUC in internal validation. The deep learning model also showed good discrimination, with a 0.952 AUC in internal validation and a 0.893 AUC in external validation. All the integration models were significantly better than machine learning or deep learning alone, with the best AUC of 0.969 and 0.967 in internal validation and external validation, respectively. Stepwise validation demonstrated that with the PM diameter decreasing from 9mm to 2mm, the AUC initially remained stable and gradually decreased in all models and the integration models were the most stable. ***Conclusion:*** The novel integration models combining traditional radiomics and deep learning features provided noninvasive discrimination of subcentimeter pulmonary metastases from benign pulmonary nodules, even with minimal sizes, and was more effective than machine learning or deep learning alone.

## EPS-069

### Modeling Clinical Radioiodine Uptake by Using Organoids Derived from Differentiated Thyroid Cancer

***X. Zhang***[1], *J. Liu*[2], *Z. Li*[2], *R. Huang*[1];
[1]*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA,* [2]*Department of Thyroid Surgery, West China Hospital Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** The majority of differentiated thyroid cancers (DTC) exhibit excellent prognosis under comprehensive treatments. However, about 2/3 of DTC with distant metastasis tend to de-differentiate and lose their capacity to uptake iodine, known as RAI-refractory DTC (RAIR-DTC), which may not benefit

from RAI therapy. Therefore, we intend to establish a primary tumor derived organoid model to predict $^{131}$I uptake of tumor residue and investigate potential mechanism of sodium iodine symporter (NIS) regulation. ***Materials and Methods:*** Organoids were cultured from fresh tumor tissues origined from either treatment-naive DTC patients with distant metastasis or post-RAI therapy DTC patients with tumor recurrence. The corresponding clinicopathologic data was gathered, and the consistency of the morphological and histological features between organoid and parental tissue were analyzed. RAI uptake ability of organoid was assessed by $^{131}$I uptake assay and its predictive sensitivity was checked by comparing with $^{131}$I whole-body scan of corresponding patient. Transcriptome sequencing of RAI-avid and RAIR tissues was performed to search differentially expressed genes. ***Results:*** Eight DTC patients' organoids were created. One patient had bone metastasis alone, three had lung metastasis alone, and two patients had both. One patient presented residual lymph nodes metastasis, while another had recurrence in thyroid bed. Morphological and histological analysis showed that organoids faithfully recapitulated main features of origin tumor tissue, displaying similar expression pattern of thyroid-specific markers (PAX8, TTF-1, TSHR and TG), transporter necessary for iodine uptake (NIS), and proliferation marker (Ki-67). All patients received RAI therapy after surgery, and according to their post-therapy whole-body scintigraphy, patients were designated as either RAI-avid or RAIR DTC. RAIR DTC organoids showed comparable $^{131}$I uptake level to an anaplastic thyroid cancer organoid control (53.0±45.8 vs 41.5±0.7 cpm/$10^5$ cells, p=0.087), while RAI-avid group presented significant higher $^{131}$I uptake (1335.8±2047.4 cpm/$10^5$ cells, P=0.027). Predictive sensitivity was 87.5% when a cut-off value less than 300 cpm/$10^5$ cell was used to distinguish RAIR from RAI-avid organoids. Transcriptome analysis revealed that 668 mRNAs were up-regulated in RAIR DTC and 743 were down-regulated. The differentially expressed genes mainly enriched in ECM-receptor interaction, PPAR signaling pathway and cGMP-PKG signaling pathway. Moreover, SLC5A5, which encoding NIS, showed substantial discrepancy (p<0.001). ***Conclusion:*** Patient derived organoids from DTC recapitulated main characteristics of their parental tissue and preserved ability to uptake radioiodine, showing potential in predicting clinical $^{131}$I-uptake status. Differentially expressed markers between RAI-avid and RAIR tissue may be latent targets in future attempt of re-differentiation therapy.

## EPS-070

### Cytoreductive efficacy of radioiodine treatment in hyperfunctioning thyroid nodules.

***A. Alomar***, *I. Blanco, F. Lozada, A. Irigaray, J. Pineda, M. Ollero, I. Saura, J. Cruz, A. Barrera, N. Rudic, M. Ribelles, A. Camarero, E. Anda, E. Goñi;*
*Hospital Universitario de Navarra (HUN), Pamplona, SPAIN.*

***Aim/Introduction:*** The treatment of choice for patients with autonomous thyroid nodule without compressive symptoms and/or suspicion of malignancy is radioactive 131-I (RAI). Although the efficacy in normalizing thyroid function is widely demonstrated, there are currently few studies that determine the effectiveness of RAI in reducing the size of the autonomous thyroid nodule. The main objective of this study is to investigate the cytoreductive effect of RAI in the treatment of hyperthyroidism in autonomous thyroid nodule, as well as the clinical, radiological, scintigraphic, and dosimetric variables that influence this effect. ***Materials and Methods:*** Two senior nuclear medicine physicians, blinded to all clinical-radiological data, reviewed treatments with radioiodine (empirical dose) for hyperthyroidism indication between 2017 and 2020. Only those cases with a clearly dominant high uptake nodule in the thyroid scintigraphy with initial and follow-up ultrasound where selected. An analysis of scintigraphic images was performed (planar acquisition 20min. post iv injection of 185MBq of 99mTc-Pertechnetate) collecting data from ROIs (total, mean, and maximum counts) in thyroid nodules/s, thyroid parenchyma, and background. Additionally, maximum diameter and volumes of the nodule/s were collected using ultrasound, both before and after treatment, as well as clinical and biochemical data to evaluate thyroid function. Follow-up was performed between 12-18 months post-treatment. ***Results:*** A total of 39 nodules (20 multinodular goiters and 19 autonomous nodules) in 38 patients were included with a mean age of 54.6±2.1 years being women 34(87.2%). After radioiodine treatment (mean dose of 13.5±0.32mCi ranging from 10 to 15mCi), a significant decrease in nodule volume was observed (p=0.000) with a volume reduction ratio (VRR) of 64.9% [IQR: 47.3-92.7] (min: 5.2%, max: 96.7%), being significantly higher in nodules <3cm (74.1%±3.0 vs 52.5%±6.1; p=0.002). The VRR was not associated with any scintigraphic characteristic studied (total, mean, or maximum counts) neither the administered dose (rho=0.285; p=0.08). Two patients (5.2%) remained hyperthyroid while 7 (18.4%) became hypothyroid at one year follow-up. No relationship was found between scintigraphic uptake in remaining thyroid parenchyma and the rate of subsequent hypothyroidism. ***Conclusion:*** This study demonstrates that the administration of a single dose of 131-I presents a significant cytoreductive effect (measured as volume decrease) at 12-18 months post-treatment for autonomous thyroid nodule, which is especially significant in nodules <3cm. There was no significant association between VRR and any of the pre-treatment scintigraphic features neither the administered dose.

## EPS-071

### The effect of radioiodine therapy I-131 in patients with non-toxic nodular goitre

***S. Abdelrazek***, *J. Mysliwiec, P. Szumowski, W. Madra, L. Zukowski;*
*Department of Nuclear Medicine, Medical University of Bialystok, Bialystok, POLAND.*

***Aim/Introduction:*** Simple goitre is defined as the enlargement of the thyroid gland, in the absence of autoimmune thyroid disease, malignancy, or inflammation, still constitutes a major diagnostic and therapeutic challenge. Radioiodine therapy (RAIT) is non-invasive, safe and cost effective method of therapy for reduction of goitre. There is no consensus regarding the optimum treatment of benign non-toxic goitre. Randomised studies have shown that levothyroxine has poor evidence of efficacy and is inferior to radioiodine therapy regarding goitre reduction. The aim of our study was to evaluate the short term efficacy of radioiodine therapy to reduce thyroid volume with minimal risk of hypothyroidism in patients with non-toxic nodular goitre. ***Materials and Methods:*** We treated 2200 patients, aged 20-90 years; (72%) of the studied groups were female and (24%) male; the mean radioiodine uptake (RAIU) was 42% and thyroid volume ranged between 42-190ml. Qualification of these patients were based on normal levels of serum fT3, fT4, TSH and characteristic appearance on thyroid scans and ultrasound. Malignant changes were excluded in all suspected nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 -800 MBq (465 ± 191 MBq). The mean absorbed dose was 204 ± 25 Gy, and was proportional to

thyroid volume. Thyroid ultrasonography, and thyroid scan with RAIU at 24hours was done before and after 12 months of RAIT. Follow up control for the evaluation of fT4, TSH was done every 6 weeks. ***Results:*** After 12 months of radioiodine therapy a mean thyroid volume reduction of 51% was achieved. Approximately half of the effect is obtained within the first 3 months. Euthyroidism persist in 91% of patients, and hypothyroidism develop in 9% of patients. All patients were highly satisfied; with improvement in obstructive symptoms and exercise tolerance in the majority of patients. ***Conclusion:*** Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of the goiter volume and should not be restricted to elderly patients, or to patients with high operative risk, but should be used as first choice in every patient with non toxic nodular goitre with thyroid volume > 40 ml. Surgery should be reserved as first choice if malignancy is suspected. The reduction of thyroid volume with low percent of hypothyroidism, were due to well accurate measurement of administered activity, relatively high effective half-life, & well-organised follow up.

## EPS-072

### Variables Associated With Positive [$^{18}$F]F-Choline Pet/Ct Uptake In Primary Hyperparathyroidism With Negative [$^{99m}$Tc]Tc-Mibi Scintigraphy

***M. Guerra Gómez***, *J. Cuenca Cuenca, N. Valerdiz Menéndez, A. Rodríguez Pajuelo, J. Tirado Hospital, J. Jiménez-Hoyuela García; University Hospital Virgen del Rocío, Seville, SPAIN.*

***Aim/Introduction:*** The aim of this study was to identify the variables associated with positive uptake on [$^{18}$F]F-Choline PET/CT in cases of primary hyperparathyroidism (PHP) with negative preoperative [$^{99m}$Tc]Tc-MIBI scintigraphy. ***Materials and Methods:*** An observational case-control study was performed. Patients with histopathologically confirmed PHP with negative [$^{99m}$Tc]Tc-MIBI scintigraphy and positive [$^{18}$F]F-Choline PET/CT were included as cases. Patients with histopathologically confirmed PHP with positive [$^{99m}$Tc]Tc-MIBI scintigraphy were included as controls. Baseline clinical, biochemical and ultrasound variables before surgical treatment were analysed. Additionally, the incidence of post-surgical hypoparathyroidism was studied in both cohorts, as well as the histological variables (predominant cell type, growth pattern, location and size of adenoma). Logistic regression analysis was used to analyze the factors that influence the uptake of [$^{18}$F]F-Choline. ***Results:*** 79 patients were included. 26 cases (mean age 56.6 years, 76.9% female) and 53 controls (mean age 60.2 years, 76.4% female). Pre-surgical ultrasound study showed a higher frequency of cystic adenomas with calcifications and lobulated borders in cases compared to controls ($p < 0.05$). Multiglandular disease was also more frequent in PHP cases with positive [$^{18}$F]F-Choline uptake compared to controls (30.8% vs. 13.2%, p=0.061), as was the incidence of post-surgical hypocalcemia (19.2% vs. 7.5%, p=0.125) and lower post-surgical PTH level (16.1 vs. 47 pg/ml, p=0.052). Histological analysis showed a lower glandular volume in cases compared to controls (1.5 vs. 2.02 cc, $p < 0.001$). No significant differences were found in predominant cell type. A higher frequency of follicular growth pattern was observed in cases compared to controls (31.6% vs. 10.6%, p=0.03). In multivariate analysis, [$^{18}$F]F-Choline uptake in patients with negative [$^{99m}$Tc]Tc-MIBI scintigraphy was associated with lower glandular volume (adjusted Odds Ratio (AOR) 0.371, 95% CI [0.15, 0.94], p=0.037), follicular growth pattern (AOR 0.1, 95% CI [0.01, 0.87], p=0.037) and the presence of atypical ultrasound features (AOR 6.18, 95% CI [1.43, 26.69], p=0.015). ***Conclusion:*** Our findings suggest that lower glandular volume, multiglandular disease, presence of atypical ultrasound features and follicular growth pattern are associated with negative [$^{99m}$Tc]Tc-MIBI scintigraphy uptake and positive [$^{18}$F]F-Choline PET/CT in primary hyperparathyroidism. These results support the use of [$^{18}$F]F-Choline PET/CT in cases of PHP with a negative preoperative localization study.

## EPS-073

### Incremental value of Tc-99m-sestamibi SPECT/CT in patients with positive planar scintigraphy in the detection of additional lesions in patients with Primary hyperparathyroidism

***R. Goel***, *N. Damle, Y. Dharmashaktu, C. Bal, P. Kumar, A. Goyal, R. Gupta, Y. Gupta, R. Aphale, G. Puri, S. Chumber; All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.*

***Aim/Introduction:*** Tc-99m-sestamibi scintigraphy is of value in non-invasively localizing abnormal parathyroid glands before surgical exploration as well as for ruling out ectopic glands in patients with primary hyperparathyroidism. However, most centres in India restrict to planar scintigraphy rather than SPECT/CT. In this retrospective analysis, we aim to demonstrate the incremental value of Tc-99m-sestamibi SPECT/CT over planar scintigraphy in detecting additional culprit lesions in patients with primary hyperparathyroidism. ***Materials and Methods:*** We retrospectively reviewed data of 313 patients(205 female, 108 male; age 2.5-80 years) with biochemical evidence of hyperparathyroidism referred from Endocrinologists(mainly from our institute) between January 2021 to December 2022. All patients were injected with 20mCi of Tc-99m-sestamibi intravenously. Planar images were acquired at 15-minute, 50-minute, and 2-hour intervals. SPECT/CT images were acquired at 50 minutes. The imaging findings were correlated with histopathology. ***Results:*** Out of the total 313 patients, 219(144-female, 75-male; age 14-80 years) patients had primary hyperparathyroidism with a mean iPTH of 360.3 pg/mL. In patients with primary hyperparathyroidism, planar scintigraphy was positive for presence of hyperfunctioning parathyroid in 146/219 patients(66.67%), while SPECT/CT detected lesions over and above planar imaging in 31/146 patients(21.2%). Of these 31 patients, planar imaging detected a total of 34 lesions, of which 4 were in right superior location, 12 in right inferior, 5 in left superior and 13 in left inferior. SPECT/CT of these 31 patients revealed 41 additional lesions out of which 14 lesions were in right superior location, 9 in right inferior, 9 in left superior and 7 in left inferior location and 2 in ectopic location(prevertebral and left upper paratracheal location respectively). Out of the 41 additional lesions on SPECT/CT, 6 were considered positive, 21 suspicious and 14 indeterminate for a parathyroid adenoma.17/31 patients underwent surgery and a total of 36 supposed lesions were excised. On a per patient analysis, SPECT/CT correctly identified lesions over and above planar imaging in 9/17 patients. On lesion-based analysis, 29/36 lesions were positive on histopathology for adenoma/hyperplasia. Of these 29 lesions, 16 were described in planar and SPECT/CT imaging. 12 were described only in SPECT/CT images. 3/12 lesions were given as positive, 6/12 as suspicious, and 3/12 as indeterminate on SPECT/CT for a parathyroid adenoma. One lesion was not described in planar or SPECT/CT images. ***Conclusion:*** Tc-99m-sestamibi SPECT/CT provides incremental value over planar scintigraphy in the detection of additional lesions thus reducing the possibility of failed parathyroidectomy in patients with primary hyperparathyroidism.

## EPS-074

### 18F-Choline PET/MR for the Localization of Hyperplastic Parathyroid: Preliminary Analysis from a Monocentric Study

***C. Gagliani***, *P. Bartoletti, V. Camozzi, S. Sperti, F. Torresan, M. Iacobone, L. Evangelista;*
*Azienda Ospedaliera Universitaria di Padova, Padova, ITALY.*

***Aim/Introduction:*** To evaluate the role of PET/MR with 18F-Choline in identifying hyperfunctioning parathyroids in patients with a history of primary or recurrent hyperparathyroidism but a negative or doubtful conventional imaging (i.e., neck ultrasonography and/or 99mTc-sestamibi scintigraphy). ***Materials and Methods:*** Between January 2020 and April 2023, 105 patients underwent PET/MR investigation with 18F-Choline. All images were reviewed by at least 2 nuclear physicians and 1 radiologist. For the interpretation of the images, both visual and semiquantitative assessment were used for PET, while MR images were only visually analyzed. For the semiquantitative PET analysis, the maximum standardized uptake value (SUVmax) was obtained. Data about surgical approach were considered, when available. ***Results:*** The detection rates of PET and MR for the localization of hyperplastic parathyroids were 82% and 56%, respectively. PET/MR was able to identify 100% of hyperplastic parathyroids in 11 patients who previously had a parathyroidectomy. The median value of SUVmax at the level of the hyperfunctioning parathyroid was 11.31 (range 2.1 - 39.7). PET/MR was positive mainly in patients with high serum calcium (median values: 14.09 vs. 2.69 mg/dL, respectively in positive and negative PET/MR), while a poor correlation with serum parathormone (PTH) was observed (median values: 105 vs. 108 pg/mL, respectively in positive and negative PET/MR). Data about surgery was available in 21/105 (20%) patients. In all 21 patients PET/MR was positive (100% true positive rate) with a final histological analysis compatible with parathyroid adenomas. ***Conclusion:*** The present study demonstrates that 18F-Choline PET/MR shows greater identification of parathyroids than MR alone. In addition, the value of serum calcium seems to play an important role in guiding patient selection, whereas serum PTH seems to play a limited role.

## EPS-075

### CXCR4-directed [$^{68}$Ga]Ga-PentixaFor PET/CT as a novel diagnostic modality in primary aldosteronism

***A. Chaman Baz***[1], *M. Gotthardt*[1], *W. Spiering*[2], *B. de Keizer*[2], *J. Deinum*[1], *J. F. Langenhuijsen*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,*
[2]*UMC Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** PA is a growing recognized form of secondary hypertension, affecting an estimated 2.6% of the hypertensive population (1). Primary aldosteronism (PA) is caused by autonomous overproduction of aldosterone by either a unilateral aldosterone-producing adenoma (APA) or by bilateral adrenal hyperplasia (BAH). Distinction ('subtyping') is crucial, PA is cured by adrenalectomy in unilateral PA and is treated by medication in bilateral PA. The reference standard in subtyping PA is currently adrenal vein sampling (AVS). However, it is invasive, costly, has limited availability and is accompanied by risk of serious complications. We propose a new diagnostic imaging modality employing the PET-tracer [$^{68}$Ga]Ga-PentixaFor, which has high accuracy in detecting APAs in PA (2). The goal of this study is to determine concordance of [$^{68}$Ga]Ga-PentixaFor PET/CT and AVS. Secondary outcomes are optimal timepoint for scanning and quantitative criteria for lateralization at the optimal timepoint. ***Materials and Methods:*** This study is part of a two-step diagnostic trial. We included patients with PA from Radboudumc Nijmegen and UMC Utrecht, confirmed by an intravenous salt-loading test. Patients underwent AVS and [$^{68}$Ga]Ga-PentixaFor PET/CT. A dynamic scan was performed to determine the optimal timepoint for scanning in the first 6 patients. The main outcome was the concordance of AVS and [$^{68}$Ga]Ga-PentixaFor PET/CT. The $SUV_{max}$ was used to determine lateralization in [$^{68}$Ga]Ga-PentixaFor PET/CT. ***Results:*** Twenty-four patients underwent adrenal vein sampling and a [$^{68}$Ga]Ga-PentixaFor PET/CT. Two patients had inconclusive AVS results and were excluded from analysis. The optimal timepoint of scanning was 1h post-injection. Using a cut-off of SUV-max-ratio of 1.4 we reached a concordance of 68%, sensitivity of 64% and specificity of 75%. Using a Bayesian prediction model, the predicted-concordance was: 67% (CI80%=54-78). ***Conclusion:*** [$^{68}$Ga]Ga-PentixaFor PET/CT is an imaging modality with high concordance with AVS. With these results we have sufficient evidence to proceed to step-2: A randomized controlled diagnostic trial, where patients will be randomized in [$^{68}$Ga]Ga-PentixaFor PET/CT or AVS. ***References:***

## EPS-076

### Role of 68Ga-DOTANOC, 18F-FDOPA and 68 Ga- Exendin PET/CT imaging in adult patients with Hyperinsulinemic Hypoglycemia(HI)

***S. Sagar***, *N. A. Damle, D. Khan, P. Kumar, C. Bal, M. Tripathi, N. Tandon, Y. Gupta;*
*AIIMS, Delhi, INDIA.*

***Aim/Introduction:*** Hyperinsulinemic hypoglycemia (HI) is a rare but potentially fatal condition. At our institution, we aimed to evaluate three tracers- 18F-FDOPA,68Ga-DOTANOC and 68Ga-EXENDIN-4 PET/CT in identifying focal pancreatic lesions in patients with HI. These imaging techniques have been shown to be useful for this purpose. ***Materials and Methods:*** 68Ga-DOTANOC and 68 Ga- ExendinPET/CT scans and clinical details of 23 adults with biochemical and clinical diagnosis of HI were reviewed. The adult patients were administered 2-3mCi 68Ga-DOTANOC, 18F-FDOPA and 68Ga-Exendin and the scan was acquired on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE). Abdominal spot images over 1-2 bed positions were acquired with 18F-FDOPA and 68 Ga- Exendin while whole body images were acquired with 68Ga-DOTANOC. ***Results:*** Out of 23 adults (14 female and 9 male), 10 adults underwent 18F-DOPA PET/CT,19 adults underwent 68Ga-DOTANOC PET/CT between 2017 to 2023 at our institution.Our results showed diffuse uptake in all 10 patients whereas 5 patients had both FDOPA PET/CT and 68-Ga DOTANOC PET/CT and DOTANOC was able to detect focal lesion in 4 patients (2 had focal uptake at head and the other 2 had uptake in the tail of pancreas).Out of these 10 patients, 5 patients also had both FDOPA PET/CT and 68-Ga EXENDIN PET/CT and EXENDIN was able to detect focal lesions in 5 patients. Out of these 5 patients 4 patients had both EXENDIN And DOTANOC PET/CT with focal localisation to same site. ***Conclusion:*** In adult patients with hyperinsulinemic hypoglycemia (HI), both 68Ga-DOTANOC and 68Ga-Exendin PET/CT are effective methods

for identifying focal pancreatic lesions. Compared to 18F-DOPA PET/CT without Carbidopa premedication, the detection rate is significantly higher for both of these imaging techniques.

## EPS-077

### Association between BAT detection (and activity) with FDG PET/CT and cancer prognostic: an Artificial Intelligence (AI) enhanced systematic review.

***P. Jané***[1], *E. Jané*[2], *E. Pirazzo Teixeira*[1], *V. Garibotto*[1], *K. Gariani*[3];
[1]*Service of Nuclear Medicine and Molecular Imaging, Hôpitaux Universitaires de Genève, Genève, SWITZERLAND,* [2]*Universidad Politécnica de Madrid, Madrid, SPAIN,* [3]*Service of Endocrinology, Diabetes, Nutrition and Therapeutic education, Hôpitaux Universitaires de Genève, Genève, SWITZERLAND.*

***Aim/Introduction:*** Brown adipose tissue (BAT) represents the main source of adaptive thermogenesis in humans providing an attractive pharmacological target to counteract obesity, insulin resistance and cardio-vascular disorders. BAT usually displays an increased uptake of 18F-FDG in positron emission tomography/computed tomography (PET/CT), making this modality the most established approach for the detection and quantification of BAT in the clinic. Some associations between BAT activity and cancer evolution have been described, however the role of BAT on cancer prognostic and development remains uncertain, thus motivating this AI-enhanced systematic review. ***Materials and Methods:*** We used the Entrez API and a local copy of the 2022 Medline dataset (courtesy of the National Library of Medicine, U.S.A) to search and retrieve all articles involving BAT and PET. We then built an automated systematic review pipeline with the help of different python tools for Natural Language Processing like Spacy, Scispacy and the Scibert model to perform text classification, entity recognition and entity linking to the Unified Medical Language System (UMLS) Metathesaurus. We defined 35 variables for the meta-analysis including study characteristics, patients' demography, clinical data, and imaging findings and created ad-hoc algorithms for the automated extraction of the necessary data from the full texts. ***Results:*** Our (semi)-automated systematic review identified an initial number of 847 articles with finally eight articles with a total of 6290 patients that fulfilled the quality criteria for inclusion after screening of titles, abstracts and full texts. The cancers studied were breast cancers, lung cancer, lymphoma, gastrointestinal cancer, thyroid cancer, melanoma, genitourinary cancer and sarcoma/carcinoma of unknown origin. The results collected from the included studies suggested that BAT activity is greater in patients with active cancer compared to age-, sex-, and BMI-matched BAT-positive patients without active cancer. In particular, patients with breast cancers have a BAT activity that appears greater than in patients with other solid tumor malignancies. Furthermore, the presence of atypical FDG uptake in neck and/or supraclavicular lesion, which may represent active BAT, was associated with HER2 and PgR expressions, and was an independent prognostic factor for patients with breast cancers. ***Conclusion:*** This (semi)-automated systematic review suggests that BAT activity detected with PET/CT is greater in patients with malignancies, especially breast cancers and may represent eventually a prognostic factor. The implementation of AI in the systematic review process significantly increases its sensitivity and efficiency, and reduces the time and resources needed.

## EPS-078

### $^{68}$Ga-DOTATATE PET/CT versus $^{18}$F- FDG PET/CT in TENIS syndrome - Impact in management and theranostics strategies - Pilot study

***L. Almeida***[1], *A. Santos*[1], *T. O. Costa*[2], *M. Araújo*[1], *L. Assumpção*[1], *M. Lima*[1], *T. Souza*[1], *D. Wittmann*[1], *E. Etchebehere*[1];
[1]*Campinas University, Campinas, BRAZIL,* [2]*Ebserh, Bahia, BRAZIL.*

***Aim/Introduction:*** TENIS syndrome (Thyroglobulin-Elevated Negative Iodine Scintigraphy) is characterized by reduced expression of sodium-iodine symporter, rising serum thyroglobulin levels (Tg), and negative whole-body I-131 scans. In such patients, somatostatin receptor imaging with $^{68}$Ga-DOTATATE PET/CT (SSR PET/CT) and $^{18}$F-FDG PET/CT (FDG PET/CT) can identify metastases. To compare the uptake pattern of SSR PET/CT and FDG PET/CT with patients with TENIS Syndrome under two conditions: elevated (eTSH) and suppressed (sTSH) TSH serum levels. Based on imaging findings in these patients, we intend to identify potential candidates for peptide receptor radionuclide therapy (PRRNT). ***Materials and Methods:*** Fifteen patients with TENIS Syndrome were prospectively enrolled. All patients underwent both SSR PET/CT and FDG PET/CT with sTSH and eTSH. All images were blindly evaluated for differences in SUVmax values and lesion detectability (local recurrence and lymph node (LN), lung, and bone metastases). The reference standard consisted of neck ultrasound, CT, MRI, PET/CT, biopsy, and follow-up. Five patients were selected for PRRNT due to lesion uptake similar to or higher than the liver. ***Results:*** On a per-patient and on a per-lesion based analysis, sTSH SSR PET/CT detected a greater number of cervical and distant LNs (both p = 0.0253 on per-patient and p=0.0176 and p=0.0391 on per-lesion, respectively) when compared to sTSH $^{18}$F-FDG PET/CT**.** Likewise, eTSH SSR PET/CT detected a greater number of patients with local recurrences (p=0.0455) and distant LN metastases (p=0.0143) and in a per-lesion based analysis greater number of cervical and distant LNs (p=0.0337 and p=0.0039, respectively) when compared to eTSH $^{18}$F-FDG PET/CT**.** No differences were found in lesion detectability for lung and bone metastases. One of three patients submitted to 3 cycles of PRRNTpresented with a visual partial response, a 20% reduction in quantitative analyses and stable disease regarding Tg and ATgAb levels. ***Conclusion:*** In patients with TENIS Syndrome, SSR PET/CT detected a greater number of loco-regional and distant LN metastases than FDG PET/CT with both sTSH and eTSH. One patient submitted to PRRNT presented a partial response to treatment. Our findings may impact in patient restaging, management and theranostics strategies with radiolabeled somatostatin analogs.

## EPS-079

### Role of Integrated $^{18}$F-Fluorocholine PET/4DCT in the localization of culprit lesions in patients with primary hyperparathyroidism

***Y. Dharmashaktu***, *N. A. Damle, C. Bal, M. Tripathi, P. Kumar, R. N. Wakankar, S. Chumber, Y. Gupta, D. K, S. Agarwal, C. Kumar, R. Goel;*
*All India Institute of Medical Sciences, Delhi, INDIA.*

***Aim/Introduction:*** 4D-CT and FCH PET/CT are excellent modalities that have evolved in the last decade to substitute the deficiencies of MIBI scan and Ultrasound in primary hyperparathyroidism. However literature is scarce on the role of integrated FCH PET/4D-CT. In the present study we assessed the lesion detection rate of integrated FCH PET/CT and 4D-CT imaging in comparison to both modalities individually. ***Materials and Methods:*** 45 patients with PHPT were evaluated from October 2020 to May 2022. All

patients underwent integrated FCH PET/4D-CT from angle of mandible to diaphragm. Scans were interpreted by a Nuclear Medicine physician and a radiologist independently with blinding and lesions were graded as positive, suspicious and negative. ***Results:*** There were 45 patients (14 males, 31 females) with mean age of 41.8 years. Mean iPTH was 163 pg/mL. 27/45 patients underwent surgery and a total of 43 lesions were excised.Overall, FCH PET/CT was able to detect lesions in 36/45 (80%) patients, 4D-CT in 32/45 (71.1%) patients and integrated FCH PET/4DCT in 39/45 (86.6%) patients.In the 27 operated patients, 4D-CT was able to detect a culprit lesion in 23/27 (85.1 %) patients and FCH PET/CT in 26/27 patients (96.2%).On a per patient analysis based on histopathology, FCH PET/CT was able to correctly detect the culprit lesion(s) in 25/27 patients (92.5%), 4D-CT in 21/27 (77.7%) patients and integrated in 25/27 patients (92.5%), i.e. true positive cases.Hence, on per patient based analysis, both the sensitivity and lesion detection rates of FCH PET/CT, 4D-CT and integrated FCH PET/4D-CT were same i.e., 92.5%, 77.7% and 92.5% respectively. On per lesion based analysis, sensitivity, specificity and detection rate for FCH PET/CT, 4D-CT and integrated FCH PET/4D-CT was 91.8%, 50%, 94.4%; 72.9%, 66.6%, 72.9% and 91.8%, 50%, 94.4% respectively. ***Conclusion:*** FCH PET/CT performed equally well on a per patient and per lesion basis in the operated group of patients. Integrated imaging however increased surgeon confidence in going ahead with the surgeryIntegrated FCH PET/4D-CT imaging also ensures patient comfort (single sitting procedure) along with lesser radiation by avoiding one extra NCCT compared to separate procedures Integrated imaging may be preferred if both investigations are planned anyway.

## EPS-080

### 18F-Fluorocholine PET/CT and scintigraphy detection rate stratified by PTH levels in parathyroid imaging

***N. Jacquet-Francillon****, I. Morelec, M. Dietz, A. Clotagatide, J. Tordo, L. Al-Mansour, S. Isal, A. Flaus;*
*Hospices Civils de Lyon, Lyon, FRANCE.*

***Aim/Introduction:*** [$^{18}$F]-Choline PET/CT is used more and more in addition to [$^{99m}$Tc]-SestaMIBI scintigraphy and ultrasonography, sometimes even as a first-line imaging modality for parathyroid imaging. The aim of our study is to evaluate the detection rate (DR) of [$^{18}$F]-Choline PET/CT and [$^{99m}$Tc]-SestaMIBI scintigraphy according to the PTH level. ***Materials and Methods:*** In one academic center, we retrospectively included 253 patients with hyperprathyroidism. The detection rate of hyperfunctioning parathyroid glands was calculated in 7 subgroups of serum PTH level for [$^{18}$F]-Fluorocholine PET/CT and [$^{99m}$Tc]-SestaMIBI scintigraphy. Linear and exponential regression curves have been calculated. ***Results:*** DR of [$^{18}$F]-Fluorocholine PET/CT varied from 45.5% for serum PTH < 50 ng/mL to 89.2% for serum PTH > 150 ng/mL. DR of [$^{99m}$Tc]-SestaMIBI scintigraphy varied from 40.0% for serum PTH < 50 ng/mL to 90.5% for serum PTH > 150 ng/mL. Linear and exponential regression curves confirmed a relationship between DR and PTH level. Detection rate of [$^{18}$F]-Fluorocholine PET/CT is slightly superior to that of scintigraphy for the lowest PTH levels. ***Conclusion:*** Our study establishes a pre-test probability of identifying a parathyroid lesion before [$^{18}$F]-Choline PET/CT or [$^{99m}$Tc]-SestaMIBI scintigraphy . ***References:*** [1] Araz M, Soydal Ç, Özkan E, Kır MK, İbiş E, Güllü S, et al. The efficacy of fluorine-18-choline PET/CT in comparison with 99mTc-MIBI SPECT/CT in the localization of a hyperfunctioning parathyroid gland in primary hyperparathyroidism. Nucl Med Commun. ### Concordance between 18F-Fluorocholine PET-CT and surgery in the localization of parathyroid adenomas in patients with primary hyperparathyroidism

***P. Daudén Oñate***[1]*, A. Ortega Candil*[1]*, C. Rodríguez Rey*[1]*, G. Cuesta Domingo*[1]*, S. Ochagavía Cámara*[1]*, R. Cano Carrizal*[2]*, I. Domínguez Serrano*[1]*, S. Mera Carreiro*[1]*, M. Meneses Navas*[1]*, P. Nespral Torres*[1]*, P. Romero Fernández*[1]*, A. Berardinelli*[1]*, M. Cabrera Martín*[1]*, P. Bascuñana Almarcha*[1]*;*
*[1]Hospital Clínico San Carlos, Madrid, SPAIN,*
*[2]Hospital Infanta Sofía, Madrid, SPAIN.*

***Aim/Introduction:*** Parathyroid adenomas are the most common cause of primary hyperparathyroidism, being solitary in 90% of the cases. Definitive treatment consists of surgical resection of the hyperfunctioning gland, being essential its pre-surgical localization using imaging tests. Our aim is to determine the concordance between 18F-fluorocholine positron emission tomography / computed tomography (choline PET/CT) and surgical findings in the localization of parathyroid adenoma in patients with primary hyperparathyroidism. We also intend to test whether the acquisition on digital equipment increases the reliability of the technique. ***Materials and Methods:*** Retrospective study of 154 patients with primary hyperparathyroidism and negative/discordant conventional imaging tests (neck ultrasound and technetium-99m sestamibi (MIBI) scintigraphy), who underwent choline PET/CT between 2019-2023. We included those patients who underwent resection up to the date of analysis, constituting a final sample of 48 patients. We defined four quadrants of parathyroid adenoma localization: right superior, right inferior, left superior and left inferior. Twenty-seven studies were acquired in analog equipment (AE) and 21 in digital equipment (DE). ***Results:*** The mean age was 63.9±10.6 years, being more frequent in women (81,25%). The interval between PET-CT and surgery was 340±234 days, being the right lower pole the most frequent location (39,62%). The mean PET-CT lesion size was 7.22±3.63mm with mean Standardized Uptake Value (SUVmax) 6.22±4.14. PTH values 10 minutes after resection decreased significantly (-66.88pg/mL, p<0.001). The observed agreement between surgical localization and PET-CT localization was 81,1%, with a Kappa index 0.74 (95% CI 0.60-0.87, p<0.001). The agreement observed with DE was significantly higher than that observed with AE (p=0.025): 95,5% vs 71%. The Kappa index in the ED was 0.94 (95% CI 0.82-1.00, p<0.001), compared to 0.61 (95% CI 0.41-0.81,

p<0.001) in the AE. ***Conclusion:*** Choline PET-CT is a reliable tool in the localization of parathyroid adenoma in patients with primary hyperparathyroidism and inconclusive/discordant conventional imaging tests, especially with the new DE. This allows a minimally invasive surgical approach, reducing surgical morbidity.

## EPS-082

### Impact of Radioactive Iodine on Survival outcomes for Differentiated Thyroid Carcinoma - Understanding the Factors at Play

***A. Al ibraheem***, *U. Al-Rasheed, A. S. Abdlkadir, N. Mashhadani, S. Ruzzeh, D. A. Al-Adhami, I. Mohamad, B. Hamdan, R. Kheetan, M. E. Juweid, A. Mansour, F. Istatieh;*
*King Hussein Cancer Center, Amman, JORDAN.*

***Aim/Introduction:*** Differentiated thyroid cancer (DTC) is the most common type of endocrine cancer, and its incidence is increasing worldwide. Treatment of DTC is multi-factorial, involving a combination of surgical, hormonal, and nuclear medicine (NM) therapies. NM therapies typically involve the administration of radioactive iodine (RAI). RAI is administered following thyroid surgery in order to thyroid remnant ablation, deliver adjuvant therapy, or treat identifiable disease. There is a scarcity of reports on the long-term outcome of DTC in developing countries at centers of excellence. The purpose of this study was to evaluate the effect of radioactive iodine therapy (RAI) and other patient-related factors on the five-year survival of 555 patients with primary thyroid cancer who were diagnosed and treated at KHCC from 1998 to 2021. ***Materials and Methods:*** Data from a tertiary referral cancer center were collected and analyzed retrospectively. A cohort of 555 patients who were diagnosed with biopsy-proven thyroid cancer was investigated. Baseline statistics were reported using measures of central tendency and dispersion for continuous variables and proportions for categorical variables. Descriptive data were compared across groups using Student's t-test for continuous variables and Chi-square or Fisher's exact tests for categorical variables. A univariate and multivariate analysis was performed using a Cox regression model. The Kaplan-Meier method was used for survival analysis. A log-rank test was used to compare the survival curves. All tests were two-sided, and a p value of less than 0.05 was considered statistically significant. ***Results:*** A total of 26 patients died from thyroid cancer during the median follow-up period of 73 months. It's noteworthy that 18 other patients died from non-disease specific reasons (breast cancer, Sepsis, Ischemic heart disease, and renal failure due to diabetes) were censored in the present study. The 5-year survival for patients with DTC was found to be high (91%), with a mean estimated survival time of 168.3 months. Age and distant metastasis were identified as the main negative prognostic factors, while RAI treatment was found to be a significant factor in improving prognosis. ***Conclusion:*** The large majority of patients with thyroid cancer (93.33%) in our study cohort had an excellent prognosis, comparable to published data from other studies. Radioiodine therapy was found to be protective against poor prognosis. These findings suggest that appropriate treatment and adherence to clinical guidelines can improve outcomes for patients with DTC.

## EPS-083

### Differential serum miRNA profile in well differentiated thyroid cancer and benign thyroid disease. Prognosis of patients with this miRNA profile five years after radioiodine treatment

***O. Bourogianni***[1], *N. Kapsoritakis*[1], *E. Tsitoura*[2], *A. Tsaroucha*[1], *G. Lamprakopoulos*[1], *M. Stathaki*[1], *E. Papadaki*[1], *S. Koukouraki*[3];
[1]*Department of Nuclear Medicine, University Hospital of Crete, Heraklion, GREECE,* [2]*Laboratory of Molecular and Cellular Pneumonology, Medical School, University of Crete, HERAKLION, GREECE,* [3]*Department of Nuclear Medicine, Medical School, University of Crete, Heraklion, GREECE.*

***Aim/Introduction:*** The increased incidence of papillary thyroid cancer (PTC) in Crete, led us to study the expression of a panel of 84 mature miRNAs in patients of the island of Crete. MiRNAs are small non-coding RNAs of approximately 19-25 nucleotides in length that are responsible for the posttranscriptional regulation of gene expression. The objective of the current study was to identify circulating miRNAs that might be used as clinical biomarkers in patients with PTC. We set out to identify (1) circulating miRNAs in preoperative serum samples from patients with PTC (2) different expression of miRNAs in patients with PTC and patients with benign thyroid nodules (3) the efficacy of radioiodine treatment (4) the prognosis of patients with this miRNAs profile five years after total thyroidectomy and radioiodine treatment(RAIT). ***Materials and Methods:*** Blood samples of peripheral venous blood were obtained one day before surgery. Centrifugation at 2500 g for 10 minutes was performed to separate serum from other blood components. The supernatant was separated from the cellular layer and immediately stored at -80°C A biobank of 45 samples was generated. All pathological findings were confirmed after surgery. The enrolled patients were divided into two groups: benign nodules (BN) and PTC. RNA was isolated. For the analysis of microRNA expression levels, total RNA were used in reverse transcriptase and quantitative PCR reactions. The efficacy of RAIT and clinical outcome 5 years later was evaluated according to the biochemical or structural evidence of disease. ***Results:*** By analyzing data using special data analysis tools we identified 2 miRNAs significantly deregulated in PTC compared to BN. These included 1 upregulated and 1 downregulated miRNAs. Especially miR23a-3p and miR- 574-3p were the most accurate in discriminating between PTC patients and patients with benign thyroid nodules. None of the rest of 84 miRNAs was significantly different between the two groups, although the mean preoperative serum level of miR-150-5p, miR-21-5p in the PTC group was more than 2 fold than that found in samples from patients with BN. The clinical outcome five years following RAIT ablation in all patients with PTC was excellent, ***Conclusion:*** Identification of miRNA signatures in serum for PTC diagnosis could probably serve as a stable, sensitive, and non-invasive biomarker for discrimination between PTC and benign thyroid disease. Prognosis of patients with this miRNA profile seems to be excellent five years after thyroidectomy and radioiodine treatment.

***Aim/Introduction:*** In doxorubicin-induced cardiomyopathy (DIC), drug-induced cardiomyocyte damage or death occurs via various molecular mechanisms, including endoplasmic reticulum stress, oxidative stress, iron metabolism, $Ca^{2+}$ homeostasis dysregulation, sarcomeric structure alterations, gene expression modulation, and apoptosis. However, it is still unclear how sigma 1 receptors (σ1R) are related to DIC. In this study, we aimed to evaluate the expression of the σ1R using radiolabeled 2-[4-(2-iodophenyl) piperidino]cyclopentanol (OI5V) in the DIC rat model. ***Materials and Methods:*** Wistar rats were injected with doxorubicin (2 mg/kg/week, intraperitoneal), while the control group was injected with saline (2 mL/kg/week, intraperitoneal) (n=4-6 for each group). Gated $^{99m}$Tc-MIBI SPECT was performed on the rats to evaluate cardiac function before and at 3, 5, 7, and 8 weeks after injection. We measured organ uptake (heart, blood, kidney, lung, pancreas, liver, and muscle) of $^{125}$I-OI5V, and heart uptake of $^{99m}$Tc-MIBI was measured before and at 3, 5, 7, and 8 weeks after injection. ***Results:*** The rats did not die during the observation period and showed increased body weight. In cardiac function, end-diastolic and end-systolic volume significantly increased 5 weeks after doxorubicin injection and ejection fraction started to decrease 7 weeks after injection. Post-mortem tissue counting showed that $^{125}$I-OI5V uptake started to decrease 5 weeks after injection in the heart and kidney, and started to increase 5 weeks after injection in the blood. The uptake in the lung, pancreas, liver, and muscle was not changed in the observation period. $^{99m}$Tc-MIBI uptake of the heart correlated well with $^{125}$I-OI5V uptake ($R^2 = 0.8$, $P < 0.0001$). ***Conclusion:*** Our study confirmed the dynamic expression pattern of σ1R after doxorubicin injection, with a decrease of σ1R expression in the heart demonstrated by post-mortem tissue counting. σ1R may be a feasible target for monitoring DIC by confirming the decline in expression.

### OP-285
**Early evaluation of organ fibrosis in Angiotensin II-induced hypertensive mouse model using $^{68}$Ga-FAPi46 PET**
***J. Byun***[1,2,3], *Y. Kim*[1,3], *Y. Lee*[1], *J. Paeng*[1], *K. Kang*[1], *G. Cheon*[1];
[1]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Biomedical Sciences, Seoul National University, Seoul, KOREA, REPUBLIC OF,* [3]*Cancer Research Institute, Seoul National University, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** In chronic hypertension (HT), injury and fibrosis occurs in major organs. This study aims to evaluate the feasibility of $^{68}$Ga-FAPi46 PET in the early assessment of cardiac and renal fibrosis in a HT animal model. ***Materials and Methods:*** To induce HT in mice, Angiotensin II was infused to Balb/c male (8 weeks old) mice via subcutaneously implanted osmotic minipumps for 4 weeks. As a treatment group, losartan was treated to a subgroup of the model. Biodistribution study and $^{68}$Ga-FAPi46 PET/MRI were performed 1, 2 and 4 weeks after HT induction. Target-to-background ratio (TBR) and percent of injected dose per gram (%ID/g) were measured in PET images and biodistribution, respectively. ***Results:*** At the first week, the heart and kidney uptake of $^{68}$Ga-FAPi46 was significantly increased in HT model (2.18±0.38 vs. 1.36±0.28, $P < 0.001$, TBR; 2.91±0.92 vs. 1.11±0.29, $P < 0.001$, %ID/g). $^{68}$Ga-FAPi46 uptake was also increased at the second week (2.60±0.24, $P < 0.001$ TBR; 2.99±1.52, $P < 0.05$, %ID/g), the uptake was normalized by losartan treatment (1.49±0.3, $P < 0.001$ TBR; 2.11±0.6, %ID/g). However, there was no pathological fibrosis at the first and second weeks. There was also no renal function change shown on serum blood urea nitrogen (31.44±5.72 vs. 31.28±4.02mg/dL) and creatinine levels (0.36±0.01 vs. 0.30±0.01mg/dL). ***Conclusion:*** In the HT mouse model, $^{68}$Ga-FAPi46 uptake is increased early after HT before pathological or functional change occurs. This study implies that $^{68}$Ga-FAPi46 PET can be used for early evaluation and diagnosis of cardiac and renal fibrosis progression in hypertensive organ injury.

## OP-286

### The evolution and prognostic value of $^{68}$Ga-Pentixafor uptake in the myocardium after acute infarction

***P. Wu***[1,2], *S. He*[3], *M. Yan*[1], *H. Wang*[1,2], *X. Liu*[4], *Z. Xiang*[1], *L. Xu*[1,5], *Y. Zhao*[1,5], *X. Li*[6], *M. Hacker*[6], *Z. Wu*[1,2], *S. Li*[1,2];
[1]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, CHINA,* [3]*Department of Radiology, First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [4]*Department of Radiology, Shanxi Bethune Hospital(Shanxi Academy of Medical Sciences, Tongji Shanxi Hospital, Third Hospital of Shanxi Medical University), Taiyuan, CHINA,* [5]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Shanxi Medical University, Taiyuan, CHINA,* [6]*Division of Nuclear Medicine, Department of Biomedical Imaging and ImageGuided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Dynamic visualization of inflammation is crucial to the anti-inflammation strategy for patients with acute myocardial infarction (AMI). The evolution and prognostic value of $^{68}$Ga-Pentixafor uptake targeting chemokine receptor 4 (CXCR4) in the myocardium of pigs has not been reported before. ***Materials and Methods:*** Six AMI and four Sham pigs serially underwent $^{68}$Ga-Pentixafor imaging early (Day 2 and Day 7) and late (Day 28 or Day 46) post-operation. The SUV of infarcted myocardium (SUVmax_MI) and remote myocardium (SUVmax_RE, SUVmean_RE) were measured, and the TBR_MI was calculated to indicate the uptake intensity. The early inflammation area by $^{68}$Ga-Pentixafor was assessed. Gated $^{18}$F-Flurpiridaz stress MPI was performed to obtain the sum stress score (SSS), and CMRI was performed to obtain cardiac function and the area of late gadolinium enhancement (LGE). To observe the inflammation ripple effect, correlation analysis of SUV_RE with SUVmax_MI at different time points and with the late cardiac function was conducted. ***Results:*** The TBR_MI of $^{68}$Ga-Pentixafor peaked before Day 2 after AMI, significantly dropped to half on Day 7, and sustained a slightly reduced level in the late phase. The late LVEF in the AMI group was significantly reduced compared to that in the Sham group (48.76±8.76% vs 65.27±2.18%, $P = 0.017$). The SUVmax_MI on Day 2 and TBR_MI on Day 7 were strongly correlated with the late LVEF and ESV ($P < 0.05$). The TBR_MI on Day 2 was strongly correlated with the late SSS ($r = 0.891$, $P = 0.017$). No significant difference was found among SUV_RE at different time points ($P > 0.05$). However, on Day 2 early after AMI, SUVmax_RE ($r = 0.854$, $P = 0.031$) and SUVmean ($r = 0.861$, $P = 0.028$) were significantly correlated with SUVmax_MI. A strong correlation was found between SUV_RE on Day 2 and the late ESV ($r = 0.886$, $P = 0.019$). The early inflammatory area assessed by $^{68}$Ga-Pentixafor was strongly correlated with the LGE area assessed by CMRI ($r = 0.989$, $P = 0.001$). ***Conclusion:*** The inflammation in the infarcted myocardium surged 2 days early after AMI and dropped dramatically in the first week. The higher the early $^{68}$Ga-Pentixafor uptake in the infarcted myocardium, the worse the following perfusion or cardiac function. The inflammation response at peak spread to the remote myocardium, which may involve the contemporary or following cardiac function. Further studies are warranted to clarify the prognostic value and the relative mechanism of the remote myocardium.

## OP-287

### Translocator protein 18kDa positron emission tomography imaging of $^{18}$F-FDPA in rabbits with vulnerable atherosclerosis plaques

***W. Dong****, J. Jiao, T. Mou, Y. Zhang, H. Mi;*
*Beijing Anzhen Hospital, Beijing, CHINA.*

***Aim/Introduction:*** The aim of this study was to investigate the potential of N, N-diethyl-2-(2-(4-$^{18}$F-fluorophenyl)-5,7-dimethylpyrazolo[1,5-a] pyrimidin-3-yl) acetamide ($^{18}$F-FDPA), a translocator protein 18kDa (TSPO) targeted radiotracer, for vulnerable atherosclerotic plaques (VAP) imaging. ***Materials and Methods:*** Eighteen New Zealand rabbits were randomly divided into group A (abdominal aortic strain and high-fat diet, n=6), group B (abdominal aortic strain, high-fat diet and subcutaneous injection of Evolocumab 7 mg/kg/2 weeks, n=6), and group C (sham surgery and normal diet, n=6). Optical coherence tomography (OCT) was performed at 8, 12 and 20 weeks after the operation. On the day after OCT, 18F-FDPA PET/CTA was performed. Standardized uptake value (SUVmax) of 18F-FDPA was measured on abdominal aorta. Standardized uptake value (SUVmean) of 18F-FDPA in left ventricular SUVblood pool served as background reference. The target-to-background ratio (TBRmax) was calculated as follows: TBRmax = SUVmax/SUVblood pool. At the 8th and 12th weeks, one rabbit was killed in each group after PET/CTA. Others were killed 20 weeks after PET/CTA. The abdominal aorta was obtained and performed micro-PET/CT imaging immediately. Pathological HE staining, TSPO and CD68 immunofluorescence staining and TSPO western blot analysis were performed on arterial sections. ***Results:*** There was no statistically significant difference in TBRmax between group A and group B at 8 weeks and 12 weeks after operation. At 20 weeks after operation, TBRmax in group A was significantly higher than that in the group B ($4.78 \pm 1.04$ vs. $2.21 \pm 0.16$, $P = 0.048$) and group C ($4.78 \pm 1.04$ vs. $0.78 \pm 0.20$, $P < 0.001$). In OCT images, more large lipid core, thin fibrous caps and macrophages were observed in group A than in group B, especially in the area with high TBRmax of 18F-FDPA. In the PET/CTA study, the radioactivity of low density lipid plaques was higher than that of normal aorta. The micro-PET/CT images in vitro showed that the radioactivity in the white protruding plaque area increased. The HE staining study showed that there were more vulnerable plaques of AHA type in these areas, indicating the relation between TBRmax and VAP. TSPO and CD68 staining and western blot analysis confirmed the increased expression of TSPO and macrophages in these areas. In addition, more VAP was observed in group A than that in group B, which was consistent with the results of PET/CTA. ***Conclusion:*** 18F-FDPA PET imaging can visualize VAP and evaluate the vulnerability of arterial plaque after the intervention of Evolocumab.

## OP-288

### $^{99m}$Tc-AFN: A Nanobody-Based SPECT Radiotracer with Clinical Potential for Noninvasive Monitoring of Fibroblast Activity After Myocardial Infarction

***X. Zhang***[1], *Z. Ai*[1], *C. Li*[2], *B. Jia*[2], *M. Yang*[1];
[1]*Department of Nuclear Medicine, Beijing Chaoyang Hospital, Beijing, CHINA,* [2]*Medical Isotopes Research Center and Department of Radiation Medicine, School of Basic Medical Sciences, Peking University, Beijing, CHINA.*

***Aim/Introduction:*** Myocardial infarction (MI) is the most prevalent cause of morbidity and mortality among all cardiovascular diseases[1]. The temporospatial presence of activated fibroblasts in the injured myocardium predicts the quality of cardiac

remodeling after MI. Therefore, noninvasive monitoring of activated fibroblasts after MI is of great significance. Fibroblast activation protein (FAP) expression is upregulated in activated fibroblasts. PET imaging with radiolabeled FAP inhibitors (FAPIs) has been developed and characterized for post-MI fibroblast activation in previous studies. However, challenges remain for FAPIs based imaging probes due to slow clearance from the blood stream and relative low specificity. It is an urgent clinical need for an improved noninvasive tool to evaluate the FAP expression levels to guide the treatment and the prognosis in MI patients. Nanobodies, also known as single-domain antibodies, are the smallest antibody fragment with antigen-binding capability. Nanobodies have been developed rapidly as targeted probes for molecular imaging owing to their high affinity, improved stability and rapid blood clearance. Therefore, FAP targeted nanobody can be a promising molecular probe for noninvasive imaging of activated fibroblasts with high signal to noise ratios and fast blood elimination in preclinical studies. ***Materials and Methods:*** The FAP-targeting nanobody (AFN) was produced after immunization of healthy alpacas with recombinant FAP protein. $^{99m}$Tc-AFN was prepared by site-specific labeling. MI mice were scanned with $^{99m}$Tc-AFN or $^{99m}$Tc-FAPI SPECT/CT (3, 7, 14, 28 d after MI). Dynamic $^{99m}$Tc-AFN SPECT and blocking studies were performed on MI mice 7 d after coronary ischemia reperfusion. Autoradiography, HE staining and immunofluorescence staining were carried out for ex vivo validation, aiming to evaluate the correlation of fibrosis degree and SPECT serial imaging. ***Results:*** $^{99m}$Tc-AFN uptake in the injured myocardium peaked on day 7 after coronary ischemia reperfusion. The tracer accumulated intensely in the MI territory, with much higher signal to noise ratios compared with $^{99m}$Tc-FAPI. ***Conclusion:*** $^{99m}$Tc-AFN represents a promising radiotracer for in vivo SPECT imaging of post-MI fibroblast activation. ***References:*** 1. ## OP-289

### Temporal characterisation of inflammation and active collagen biosynthesis in the rat heart post myocardial infarction, using novel Positron Emission Tomography (PET) radiotracers.

***V. Reid***[1,2], *M. G. MacAskill*[1,2], *K. Pandya*[1], *A. Arcidiacono*[1], *C. Alcaide Corral*[1,2], *T. E. F. Morgan*[1,2], *V. Balogh*[1], *L. M. Riley*[3], *T. Fujisawa*[1], *N. L. Mills*[1,4], *R. J. Lennen*[1,2], *M. A. Jansen*[1,2], *G. A. Gray*[1], *A. H. Baker*[1,5], *D. E. Newby*[1], *A. Sutherland*[3], *A. A. S. Tavares*[1,2];
*[1]Centre for Cardiovascular Sciences, University of Edinburgh, Edinburgh, UNITED KINGDOM, [2]Edinburgh Imaging, University of Edinburgh, Edinburgh, UNITED KINGDOM, [3]School of Chemistry, University of Glasgow, Glasgow, UNITED KINGDOM, [4]The Usher Institute, University of Edinburgh, Edinburgh, UNITED KINGDOM, [5]CARIM, School for Cardiovascular Diseases, Maastricht University, Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Myocardial infarction (MI) is a common precursor of Heart Failure (HF) and remains a leading cause of death worldwide. Following an MI, inflammation and active collagen biosynthesis are fundamental for myocardial repair and are key contributors to aberrant ventricular remodelling. The mechanisms underlying this close interaction between inflammation and collagen synthesis remain unknown and can be difficult to investigate due to lack of selective, in vivo biomarkers for active collagen synthesis. This study aims to characterise the temporal profile of cardiac inflammation and active collagen biosynthesis in a rat coronary artery permanent ligation model using novel Positron Emission Tomography (PET) radiotracers, [$^{18}$F]LW223 [1], cis-4-[$^{18}$F]fluoro-L-proline, and trans-4-[$^{18}$F]fluoro-L-proline [2]. ***Materials and Methods:*** Adult male Sprague-Dawley rats underwent permanent coronary artery ligation (CAL) to induce MI. At 1-, 2-, 4-, and 12-weeks post-MI, in vivo PET/CT imaging was performed with cis-4-[$^{18}$F]fluoro-L-proline and trans-4-[$^{18}$F]fluoro-L-proline which measure fibrillary collagen and triple-helical collagen respectively. Cardiac MRI and T1 mapping were completed to assess extracellular volume (ECV), infarct size and functional outcome. In vitro autoradiography with [$^{18}$F]LW223, a ligand for the inflammatory biomarker translocator protein (TSPO), was completed on MI heart sections post-scanning to assess the temporal profile of inflammation in this model. ***Results:*** Significant upregulation of both cis- and trans-4-[$^{18}$F]fluoro-L-proline occurred within the infarct region of the anterior left ventricle (LAV) following MI. Relative Standard Uptake Value (SUVr) for trans-4-[$^{18}$F]fluoro-L-proline increased at 2, 4 and 12-weeks post-MI ($p<0.05$), relative to naïve controls, while cis-4-[$^{18}$F]fluoro-L-proline uptake peaked at 4weeks post-MI ($p<0.01$). Peak signal for both tracers in the remote, non-infarcted region of the posterior left ventricle (LPV) occurred at 12-weeks post-MI, indicative of detrimental ventricular remodelling. Cardiac MRI imaging showed significant increases in ECV in the LAV from 1-week post-MI onwards ($p<0.0001$), relative to naive, but was not able to detect changes in the LPV. Binding of [$^{18}$F]LW223, measured as ratio of Total to Non-Specific binding (T:NS), peaked at 2-days and 4-weeks post-MI in the LPV ($p<0.01$) and remains elevated across all time-points in the LAV post-MI. ***Conclusion:*** [$^{18}$F]LW223, cis-4-[$^{18}$F]fluoro-L-proline and trans-4-[$^{18}$F]fluoro-L-proline can be used to assess temporal changes in inflammation and collagen biosynthesis at a regional level in the heart post-MI. Time-course dynamics indicate potential interplay between these two responses and identify critical intervention time-points for modulation of post-infarct cardiac inflammation and collagen biosynthesis. ***References:*** [1] MacAskill et al. J. Nuc. Med. 2021; 62:536-544 [2] Morgan et al. J. Org. Chem. 2021; doi: 10.1021/acs.joc.1c00755

## OP-290

### Positive Protective Effects of Sigma-1 Receptor Stimulation with Fluvoxamine after Myocardial Ischemia and Reperfusion in Rat

***X. Zhang***[1], *H. Wakabayashi*[1], *H. Mori*[1], *T. Hiromasa*[1], *Z. Chen*[1], *T. Kozaka*[2], *K. Ogawa*[3], *S. Kinuya*[1], *J. Taki*[1,4];
*[1]Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, Ishikawa, JAPAN, [2]Division of Probe Chemistry for Disease Analysis, Research Center for Experimental Modeling of Human Disease, Kanazawa University, Kanazawa, Ishikawa, JAPAN, [3]Institute for Frontier Science Initiative, Kanazawa University, Kanazawa, Ishikawa, JAPAN, [4]PET Center, Kanazawa Advanced Medical Center, Kanazawa, Ishikawa, JAPAN.*

***Aim/Introduction:*** Sigma-1 receptor (Sig-1R) is considered a pluripotent modulator with multiple functional manifestations in the living system. Sig-1R is expressed in cardiomyocytes as a chaperon, regulates the response to ER stress, modulates calcium handling, and affects the function of voltage-gated ion channels in abnormal statutes, including myocardial ischemia. However, the role of Sig-1R in postischemic myocardium is still unclear. This study investigated the impact of protective effect with stimulation of Sig-1R by fluvoxamine, an agonist of the Sig-1R, after myocardial ischemia and reperfusion in a rat. ***Materials and Methods:*** The left coronary artery occlusion was performed for 20 min on Wistar rats (n=24), followed by reperfusion. Rats were randomly divided

into two groups for two weeks of intraperitoneal therapy with saline (control group) or fluvoxamine (10 µg/kg each, F group). Electrocardiography (ECG)-gated SPECT with $^{99m}$Tc-MIBI was performed on the 1, 14, and 28 days after reperfusion, respectively, to evaluate the function of the left ventricle. Triple-tracer autoradiography with $^{125}$I-OI5V (a vesamicol analog allows the noninvasive imaging of Sig-1R expression), $^{99m}$Tc-MIBI, and $^{201}$TlCl was performed 29 days after reperfusion to assess the salvaged and nonsalvaged areas. Paired t-test was used to evaluate the efficacy after dosing. ***Results:*** The left ventricular ejection fraction (LVEF) of the F group demonstrated an improvement after 2-week dosing (D14-D1: 6±7, p=0.03), while it didn't occur in rats of the control group (D14-D1: -1±11, n.s.), and this tendency remained 2 weeks after medication (D28-D1, F group: 8±5, p<0.01 vs. D28-D1, control group: 1±10, n.s.). End diastolic volume (EDV) and end-systolic volume (ESV) increased in both groups after ischemia and reperfusion. However, the rise tended to be smaller in the F group (D14-D1 ESV: 36±42, p=0.03) than in the control group (D14-D1 ESV: 80±111, p=0.03). The increase showed a slight fallback once the medication was stopped in the F group (D28-D14 EDV: -7±69, n.s.; D28-D14 ESV: -12±61, n.s.), while it tended to continue in the control group (D28-D14 EDV: 23±54, n.s.; D28-D14 ESV: 3±42, n.s.). The autoradiography confirmed no differences between the groups in the salvaged and non-salvaged areas. Though with no significant difference, a lower OI5V uptake was observed in the F group than in the control group. ***Conclusion:*** Stimulating Sig-1R with fluvoxamine contributed to LV remodeling suppression and LVEF recovery after ischemia-reperfusion injury. We confirmed that this pathway is cardioprotective, and targeting the Sig-1R can potentially be effective as a new cardioprotective therapeutic strategy.

## OP-291

### C-X-C Motif Chemokine Receptor 4-Directed PET Signal in the Arterial Tree is not Consistently Linked to Calcified Plaque Burden and Cardiovascular Risk

***N. Hasenauer***[1], *A. Kosmala*[1], *S. E. Serfling*[1], *K. Michalski*[1], *M. Fröhlich*[2], *N. Dreher*[1], *P. E. Hartrampf*[1], *T. Higuchi*[1,3], *A. K. Buck*[1], *A. Weich*[2,4], *T. Reiter*[5], *R. A. Werner*[1,4,6];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY,* [3]*Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN,* [4]*NET-Zentrum Würzburg, European Neuroendocrine Tumor Society Center of Excellence (ENETS CoE), University Hospital Würzburg, Würzburg, GERMANY,* [5]*Internal Medicine I, University Hospital Würzburg, Würzburg, GERMANY,* [6]*Johns Hopkins School of Medicine, The Russel H Morgan Department of Radiology and Radiological Sciences, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** C-X-C motif chemokine receptor 4 (CXCR4) is overexpressed on a multitude of cells involved in inflammatory processes and has been shown to play an important mediating role during the evolution of atherosclerotic plaques. Therefore, we analyzed focal tracer uptake in the arterial tree in patients imaged with CXCR4-directed PET/CT and aimed to determine relevant associations between vessel wall calcification (derived from CT as a known non-invasive imaging biomarker of cardiovascular risk) and cardiovascular risk factors (CVRF). ***Materials and Methods:*** 55 oncologic patients who underwent CXCR4-directed [$^{68}$Ga] Ga-PentixaFor PET/CT were examined. Arterial wall CXCR4 uptake in 7 large arterial vessel segments was assessed visually (providing the number of CXCR4(+) sites) and quantitatively (to determine target-to-background ratios [TBR]). PET-based findings were then correlated with CVRF, calcified plaque burden (including number of calcified plaques, plaque thickness and calcification circumference), and image noise by using coefficient of variation (CoV; derived from unaffected hepatic parenchyma). We also investigated interactions between CXCR4-avid tumor volume (TV) and in-vivo arterial uptake. ***Results:*** In 55/55 (100%), CXCR4(+) arterial sites were recorded in 996 instances, with concomitant calcification in 360/996 (36.1%). CXCR4(+) sites correlated significantly with number of calcified plaques (r=0.28, P=0.04). A comparable trend was also observed for calcified plaque thickness and calcification circumference (r=0.26 and P=0.06, respectively). PET-derived TBR, however, showed no relevant correlations with calcified plaque burden (r≤0.03; P≥0.80). In univariate analysis, the following clinical parameters were associated with the number of CXCR4(+) sites in the arterial tree: sex (female; Odds Ratio [OR], 0.59), age (OR, 1.03), BMI (OR, 1.07), and image noise-related CoV (OR, 1.08, P≤0.03). On multivariate analysis, however, only sex (OR [female], 0.81), age (OR, 1.02), and CoV (OR, 1.05) remained significant (P≤0.01). For TBR, we recorded relevant associations with CoV (OR, 1.02) and BMI (OR, 1.03; P≤0.01, respectively) on univariate analysis. Multivariate testing, however, showed significance only for CoV (OR, 1.02; P<0.05). Last, there was no relevant association between CXCR4-avid TV and arterial wall-derived TBR (r=0.11; P=0.42). ***Conclusion:*** CXCR4-directed molecular imaging provides high focal arterial wall uptake and is moderately associated with calcified plaque burden. This phenomenon, however, was not persistently linked to CVRF, but rather driven by image noise.

## OP-292

### Molecular Imaging in Cardio-Oncology: Detecting Cardiotoxicity of Breast Cancer Treatments Through Radionuclide Ventriculography and Novel Cardiac Biomarkers Assessment

***A. Lazar***[1], *M. Mutuleanu*[1,2], *I. Irimescu*[1,3], *R. Maaz*[1], *C. Petroiu*[1], *M. Gherghe*[1,2];
[1]*Institute of Oncology "Professor Doctor Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA,* [3]*Applied Sciences Doctoral School, Politehnica University, Bucharest, ROMANIA.*

***Aim/Introduction:*** Human epidermal growth factor receptor 2 (HER2) is overexpressed in roughly 20% of the breast cancers diagnosed nowadays, paving the path for treatment with HER2-inhibitors. The monoclonal antibodies trastuzumab and pertuzumab represent the main HER2 inhibitors used for the treatment of HER2-positive breast cancer, associated or not with chemotherapy. The clinical benefits of HER2-inhibitors are well documented, however the possible cardiac adverse reactions need to be considered. The aim of our study was to determine whether monitoring cardiac function through radionuclide ventriculography (RNV) and cardiac biomarkers could detect the cardiac involvement in breast cancer patients following combination therapy with trastuzumab, pertuzumab and docetaxel. ***Materials and Methods:*** Our prospective study included 22 patients suffering from HER2-positive breast cancer, who had their left ventricular ejection fractions (LVEF) and cardiac biomarkers assessed both at the beginning (T0) and after 6 months (T1) of treatment with trastuzumab, pertuzumab and docetaxel. Among all of the enrolled patients, two blood specimens were collected to assess circulating cardiac biomarkers: cardiac troponin I (cTnI), amino-terminal fragment of the prohormone brain-type natriuretic peptide (NT-proBNP), amino-terminal fragment of

the prohormone atrial-type natriuretic peptide (NT-proANP), suppression of tumorigenicity 2 protein/interleukin-33R (ST2/IL33), growth differentiation factor 15 (GDF-15). After "in vivo" radiolabeling of the erythrocytes with $^{99m}$Tc-pyrophospate, planar RNV and bloodpool single photon emission computed tomography (BP-SPECT) were performed in each patient on a for both timepoints. Obtained results were statistically correlated. ***Results:*** The average LVEF decrease between the two timepoints was approximately 4%. Five patients (22.72%) fulfilled the criteria for cardiotoxicity, presenting a decrease in LVEF of over 10%, to below 50%, between T0 and T1. LVEF obtained on BP-SPECT were slightly higher than those obtained on gated planar images: mean LVEF of 57.77±6.21% on planar RNV versus 57.95±5.89% on BP-SPECT for T0, respectively of 53.36±7.30% on planar RNV versus 54.95±6.89% on BP-SPECT for T1. NT-proBNP negatively correlated with the LVEF values obtained both at T0 and T1 ($r=-0.615$ for T0 and $r=-0.751$ for T1, $p<0.05$ for both). The ST2/IL-33R proved statistically significant correlations at T1 ($r=-0.547$, $p<0.05$). The values of the other cardiac biomarkers evaluated in our study changed between the two examinations, but with no statistical significance. ***Conclusion:*** Our results confirmed the good cardiac safety profile of this therapeutic scheme, while suggesting that a combination of radionuclide ventriculography and dosing of NT-proBNP and ST2-IL33R could help in early detecting the cardiac impairment.

**Translation of a drop-in beta probe for robotic radio guided surgery**

***F. Collamati***[1], *R. Mirabelli*[1], *R. Faccini*[2], *F. Ceci*[3], *E. Bertani*[4], *G. Musi*[5], *M. N. van Oosterom*[6], *F. van Leeuwen*[7], *S. Morganti*[1]; [1]*INFN Rome, Roma, ITALY,* [2]*Università Roma Sapienza, Roma, ITALY,* [3]*1.IEO European Institute of Oncology, Nuclear Medicine, Milano, ITALY,* [4]*2.IEO European Institute of Oncology, Division of Digestive Surgery, Milano, ITALY,* [5]*IEO European Institute of Oncology, Division of Urology, Milano, ITALY,* [6]*Leiden University Medical Center | Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden, NETHERLANDS,* [7]*Leiden University Medical Center | Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden, ITALY.*

***Aim/Introduction:*** Recently, an innovative approach to radio guided surgery has been proposed, exploiting the intraoperative localization of beta-particle-emitting tracers (e.g., 18F-FDG, 68Ga-PSMA or 90Y-DOTATOC). After laboratory and Monte Carlo tests, this technique, based on the detection of short-penetration beta particles, has been recently validated in vivo with encouraging results. The surgical trend to move towards (robotic) minimal-invasive surgery has created a need for compatible tethered modalities [1]. In this paper, we present the design and clinical translation of a drop-in beta probe. ***Materials and Methods:*** The drop-in beta probe is based on a scintillating crystal of p-terphenyl read by a silicon photomultiplier. Designs were driven by practical requirements to in vivo use with the robotic surgical platform, including: the small form factor (needing to enter via the 12 mm trocar), biocompatible materials, adaption to the common robotic instruments and compatibility with sterilization protocols. To optimize the detection sensitivity, tailored Monte Carlo simulations were used. Specifically, CT data were used to reconstruct in Geant4 the geometry of the patients, and PET images to generate primary particles, with the aim of estimating the far-background counting (i.e. the one from annihilation photons in the whole patient), tissue-background counting and tissue-target counting. Following ex vivo tissue validation [2], the technique was evaluated during 68Ga-PSMA/68Ga-DOTATOC radioguided surgery. ***Results:*** A tethered drop-in beta probe was created that is fully compliant with the requirements of robotic surgery, proving to withstand several sterilization cycles, while remaining sensitive to beta particles. Its overall efficiency was found to be comparable to the open surgery version (~% to gammas and >90% to >100keV betas). After insertion in the surgical field, the surgeon was able to autonomously manipulate the probe using the robotic ProGrasp Forceps instrument. As compared to real tissue/in vivo data, the Monte Carlo simulations proved to have an accuracy of the order of 20% in the estimation of the "far tissue background" to probe countings. Sensitivity/Specificity of the order of 70%-90% were found in first in vivo tests on 68Ga-PSMA prostate cancer robotic RGS[3]. ***Conclusion:*** We present our translational efforts regarding a tethered drop-in beta probe for robotic guided surgery. Our findings underscore the validity of this form of RGS, thereby providing a basis for the more widespread implementation of PET-tracers during radioguided robotic surgery. ***References:*** [1] Dell'Oglio et al., Eur Urol, 2021 [2] Collamati et al., EJNMMI Res, 2020 [3] Ceci, talk at EAU 2023

### OP-295

**Live Nuclear/X-ray Imaging during Radioembolization Interventions using a Novel Hybrid C-arm Scanner**

***M. Dietze****, M. B. M. Meddens, R. van Rooij, A. J. A. T. Braat, B. de Keizer, R. C. G. Bruijnen, M. G. E. H. Lam, M. L. J. Smits, H. W. A. M. de Jong;*
*University Medical Center Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** The current hepatic radioembolization workflow consists of a pre-treatment procedure using Tc-99m-MAA particles for safety and planning purposes after which the treatment with Y-90 ionizing microspheres is performed. Ideally, the pre-treatment procedure and the treatment would be merged in a single session since this reduces the number of interventions from two to one and potentially improves the prognostic power of the Tc-99m-MAA distribution. Such a single-session procedure requires the distribution of the Tc-99m-MAA particles to be evaluated during the intervention, which is currently not feasible. ***Materials and Methods:*** In the UMC Utrecht, we have developed a compact and mobile hybrid c-arm scanner (named IXSI) dedicated to the intervention room which can perform simultaneous fluoroscopic x-ray, planar scintigraphic and SPECT/CBCT imaging using a novel dual layer detector [1]. We have tested the safety and feasibility of using IXSI in radioembolization in a clinical study with 12 patients. For all 12 patients, images were acquired during the injection of Tc-99m-MAA to study dynamic

processes in the particle distributions. For nine patients, a SPECT/CBCT scan was acquired in the intervention room directly after the injection of Tc-99m-MAA. And for six patients, the lung-shunt fraction was measured in the intervention room using planar imaging. ***Results:*** Based on questionnaires and tracking of adverse events, it was determined that IXSI can be safely introduced in the intervention room during radioembolization interventions. The planar hybrid images had adequate angiographic and nuclear image quality and live imaging demonstrated that the Tc-99m-MAA particle distribution can change as more particles are injected. The SPECT images from IXSI were compared with the SPECT images from a conventional clinical scanner and found to have a similar dosimetric quality. The lung-shunting fraction as measured by IXSI was compared with the measurement by a clinical scanner and found to be lower owing to the shorter time between injection and imaging. ***Conclusion:*** A new hybrid c-arm scanner can safely be incorporated into the radioembolization workflow for real-time x-ray/nuclear guidance and dosimetry during the intervention. New insights into the dynamics of radioembolization interventions were obtained. The next stage of this project is to move towards a single-session radioembolization treatment. ***References:*** [1] Dietze, Martijn MA, et al. ## OP-296

### Investigation of a CZT-based hand-held gamma-camera for pre-clinical imaging of alpha-emitter $^{225}$Ac

***D. Roth***[1], *Z. Ells*[2], *M. Dahlbom*[2], *J. Strand*[3,4], *C. Mona*[2,5], *P. Jean Jean*[2,5], *M. Ljungberg*[1], *S. Strand*[1];
[1]*Medical Radiation Physics, Lund, Lund University, Lund, SWEDEN,* [2]*Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, University of California – Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [3]*Department of Clinical Sciences Lund, Oncology, Lund University, Lund, SWEDEN,* [4]*Department of Hematology, Oncology, Radiation Physics, Skåne University Hospital, Lund University, Lund, SWEDEN,* [5]*Jonsson Comprehensive Cancer Center, University of California – Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** $^{225}$Ac is an alpha-emitting radionuclide with promising applications for radiopharmaceutical therapy. Its decay-chain releases alpha and beta particles, as well as two gamma-photons with energies and yields suitable for imaging: 218 keV (11 %) from $^{221}$Fr and 440 keV (26 %) from $^{213}$Bi. Activity-quantification and dosimetry is important for assessing or predicting treatment outcome. The aim of this project is to investigate the capabilities of a small gamma-camera for imaging and activity-quantification of $^{225}$Ac in a pre-clinical setting. ***Materials and Methods:*** A CdZnTe-based hand-held gamma-camera was used with a medium-energy high-resolution parallel-hole collimator, providing imaging with a 4x4 cm$^2$ field-of-view and a 16x16 image-matrix (1). The camera was operated using in-house written software, allowing energy spectra to be saved for each individual image-pixel after each measurement. In subsequent analyses, images were created for energy-windows placed over the 218 keV and 440 keV peaks. Calibration and characterisation and measurements were performed to assess the camera's image-uniformity, sensitivity, and spatial resolution for $^{225}$Ac. Image-quality was additionally evaluated using a 3D-printed mouse phantom with a fillable tumour and liver cavity, for which ventral planar images were acquired. SPECT projections were also acquired of the mouse phantom using a motorised rig. In-vivo measurements were performed on NCG mice with PC3-PIP tumours implanted on the upper flank. Imaging was performed at different time points up to 25 h after injection of [$^{225}$Ac]Ac-PSMA-617. ***Results:*** Imaging of $^{225}$Ac was feasible, although septal penetration of 440 keV photons was notable. Due to the energy-response of the CdZnTe-detector, the 218 keV window was also affected. At a source-collimator distance of 10 mm, the sensitivity was 81 cps/MBq and 68 cps/MBq, for the 218 keV and 440 keV windows, respectively. At 100 mm, the corresponding values were 25 cps/MBq and 15 cps/MBq. Measurements on the mouse phantom demonstrated that the liver and tumour could be distinguished. Septal-penetration-related background was present in images for both energy-windows, but lower in the 218 keV window. The bio-distribution of [$^{225}$Ac]Ac-PSMA-617 could be measured in the mice. Further analysis will be carried out and presented. ***Conclusion:*** Pre-clinical imaging of $^{225}$Ac can be performed with the hand-held camera. ***References:*** 1. Roth D, Larsson E, Sundlöv A, Sjögreen Gleisner K. Characterisation of a hand-held CZT-based gamma camera for $^{177}$Lu imaging. EJNMMI Physics. 2020;7(1).

## OP-297

### CT-guided percutaneous marking of small pulmonary nodules with [$^{99m}$Tc]Tc-Macrosalb is very accurate and allows minimally invasive lung-sparing resection: a single-centre quality control

***N. Doncic****, C. J. Zech, D. Wild, H. Bachmann, M. Mallaev, N. Tsvetkov, A. Hojski, M. T. L. Takes, D. Lardinois;*
*Basel University Hospital, Basel, SWITZERLAND.*

***Aim/Introduction:*** The detection of small lung nodules in thoracoscopic procedure is difficult when the lesions are not localized within the outer border of the lung. In the case of ground-glass opacities, it is often impossible to palpate the lesion. The marking of lung nodules with radiotracer is a known technique. We analysed the accuracy and safety of the technique and the potential benefits of operating in a hybrid operating room. ***Materials and Methods:*** 57 patients, including 33 (58%) females with a mean age of 63.3 years (range 21-82) were included. In 27 patients, we marked and resected the lesion in a hybrid room. In 30 patients, the lesion was marked at the department of radiology the day before resection. [99mTc]Tc- Macrosalb was used at an activity of 1 MBq in the hybrid room and at an activity of 3 MBq the day before to get technical feasible results. Radioactivity was detected using the gamma detection system with endoscopic probe. ***Results:*** Precise detection and resection of the nodules was possible in 95% of the lesions and in 93% of the patients. Complete thoracoscopic resection was possible in 90% of the patients. Total conversion rate was 10%, but conversion due to failure of the marking of the nodule was observed in only 5% of the patients. Histology revealed 28 (37%) primary lung cancers, 24 (32%) metastases and 21 (28%) benign lesions. In 13 (23%) of the patients, minor complications were observed. None of them required additional interventions ***Conclusion:*** The radio-guided detection of small pulmonary nodules is very accurate and safe after CT guided injection of [99mTc]Tc-Macrosalb. Performing the operation in a hybrid room has several logistic advantages and allows using lower technetium-99m activities. The technique allows minimally invasive lung sparing resection and prevents overtreatment of benign and metastatic lesions. ***References:*** 1. ## OP-298

### A truncated 14-amino acid myelin protein zero targeting peptide for fluorescence-guided nerve preserving surgery

***N. Berehova***, *M. P. van Meerbeek, S. Azargoshasb, L. J. Slof, S. Navaei Lavasani, M. N. van Oosterom, F. W. B. van Leeuwen, T. Buckle;*
*Leiden University Medical Center, Leiden, NETHERLANDS.*

***Aim/Introduction:*** The growing implementation of image-guided head-and-neck surgery have exposed the need to exploit molecular targeted nerve-sparing interventions, an application that relies on the availability of nerve specific tracers. In this paper we describe the development of a truncated peptide that has an optimized affinity for protein zero (P0), the most abundant protein on myelin. ***Materials and Methods:*** Further C- and N-terminal truncation was performed on the lead peptide Cy5-$P0_{101-125}$. The resulting nine Cy5 labelled peptides were characterized based on their (photo)physical properties, P0 affinity and in vitro staining. These characterizations were combined with P0 crystal structure evaluations to select the optimized tracer Cy5-$P0_{112-125}$. A near-infrared Cy7-functionalized derivative (Cy7-$P0_{112-125}$) was used to perform initial fluorescence-guided surgery evaluations in a porcine model. ***Results:*** The 26 amino acid lead compound Cy5-$P0_{101-125}$ could be reduced to the 14 amino acid Cy5-$P0_{112-125}$, while inducing a 1.5-fold affinity gain. The peptide design could be corroborated by interactions observed in the crystal structure of the extracellular portion of P0. The near-infrared analogue Cy7-$P0_{112-125}$ supported nerve illumination during nerve surgery in a porcine head-and-neck model. ***Conclusion:*** Methodological truncation yielded a second generation P0-specific peptide. Initial surgical evaluations suggest the peptide can support molecular targeted nerve imaging. ***References:*** Buckle, T.; Hensbergen, A.W.; van Willigen, D.M.; Bosse, F.; Bauwens, K.; Pelger, R.C.M.; van Leeuwen, F.W.B. ## OP-299

### Metabolic 18F FDG PET/CT Guided Intrathoracic Tumor Biopsies: An Analysis of Initial Experience from Central India.

***M. Ravina***, *R. Ganga, A. Behera, T. Lukose, S. Krishna, S. Dasgupta, R. Kote, A. Rath;*
*All India Institute of Medical Sciences, Raipur, Raipur, INDIA.*

***Aim/Introduction:*** The purpose of this study is to investigate the feasibility and diagnostic efficacy of the robotic navigation system assisted 18F FDG PET/CT guided biopsy of intrathoracic tumors. ***Materials and Methods:*** 30 Patient with FDG avid intrathoracic tumors were included in the study. These patients underwent robotic navigation system assisted 18F FDG PET/CT guided biopsies. Patients were immobilized using a vacuum assisted patient arrestor bed during the entire procedure. Regional single bed preprocedural PET/CT imaging was acquired and transferred into the automated robotic navigation system (ARNS). A target lesion and safe trajectory from entry point were chosen using the images on the planning console. Biopsy trajectory and site was decided based on the safety of the needle path, tumor location, its relation to the vital structures, accessibility, avidity and presence of necrosis. The trajectory was then confirmed and the data was fed to the robotic arm system. Planned trajectory was executed using the robotic arm. Proposed entry site was highlighted with laser markers on the patient's chest. Multiple biopsies were taken using Semiautomatic Core Biopsy Gun. Low dose check CT was done to look for any complications. ***Results:*** 30 patients were included in the study. Mean age of patients was 56.13 years (95% CI: 51.78-60.49yrs) and 73.3% (n:22) of patients were male. Left lung mass was seen in 60% (LUL:03, LLL:10, LLL:07), 40% had right lung mass (RUL:01, RML:08, RLL:01). Mean size of the tumor was 5.74cm x5.13cm x7.14cm (min: 1 patient had diffuse FDG uptake with no tumour localization). 100% patents had heterogenous uptake in 18F FDG PET/CT. Mean SUV max was 17.63 (95% CI: 14.11-21.19). Mean target distance was 40.8mm (95%CI: 35.6-45.9; min:17mm max:80mm). 56.7% (n:17) and 43.3% (n:13) underwent biopsy in supine and prone positions respectively. Mean of number of cores taken was 4.47 (min:03 max:06). Sample adequacy and positive diagnosis was achieved in 100% of the patients. 70%(n:21) had non-small cell lung cancer, 16.7% (n:5) had tuberculosis, 2 patients had metastasis from carcinoma rectum; small cell lung cancer, lymphoma and neuroendocrine tumor was diagnosed in 1 patient each. 83.3% (n:25) had no complications. 3 patients had minimal pneumothorax and 1 patient had minor bleeding from biopsy site. Mean VAS score for pain was 1.63 (95% CI:1.26-2.01). ***Conclusion:*** The study confirms that PET/CT guided intrathoracic lung mass biopsy has a good diagnostic yield to establish a pathological diagnosis.

## OP-300

### Gamma-Flex, a novel flexible gamma probe for minimal invasive laparoscopic interventions

***M. van Oosterom***[1], *L. J. Slof*[1], *S. Navaeilavasani*[1], *S. Azargoshasb*[1], *K. Schwenkenbecher*[2], *J. Scheltes*[3], *F. W. B. van Leeuwen*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*Crystal Photonics, Berlin, GERMANY,* [3]*DEAM, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Radioguided surgery is commonly used as a means to intraoperatively localize lesions e.g., sentinel lymph nodes or PSMA expressing metastases [1]. Thereby the technique allows surgeons to identify the exact lesions intraoperatively as found during preoperative imaging at the Nuclear Medicine department. To this end, the handheld gamma detection probe has been the staple modality. Unfortunately, moving to minimal-invasive laparoscopic applications, working through key-holes (i.e., trocars) has drastically limited its utility. Especially the restriction in movements limits the intraoperative target-identification process [2]. To enable laparoscopic radio guidance with a greater degree-of-freedom, we have devised a steerable laparoscopic gamma probe. ***Materials and Methods:*** A laparoscopic steerable gamma probe was designed using 3D CAD software and produced using computerize-numerical-control turning machines. Collimation designs were fabricated out of tungsten, the detector was based on GAGG(Ce) scintillation

crystals, the probe shaft was created out of medical grade stainless steel (SS 316L) and medical grade plastics (i.e., POM). To allow for monitoring of probe movements during its use and evaluate the benefit with respect to rigid laparoscopic gamma probes, a miniaturized electromagnetic sensor was incorporated in the probe detection head. In a laparoscopic phantom model (simulating typical pelvic lymph node applications), the effect of the enhanced flexibility on the dexterity was directly compared to a traditional rigid laparoscopic probe based on similar detector configurations. ***Results:*** The Gamma-Flex prototype supports radio-guidance with 6 degrees-of-freedom, where the traditional rigid instrument only supports 4. Bending angle of the steerable shaft supported a movement range from -45 to +45° over two angles around the instrument's shaft, facilitated by the bending flexure joint. Multi-parametric kinematic tracking of the detector demonstrated superior dexterity compared to the rigid instrument during radioactive lymph node guidance in the laparoscopic phantom, a feature that directly related to the probe's utility during localization. Moreover, the anatomical reach of the gamma-flex prototype was superior to that of the rigid probe. ***Conclusion:*** With the creation of the Gamma-Flex prototype, a second-generation laparoscopic gamma probe has been introduced. Initial preclinical evaluation demonstrates improvements in maneuverability. Further in vivo follow-up is needed to see how this will help improve the surgical performance. ***References:*** [1] van Oosterom et al., Expert Review Medical Devices, 2019 [2] Dell'Oglio et al., European Urology, 2021

## OP-301

### Performance Evaluation of $^{18}$F-PSMA and $^{68}$Ga-PSMA in a Novel MicroPET/CT System Dedicated to Radioguided Surgery

***A. Moraitis***[1], *C. Darr*[2], *T. Kahl*[2], *L. Püllen*[2], *W. Jentzen*[1], *D. Kersting*[1], *B. Hadaschik*[2], *K. Herrmann*[1], *W. P. Fendler*[1], *P. Fragoso Costa*[1];
[1]*Department of Nuclear Medicine at University Hospital Essen, Essen, GERMANY,* [2]*Department of Urology at University Hospital Essen, Essen, GERMANY.*

***Aim/Introduction:*** $^{18}$F-PSMA and $^{68}$Ga-PSMA are highly relevant radiotracers for prostate cancer and have demonstrated feasibility for intraoperative margin assessment in the context of radical prostatectomy. In this phantom study, we report the imaging properties of both tracers in a novel silicon photomultiplier based microPET/CT system dedicated to radioguided surgery. ***Materials and Methods:*** Spatial resolution (FWHM), linearity, and detectability (given as contrast-to-noise ratio, CNR) were determined for $^{18}$F and $^{68}$Ga using a line-source phantom and a sphere-phantom consisting of a cylindrical background region and a 1-ml spherical insert. The line-source phantom was filled with 15 MBq/ml (≈ 1 µl effective volume) to provide good count statistics. The sphere-phantom was filled with around 20 kBq/ml (sphere) at a sphere-to-background ratio of eight, based on observations in prostate specimens. The sphere-phantom was scanned over several half-lives (until activity concentration < 0.3 kBq/ml). All scans were performed on the Aura 10 microPET/CT system (XEOS, Ghent, Belgium). Emission times were default 10 minutes and attenuation and scatter corrected images were reconstructed into a 252×252 transverse matrix with a cubical voxel size of $(0.4\ mm)^3$ using a 3D-MLEM algorithm with 20 iterations. ***Results:*** Axial and transaxial spatial resolution (FWHM) were 1.77 mm and 1.87 mm for $^{18}$F, and 3.19 mm and 3.24 mm for $^{68}$Ga, based on gauss-fitting over line profiles in consecutive image slices. The lower volume limit was therefore estimated to be 0.003 ml and 0.017 ml for $^{18}$F and $^{68}$Ga, respectively. Linearity of the imaged signal was given for a wide activity concentration range with each $^{18}$F and $^{68}$Ga ($r^2$ = 0.98 down to 1 kBq/ml). Initial CNR was 14 for $^{18}$F at 18 kBq/ml, and 16 for $^{68}$Ga at 27 kBq/ml, and decreased gradually to 3.9 for $^{18}$F at 0.22 kBq/ml and 3.7 for $^{68}$Ga at 0.24 kBq/ml. Minimum detectable activity concentration was 0.4 - 0.5 kBq/ml for both radionuclides. Segmentation of the sphere based on visual assessment and thresholding was impaired for activity concentrations below 1 kBq. ***Conclusion:*** Given the default acquisition and reconstruction parameters, the Aura 10 performs well with $^{18}$F and $^{68}$Ga for intraoperative specimen imaging. The spatial resolution is compatible with clinical requirements, and the high detectability allows for implementation of several intraoperative imaging workflows. Further optimisation is required to attain accurate and reliable segmentation at low activity concentrations.

## Clinical Oncology Track - TROP Session: Neuroendocrine Tumors - Diagnosis

## OP-302

### First-in-human Study of an Optimized, potential Kit-type, SSTR Antagonist $^{68}$Ga-DATA$^{5m}$-LM4 in Neuroendocrine Tumors

***J. Zhang***[1], *L. Greifenstein*[2], *V. Jakobsson*[1], *C. Kramer*[2], *C. Landvogt*[2], *C. Mueller*[2], *R. P. Baum*[2];
[1]*National University of Singapore, Singapore, SINGAPORE,* [2]*Curanosticum Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

***Aim/Introduction:*** The aim of this study was to assess the feasibility of using a novel kit-type SSTR antagonist $^{68}$Ga-DATA$^{5m}$-LM4 for PET imaging and evaluate the safety, biodistribution, and preliminary diagnostic efficacy of $^{68}$Ga-DATA$^{5m}$-LM4 in patients with metastatic neuroendocrine tumors. ***Materials and Methods:*** Twenty-seven patients (19 male and 8 female; mean age, 61.0 ± 12.1y) with histopathologically confirmed well-differentiated NETs underwent $^{68}$Ga-DATA$^{5m}$-LM4 PET/CT for the staging and restaging or patient selection for PRRT. All the patients underwent PET/CT scans 60 min after intravenous injection of 1.85 MBq (0.05 mCi) per kilogram of body weight (151 ± 54 MBq mean ± SD) of $^{68}$Ga-DATA$^{5m}$-LM4. ***Results:*** $^{68}$Ga -DATA$^{5m}$-LM4 was well tolerated in all patients, with no adverse symptoms being noticed or reported. The normal organ uptake of $^{68}$Ga-DATA$^{5m}$-LM4 in the thyroid gland, pancreas, and spleen was significantly lower ($P < 0.05$), particularly in the liver as compared to $^{68}$Ga-DOTA-TATE (3.90 ± 0.88 vs 9.12 ± 3.64, $P < 0.000001$). $^{68}$Ga-DATA$^{5m}$-LM4 uptake in the liver and spleen was significantly lower than the $^{68}$Ga-DOTA-TOC uptake ($P = 0.0166$ and $P = 0.0098$, respectively). In NETs patients, tumors lesions showed high uptake intensity on $^{68}$Ga-DATA$^{5m}$-LM4 PET/CT, with the highest SUVmax up to 167.93 (mean ± SD, 44.47 ± 36.22). With SUVmean of healthy liver parenchyma, the kidney, and blood pool as background, tumor-to-background ratios were 20.32 ± 19.97, 4.30 ± 3.03, and 38.63 ± 35.97, respectively. ***Conclusion:*** The new SSTR antagonist $^{68}$Ga-DATA$^{5m}$-LM4 can be conveniently labeled with high radiochemical yields and purities. Our first clinical data demonstrate excellent imaging performance of the new antagonistic SSTR ligand $^{68}$Ga-DATA$^{5m}$-LM4. Application of the tracer in patients with disseminated metastases NETs showed a superior biodistribution with very high tumor contrast and low uptake in thyroid glands and spleen, and especially in the liver as compared to the agonistic SSTR ligands, which facilitates favorable lesion detection of $^{68}$Ga-DATA$^{5m}$-LM4. The advantageous imaging

characteristics, along with the very convenient, potential „kit-type" production, makes $^{68}$Ga-DATA$^{5m}$-LM4 an overall extraordinary promising radiopharmaceutical for the staging and restaging of NET patients and especially for the detection of very small hepatic metastases.

## OP-303

### A Prospective Evaluation of [$^{18}$F]AlF-NOTA-LM3 in Patients with Well-differentiated Neuroendocrine Tumors: Head-to-head Comparison with$^{68}$GaDOTATATE

***M. Liu***, *W. Zhu, Y. Zhang, C. Ren, H. Zhang, Z. Huang, L. Huo; Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** SSTR antagonists have shown better performance than analogs for somatostatin receptor imaging. The aim of this study was to evaluate safety, biodistribution and diagnostic efficacy of [$^{18}$F]AlF-NOTA-LM3 PET/CT in patients with well-differentiated neuroendocrine tumors. And compare with $^{68}$Ga-DOTATATE PET/CT. ***Materials and Methods:*** Patients aged 18 to 80, with histologically confirmed well-differentiated neuroendocrine tumors (G1 and G2) were prospectively recruited to the study. All patients performed [$^{18}$F]AlF-NOTA-LM3 PET/CT and $^{68}$Ga-DOTATATE PET/CT within a week and the interval between the two scans were at least 24 hours. Safety of [$^{18}$F]AlF-NOTA-LM3 were assessed. Physiologic normal-organ uptake, lesion numbers, standardized uptake values (SUVmax) of tumor, and tumor-to-background ratio (TBR) were compared head-to-head. ***Results:*** A total of 15 patients were enrolled in this study. No adverse events related to the radiopharmaceuticals were reported. The physiological uptake of [$^{18}$F]AlF-NOTA-LM3 was significantly lower than $^{68}$Ga-DOTATATE in abdominal organs (including liver, spleen, pancreas, stomach, small intestine, renal cortex) and bone marrow. On per-patient basis, [$^{18}$F]AlF-NOTA-LM3 had a higher detection rate for liver lesions and lymph node lesions. In 9 patients with liver metastases, 78% (7/9) showed more liver lesions on [$^{18}$F]AlF-NOTA-LM3 than on $^{68}$Ga-DOTATATE, 11% (1/9) showed the opposite, and the remaining 11% (1/9) showed identical results. In 8 patients with lymph node metastases, 75% (6/8) detected more lymph node lesions on [$^{18}$F]AlF-NOTA-LM3, whereas 25% (2/8) showed comparable results with both tracers. On per-lesion basis, [$^{18}$F]AlF-NOTA-LM3 detected significantly more liver metastases (275 vs. 219, P=0.028) and lymph node metastases (21 vs. 14, P=0.020) than $^{68}$Ga-DOTATATE. Both tracers were comparable in detection of pancreatic lesions (21 vs. 20, P = 0.317), duodenum lesions (5 vs. 5, P = 1.000), and bone metastases (5 vs. 6, P = 0.317). No significant difference of tumor SUVmax were observed between [$^{18}$F]AlF-NOTA-LM3 and $^{68}$Ga-DOTATATE PET/CT. However, [$^{18}$F]AlF-NOTA-LM3 showed higher TBR of liver lesions, pancreatic lesions, and bone lesions. ***Conclusion:*** [$^{18}$F]AlF-NOTA-LM3 performed better in detection of liver metastases and lymph node metastases than $^{68}$Ga-DOTATATE, with a better tumor-to-background ratio.

## OP-304

### Superiority of $^{68}$Ga-DOTATATE PET/CT compared to $^{18}$F-FDG PET/CT, MRI of the spine, and whole-body diagnostic CT and MRI in the detection ofspinal bone metastases associated with pheochromocytoma and paraganglioma

***A. Jha***[1], *M. Patel*[1], *A. Ling*[1], *R. Shah*[1], *C. C. Chen*[1], *C. Millo*[1], *M. A. Nazari*[1], *N. Sinaii*[1], *K. Charles*[1], *M. J. Kuo*[1], *T. Prodanov*[1], *B. Saboury*[1], *S. Talvacchio*[1], *A. Derkyi*[1], *J. del Rivero*[1], *G. O'Sullivan Coyne*[1], *A. P. Chen*[1], *N. Nilubol*[1], *P. Herscovitch*[1], *F. I. Lin*[1], *D. Taïeb*[1], *A. C. Civelek*[2], *J. A. Carrasquillo*[1], *K. Pacak*[1];

***Aim/Introduction:*** Pheochromocytomas and paragangliomas (PPGLs) are rare catecholamines-producing neuroendocrine tumors that cause life-threatening complications. Bone-metastases are observed in upto 71% of metastatic PPGL patients. Furthermore, 20% of metastatic PPGL patients have metastasis exclusively to bone with spine being the most common location (81%). Bone-metastases weaken and destroy skeletal tissue and predispose patients to skeletal-related-events. Data regarding head-to-head comparison between functional and anatomic imaging modalities to detect spinal bone metastases in PPGL are limited. The aim of this study is to compare the diagnostic performance of $^{68}$Ga-DOTATATE PET/CT, $^{18}$F-FDG PET/CT, MRI of the spine ($MRI_{spine}$), and contrast-enhanced whole-body CT ($CT_{WB}$) and MRI ($MRI_{WB}$) for the detection of PPGL-related spinal bone-metastases. ***Materials and Methods:*** Between 2014 and 2020, PPGL participants with spinal bone-metastases underwent $^{68}$Ga-DOTATATE PET/CT, $^{18}$F-FDG PET/CT, $MRI_{spine}$ (sagittal T1w, sagittal STIR, axial T1w, and axial T2w), $MRI_{WB}$, and $CT_{WB}$. Per-patient and per-lesion detection rates were calculated. Counting of spinal bone-metastases was limited to a maximum of one lesion per vertebrae. A composite of all scans served as an imaging comparator. McNemar test was used to compare detection rates between the scans. Two-sided p values <0.05 were considered statistically significant. ***Results:*** Forty-three consecutive participants [females, 22; median age, 22 years, harboring mutations in SDHx (N=30), NF1 (N=1), HIF2A (N=1), and negative for mutations (N=11)] with $MRI_{spine}$ were included in this prospective study. They also underwent $^{68}$Ga-DOTATATE PET/CT (N=43), $^{18}$F-FDG PET/CT (N=43), $MRI_{WB}$ (N=24), and $CT_{WB}$ (N=33). Forty-one of 43 participants were positive for spinal bone-metastases, with 382 lesions on the imaging comparator. $^{68}$Ga-DOTATATE demonstrated a per-lesion detection rate of 377/382 (98.7%) which was significantly superior compared to $^{18}$F-FDG (72.0%, 275/382, p<0.001), $MRI_{spine}$ (80.6%, 308/382, p<0.001), $MRI_{WB}$ (55.3%, 136/246, p<0.001) and $CT_{WB}$ (44.8%, 132/295, p<0.001). The per-patient detection rate of $^{68}$Ga-DOTATATE was 41/41 (100%) which was higher compared to $^{18}$F-FDG (90.2%, 37/41), $MRI_{spine}$ (97.6%, 40/41), $MRI_{WB}$ 22/23 (95.7%,), and $CT_{WB}$ 27/33 (81.8%), statistical significance reached only with $CT_{WB}$ (p=0.041). Furthermore, $^{68}$Ga-DOTATATE was found to detect greater or equal true-positive lesions compared to $^{18}$F-FDG in 40/41 (97.6%), $MRI_{spine}$ (41/41, 100.0%), $MRI_{WB}$ (23/23, 100.0%), and $CT_{WB}$ (33/33, 100.0%). ***Conclusion:*** $^{68}$Ga-DOTATATE showed a significantly superior per-lesion detection rate of spinal bone-metastases compared to $^{18}$F-FDG, $MRI_{spine}$, $MRI_{WB}$, and $CT_{WB}$. Besides providing a whole-body analysis, it maybe the imaging modality-of-choice to evaluate metastatic spine disease especially in the treatment planning and response assessment of the targeted-radionuclide-therapy ($^{223}RaCl_2$, $^{177}$Lu/$^{90}$Y DOTA-analogs) in patients with bone-only metastatic PPGL.

## OP-305

### Prognostic Value of C-X-C motif Chemokine Receptor 4-directed Molecular Imaging in Patients with Advanced Adrenocortical Carcinoma

***W. Schlötelburg***[1], *P. E. Hartrampf*[1], *A. Kosmala*[1], *S. E. Serfling*[1], *A. Schirbel*[1], *A. K. Buck*[1], *M. Fassnacht*[2], *S. Hahner*[2], *R. A. Werner*[1,3];
[1]*Department of Nuclear Medicine, University Hospital of Würzburg, GERMANY,* [2]*Division of Endocrinology and Diabetes, Department of Medicine I, University Hospital of Würzburg, GERMANY,* [3]*The Russel H. Morgan Department of Radiology and Radiological Science, Johns Hopkins Unversity School of Medicie, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** In an ex-vivo setting, C-X-C motif chemokine receptor 4 (CXCR4) is highly expressed in sites of disease in patients affected with adrenocortical carcinoma (ACC)(1). We aimed to determine the predictive value of CXCR4-targeting [$^{68}$Ga]

Ga-PentixaFor PET/CT for outcome relative to clinical parameters. ***Materials and Methods:*** We identified 41 advanced, metastasized ACC patients imaged with [$^{68}$Ga]Ga-PentixaFor PET/CT. Scans were assessed visually and on a quantitative level by manually segmenting the tumor burden (providing tumor volume, peak/mean/maximum standardized uptake values [SUV] and fractional tumor activity [FTA], defined as mean SUV multiplied by TV). Clinical parameters included sex, previous therapies, age, Weiss-Score, and Ki67 index. Following imaging, overall survival (OS) was recorded. ***Results:*** After [$^{68}$Ga]Ga-PentixaFor PET/CT, median OS was 257 days (range, 27 - 2913 days). On univariable analysis, only presence of CXCR4-positive peritoneal metastases (PM, HR 2.04, 95%CI 1.02 - 4.07) was significantly linked to shorter OS (P=0.04). FTA revealed a trend towards significance (P=0.07), while all other PET-based parameters were not associated with survival (P≥0.14). Moreover, none of the clinical parameters (Sex, age, Weiss-Score, Ki67 index) showed relevant associations with OS (P≥0.66). On Kaplan-Meier analysis, presence of CXCR4-positive PM was linked to decreased survival (no PM, median OS, 11.41 months vs presence of PM, 6.41 months, P<0.04), which was also observed for increased FTA (above median [434], 13.3 months vs below median, 6.41 months, P<0.02). ***Conclusion:*** In advanced ACC patients, presence of CXCR4-expressing peritoneal lesions and increasing FTA on [$^{68}$Ga]Ga-PentixaFor PET/CT may be linked to less favorable outcome, while clinical parameters failed to provide outcome benefits. Funding: IZKF Z-2/91 ***References:*** (1) Bluemel C et al. Investigating the Chemokine Receptor 4 as Potential Theranostic Target in Adrenocortical Cancer Patients. Clin Nucl Med . 2017 Jan;42(1):e29-e34.

## OP-306

### "Novel $^{99m}$Tc-labelled somatostatin antagonists in the diagnostic algorithm of neuroendocrine neoplasms" - results of a multicenter phase I clinical trial - TECANT

***M. Opalinska***[1], *I. Virgolini*[2], *L. Lezaic*[3], *G. di Santo*[2], *C. Decristoforo*[2], *P. Kolenc*[3], *R. Mikolajczak*[4], *A. Studen*[5], *P. Garnuszek*[4], *U. Simoncic*[5], *M. ***Aim/Introduction:*** The management of patients with neuroendocrine neoplasms (NEN) has improved substantially since the introduction of radiolabelled somatostatin analogues targeting overexpressed somatostatin receptors (SSTR). Accurate assessment of SSTR status of primary focus/metastases is crucial to determine the personalized approach to the treatment. Recently it has been shown that novel molecular probes, SSTR2-antagonists, recognize more binding sites in comparison to the widely used SSTR2-agonists and hence they improve diagnostic efficacy, especially when the density of SSTR is low. The aim of the project is to initiate a clinical feasibility study with a novel $^{99}$mTc-labelled SSTR2-antagonist as a sensitive probe to assess the SSTR status in NEN patients, and to develop a robust, reproducible quantitative imaging method. ***Materials and Methods:*** On the basis of extensive preclinical studies the most promising SSTR2 antagonist N4-LM3 (p-Cl-Phe-cyclo(D-Cys-Tyr-DAph(Cbm)-Lys-Thr-Cys)-D-Tyr-NH2 (TECANT1) was selected for clinical translation.Ten patients with advanced NEN and SSTR positivity confirmed by routinely used SSTR imaging based on a radiolabelled agonist were enrolled in this phase I multicentre clinical study(EudraCT no: 2019-003379-20). Safety, tolerability, human pharmacokinetics, dosimetry and NEN targeting properties of the compound tested were assessed. Comparability of clinical and imaging data collected at all clinical centres were provided by centralized secured database for standardization of image analysis and integration of statistical tools. ***Results:*** By now SPECT/CT imaging with the [$^{99m}$Tc]Tc-TECANT1 as Investigational Medicinal Product (IMP) was performed in 7 out of 10 patients. No IMP related side effects were observed. Rapid distribution with predominant renal excretion with typical pattern of SST analogues was observed, [$^{99m}$Tc]Tc-TECANT1 tumour uptake was visible as early as 5minutes after its administration and was retained 24 hours p.i. NEN lesions were very well visible in all examined patients. In certain patients lesion contrast was superior to images obtained with 68Ga-SSTR agonists. In all cases high tumour to background ratio was obtained, with the highest values at 4 hours after IMP injection. ***Conclusion:*** Images obtained with the $^{99m}$Tc-labelled SSTR2-antagonist TECANT1 appear to be of great clinical value. Favourable toxicological and pharmacological profile was observed. Detailed quantitative analysis will be reported to support the initial highly comparable diagnostic performance to SSTR-PET.TECANT1 holds great promise to enable a reliable and widely available method for quantitative assessment of SSTR status and to improve the decision-making diagnostic and therapeutic algorithm as one of the key elements in a personalised approach to the management of NEN patients. Funding: ERAPerMed, FWF Austria, NCBiR Poland, MIZS Slovenia

## OP-307

### Comparison of [$^{68}$Ga]Ga-DOTANOC and [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 PET/CT in the same patient group with neuroendocrine tumors.

***R. V***[1], *S. Ballal*[1], *M. Yadav*[1], *F. Roesch*[2], *P. Sheokand*[1], *M. Martin*[2], *M. Tripathi*[1], *R. Sahoo*[1], *C. Bal*[1];
[1]*AIIMS, Delhi, INDIA,* [2]*Johannes Gutenberg university of Mainz, Mainz, GERMANY.*

***Aim/Introduction:*** Neuroendocrine tumors (NETs) are slow-growing tumors that express high levels of somatostatin receptors (SSTRs). SSTR imaging uses radio-labeled somatostatin analogs which bind to the somatostatin receptors (SSTR1-5), commonly over-expressed in NETs. NETs have shown a rising trend in incidence over the past four decades due to increasing awareness and better diagnostic tools. Recent studies have shown radiolabeled SSTR antagonists are superior for cancer theranostics compared with agonists (1-3). In this retrospective study, we aim to compare the diagnostic efficacy between [$^{68}$Ga]Ga-DOTANOC with [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 in the detection of primary and metastatic lesions in NET patients. ***Materials and Methods:*** Histologically proven NET patients who underwent [$^{68}$Ga]Ga-DOTANOC and [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 PET/CT scans were retrospectively analysed. Both imaging modalities were compared according to patient-based and lesion-based analysis. The qualitative analysis involved visual judgment of radiotracer uptake that was validated by the morphological findings on CT which was considered as the reference standard.Quantitative comparisons between the radiotracers were presented as standardised uptake value (SUV) corrected for lean body mass:

SULpeak, and SULavg. ***Results:*** 29 patients with a mean age of 49 years (range: 25 - 67 years; 14 women and 15 men) with confirmed NET were evaluated. Histology revealed low-grade NETs (G1) in 13 patients, intermediate grade (G2) in 7, and high grade (G3) in 9. 51.7% of patients (15/29) had distant metastases, and 48.2% (14/29) of patients demonstrated locally advanced disease. In total, 390 lesions were confirmed by cross-sectional diagnostic CT. The lesion-based sensitivity of [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 PET was 84% (328/390), compared with 66.6% (260/390) for [$^{68}$Ga]Ga-DOTANOC PET (P<0.0001). According to lesion-based analysis, on diagnostic CT, 29 patients had 25 primary tumors, 69 lymph nodes, 7 lung metastases, 261 liver metastases, and 28 bone metastases. [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 scan identified more abnormal lesions than [$^{68}$Ga]Ga-DOTANOC in all the primary and metastatic sites with a maximum marked difference in the liver [87.3% vs 67% ; P <0.0001 ( 228 vs. 175 compared to 261 lesions on CT) and bone metastases [100% vs 32%; P<0.0001 (28 vs. 9 compared to 28 lesions on CT)]. Quantitatively, the tracer uptake [SULpeak, and SULavg] was significantly higher in [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 than with [$^{68}$Ga]Ga-DOTANOC PET for primary tumor (P<0.05). ***Conclusion:*** The SSTR ligand antagonist tracer [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 detected significantly more lesions than the [$^{68}$Ga]Ga-DOTANOC in patients with NETs. [$^{68}$Ga]Ga-DATA$^{5m}$-LM4 is a promising radiopharmaceutical for the staging and restaging of NETs. However, the clinical significance has to be proven in a larger sample size.

## OP-308

### Prognostic value of the post-treatment $^{177}$Lu-DOTATOC scintigraphy in NET patients undergoing PRRT.

***S. Leyser***[1,2], *H. Lanzafame*[1,2], *D. Kersting*[1,2], *R. Seifert*[1,2], *F. Zarrad*[1], *H. Lahner*[3], *N. Unger*[3], *W. P. Fendler*[1,2], *K. Herrmann*[1,2], *M. M. Weber*[1,4];
[1]*Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [2]*German Cancer Consortium (DKTK), Partner site University Hospital Essen, Essen, GERMANY,* [3]*Department of Endocrinology West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [4]*German Cancer Consortium (DKTK), Partner site University Hospital Essen, Essen, Germany, Essen, GERMANY.*

***Aim/Introduction:*** With the 2018 FDA approval of [$^{177}$Lu]-DOTATATE following the successful NETTER-1 trial peptide radioreceptor therapy (PRRT) has been established as a 2$^{nd}$ line treatment option for grade 1-2 neuroendocrine tumors (NETs) of gastroenteropancreatic origin. However, assessment of sufficient target expression was performed in this trial with somatostatin receptor (SSR) scintigraphy, a modality largely replaced by SR-PET due to superior sensitivity creating a need for alternative imaging parameters. We therefore aimed to evaluate the prognostic value of other imaging, such as semiquantitative analysis of the PET/CT as well as the Krenning-Score evaluated on the planar 1$^{st}$ cycle post-treatment [$^{177}$Lu]-DOTATOC-scintigraphy (PTS1), acquired 24h p.i. with regards to progression-free (PFS) and overall survival (OS). ***Materials and Methods:*** We included patients with histopathological diagnosis of NET, who underwent at least 2 PRRT cycles between January 2009 and July 2019, with available PTS1. Target SR expression was graded using the established, SRS-based Krenning criteria and mean SUVmax/-mean on baseline [$^{68}$Ga]-DOTATOC PET/CT for up to 9 lesions per patient. Progression free survival was defined as the interval from the first PRRT cycle to radiological progression (RECIST 1.1), clinical progression (ruled by a board-certified endocrinologist) or death. Time-to-event data (PFS and OS) were described using Kaplan-Meier curves and compared by use of log-rank test. ***Results:*** 115 patients were deemed eligible; of these 33 (28.7 %) had grade 1, 73 (63.5%) grade 2, and 9 (7.8%) grade 3 NETs. Median PFS was 22.3 months (range 2.8-148.9) and median OS was 48 months (range 4.3-157.1). 55 (47.8%) and 60 (52.2%) patients were classified as Krenning 3 and 4 on the post-treatment scintigraphy, respectively. In the Kaplan-Meier-analysis, Krenning score 4 vs. 3 was associated with a significantly longer PFS (35.9 vs. 16.2 months; p<0.001), as well as a significantly longer OS (75.3 vs. 41.8 months; p=0.001). Baseline [$^{68}$Ga]-DOTATOC PET/CT SUV was not significantly associated with PFS (p=0.36) and OS (p=0.53), underlining the independent value of the [$^{177}$Lu]-DOTATOC based Krenning score. ***Conclusion:*** Krenning score evaluated on PTS1 was a strong prognosticator for PFS and OS, whereas SUV was not. Patients with a Krenning score 3 demonstrated shorter survival and might thus benefit from a intensified treatment and folllow-up.

## OP-309

### Optimized segmentation of neuroendocrine tumor lesions on somatostatin receptor PET/CT imaging for therapy response assessment

***A. Chaban***[1], *J. Brosch-Lenz*[1], *Y. Song*[1], *V. Dinkel*[1], *L. Bodei*[2], *W. Weber*[1];
[1]*Klinikum rechts der Isar, der Technischen Universität München, Munich, GERMANY,* [2]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** There is increasing interest in using somatostatin receptor PET/CT (SSTR-PET/CT) for monitoring neuroendocrine tumor (NET) response to therapy. However, the conventional approach of using index lesions for response assessment is inherently limited because NETs frequently present with many metastases. We therefore investigated different approaches to capture tumor burden in patients with NETs. ***Materials and Methods:*** In this dual center study, we explored several approaches to delineate NET lesions in 156 SSTR PET/CT studies, including a global minimum SUV, a global SUV threshold based on liver or spleen SUVs, and separate thresholds for lesions in different sites of the body (liver, abdomen outside the liver, and lung/skeleton). Promising approaches were further evaluated in a group of 30 patients with a total 295 of well-defined lesions. In this group sensitivity, specificity, and area under the curve (AUC) were calculated for correct localization of metastases. The total tumor volume (TTV) of the best automated approach was compared with the sum of tumor volumes determined by segmenting lesions with a 42% threshold of their respective SUVmax which served as the reference standard. Finally, the inter-observer variability of the automated method was assessed. ***Results:*** Global thresholds for lesion delineation did not result in a reliable delineation of metastases and were not further investigated. In contrast, site-specific thresholds allowed for accurate lesion delineation. The best threshold for segmentation of liver metastases was normal liver SUVmax+2.2 g/ml, which resulted in a sensitivity, specificity, and AUC of 0.95, 0.97, and 0.96, respectively. The best threshold for bone and intrapulmonary metastases was a SUV of 2.0 g/ml with a sensitivity, specificity, and AUC of 1.00, 0.97, and 0.98, respectively. For extrahepatic lesions the best threshold was the liver SUVmax with a sensitivity, specificity, and AUC of 0.94, 0.83, and 0.89, respectively. Median TTVs measured with the automated approach was systematically larger (mean: 62 ml, range: 3 ml-588 ml) than TTV measured by individual segmentation of lesions (mean: 53 ml, range: 2 ml358ml,

p<0.01) but both parameters were closely correlated (r=0.88). The automated approach showed excellent reproducibility of TTV measurements between the two observers (r=0.99). ***Conclusion:*** SUV-based thresholding of SSTR PET images with site-specific thresholds is a promising approach for automated segmentation of NET lesions that can be easily implemented clinically. TTVs derived from this approach may be used as a new measure of tumor burden and to assess tumor response to therapy.

## OP-310

### Diagnostic performance of functional imaging with $^{68}$Ga-DOTATATE PET/CT, $^{18}$F-FDG PET/CT, and $^{18}$F-FDG PET/CT, and anatomic imaging with whole-body CT and/or MRI in the detection ofSDHD-related pheochromocytoma and paraganglioma - A comparative prospective study

***A. Jha***, *M. Patel, A. Ling, C. C. Chen, C. Millo, K. Charles, M. Kuo, T. Prodanov, M. A. Nazari, S. Talvacchio, A. Derkyi, J. del Rivero, A. P. Chen, N. Nilubol, P. Herscovitch, F. I. Lin, D. Taïeb, J. A. Carrasquillo, A. C. Civelek, K. Pacak;*
*National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Patients with germline SDHD pathogenic variants (encoding succinate dehydrogenase subunit D) predominantly develop head and neck paragangliomas (HNPGLs), and might coexist with paragangliomas arising from other locations. The risk of metastatic disease is approximately 5%, however, multifocality of paragangliomas is observed in about 75% of patients. The performance of $^{68}$Ga-DOTATATE PET/CT in SDHD-related pheochromocytomas/paragangliomas (PPGLs) is currently unknown. The purpose of this prospective study was to evaluate and compare the diagnostic performance of $^{68}$Ga-DOTATATE PET/CT to $^{18}$F-FDG PET/CT, $^{18}$F-L-dihydroxy-phenylalanine ($^{18}$F-FDOPA) PET/CT, and whole-body CT and/or MRI (CT/MRI) in detection of SDHD-related PPGLs. ***Materials and Methods:*** $^{68}$Ga-DOTATATE PET/CT was prospectively performed in 38 patients (females:males, 24:14; mean age, 44±13 years) with SDHD-related PPGLs. All patients also underwent $^{18}$F-FDG PET/CT and CT/MRI, with 35/38 patients also undergoing $^{18}$F-FDOPA PET/CT. Per-patient and per-lesion detection rates were compared for all imaging modalities. The median duration between $^{68}$Ga-DOTATATE and $^{18}$F-FDG, $^{18}$F-FDOPA, and CT/MRI were 2, 1, and 2.5 days, respectively. A composite of all functional and anatomical imaging studies served as an imaging comparator. McNemar test was used to compare detection rates between $^{68}$Ga-DOTATATE PET/CT and the other imaging modalities. Two-sided p values <0.05 were considered significant. ***Results:*** All patients were positive for PPGLs demonstrating 249 lesions on the imaging comparator. Thirty-five patients presented with HNPGLs whereas 13 presented with additional primaries located outside the head and neck region (adrenal, n=4; mediastinum, n=8, and abdomen, n=6), and 2 presented with metastases alone. Twenty-six (17 in head and neck and 14 outside the head and neck) patients also demonstrated metastases. $^{68}$Ga-DOTATATE PET/CT demonstrated a per-lesion detection rate of 243/249 [97.6%, 95% confidence interval (CI): 94.8-99.1%]. $^{18}$F-FDG PET/CT, $^{18}$F-FDOPA PET/CT, and CT/MRI showed significantly lower per-lesion detection rates of 130/249 (52.2%, 95% CI: 45.8-58.6%; p<0.001), 203/244 (83.2%, 95% CI: 77.9-87.7%; p<0.001), and 211/249 (84.7%, 95% CI: 79.7-89.0%; p<0.001), respectively. The per-patient detection rates of $^{68}$Ga-DOTATATE PET/CT, $^{18}$F-FDG PET/CT, $^{18}$F-FDOPA PET/CT, and CT/MRI were 38/38 (100%, 95% CI: 90.8-100%), 35/38 (92.1%, 95% CI: 78.6-98.3%), 34/35 (97.1%, 95% CI: 85.1-99.9%), and 38/38 (100%, 95% CI: 90.8-100%), respectively. ***Conclusion:*** $^{68}$Ga-DOTATATE PET/CT showed a significantly superior per-lesion detection rate compared to all other functional and anatomical imaging modalities and may be the preferred functional imaging modality to evaluate SDHD-related PPGLs. Furthermore, owing to the $^{68}$Ga-DOTATATE avidity of PPGLs in these patients, cold somatostatin analog and/or peptide receptor radionuclide therapy can be considered as one of the therapeutic options.

### Prognostic and predictive value of imaging features in neuroblastoma using pre-treatment 123I-MIBG SPECT/CT: is there a place for radiomics?

***M. Luporsi***[1], *H. Brisse*[2], *C. Nioche*[3], *N. Jehanno*[1], *H. Fokem-Fosso*[3], *I. Buvat*[3], *G. Schleiermacher*[4], *F. Orlhac*[3];
[1]*Department of nuclear medicine, Institut Curie, PSL Research University, Institut Curie, Inserm , LITO-U1288, Paris, FRANCE,* [2]*Institut Curie, Inserm , LITO-U1288, Department of radiology, Institut Curie, PSL Research University, Paris, FRANCE,* [3]*Institut Curie, Inserm , LITO-U1288, Orsay, FRANCE,* [4]*SiREDO Integrated Pediatric, adolescents and young adults Oncology Center, Laboratory of translational research in pediatric oncology INSERM-U830, Institut Curie, Paris, FRANCE.*

***Aim/Introduction:*** Recent studies based on 123I-MIBG SPECT/CT have suggested that some radiomic features - mainly reflecting the primary tumor's volume and its shape - could be promising prognostic tools in neuroblastoma (NB). Yet, available data remain sparse and have only involved small series. The aim of this study is to assess the prognostic significance of NB's primary tumor radiomic features calculated from pre-therapeutic 123I-MIBG SPECT/CT (MIBG) images and to explore their ability to predict NMYC status. ***Materials and Methods:*** Patients (<18 yo) with a newly diagnosed NB and a pre-therapeutic 123I-MIBG scan performed on a SPECT/CT (Discovery GE 670) between 2012 and 2020 in our institution were retrospectively included. Genomic, histological, biological and CT data at diagnosis as well as survival (> 2 years of follow-up) were collected from medical records. The segmentation of the primary tumor and extraction of 18 radiomic features were performed using LIFEx software (version 7.3.25) [1]. The ability of radiomic features to identify NMYC status was assessed using the Youden Index (=Se+Sp-1) and the Wilcoxon test. Kaplan-Meier analysis was performed and the estimated OS probabilities for two different groups of patients were obtained for the cut-off that leads to the lowest p-value in log-rank tests. ***Results:*** 92 patients were enrolled (32 female) with a mean age of 27±32 months at diagnosis (range [1-178], < 18 months: 52%). 52/92 patients had a metastatic disease (42 stage M, 10 Ms) and 36/92 patients were considered with a high-risk NB . 9 features were independently associated with the NMYC amplification (Wilcoxon test: p<0.05). NMYC amplified tumors (18/92) exhibited higher Metabolic Volume values (volume normalized by the body surface area, p=0.005), higher Asphericity values (p<0.001) and higher Kurtosis values (p=0.017) than non-NMYC amplified lesions. Asphericity was the most discriminant feature with a Youden index of 0.48 (Se=78%;Sp=70%). Established prognostic features

at diagnosis (age, INRGSS stage, LDH, MKI, INPC, genomic profiles and baseline SIOPEN score) were all predictive of survival ($p<0.05$). Metabolic Volume, Asphericity and Kurtosis of the primary tumors were additionally predictive of survival (log-rank test: $p\leq0.05$). ***Conclusion:*** In this largest series to date, radiomic features extracted from pre-therapeutic MIBG are strongly associated with the NMYC status and overall survival, and could be used for as new biomarkers for prognostic stratification. ***References:*** [1] Nioche et al. Cancer Res 2018.

## OP-312

### Comprehensive Analysis of 18F-MFBG Biodistribution and Variability in Pediatric Neuroblastoma Patients

***P. Wang***[1,2], *H. Zhang*[1], *Y. Zhang*[1], *T. Li*[1], *H. Jing*[1], *F. Li*[1], *J. Zhang*[2];
[1]*Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, CHINA,* [2]*Department of Diagnostic Radiology, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** $^{18}$F-MFBG is a promising PET tracer for diagnosing neural crest tumors, particularly neuroblastoma. This study aims to provide a comprehensive analysis of 18F-MFBG biodistribution in pediatric neuroblastoma patients, focusing on the uptake in normal organs and the variability observed in the liver, pancreas, and brown adipose tissue. ***Materials and Methods:*** We retrospectively analyzed consecutive $^{18}$F-MFBG PET/CT scans of patients with neuroblastoma. Two experienced nuclear medicine physicians interpreted the PET/CT studies using MIM software, and quantitative analysis was performed on normal tissues, reporting the SUVmax. ***Results:*** Quantitative analysis of $^{18}$F-MFBG biodistribution was performed on 10 patients with negative PET findings, confirmed by follow-up. $^{18}$F-MFBG exhibited stable and reproducible biodistribution in normal organs, with the highest SUVmax observed in the salivary glands ($9.0 \pm 0.8$; range, 3.8-16.2), myocardium ($6.9 \pm 0.4$; range, 3.0-10.3), and adrenal glands ($4.5 \pm 0.2$; range, 3.1-6.0). Lower SUVmax was observed in the small intestine, renal parenchyma($1.6 \pm 0.1$; range, 0.9-2.9), and spleen, and stomach, while the lowest SUVmax was found in muscle, bone ($0.6 \pm 0.05$; range, 0.3-1.0), and lungs. The head of the pancreas displayed higher uptake ($3.0 \pm 0.2$ vs. $2.6 \pm 0.2$; $P=0.007$) compared to the body and tail. In an extended analysis of 121 neuroblastoma patients, we observed three patterns of 18F-MFBG uptake in normal liver tissue: (1) uniform uptake with LRR of $1.2 \pm 0.1$ (range, 1.0-1.4); (2) higher uptake in the left lobe with uniform uptake in both lobes (LRR, $1.8 \pm 0.3$, range, 1.5-2.8); and (3) increased uptake in the hepatic margin with IRR of $2.0 \pm 0.5$ (range, 1.5-3.4). Uniform uptake in the whole liver was observed in similar proportions of 38.5% and 36.4% in adults and children, respectively. High gallbladder uptake was observed in one patient. Brown adipose tissue was detected in 11 patients (9.1%), with five located around the neck and supraclavicular region, and six along the T1-2 spine. These findings are particularly important as they provide insights into the variability of $^{18}$F-MFBG uptake that may impact image interpretation. ***Conclusion:*** Understanding the biodistribution of $^{18}$F-MFBG and its variability is essential for accurate image interpretation and clinical management of pediatric neuroblastoma patients. This study presents a comprehensive analysis of $^{18}$F-MFBG biodistribution, which will aid physicians in better interpreting PET images and making more informed clinical decisions.

## OP-313

### The $^{18}$F-FDG PET/MRI radiomics nomogram for differentiating high-risk and non-high-risk patients of the International Neuroblastoma Risk Group Staging System

***J. Liang;***
杭州通用医学影像诊断中心，杭州，*CHINA.*

***Aim/Introduction:*** To develop and validate an $^{18}$F-FDG PET/MRI radiomics nomogram to distinguish high-risk and non high-risk patients in the International Neuroblastoma Risk Group staging system (INRGSS). ***Materials and Methods:*** The $^{18}$F-FDG PET/MRI imaging data of 124 patients with neuroblastoma were analyzed retrospectively, which were divided into training set (n=93) and verification set (n=31). The radiomics features were extracted from PET images and T2WI images, and a radiomics score (Rad score) was calculated. Then single factor and multivariate logistic regression analysis were used to screen out independent clinical factors and build a clinical model. Based on Rad score and independent clinical factors, a radiomics nomogram was developed. The performance of the clinical model, Rad score and nomogram was evaluated by receiver operating characteristic (ROC) curve, calibration curve and decision curve analysis (DCA). ***Results:*** Eight radiomics features were selected to construct the radiomics model. There were significant differences between high-risk and non high-risk patients in patient age, INRG stage, MTV(metabolic tumor volume), TLG (total lesion glycolysis) and Rad scores. The radiomics nomogram combining Rad scores with the clinical factors described above showed favorable predictive value for distinguishing high and non-high risk, with AUC values of 0.973 and 0.969 in the training and validation sets, respectively. The calibration curve showed that the nomogram of radiomics had goodness of fit, and DCA proved that the nomogram of radiomics was useful in clinical practice. ***Conclusion:*** The radiomics nomogram combining Rad score and clinical factors can well predict high-risk and non high-risk patients of INRGSS. It may be helpful for disease follow-up and management in clinical practice, and assist in individualized and precise treatment of neuroblastoma.

## OP-314

### First clinical experience with [$^{64}$Cu]Cu-NOTA-ch14.18/CHO to visualize GD2 by PET in several pediatric tumor entities - Biodistribution and preliminary dosimetry

***N. Trautwein***[1,2], *J. Schwenck*[1,2,3], *C. Seitz*[4,5], *S. von Beschwitz*[1], *G. Reischl*[2], *S. Scheuermann*[4,5], *P. Lang*[4], *J. Schaefer*[6], *B. Pichler*[2,3], *C. la Fougère*[1,3], *H. Dittmann*[1];
[1]*1Department of Nuclear Medicine and Clinical Molecular Imaging, Tuebingen, GERMANY,* [2]*2Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Tuebingen, GERMANY,* [3]*3Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", Tuebingen, GERMANY,* [4]*4Department of General Pediatrics, Hematology and Oncology, University Children's Hospital Tuebingen, Tuebingen, GERMANY,* [5]*5Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", Tuebingen, GERMANY,* [6]*6Department of Diagnostic and Interventional Radiology, Tuebingen, GERMANY.*

***Aim/Introduction:*** The disialoganglioside GD2 is overexpressed in several malignant tumor entities. Since EMA approval in 2017, dinutuximab beta, a GD2 targeting antibody, has been established to treat neuroblastoma (1). Currently clinical trials for the treatment of osteosarcoma (NCT02484443) and initial trials in Ewing sarcoma are ongoing. Due to the variable GD2

expression of tumors and severe side effects of dinutuximab beta therapy, non-invasive evaluation of GD2 expression is highly desirable. To address this issue, a GD2-targeting PET-tracer, [$^{64}$Cu]Cu-NOTA-ch14.18/CHO ($^{64}$Cu-GD2) was developed (2). Here, we evaluated the biodistribution and estimated the dosimetry of the $^{64}$Cu-GD2 PET-Tracer. ***Materials and Methods:*** A total of 11 patients (7 male, 4 male, mean age: 13.9 ± 5.0). Patients had a histology confirmed neuroblastoma (6), osteosarcoma (3) or Ewing sarcoma (2). $^{64}$Cu-GD2 PET/MRI was performed in approximately 21 hours (range: 17-25 hours) after i.v. injection of 2-5 MBq/kg of $^{64}$Cu-GD2. In 6 patients, a second scan was executed 43 hours p.i. (range: 41-44 hours) tumor and organ doses were estimated in the subgroup of patients who had two scans using OLINDA® software. Tissue uptake in organs was quantified by $SUV_{max}$ and $SUV_{mean}$ of a defined spherical volume of interest (VOI), while $SUV_{mean}$ of tumor lesions was evaluated by a 41% isocontour of the $SUV_{max}$. In two patients tumorlesion were resected and stained. ***Results:*** No high-grade side effects were observed; one patient reported minor dizziness. In 9 of 11 patients (81%), suspicious tumor lesions were detected by PET/ MRI. In 8 of these 9 patients (89%) at least one metastasis with an increased $^{64}$Cu-GD2 uptake was detected. A high tumor uptake ($SUV_{max}$ >10) was measured in 4 of 8 patients (50%). In the case of GD2-positive lesions, an excellent tumor to background ratio with at least 6-fold higher uptake was observed in bones, muscles or lungs. The highest organ dose was measured in the liver (mean: 0.15 mGy/MBq; range: 0.04-0.21) while whole body dose was 0.03 mGy/MBq (0.02-0.04). ***Conclusion:*** $^{64}$Cu-GD2 PET is a promising tool to visualize GD2 expression in various cancers. By using the universal NOTA chelator, labeling with $^{177}$Lu seems feasible. Due to uptake values up to SUVmax 30, future considerations of radioimmunotherapy will be possible. Since dinutuximab beta is already an approved therapy for neuroblastoma, $^{64}$Cu-GD2 may be used for therapy stratification. ***References:*** (1) EMA. European public assessment report for Qarziba (2) Schmitt J, Translational immunoPET imaging using a radiolabeled GD2 Theranostics

## OP-315

### Reaching the target dose with one single [$^{131}$I]-mIBG treatment in high-risk neuroblastoma. The determinant impact of the primary tumour

***F. Fiz***[1], *A. Cirone*[1], *S. Righi*[1], *M. Massollo*[1], *L. Amoroso*[2], *G. Bottoni*[1], *M. Conte*[2], *M. Gambaro*[1], *F. Massone*[1], *G. Semino Bruzzone*[1], *S. Orengo*[1], *S. Sorrentino*[2], *A. Garaventa*[2], *A. Piccardo*[1];
[1]*Ospedale Galliera, Genova, ITALY,* [2]*IRCCS Istituto Giannina Gaslini, Genova, ITALY.*

***Aim/Introduction:*** [$^{131}$I]I-MIBG is an efficacious treatment for children with metastasized neuroblastoma (NBL). However, treatment effectiveness is linked to the effective dose absorbed by the target; to achieve a sufficient effect, a 4 Gy whole-body dose threshold has been proposed. Achieving this goal often requires administering [$^{131}$I]I-MIBG twice back-to-back (tandem therapy), which may cause high-grade haematological toxicity. In this study, we tried to assess the factor predicting the achievement of 4 Gy whole-body dose with a single radiopharmaceutical administration. ***Materials and Methods:*** Children affected by metastatic NBL and treated with a high [131I]I-MIBG activity (>450 MBq/Kg) were evaluated retrospectively. Kinetics measurements were carried out at multiple time points to estimate the whole-body dose. The resulting whole-body dose was compared with clinical and activity-related parameters. ***Results:*** Seventeen children (12 girls, median age 3 years, age range 1,5-6,9 years) were included. Eleven of them still bore the primary tumour. They received an average activity of 563±80 MBq of [$^{131}$I]I-MIBG per Kg of body weight. The resulting median whole-body dose was 2,88 Gy (range 1,63-4,22 Gy). There was a direct correlation between the tracer biological half-life and the whole-body dose (R: 0,878, p<0,001); in turn, the volume of the primary tumour was correlated with the [$^{131}$I]I-MIBG half-life. As a result, children who had a "bulky" primary (>30 ml) received a higher whole-body dose than those with smaller or surgically removed primaries (3,42±0,74 Gy vs 2,48±0,65 Gy, respectively p=0,016). Conversely, the correlation between activity/Kg and whole-body dose was moderate (R: 0,42 p=0,093). ***Conclusion:*** These data suggest that the presence of a bulky primary tumour can significantly prolong the [$^{131}$I]I-MIBG biological half-life, effectively increasing the absorbed whole-body dose. This information could be used to model the administered activity, allowing to attain the target dose without the need of a two-step radiopharmaceutical administration.

## OP-316

### Utility and Optimal Scan Time of Diagnostic and Post-therapeutic Whole-Body Scan in Children and Young Adult Patients Administered with Iodine-131

***P. Kumar****, C. Bal, N. A. Damle;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** The utility of Dx-WBS (diagnostic whole-body scan) in patients with differentiated thyroid cancer (DTC) is controversial. The optimal time of acquisition of WBS has not yet been established even extensive routine use of the same in clinical practice. Moreover, the optimal time of WBS acquisition is important in children as it has potential to alter the patient management. The aim of this study was to find out the optimal time of acquisition of WBS of both the diagnostic and post-therapy scan (PTS) in children and young adults with DTC. ***Materials and Methods:*** Children and young adults (≤21 y) with DTC had undergone serial WBS at 24h, 48h and/or ≥72h after diagnostic as well as therapeutic dosage administration. All the serial WBSs were blinded and reviewed by nuclear medicine physicians for detection of lesions. The utility of Dx-WBS and PTS was determined based on the additional lesion(s) that could alter the administered therapy activity of $^{131}$I. The optimal time of acquisition for Dx-WBS/PTS was evaluated based on the first appearance of lesion in $^{131}$I WBS. ***Results:*** Ninety-five children and young adults (M=27; F=68) with mean age of 17.9±3 y were evaluated. Ten patients (10.5%) had no evidence of disease on Dx-WBS and were considered surgically ablated, and hence were excluded from the study. Eighty-five included patients received 74 MBq (2 mCi) of $^{131}$I administered for Dx-WBS followed by the therapeutic activity ranging from 1.11-5.55 GBq (30-150 mCi) $^{131}$I depending on the extent of disease. There were no additional lesions seen on serial Dx-WBS or PTS in patients with intact thyroid lobe and thyroid remnant. In patients with nodal metastases, additional nodes were seen in 2/32 patients in ≥48h Dx-WBS and 1/32 patients in PTS at 72h but was clinically not relevant as it did not alter the Rx dosage of $^{131}$I. The serial Dx-WBS missed pulmonary metastases in 3/17 (17.6%) patients that was visualized in PTSs. The optimal time of acquisition of Dx-WBS and PTS was found to be at 48 h and 72 h, respectively in children and young adult patients with pulmonary metastases. ***Conclusion:*** The Dx-WBS and PTS both appear useful in children and young patients with DTC and should be done at 48h and 72h, respectively.

## OP-317

### SPECT/CT in the diagnosis of Ectopic Gastric Mucosa-Meckel's Diverticulum

***Z. Koç***[1], *P. Özcan*[1], *F. Tuncel*[2], *C. İsbir*[3], *Y. Usta*[4];
[1]*Mersin University Hospital Nuclear Medicine Dpt., Mersin, TÜRKIYE,* [2]*Mersin University Hospital Pathology Dpt., Mersin, TÜRKIYE,* [3]*Mersin University Hospital Pediatric Surgery Dpt., Mersin, TÜRKIYE,* [4]*Mersin University Hospital Pediatric Gastroenterology Dpt., Mersin, TÜRKIYE.*

***Aim/Introduction:*** The imaging of Meckel's Diverticulum (MD) is based of accumulation of Tc-99m pertechnetate in the Ectopic Gastric Mucosa (EGM) content. Although the diagnostic accuracy of this imaging modality is high there are some overlap patients with coexisting gastrointestinal bleeding and false positive causes hampering diagnostic power. Althogh there are several case reports about the diagnostic facility of SPECT/CT in ectopic gastric mucosa determination there are no large studies in the literature (1-3). The aim of this study was to evaluate the possible contribution of SPECT/CT in EGM-MD diagnosis and to determine the indication of this additional imaging modality. ***Materials and Methods:*** 52 pediatric patients (24 girls, 28 boys; mean: 8,06±5,22 years old) who have suspicion of MD and referred for scintigraphy were evaluated retrospectively. Additional SPECT/CT were performed to selected five cases among the group. The results of the scintigraphy as well as SPECT/CT were compared with endoscopy, pathology and/or follow up results. ***Results:*** There were nine patients with equivocal study results, twelve positive results and the others were considered negative MD scintigraphy. One patient was out of follow up and ten patients underwent surgery. Only one single patient was negative during surgery but scintigraphy was also negative. The diagnostic sensitivity, specificity and accuracy were 100%, 95% and 96% respectively. Among 5 patients with SPECT/CT results one patient was only diagnosed by only SPECT/CT who had EGM in duplication cyst, one equivocal patient was diagnosed as descending colon bleeding and one patient's lesion was clearly delineated by SPECT/CT. ***Conclusion:*** SPECT/CT has clear advantages over standard planar scintigraphy imaging in EGM-MD determination. This modality might decrease equivocal and false positive results but this issue has to be addressed with further studies. ***References:*** Yang J, Tian D, Wu L, Dong M, Zhong J.Meckel's diverticulum with polypoid hyperplasia of ectopic gastric mucosa diagnosed by double-balloon enteroscopy and single-photon emissioncomputed tomography/computed tomography.J Int Med Res. 2020 Sep;48(9):300060520955055. ## OP-318

### Re-evaluating the milk scan protocol, perplexing or potentially prognostic?

***K. Hlongwa***[1], *A. Brink*[1], *S. M. Peters*[2], *S. More*[1];
[1]*Red Cross War Memorial Children's Hospital and University of Cape Town, Cape Town, SOUTH AFRICA,* [2]*Groote Schuur Hospital and School of Public Health and Family Medicine, University of Cape Town, Cape Town, SOUTH AFRICA.*

***Aim/Introduction:*** Gastro-oesophageal reflux (GER) and pulmonary aspiration occur in children of all ages. Milk scans have been used for the detection of GER for decades. There are various documented protocols for milk scans in search of GER with no universally accepted protocol. We recently amended our protocol from imaging patients for 30 minutes and assessing gastric emptying at 2 hours to imaging patients for 60 minutes and assessing gastric emptying at 3 hours due to the potential of missing episodes of reflux and overclassifying delayed emptying when normal. This study aims to assess the value of the change in protocol in being able to detect significant number of refluxes. ***Materials and Methods:*** We retrospectively reviewed the scans of all patients who presented for milk scans at the Red Cross War Memorial Children's Hospital from 1 November 2021 to 30 November 2022. The number of reflux episodes detected in patients imaged with the 30-minute protocol in comparison to the number detected with the 60-minute protocol was reviewed. The episodes of reflux were classified with an in-house severity scale and gastric emptying was evaluated at different time intervals. Delayed gastric emptying at 2 hours was quantified as residual activity in the stomach >37% and at 3 hours as >80% emptying into the bowel. ***Results:*** A total of 205 studies were reviewed over the 13-month period. In the 30-minute studies, 400 reflux episodes were observed in 70 patients, 7 were classified as normal, 9 mild reflux, 19 moderate reflux, 35 severe reflux, with 21 patients demonstrating delayed gastric emptying at the 2-hour images. 11/21 patients with delayed gastric emptying had no reflux and 10/21 patients had reflux of varying classifications.In the 60-minute studies, 537 reflux episodes were observed in 65 patients, 16 were classified as normal, 8 mild reflux, 15 moderate reflux, 26 severe reflux with 12 patients demonstrating delayed gastric emptying at the 3-hour images. 8/12 patients with delayed emptying had no reflux and 4/12 had reflux of varying classifications.No statistically significant difference was seen between the detection of refluxes in 30-minute vs 60-minute studies. Chi-Square statistic = 5.201, p-value = 1.57659. ***Conclusion:*** Our findings did not demonstrate an additional benefit of changing the milk scan protocol imaging time. A standardized study comparing similar patient populations with the question of reflux may be valuable in order to establish a common practice.

## OP-319

### Predictive Value of Diuretic Renogram for Progressive Hydronephrosis in Perinatally Detected Unilateral Hydronephrosis

***C. Lin***[1], *P. Chuang*[2], *I. Tsai*[3], *M. Cheng*[4];
[1]*National Taiwan University Hospital, Taipei City, TAIWAN,* [2]*Department of Nuclear Medicine, National Taiwan University Hospital Yunlin Branch, Douliu City, TAIWAN,* [3]*PEDIATRICS National Taiwan University Children Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [4]*Nuclear Medicine National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN.*

***Aim/Introduction:*** The aim of our study was to review the long-term outcome of perinatally detected hydronephrosis and try to find the predictors by first diuretic renogram. ***Materials and Methods:*** We retrospectively analyzed patients who received diuretic renogram with furosemide in a tertiary medical center. Predictive values derived from diuretic renogram included: differentiated renal function (DRF), furosemide half-clearance time ($T_{1/2}$), cortical transit time (CTT) and response to furosemide stimulation (RFS). Decreased DRF was defined as DRF below 45% at the hydronephrotic side. The diuretic $T_{1/2}$ was the time at which the time-activity curve decreases to half its maximal activity. Prolonged isotope washout rate was defined if $T_{1/2} > 15$

minutes. Delayed CTT was defined as the absence activity in the subcortical structures within 3 minutes of tracer injection. Patients were followed at least 2 years to monitor for disease deterioration. The primary endpoint is the time of first occurrence of one of the signs of disease deterioration, defined as urinary tract infection, flank pain, upgraded hydronephrosis defined by Society of Fetal Urology (SFU) grade in serial renal ultrasound (US), or intervention to relieve hydronephrosis. Cox proportional hazard model and Kaplan-Meier Method were applied to identify predictors. ***Results:*** From January 2013 to March 2021, a total of 31 infants (24 boys and 7 girls) received diuretic renogram at mean age of 9.01 ± 9.68 months. Out of 31 patients, disease deterioration occurred in 16 (51.6%) patients and the mean follow-up period was 24.9 months (IQR: 3.4 to 44.9). By Cox regression analysis, decreased DRF was the only factor significantly associated with disease deterioration (HR: 3.501; 95% CI: 1.240 - 9.885; p = 0.018). Patients with decreased DRF (<45%) had shorter time to deterioration of 3.19 ± 2.11 months. In contrast, the median time to deterioration period in patients with preserved DRF (>45%) at the hydronephrotic kidney was not reached at the time of analysis (p = 0.012). ***Conclusion:*** Decreased DRF (<45%) in initial diuretic renogram is a prognostic factor for disease deterioration in children with perinatally detected unilateral hydronephrosis. In addition, lower DRF indicate rapid deterioration, and may need earlier intervention.

**ThyroPIX - Mobile Compton camera based on Timepix3 technology for monitoring of thyroid gland cancer treatment**
***E. Trojanova***[1], *D. Doubravova*[1], *R. Kaderabek*[2], *V. Poriz*[3], *T. Kracmerova*[4];
[1]*ADVACAM s.r.o, Prague, CZECH REPUBLIC,* [2]*Radalytica as.s, Prague, CZECH REPUBLIC,* [3]*Radalytica a.s., Prague, CZECH REPUBLIC,* [4]*Fakultní nemocnice v Motole, Prague, CZECH REPUBLIC.*

***Aim/Introduction:*** Thyroid tumors are relatively rare, but their incidence is steadily increasing in recent times. The goal of preclinical and clinical studies is therefore to find a way to detect and successfully treat this type of cancer early. The main problem is that the current imaging methods don't provide sufficient spatial resolution to reveal the remnants after the chirurgical removal of the gland. Due to their presence the disease relapses. ThyroPIX is a new-generation multimodal device for imaging the thyroid gland and thyroid cancer treatment monitoring. ***Materials and Methods:*** . ThyroPIX is a new-generation multimodal device for imaging the thyroid gland and thyroid cancer treatment monitoring. The ThyroPIX device is equipped with a fully spectral single-photon counting detector of a new generation based on Timepix3 technology which exploits the ability to measure the position, energy, and time of every detected particle. Thanks to this information related to very precise time detection of every incoming gamma photon is possible to determine the position of the interaction of primary and Compton scattered photons in sensitive layers of detector materials. Together with the energy information direction of a primary photon is then calculated and based on the backward reconstruction the source is localized in space.This new imaging method concept called the Compton camera brings possibilities of emission imaging for various types of radioisotopes of a broad range of energies. This approach leads to the development of a unique system without using any other usually necessary equipment (e.g. heavy collimators). Besides the absence of collimators, the main benefits of the novel system include better spatial resolution, low weight, and significantly higher sensitivity. Thanks to the implementation of the detector on a mobile collaborative robotic arm and the execution of either a planar or tomographic image, it will be possible to perform a quick, basic examination of the patient in any part of the hospital. ***Results:*** This contribution presents the imaging system and shows the measured data and its results in the framework of preclinical tests on phantoms. ***Conclusion:*** Thanks to the implementation of the detector on a mobile collaborative robotic arm and the execution of either a planar or tomographic image, it will be possible to perform a quick, basic examination of the patient in any part of the hospital. ***References:*** [1] TURECEK, D., J. ### Quantification of amyloid load from [18F]florbetaben PET scans agrees with histopathology, visual read, and clinical progression

***G. Kolinger***[1], *L. Tiraboschi*[1], *F. Padovano*[2], *D. Braca*[2], *M. Spitilli*[2], *G. Lucidi Pressanti*[3], *S. Bullich*[1], *R. Mazza*[2];
[1]*Life Molecular Imaging GmbH, Berlin, GERMANY,* [2]*Nuclear Medicine Unit, "G. Mazzini" Hospital, Teramo, ITALY,* [3]*Services Department, "G. Mazzini" Hospital, Teramo, ITALY.*

***Aim/Introduction:*** Positron emission tomography (PET) with [18F]florbetaben allows the detection of amyloid-beta (Aβ) plaques in the brain. While quantification of amyloid PET is already commonly done in research studies and clinical trials, quantification can also assist clinicians in interpreting [18F]florbetaben images. However, quantification can be software-dependent, therefore it is important to test available software before clinical use. To this end, this work compared quantitative results from CortexID (v1.6 ext.6, GE Healthcare) with histopathology confirmation of Aβ in the brain, visual read (VR) from five independent readers, and longitudinal progression of clinical status and Aβ load. ***Materials and Methods:*** In total, 338 scans were quantified using the whole cerebellum as reference region and the Composite as target region for the calculation of Standardized Uptake Value Ratio (SUVR). 87 scans of subjects with histopathology confirmation of presence/absence of Aβ plaques in the brain (using a combination of Bielschowsky silver staining and immunohistochemistry as standard of truth) were used to define a Aβ positivity quantitative cut-off using receiver operator characteristic curve analysis. Meanwhile, the scans of 100 healthy control subjects with a consensus negative VR were used to define an early pathology cut-off by the 95% quantile. To assess the concordance between the positivity cut-off and VR, an independent set of 174 images was quantified and evaluated by five independent readers. Finally, 40 subjects with mild-cognitive impairment (MCI) had at least one follow-up scan 1 and/or 2 years after baseline and clinical assessment 2 and/or 4 years after baseline. This cohort was quantified to evaluate longitudinal changes in Aβ load and clinical progression. ***Results:*** Quantitative results agreed with histopathology (sensitivity of 0.94[0.84-0.99] and specificity of 0.94[0.81-0.99]), leading to an optimal positivity cut-off of SUVR=1.24 and an agreement of 95%[92%-99%] with VR. Furthermore, an early pathology cut-off based on healthy controls was found to be SUVR=1.15, therefore quantification below that on the Composite region indicates absence or sparse presence of Aβ plaques in the brain. None of the MCI subjects with Composite SUVR<1.24 at baseline (n=19) progress to Alzheimer's disease (AD) at clinical follow-up. Meanwhile 19 of 21 MCI subjects above the cut-off at baseline progressed to AD. However, the accumulation rate between those groups was not significantly different. ***Conclusion:*** Quantification of [18F]florbetaben amyloid PET scans using CortexID can be a valuable tool as adjunct to VR in cross-sectional settings.

## EPS-086

### 2-layer Hemispheric PET featuring different materials on each layer

***K. Scheiff****, A. Pashazadeh, C. Hoeschen;*
*Otto-von-Guericke-University Magdeburg, Magdeburg, GERMANY.*

***Aim/Introduction:*** Positron Emission Tomography (PET) is used for the diagnostic and research purposes of a wide range of brain diseases, requiring high resolution of about 1mm. To achieve such resolution, brain-dedicated geometries have been proposed and prototyped in recent years. [1] Many of these PET-systems use (hemi-)spherical geometries to minimize the scanner's radius and reach a desired resolution. [2] Like most PET-systems, brain-dedicated geometries commonly utilize detectors with pixelated crystals. However, over the last decade, detectors using monolithic crystals have achieved intrinsic resolutions comparable to pixelated ones. [3] Since the intrinsic resolution of monolithic crystals is related to their thickness, a second layer of detectors can be added to achieve the same total crystal depth as that used in pixelated detectors and to close gaps in the positioning of the first layer. By having pixelated crystals on the inner layer and monolithic detectors on the outer layer, time-of-flight resolution and depth of interaction resolution can be achieved, respectively. Use of two layers also allows the combination of different materials on each layer. In the simulation study, we compared the sensitivity performance of three 2-layer geometries, with different material combinations. ***Materials and Methods:*** The simulation study was conducted using the GEANT4 toolkit GATE. We simulated several 2-layer hemispheric PET-geometries with detectors, employing pixelated crystals in the inner layer and monolithic crystals in the outer layer. To assess the performance of the three crystal combinations, we used LSO-LSO as the benchmark for LSO-BGO, and LYSO-LYSO for LYSO-BGO, and LYSO-LSO as the proposed inner-outer layer crystals. ***Results:*** Depending on the material combination, sensitivity modification differs 6,6% for one of the simulated LSO-BGO geometries and up to 167% for one LYSO-BGO geometries, depending on the activity. ***Conclusion:*** The usage of different materials on each layer shows high enhancement of sensitivity for the two investigated LYSO combinations. Further investigation on the coincidence distribution and impact on measurement precision are highly interesting for improving the sensitivity of 2-layer geometries. ***References:*** [1] Ciprian Catana, Development of Dedicated Brain PET Imaging Devices: Recent Advances and Future Perspectives, J. Nucl. Med. 2019 Aug.; 60(8):1044-1052. [2] Hideaki Tashima et al 2019, First prototyping of a dedicated PET system with the hemisphere detector arrangement, 2019 Phys. Med. ## EPS-087

### Survey of Patient Journeys throughout Nuclear Medicine Services

***A. Brink***[1], *K. Pathmaraj*[2], *M. Marengo*[3], *B. Arends*[4], *Z. Jawa*[5], *R. Jaimovich*[6], *T. Pascual*[7], *S. Rubow*[8], *L. Torres*[9], *S. Vinjamuri*[10], *E. Woodrow*[11], *M. Dondi*[1], *D. Paez*[1];
[1]*International Atomic Energy Agency, Vienna, AUSTRIA,* [2]*Austin Health, Melbourne, AUSTRALIA,* [3]*University of Bologna, Bologna, ITALY,* [4]*Catharina Ziekenhuis, Eindovhen, NETHERLANDS,* [5]*SQUH, Muscat, OMAN,* [6]*Universidada Catolica de Chile, Santiago, CHILE,* [7]*PNRI, Manila, PHILIPPINES,* [8]*University of Stellenbosch, Stellenbosch, SOUTH AFRICA,* [9]*CENTIS, Havana, CUBA,* [10]*Liverpool University Hospital, Liverpool, UNITED KINGDOM,* [11]*Singapore General Hospital, Singapore, SINGAPORE.*

***Aim/Introduction:*** Quality standards in health care are increasing, knowledge and experience in the use of tools for quality management (QM) has to grow accordingly. The International Atomic Energy Agency (IAEA) developed and supported the implementation of the QUality Audits in Nuclear Medicine (QUANUM). The QUANUM portfolio includes the QUANUM

self-assessment and audit-tool, staffing calculator and "the Basics of Quality Management for NM Practices" book, it will be expanded by introducing quality indicators aimed at surveying the overall journey of a patient in a NM Department, integrating the use of patient and referring physician surveys. ***Materials and Methods:*** A QUANUM advisory committee, composed of NM professionals with experience in QM and auditing prepared a Patient Journey Audit Tool (PJAT) based on an audit tool developed and applied at the Department of Molecular Imaging and Therapy, Austin Health, Australia. The IAEA-PJAT, is constructed to monitor all the phases of the process including; referral; procedure justification; booking the appointment; patient and appointment instructions; clinical history assessment; patient consent and preparation; the procedure itself; adverse or unexpected events; deviations from standard practice; post procedure instructions; patient release/discharge; report generation and dissemination. The instrument is suited to monitor diagnostic and therapeutic procedures. "Customer" satisfaction surveys were developed. The patient satisfaction survey comprises 13 questions, with checkboxes to rate an answer and a field for free text comments or suggestions. The referrers survey includes 19 questions, assessing the level of satisfaction of clinical practictioners who refer patients to NM. ***Results:*** The example initiative at Austin Health evaluated over 60 patient journey experiences and resulted in a significant improvement on aspects of medication safety, reducing risk of extravasation and misadministration, helping to keep administered radiopharmaceutical doses under relevant Diagnostic Reference Levels (DRL), and improving timing of NM and PET/CT scans, amongst others. This showed that patient journey audits are essential to prove compliance with regulatory standards, international or national guidelines as well as IAEA recommendations. It is expected that the application of the IAEA-PJAT tool, developed to monitor all the phases of the NM services under the QUANUM umbrella, will contribute significantly to the same goals at a global scale. ***Conclusion:*** The IAEA-PJAT tool will shortly be available at the IAEA's Human Health Campus as a spreadsheet that can be used "as it is" or adapted according to local needs. It is envisaged that this will help improve quality and safety central to patient care.

## EPS-088

### Development of phantom analysis software package for Japanese Society of Nuclear Medicine PET imaging site qualification program

***K. Matsumoto***[1], *H. Daisaki*[2], *S. Yoshida*[3], *K. Nishida*[3], *N. Tamaki*[1]; [1]*Kyoto College Of Medical Science, Kyoto, JAPAN,* [2]*Gunma Prefectural College of Health Sciences, Maebashi, JAPAN,* [3]*Nihon Medi-Physics Co.,Ltd., Tokyo, JAPAN.*

***Aim/Introduction:*** The Japanese Society of Nuclear Medicine (JSNM) certifies PET imaging site for the purpose of standardization of imaging methods and improvement of data reliability in PET imaging [1,2]. It is important to confirm phantom test of procedures and meet the criteria prior a PET imaging site certification before. The purpose of this study was to develop an analysis software "PETquactIE (PET quality control tool of image of image evaluate)" for the brain amyloid [3] and the whole-body FDG imaging [4]. ***Materials and Methods:*** The developed analysis software is capable of semi-automatically analyzing the geophysical evaluations in the phantom test procedure, absolute quantitation, resolution, recovery coefficient, contrast, uniformity, image noise etc., and the analysis results can be displayed and saved. A PETquactIE also has a ROI template to calculate contrast in NEMA Body phantom and Hoffman phantom. The method was evaluated on a diverse set of 10 NEMA and 10 Hoffman phantom PET/CT scans. NEMA phantoms were filled with radioactive tracer solution at 4:1 activity ratio over background, and Hoffman phantoms were filled with 20 MBq of $^{18}$F solution [2]. This analysis software method was compared to the manual analysis of PET phantom images by JSNM experts. ***Results:*** Results of all analyses were comparable to the JSNM evaluations. ***Conclusion:*** A PETquactIE, which allows easy phantom analysis, was considered a useful tool prior to the PET imaging site certification, and could be also used to set conditions for the PET camera. ***References:*** [1] Senda M. Standardization of PET imaging and site qualification program by JSNM: collaboration with EANM/EARL. Ann Nucl Med. 2020;34(11):873-874. [2] Japanese Society of Nuclear Medicine. ### Insertion of Synthetic Lesions for the Clinical Assessment of AI-based reconstruction algorithms

***Q. Maronnier***[1], *A. Latgé*[1], *K. Su*[2], *F. Courbon*[1], *O. Caselles*[1]; [1]*Oncopole Claudius Regaud, Toulouse, FRANCE,* [2]*GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Over the past decade, Artificial Intelligence (AI) solutions spread widely in healthcare especially for clinical application. A deep learning software called Precision Deep Learning (PDL) is available in our nuclear medicine department, but not currently used in clinical practice. This solution simulates Time-Of-Flight effect on PET images for the improvement of small lesion detectability. In this study, we assess the first results of its quantitative impact on clinical data using the Insertion of Synthetic Lesions (ISL) method. ***Materials and Methods:*** The study was performed on the Omni Legend (General Electric Healthcare, Waukesha, WI USA). We selected two 18F-FDG cases of different Body Mass Index (BMI) (20 and 32) and used each one as a baseline for the insertion of 8 synthetic lesions distributed in relevant anatomical locations. For each insertion site, we simulated spherical lesions with varying diameters (6, 8 and 10 mm) and contrasts (4:1, 6:1, 8:1 and 10:1). All resulting datasets were reconstructed using Bayesian penalized likelihood (BPL) reconstruction algorithm without and with PDL. We used the three PDL settings: High (H), Medium (M) and Low (L). These parameters correspond to different levels of contrast-enhancement-to-noise trade off [1]. For each clinical case, we calculated the Signal-to-Noise Ratio (SNR) measured from the liver. We also assessed lesions quantitation by measuring SUVmean with spherical VOIs of the same volume as the corresponding synthetic lesions. Finally, we calculated Recovery Coefficient (RC) from theoretical and measured SUV (RC-SUV) and then compared the results obtained according to the reconstruction algorithm. ***Results:*** PDL application showed enhanced SNR calculated from the liver of each patient. The magnitude of this improvement stems from the PDL parameter used (SNR-Native < SNR-PDL-H < SNR-PDL-M < SNR-PDL-L). Regarding SUV metrics of synthetic lesions, we highlighted an average increase of 20% in RC-SUV using PDL-H, 5% with PDL-M and an average decrease of 7% with PDL-L.

Comparing the results obtained for each patient, we observed a significant improvement for the case presenting the highest BMI. ***Conclusion:*** The ISL method is an efficient tool for assessing the impact of new AI-based software solutions through ground truth. ***References:*** [1] Mehranian A, Wollenweber SD, Walker MD, Bradley KM, Fielding PA, Huellner M, et al. Deep learning-based time-of-flight (ToF) image enhancement of non-ToF PET scans. Eur J Nucl Med Mol Imaging. 2022 Sep 1;49(11):3740-9.

### Anatomy-based correction of kidney PVE on $^{177}$Lu SPECT images

***J. Salvadori***[1], *O. Allegrini*[1], *I. Namer*[1,2];
[1]*Institut de cancérologie Strasbourg Europe (ICANS), Strasbourg, FRANCE,* [2]*ICUBE UMR 7357, Strasbourg, FRANCE.*

***Aim/Introduction:*** In peptide-receptor-radionuclide-therapy (PRRT), accurate quantification of kidney activity on post-treatment SPECT images paves the way for patient-specific treatment. Due to the poor spatial resolution of SPECT images, partial volume effect (PVE) is one of the most important quantitative biases. Thanks to PET research in this area, effective anatomy-based PVE correction techniques are freely available. In this study, we aimed to evaluate the possibility to use these methods for SPECT modality and their performances to recover the accurate activity concentration of realistic kidney geometries on $^{177}$Lu SPECT images recorded in clinical condition. ***Materials and Methods:*** Based on the patients' CT scan data, three pairs of fillable kidneys with surface area-to volume ratio ranging from 1.5 to 2.8 $cm^{-1}$, were 3D printed. A modular fixation system dedicated to the IEC phantom was also modeled and printed. Fully quantitative $^{177}$Lu SPECT/CT recordings were performed for the three modified IEC phantoms and for 6 different kidney-to-background ratios (KBRs: 2, 4, 6, 8, 10, 12) using our optimized clinical protocol for $^{177}$Lu-DOTATATE. Two VOI-based [Geometric Transfert Matrix (GTM) and Labbé (LAB)] and three voxel-based [iterative Yang (IY), multi-target correction (MTC) and region-based voxel-wise correction (RBV)] methods were evaluated on this data set. The kidney recovery coefficients (RCs) were determined from anatomical CT-based segmentations. Additionally, background RC was determined for voxel-based method by using the background ROIs defined in the image quality test of the NEMA NU-2 2018 protocol. ***Results:*** For all recordings, accurate background quantification was achieved with RCs ranged 0.99 to 1.06 (mean 1.04). Without PVE correction, the kidney RCs ranged from 0.62 to 0.84 (mean 0.75). For a KBR of 12, all anatomy-based method were able to recover the kidneys activity concentration with an error < 7%. All methods had a similar degradation of performances with decreasing KBR. Compared with a KBR of 12, the average loss of recovery was 3, 8, 13, 26, and 56% for KBRs of 10, 8, 6, 4, and 2, respectively. The LAB method was the less sensitive to PSF mismatch (mean positive bias of 10% for an overestimation of 4 mm). All others methods had the same behavior (mean positive bias of 14% for an overestimation of 4 mm). Among the voxel-based methods, IY and RBV performed better than MTC in the vicinity of high-gradient areas. ***Conclusion:*** Anatomy-based PVE correction enable accurate SPECT quantification of the $^{177}$Lu activity concentration inside realistic kidney geometries.

## EPS-091

### The optimum earliest total-body 68Ga-FAPI-04 PET scan timing: An evidence-based single-centre study

***Z. Zheng***, *H. Gao, Y. Lin, H. Yu, W. Mao, R. Yang, Y. He, X. Chen, H. Wu, P. Hu, H. Shi;*
*Zhongshan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** We aimed to investigate the optimum earliest positron emission tomography (PET) scan timing after $^{68}$Ga-fibroblast activation protein inhibitor-04 ($^{68}$Ga-FAPI-04) injection to shorten patients' waiting time, reduce patient discomfort, and improve the diagnostic workflow. ***Materials and Methods:*** In this prospective study, we enrolled 30 patients with suspected malignant tumours who underwent 60-min dynamic $^{68}$Ga-FAPI-04 total-body PET/CT scans with reconstruction at 10-min intervals (G0-10, G10-20, G20-30, G30-40, G40-50, and G50-60) and evaluated the $^{68}$Ga-FAPI-04 uptake patterns. The standardised uptake value (SUV), the liver signal-to-noise ratio (SNR), and the lesion-background ratios (LBRs) for the different time windows were calculated to evaluate image quality and lesion detectability. The 30-40 min period was then split into 5-min intervals starting from every minute for further evaluation of image quality. The G50-60 values were considered as the reference. ***Results:*** The SUVmean of normal organs decreased with time. In the images reconstructed at 10-min intervals, the liver SNR decreased with time. Longer acquisition times were associated with lower background uptake and better image quality. Some lesions could not be detected until G30-40. The lesion detection rate, uptake, and LBRs of all lesions did not differ significantly among the G30-40, G40-50, and G50-60 scans (all $P > 0.05$). The SUVmean and LBRs of primary tumours in the reconstructed images obtained at 5-min intervals between 30 to 40 min did not differ significantly; however, for metastatic and other positive lesions, the G34-39 and G35-40 images showed significantly better SUVmean and LBRs than the other images. The G34-39 and G50-60 scans showed no significant differences in lesion uptake, LBRs, and lesion detection rate (all $P > 0.05$). ***Conclusion:*** The optimum earliest time point to start acquisition was 34-min after injection of $^{68}$Ga-FAPI-04. With a reasonable acquisition time, the image quality could still meet diagnostic requirements.

## EPS-092

### Comparison of a 3D printed wall-less phantom with a conventional NEMA phantom for establishing threshold-based segmentation methods

***A. Zounek***[1], *A. Zatcepin*[1,2], *A. Delker*[1], *F. Gildehaus*[1], *A. Bollenbacher*[1], *G. Böning*[1], *P. Bartenstein*[1,2], *N. L. Albert*[1,3,4], *S. Ziegler*[1], *L. Kaiser*[1];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY,* [3]*German Cancer Consortium (DKTK), Partner Site Munich, German Cancer Research Center (DKFZ), Munich, GERMANY,* [4]*Bavarian Cancer Research Center (BZKF), Erlangen, GERMANY.*

***Aim/Introduction:*** Phantoms are an important tool for quality control and calibration of PET systems. Performance measurements are routinely performed according to NEMA standards using phantom designs with fillable inserts. However, previous studies have shown that inactive walls may lead to quantification errors for non-zero background signal [1]. The aim of this work was to confirm whether the NEMA phantom can be reliably applied to establish or validate threshold-based segmentation methods. This was achieved by comparing phantom measurements using the

NEMA NU-2001 PET body phantom with measurements using 3D printed and thus wall-less radioactive spheres [2]. ***Materials and Methods:*** The 3D printed phantom was designed in CAD software to resemble NEMA specifications and manufactured using a stereolithography printer. Radioactive spheres were obtained by mixing [$^{18}$F]FDG with the resin before printing. Images were acquired on a Siemens Biograph mCT PET/CT system with two different background fractions ($BF_{3D}$) of 0.12 and 0.6. To ensure comparability, PET images of the NEMA phantom were acquired according to the EARL accreditation protocol with $BF_{EARL}$=0.1. The conventional NEMA and the 3D printed phantoms were compared using background-corrected volume reproducing thresholds (VRT). ***Results:*** The VRT values were similar for both phantoms in the high contrast images ($BF_{EARL}$=0.1 and $BF_{3D}$=0.12), ranging from 45% to 50% for all six sphere diameters with a mean percentage difference of 3%. VRT values were also similar for both measurements of the 3D printed phantom ($BF_{3D}$=0.12 and 0.6), ranging from 37% to 50% with a mean percentage difference of 7%. ***Conclusion:*** The feasibility of 3D printing as a method for producing radioactive wall-less objects as demonstrated in previous studies [2] was confirmed successfully. The high-contrast NEMA phantom measurement using fillable spheres yielded almost identical VRTs as the measurement with the wall-less spheres phantom and is therefore equally suitable for the validation of threshold-based segmentation methods. Moreover, the measured phantom data confirm the theoretical findings of Hofheinz et al. [1], indicating a low influence of cold walls for high contrast images and predicting that VRT is independent of BF in wall-less phantoms. Objects of higher geometrical complexity and lower contrast, which are potentially stronger affected by wall-related effects, can easily be produced in the future using 3D printing. ***References:*** 1.Hofheinz et al. Effects of cold sphere walls in PET phantom measurements on the volume reproducing threshold. Physics in Medicine and Biology. 2010;55(4):1099-113.2.Gillett et al. 3D printing 18F radioactive phantoms for PET imaging. EJNMMI Physics. 2021;8(1).

## EPS-093

### Discrepancies in commercial Y-90 vial's activity assessments: Monte Carlo simulations provide a possible explanation

***L. Auditore***[1,2], *D. Pistone*[1,2], *A. Italiano*[3,4], *E. Amato*[1,2], *S. Gnesin*[5]; *[1]Department of Biomedical and Dental Sciences and of Morphofunctional Imaging (BIOMORF), University of Messina, Italy, Messina, ITALY, [2]INFN, National Institute for Nuclear Physics, Section of Catania, Italy, Catania, ITALY, [3]Istituto Nazionale di Fisica Nucleare (INFN) - Sezione di Catania, Catania, ITALY, [4]Department of Mathematical and Computer Science, Physical Sciences and Earth Sciences (MIFT), University of Messina, Italy, Messina, ITALY, [5]Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** Selective Internal RadioTherapy (SIRT), also known as Trans-Arterial RadioEmbolization (TARE), performed with resin/glass $^{90}$Y-labeled microspheres, is currently employed worldwide and an accurate determination of the therapeutic administered activity is key in dose/response studies aiming at the optimization of the treatment safety and efficacy. In a recent multicentre study [1] discrepancies between PET/CT measured activity and vendor-calibrated activity for $^{90}$Y glass and resin microspheres were found. This study investigated the possible origin of these discrepancies using Monte Carlo (MC) simulations. ***Materials and Methods:*** We used the GAMOS MC software to model three vial configurations: $^{90}$Y-chloride, $^{90}$Y-labeled glass and resin microspheres, hosted in a commercial activity-meter. For the three considered configurations, we estimated the electric signal per unit of activity (I) generated in the active volume of the activity-meter.We additionally considered the production of Internal Bremsstrahlung (IB) photons, accompanying the beta decay. IB was demonstrated [2,3] playing a relevant role in determining the response of an activity-meter. The electric currents obtained for $^{90}$Y glass ($I_{glass}$) and resin ($I_{resin}$) microspheres were compared in terms of relative percent difference respect to that of $^{90}$Y-chloride ($\varepsilon_{glass}$ and $\varepsilon_{resin}$), and each other ($\delta$). The findings of this work were then compared with the experimental results from the PET multicentre study. ***Results:*** The relative percent differences, $\varepsilon_{glass}$ and $\varepsilon_{resin}$, resulted to be (30.7±5.2)% and (-17.2±2.5)% respectively, while $\delta$ was (57.8±2.4)%. By including IB in the source term the estimates of $\varepsilon_{glass}$, $\varepsilon_{resin}$, and $\delta$ become (24.6±3.9)%, (-15.0±2.2)% and (46.5±1.9)%, respectively. The relative percent difference between glass and resin microsphere activity calibrations, $\delta^*$, obtained by Gnesin et al. [1] is (46.00±0.15)% in a remarkable good agreement with the MC estimates including IB contribution. ***Conclusion:*** Our results corroborate and potentially explain the results reported in a recent multicentre study [1]. The MC simulation estimates indicate that the different geometry of the specific commercial vials and the metrological approach adopted for activity-meter calibration with $^{90}$Y chloride liquid source can explain the reported PET-based experimental discrepancies. Furthermore, IB photons confirmed to play a relevant role in accurately determining the response of the activity-meter. ***References:*** [1] Gnesin S et al. (RI-TE), University of Aveiro Incubator, PCI - Creative Science Park, Ílhavo, PORTUGAL.*

***Aim/Introduction:*** The easyPET.3D [1] is a benchtop Positron Emission Tomography (PET) scanner dedicated to high-resolution imaging of mice, with an exclusive scanning method based on a U-shape board with two axes of motion and two modules of detectors always face-to-face. We present the scanner's performance evaluation following the National Electrical Manufacturers Association (NEMA) NU 4-2008 standard [2]. ***Materials and Methods:*** Each detector module of the scanner consists of a 32 × 2 pixelated LYSO scintillator array with individual crystals measuring 2.0 × 2.0 × 30 mm$^3$. The crystal arrays are coupled to 1.3 × 1.3 mm$^2$ silicon photomultipliers via one-to-one coupling. The transaxial field-of-view (FOV) is adjustable up to 50 mm diameter and the axial length of 72 mm is suitable for imaging whole-body mice. The performance characterization includes the spatial resolution, sensitivity, counting rate performance, scatter fraction, and image quality characteristics. Furthermore, mice were scanned to evaluate the in vivo imaging capability of the easyPET.3D scanner. ***Results:*** The measured spatial resolution at the center of the axial FOV in radial, tangential, and axial directions using full width at half-maximum was 0.94, 0.99 and 0.81 mm

(0.77 $mm^3$), respectively. A peak absolute sensitivity of 0.20% was measured for 100-700 keV energy window. The peak noise equivalent counting rate for the mouse-like phantom was 177 cps at 7 MBq (350-650 keV). The recovery coefficients for 5, 4, 3, 2, and 1 mm diameter rods in the image quality phantom were: 0.64, 0.62, 0.45, 0.23, and 0.15, respectively. The uniformity was 14% and the spill-over ratios in the images of air and water filled chambers were 0.08 and 0.02, respectively. In the additional in vivo experiments, small structures such as striatum in brain imaging and vertebras in bone imaging were resolved proving the scanner's suitability for mice high-resolution molecular imaging. ***Conclusion:*** The easyPET.3D scanner provides a significant improved spatial resolution (0.87 $mm^3$ at a radial offset of 5 mm) over current commercially available preclinical PET scanners (<1-14.2 $mm^3$ at a radial offset of 5 mm). The system is suitable for the low range of activities used for small animal imaging. The overall performance showed that the easyPET.3D can produce high-quality images for preclinical applications. ***References:*** [1] https://www.ri-te.pt/[2] NEMA Standards Publication NU 4-2008, "Performance Measurements of Small Animal Positron Emission Tomographs," National Electrical Manufacturers Association, Rosslyn, 2011.

### Triple and dual PET quantification of a Small-Animal Multi-Pinhole PET/SPECT/CT System

***P. Echegoyen***, *T. Cuenca Bandín, M. Ecay, E. Prieto, M. Collantes, F. Pareja, J. Simón Martínez, I. Peñuelas, J. Martí-Climent;*
*Clínica Universidad de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** Small animal devices offer the possibility to image multiple isotopes simultaneously. However, quantitative accuracy might be affected by physical interferences. The aim was to evaluate quantitative accuracy of dual- and triple-isotope simultaneous acquisitions, combining gamma and positron emitters in a small animal PET/SPECT/CT scanner. ***Materials and Methods:*** Initially, system performance for each of the three isotope under investigation ($^{111}$In, $^{99m}$Tc and $^{18}$F) was characterized in terms of sensitivity, energy resolution and spatial resolution using standard procedures. Then, micro test tubes (~0.17 mL) were filled 4 to 6 MBq of $^{111}$In, $^{99m}$Tc and $^{18}$F. A custom methacrylate phantom was built to place the different sources in adjacent positions and to facilitate the positron annihilation. These sources were acquired individually, and then all possible dual and triple combinations were scanned. Triple acquisition was repeated switching relative positions of the sources. All data were acquired in list-mode with 1 min/bed position. Images were reconstructed with 20% window width for all photopeaks except for the 171 keV $^{111}$In photopeak for which window width was reduced to 15% to avoid overlapping with the 140 KeV photopeak. Images were reconstructed using SROSEM algorithm with filter and voxel size adapted to each radionuclide including decay, scatter and attenuation corrections. Calibration factors, previously obtained from individual sources following manufacturer protocol, were used to convert counts into activity. Images were analyzed with PMOD 4.2. Then, total activity observed in the image for each isotope was calculated and compared to the expected activity. Deviations less than 10 % were considered for acceptance. ***Results:*** Energy resolutions were 10.1% for 140 keV, 10.2% for 171 keV, 10.0% for 245 keV and 8.5% for the 511 keV peak. Measured sensitivities are 0.6 % for $^{99m}$Tc, 0.8 for $^{111}$In and 0.4 % for $^{18}$F. Spatial resolution of gamma emitters was better (0.8 mm for $^{99m}$Tc and 0.9 mm for $^{111}$In) than for $^{18}$F (1.1 mm). Quantification errors obtained for the single acquisitions were [-0.8, 4.8] %. For dual acquisitions, error increased slightly to [-6.8, 7.1] % being higher for $^{99m}$Tc and $^{111}$In affected by Compton scattering of higher energy photons. The same tendency was observed for the triple-isotope scan, where quantification error increased to [1.1, 8.8] %. ***Conclusion:*** Quantitative accuracy was preserved in simultaneous dual- and triple-isotope PET/SPECT acquisitions despite physical interferences between isotopes.

## EPS-096

### ComBat harmonization in different PET imaging scenarios

***M. Gandia-Ferrero***[1], *I. Torres-Espallardo*[2,1], *S. Prado-Wohlwend*[2], *B. Martínez-Sanchis*[2], *E. Muñoz*[3], *C. Morera*[3], *P. Bello-Arques*[2], *M. Vázquez-Martínez*[2], *S. Ginés-Cárdenas*[1], *Á. Almendros-Riaza*[1], *L. Martí-Bonmatí*[2,1];
[1]*Health Research Institute La Fe, Valencia, SPAIN,*
[2]*La Fe University and Polytechnic Hospital, Valencia, SPAIN,* [3]*Oncovision, Valencia, SPAIN.*

***Aim/Introduction:*** The extraction of quantitative information from PET images is fundamental and aids in the establishment of objective threshold values. Nowadays, different PET systems provide varying quantitative values based on many scanner parameters. Due to the increasing number of PET procedures, many hospitals have different PET devices in the same center, so there is a need to harmonize these images to get reproducible results regardless of the device. The main aim of this study is to evaluate the potential effects of harmonizing key features extracted from PET images on the diagnosis outcomes. ***Materials and Methods:*** Harmonization was performed in 2 different scenarios: for an oncology and a neurology application. In the former, 25 [68Ga]Ga-DOTA-TOC PET images form patients with uncommon neuroendocrine tumours were acquired in the same day both on a PET/CT and a PET/MR device. Since tumour uptake must be greater than the liver uptake for [177Lu] Lu-DOTA-TATE Peptide Receptor Radionuclide Therapy to be considered, SUVmax measurements from the liver and 125 lesions were harmonized between both scanners. The kappa coefficient was calculated to compare the devices agreement. In the latter, 80 [18F]FDG PET brain images were acquired in the same day both on a PET/CT and a brain-dedicated PET scanner. Since for the diagnosis of neurology diseases the SUVr values are used, those of 27 brain ROIs were harmonized between both devices. Bland-Altman analysis for each ROI was performed before and after harmonization. All data was collected from the Nuclear Medicine service of our hospital. The harmonizing technique used for the analysis was ComBat. Three different reference systems have been used for harmonization, including using each device and an arbitrary reference. ***Results:*** The kappa coefficient (k) assessed on the [177Lu]Lu-DOTA-TATE therapy consideration before harmonization was k = 0.54 (moderate agreement), and after harmonization, selecting the PET/CT, the PET/MR, and an arbitrary reference system, k was equal to 0.68 (substantial agreement), 0.04, and 0.19 (insignificant agreement), respectively. In contrast, on the harmonization of the 28 ROI SUVr values between PET/CT and brain-dedicated PET, while the Bland-Altman analysis revealed differences when comparing between both devices (e.g. Basal_Ganglia_Right: 15%; average difference: 6%) excellent results were provided after harmonization (average differences: 0%) whatever reference system was selected. ***Conclusion:*** Harmonization is a powerful tool that should be used when comparing results from different scanners to obtain information that can provide a reproducible analysis. However, choosing the appropriate variables to harmonize is crucial.

## EPS-097

### Elimination of not yet Reported Artifacts in Myocardial Perfusion Imaging Studies on Semiconductor Cardiac Gamma Camera by Covering Radiopharmaceutical Injection Site with a Shield

***A. Owczarek***[1], *P. Cichocki*[1], *Z. Adamczewski*[1], *A. Plachcinska*[2]; *[1]Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND, [2]Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Myocardial perfusion imaging (MPI) is one of the most common studies in nuclear medicine used in diagnosis of coronary artery disease (CAD). Dedicated cardiac gamma cameras with semiconductor detectors perform MPI faster and acquire higher quality images than traditional cameras. However, while working on the device for a long time, a previously unreported artifact, caused by residual activity of the radiopharmaceutical in injection site (RAiIS) in cubital fossa caught in the camera field of view (FOV) was observed. ***Materials and Methods:*** Study included 39 patients, referred for MPI using Discovery NM 530c cardiac gamma camera in last quarter of 2022, in whom RAiIS was observed in stress or rest study. In such cases image acquisition was immediately repeated, without moving the patient or changing camera settings, with injection site covered by a thyroid shield with extra layers of lead (4,5mm in total). All 39 patients were male, aged 40 to 83, and examined in routine, two day stress-rest protocol in prone position, with head and arms placed on a dedicated support. Acquired images were assessed by two experienced nuclear medicine physicians (separately for studies with and without the shield) and evaluated using a 0-4 point scale in each segment (where 0 - normal perfusion and 4 - total absence of perfusion). Summed stress, rest and difference scores (SSS, SRS and SDS, respectively) were calculated for the whole myocardium and 3 main vascular territories. ***Results:*** SSS, SRS and SDS were assessed as abnormal most often in RCA territory, least often in LCx territory. Activity in injection site was observed more often in stress studies (31/39 cases). Elimination of this artifact changed the assessment of SSS, SRS or SDS from normal to abnormal or vice versa in almost 20% of studies. LAD and RCA vascular territories were affected the most often. For stress-induced perfusion defects, in 8% of assessed vascular territories initially found defects were no longer present after applying the shield, while in 5% using the shield revealed previously invisible defects. ***Conclusion:*** Artifacts caused by RAiIS reduce the image quality and can potentially generate or obscure perfusion defects. They can be observed in patients examined in prone position, with radiopharmaceutical injected in the area of cubital fossa. Lead shield used in this study effectively mitigated them. Using such shielding or avoiding cubital fossa as injection site should be considered in patients examined in prone position.

## EPS-098

### Match/mismatch between aortic Na[$^{18}$F]F uptake on PET and macrocalcifications on CT

***G. van Praagh***[1], *M. Davidse*[2], *J. M. Wolterink*[2], *R. H. J. A. Slart*[1]; *[1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS.*

***Aim/Introduction:*** Sodium[$^{18}$F]fluoride (Na[$^{18}$F]F) has been shown to bind to active atherosclerotic processes. The evidence on the presentation of vascular Na[$^{18}$F]F in clinical PET/CT is limited. Therefore, the aim of this study is to establish a match/mismatch score between calcified plaque content on CT and Na[$^{18}$F]F-uptake on PET in the aorta. ***Materials and Methods:*** In total, 186 Na[$^{18}$F]F-PET/CT scans were retrospectively collected. The aorta was manually segmented on low-dose CT from the aortic valve to the iliac bifurcation. A publicly available deep learning algorithm was used to segment the vertebrae in each CT image.[1] The vertebral mask was dilated by 10 mm and subtracted from the aortic mask to avoid skeletal spill-over of Na[$^{18}$F]F. For each patient, calcium HU values were retrieved using a 130 HU threshold on CT and Na[$^{18}$F]F-hotspot values using an adaptive 50% $SUV_{peak}$ threshold on PET. To get a population image of the distribution of these values, all aortic masks were registered onto one patient using SimpleElastix.[2] Heatmaps for Na[$^{18}$F]F-uptake and calcium were made by obtaining a surface mesh and projecting the masks from the centerline onto the surface. For every surface point, a Spearman's correlation with Bonferroni correction was done between calcium values and Na[$^{18}$F]F values of that point and its 500 closest points. Besides, in every slice in every patient, target-to-bloodpool ratios (TBR) were calculated within the calcium masks and in the aortic wall except the calcium masks. ***Results:*** A strong positive correlation (r=0.77, P<0.0001) was found between the calcium values and Na[$^{18}$F]F values on the population image. Of all locations, 79% had a correlation above zero (63% P<0.05), of which 25% above 0.6 (all P<0.05), whereas 21% was below zero (9% P<0.05) and 0% below -0.6. Calcifications were most clearly present in the inferior abdominal aorta and the inferior aortic arch. For most Na[$^{18}$F]F-uptake this was similar (match), but also in the superior abdominal aorta. Significantly higher TBR values were found outside the calcium masks than inside the calcium masks (P<0.0001) (mismatch). ***Conclusion:*** This in-depth analysis of clinical Na[$^{18}$F]F-PET/CT images demonstrated a high match in location of macrocalcifications detectable on CT and Na[$^{18}$F]F-uptake on PET. Contrarily, a mismatch was found of uptake inside and outside the macrocalcifications. This might suggest that Na[$^{18}$F]F is taken up in noncalcified plaques, but not in late-phase calcified plaques. The population image provides additional insight in the uptake pattern of Na[$^{18}$F]F in the population. ***References:*** 1. doi:10.1016/j.media.2019.02.005; 2. doi:10.1109/CVPRW.2016.78

## EPS-099

### Metabolic connectivity changes of patients with post-COVID-19 condition: a reorganization of the olfactory cognitive pathway?

***M. Doyen***[1,2], *T. Horowitz*[3], *A. Bruyere*[4], *F. Goehringer*[4], *A. Verger*[1,2], *E. Guedj*[3]; *[1]Department of Nuclear Medicine and Nancyclotep Imaging Platform, CHRU Nancy, F-54000 Nancy, FRANCE, [2]Université de Lorraine, IADI, INSERM U1254, F-54000 Nancy, FRANCE, [3]Nuclear Medicine Department, Aix-Marseille University, APHM, CNRS, Centrale Marseille, Institut Fresnel, Timone Hospital, CERIMED, Marseille, France, Marseille, FRANCE, [4]Department of Infectious Diseases, CHRU Nancy, 54000, Nancy, FRANCE.*

***Aim/Introduction:*** Post-COVID-19 condition could be associated with a brain network impairment from olfactory pathway. The aim of this study was to evaluate the metabolic changes of connectivity in post-COVID-19 conditions patients. ***Materials and Methods:*** One hundred and eighty patients (48.5±11.8 years old, 112 women) with post-COVID-19 condition having performed a brain 18F-FDG PET in two French centers (113 in Marseille, 67 in Nancy) were included. Brain 18F-FDG PET scans of patients were compared with age and sex-matched healthy controls (respectively 56 and 64 in Marseille and Nancy) using voxel-to-voxel groups comparisons. Metabolic connectivity of post-COVID-19 condition patients, as compared to those of

healthy controls, was studied through seed correlations of the maximal cluster extracted from the group's comparisons and sparse inverse covariance estimations (SICE). ***Results:*** Patients with post-COVID-19 condition showed hypometabolisms in the bilateral temporal lobes with a right predominance, the right thalamus, the right fronto-orbital cortex, the brainstem and the cerebellum (p-voxel<0.005, corrected for the cluster volume). Seed correlations from the maximal hypometabolic cluster involving the right temporal lobe and the cerebellum showed increased connectivity with the cerebellum and the left thalamus and decreased connectivity with bilateral temporal lobes and the prefrontal cortex especially in the olfactory gyri. SICE confirmed these findings with an increase connectivity between the prefrontal cortex, the cerebellum, the thalamus and the brainstem, observed in both the whole population and in each center respectively, and a decreased of connectivity of temporal lobes, especially the right one, with the right fronto-orbital cortex. ***Conclusion:*** The study of metabolic connectivity in post-COVID-19 conditions patients shows a switch of connectivity within the hypometabolic post-COVID-19 network with a decrease of connectivity from the temporal lobes, preferentially the right one and with the olfactory cortex and an increase of connectivity within the cerebellum, the thalamus and the brainstem. These findings suggest a reorganization of the cognitive olfactory pathway.

### Impact of $^{68}$Ga-specific PET Reconstruction on Image Quality of Patient Data

***P. Gavriilidis***[1,2,3], *A. Marinus*[4,1], *M. Koole*[3], *T. W. Deller*[5], *F. P. Jansen*[5], *F. M. Mottaghy*[6,1,2], *R. Wierts*[1,2];
[1]*Maastricht University Medical Center, Maastricht, NETHERLANDS,* [2]*Maastricht University, Maastricht, NETHERLANDS,* [3]*Katholieke Universiteit Leuven, Leuven, BELGIUM,* [4]*Eindhoven University of Technology, Eindhoven, NETHERLANDS,* [5]*GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA,* [6]*RWTH University Hospital, Aachen, GERMANY.*

***Aim/Introduction:*** In recent years, the utilization of $^{68}$Ga in clinical positron emission tomography (PET) imaging has increased. However, in comparison to the commonly used $^{18}$F, $^{68}$Ga features higher positron range (PR) affecting image quality. We present a positron range correction (PRC) method to enhance $^{68}$Ga PET image quality and quantification. ***Materials and Methods:*** The PR distribution profile of $^{68}$Ga in water was determined using Monte Carlo simulations and modeled as a spatially invariant Gaussian function. Of this function, the FWHM was calculated. PRC was performed by adding this to the Gaussian filter applied in the image space of the Hybrid-Space PET Point Spread Function (Hybrid PSF) [1] after subtracting the FWHM of $^{18}$F. $^{68}$Ga-specific Hybrid PSF ($^{68}$Ga-specific PSF) reconstructions were introduced as corrections to OSEM+PSF (2 iterations, 34 subsets) and Q.Clear (β=700) and were compared to the clinical used non-corrected corresponding reconstructions. The SUVmean (50% threshold of SUVmax) and SUVpeak (1 mL sphere with highest uptake) were calculated for 38 lesions from 10 patients administered with $^{68}$Ga-PSMA or $^{68}$Ga-DOTATOC. For each lesion, the contrast-to-noise ratio (CNR) was defined as the difference between the mean lesion activity concentration and mean background activity concentration scaled by the background noise. Wilcoxon signed rank test (α=0.05) was performed. ***Results:*** Analysis on all lesion showed that for both OSEM and Q.Clear reconstructions $^{68}$Ga-specific PSF significantly increased the CNR (16%; 11%) and SUVpeak (3%, 7%). For OSEM, $^{68}$Ga-specific PSF reconstructions showed similar increase in CNR (15-17%) and SUVpeak (3%) for $^{68}$Ga-DOTATOC and $^{68}$Ga-PSMA (both 19 lesions). For Q.Clear, $^{68}$Ga-specific PSF showed higher increase for $^{68}$Ga-DOTATOC compared to $^{68}$Ga-PSMA the CNR (13% vs 9%) and similar increase for SUVpeak (6-8%). SUVmean values only showed significant increase for Q.Clear (9% $^{68}$Ga-DOTATOC, 3% $^{68}$Ga-PSMA), but not for OSEM which can be explained by a slower rate of convergence of the $^{68}$Ga-specific PSF reconstruction. For both OSEM and Q.Clear, lung lesions (4 lesions) showed smaller, non-significant, changes in CNR (6% OSEM, 6% Q.Clear) and SUVpeak (-1% OSEM, 5% Q.Clear) compared to the significant changes observed in soft-tissue (26 lesions; CNR:17% OSEM, 10% Q.Clear; SUVpeak:3% OSEM, 6% Q.Clear) and bone lesions (8 lesions; CNR:16% OSEM, 17% Q.Clear; SUVpeak: 6% OSEM, 10% Q.Clear). ***Conclusion:*** PRC of $^{68}$Ga improves the quality and quantification of $^{68}$Ga PET patient data. ***References:*** [1] T. W. Deller et al., IEEE Nucl Sci Symp Conf Rec, 2021, pp. 1-5.

### Clinical evaluation of a deep learning-based CT-free attenuation and scatter correction

***S. Xue***[1], *H. Zhou*[1], *R. Guo*[2], *M. Viscione*[1], *A. Rominger*[1], *B. Li*[2], *K. Shi*[1];
[1]*University of Bern, Bern, SWITZERLAND,* [2]*Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** The burden of ionizing radiation is a significant concern in the practice of positron emission tomography/computed tomography (PET/CT) imaging, which limits its application in many situations. Deep learning (DL)-based methods have been proposed as a substitute for CT-based PET attenuation and scatter correction for CT-free PET imaging [1]. However, evaluation based on physical metrics alone is inadequate. The purpose of this study is to systematically evaluate the clinical potential of the developed CT-based PET attenuation and scatter correction method. ***Materials and Methods:*** Whole body PET images of 359 patients using $^{18}$F-FDG, $^{18}$F-PSMA, $^{68}$Ga-DOTA-TOC, $^{68}$Ga-DOTA-TATE, $^{68}$Ga-FAPI, acquired with clinical PET scanners, including Biograph Vision (Siemens Healthineers), United Imaging uMI 780 (United Imaging), Discovery MI (General Electric Healthcare) in Shanghai and Bern, were included for the clinical evaluation. DL-corrected PET images were compared to reference locations of clinically or pathologically proven metastases to determine the normalization score for each lesion and the normalization score for each case. ***Results:*** Among all tested methods, the Decomposition-based DL method achieved the highest mean score (98.9), outperforming both the conventional 2D DL (90.9) and 3D DL (77.8). From the CT-based corrected PET scans, a total of 1018 lesions were detected, with the highest number of true positive markings observed for the Decomposition-based DL method (965), followed by 2D (820) and 3D (765) DL. False positives were also detected for some cases (117 for 2D, 125 for 3D, and 65 for Decomposition-based DL). Case studies of uptake lesions revealed the superior lesion detection sensitivity of the Decomposition-based DL method, particularly in internal organs such as the liver, lungs, and spine. ***Conclusion:*** The clinical evaluation of various external imaging tracers on different scanners confirms the effectiveness and robustness of the Decomposition-based DL method, although the observed missing lesions in some cases require further development. ***References:*** [1] Guo, R. et al., Nat Communications 13, 5882 (2022).

## EPS-102

### Influence of coils and attenuation correction methods on the performance and image quality of a preclinical PET/MR insert

***C. Kuntner***[1], *J. Friske*[1], *A. Stessl*[2], *M. Haas*[3], *L. Breyer*[1], *T. Wanek*[1], *M. Hacker*[1], *T. Helbich*[1], *I. Rausch*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*University of Applied Science, Wiener Neustadt, AUSTRIA,* [3]*Bruker BioSpin Preclinical Imaging Division, Ettlingen, GERMANY.*

***Aim/Introduction:*** Quantitative PET/MR imaging relies on applying different corrections to the PET data to obtain reliable and reproducible results. These corrections typically include normalization, decay correction, randoms correction, scatter- and attenuation correction whereby the last two rely on the knowledge of the material distribution within the scanner. In simultaneous PET/MR scanners, attenuation correction (AC) can be deduced from the MR images and predefined attenuation templates of hardware parts. However, MR-based AC is still not optimized for any imaging, and the RF coils within the PET field-of-view (FoV) may influence the scanner's performance. Therefore, the aim was to test the influence of coils and AC on the performance of a preclinical PET/MR insert. ***Materials and Methods:*** Scanner performance was evaluated using the NEMA NU-4-2008 [1] standard for assessing sensitivity, spatial resolution, noise-equivalent count (NEC) rate, and image quality. All measurements were done with three different RF coils within the PET FoV: mouse-dedicated, rat-dedicated (not PET-optimized), and big-rat-dedicated coil. In addition, the accuracy of the AC was quantitatively tested using homogeneously filled phantoms of different sizes and activity. ***Results:*** Peak absolute sensitivity depended on the presence of the different coils, whereas the spatial resolution measurements did not depend on the coils' presence. The mouse phantom NEC curve (peak 441.2 kcps at 29.3 MBq) was highest when the mouse-dedicated coil was in place. The rat phantom-based NEC curve was tested using only the rat-dedicated coils and exhibited the NEC peak of 203.1 kcps at 27.5 MBq (big-rat-dedicated coil). Activity concentrations in the NEMA IQ phantom were underestimated when using standard MR-AC, which was attributed to the absence of the phantom walls in the generated μ-maps. For the uniformly filled phantoms with wall thicknesses <1 mm, AC works fine. ***Conclusion:*** We conclude that the presence of the RF coils only slightly influences the performance of the PET/MR insert, with the most prominent variation seen for the not PET-optimized coil. AC based on generated μ-maps performed well for the uniformly filled phantoms with negligible wall size. ***References:*** [1] National Electrical Manufacturers Association. NEMA Standard Publication NU 4-2008: Performance Measurements of Small Animal Positron Emission Tomographs. Rosslyn, VA: National Electrical Manufacturers Association; 2008.

## EPS-103

### Impact of patient size on image quality of OSEM3D and BSREM reconstruction in [$^{68}$Ga]Ga-DOTA-TATE PET/MR

***C. P. W. Cox****, T. Brabander, F. A. Verburg, M. Segbers;*
*Erasmus MC, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Previous [$^{18}$F]FDG and [$^{68}$Ga]Ga-DOTA-TATE PET/CT studies using ordered subset expectation maximization (OSEM3D) based reconstruction algorithms, demonstrated non-linear relations between body weight and image quality [1-3]. Block Sequential Regularized Expectation Maximization (BSREM) algorithm reduces noise amplification during reconstruction. The impact of the reconstruction algorithm on the relation between image quality and patient size in digital [$^{68}$Ga]Ga-DOTA-TATE PET may differ from OSEM3D. The amount of activity administered to the patient is usually adjusted based on this relationship with patient size. Therefore, the aim of this study is to investigate the relation between patient size and image quality in OSEM3D and BSREM [$^{68}$Ga]Ga-DOTA-TATE PET/MR reconstructions. ***Materials and Methods:*** This study included prospective 20 and respective 28 patients who underwent a diagnostic [$^{68}$Ga]Ga-DOTA-TATE PET/MR (1.5MBq/kg and 3 (≤70kg) or 4 (≥71kg) minutes per bedposition), which was reconstructed with both OSEM3D (VUE Point FX, SharpIR, 28 iterations, 4 subsets and a 7mm Gaussian filter) and BSREM (factor β=450). PET image quality was determined by the signal-to-noise ratio (SNR) in the right liver lobe. This ratio was normalized for injected activity and acquisition time (SNRnorm). Curve fitting between SNRnorm was used with body weight, body length, body mass index, body weight/body length and lean body mass using two power fits, a nonlinear two-parameter model $\alpha p^{-d}$ and a linear single-parameter model $\alpha p^{-0.5}$. Akaike's corrected information criterion (AICc) model selection was applied to select the preferred model. ***Results:*** OSEM3D image SNR (mean=9.8±1.8, range=8.2)was significantly (t(47)=3.7, p<0.001) lower than BSREM SNR (mean=11±2.0, range=8.2). Body mass, the best predictor for both algorithms, clarified 58% (nonlinear with α=39 and d=1.0) and 43% (linear with α=4.4) of the variance in image SNR for OSEM3D. Whereas, body mass clarified only 24% of the variance for BSREM (both nonlinear with α=3.5 and d=0.44 and linear with α=4.6). AICc preferred the nonlinear (probability of correct=99.7%) model for OSEM3D. ***Conclusion:*** Body mass is the best predictor of digital PET/MR [$^{68}$Ga]Ga-DOTA-TATE image quality for both BSREM and OSEM3D. Although, this prediction is weaker for BSREM. Minimizing the effect of patient size on PET/MR [$^{68}$Ga]Ga-DOTA-TATE image quality for BSREM and OSEM3D might require different body mass adjusted dose regimens. ***References:*** 1.deGrootEH, PostN, BoellaardR, WagenaarNR, WillemsenAT, van DalenJA. ### Impact of 2.5-dimensional Deep Learning for Zero-TE MR-based Attenuation Correction on Chest FDG PET/MRI: Comparison with Conventional and 2-dimensional Deep Learning Approach

***M. Tachibana***[1], *M. Nogami*[2,3], *H. Matsuo*[1], *M. Nishio*[1], *J. Inukai-Inoue*[1], *F. Zeng*[1], *T. Kurimoto*[4], *K. Kubo*[2], *T. Murakami*[1,2];
[1]*Kobe University Graduate School of Medicine, Kobe, JAPAN,* [2]*Department of Radiology, Kobe University Hospital, Kobe, JAPAN,* [3]*Division of Medical Imaging, Biomedical Imaging Research Center, University of Fukui, Fukui, JAPAN,* [4]*GE Healthcare, Hino, JAPAN.*

***Aim/Introduction:*** Conventional magnetic resonance-based attenuation correction by 2-point Dixon MR images in the chest may underestimate the standardized uptake value (SUV) compared with positron emission tomography/ computed tomography due to the lack of bone components. In our previous study, pseudo-CT (pCT) with bone components from 360 ZTE-MRI training data set using the 2-dimensional (2D) deep learning (DL) method including unsupervised generative adversarial networks (GAN) yielded

μmaps with bone components ($\mu map_{bone\text{-}2D}$) in combination with conventional bone-lacking μmaps ($\mu map_{no\text{-}bone}$) in the chest. This study aimed to assess the feasibility of pCT and μmap ($\mu map_{bone\text{-}2.5D}$) from ZTE using 2.5-dimensional (2.5D) DL method and compare the quantitative values of the normal tissues and lesions between $\mu map_{no\text{-}bone}$-, $\mu map_{bone\text{-}2D}$-, and $\mu map_{bone\text{-}2.5D}$-besed reconstruction. ***Materials and Methods:*** Thirty-six cases with paired fluorine-18 fluorodeoxyglucose ZTE PET/MRI and PET/CT were retrospectively evaluated to compare the mean SUV (SUVmean) of the normal bone and liver in the chest region. Twenty-seven cases with lesions on chest FDG PET/MRI were also retrospectively assessed to compare the maximum SUV (SUVmax) of lesions in four regions: the lungs, mediastinum, extra-thorax, and bone. For the 2.5D method, the value of a loss function in the GAN was calculated for each of the three consecutive 2D slices, and the weighted sum of those was defined as the 2.5D loss function. Each μmap was applied to PET reconstruction on the offline workstation. The Wilcoxon signed-rank test was used to assess the SUVmean and the SUVmax. The similarity of the histogram by $\mu map_{no\text{-}bone}$, $\mu map_{bone\text{-}2D}$ and $\mu map_{bone\text{-}2.5D}$ to CTAC was estimated by the correlation coefficients. The image-quality of $pCT_{bone\text{-}2D}$ and $pCT_{bone\text{-}2.5D}$ was evaluated by two radiologists using a three-point scoring system regarding bone delineation and bone continuity. ***Results:*** The SUVmean by $\mu map_{bone\text{-}2.5D}$ was significantly larger than $\mu map_{bone\text{-}2D}$ in the normal bone and the liver ($p=0.0009$, $p< 0.0001$). The SUVmax by $\mu map_{bone\text{-}2.5D}$ was significantly larger than $\mu map_{bone\text{-}2D}$ in all regions ($p= 0.0176$). The correlation coefficients of the histogram for $\mu map_{bone\text{-}2.5D}$ and $\mu map_{bone\text{-}2D}$ were significantly higher than $\mu map_{no\text{-}bone}$ in the bone ($p<0.0001$). The image-quality scores of $pCT_{bone\text{-}2.5D}$ for bone delineation and bone continuity were significantly higher than $pCT_{bone\text{-}2D}$ in both readers ($p= 0.0106$, $p< 0.0001$). ***Conclusion:*** $\mu map_{bone\text{-}2.5D}$ are assumed to yield smaller differences in SUV with $\mu map_{CT}$ than $\mu map_{no\text{-}bone}$ and $\mu map_{bone\text{-}2D}$ in normal tissues and lesions. The result supports the feasibility of using the 2.5D method for the generation of bone components from ZTE with DL.

***Aim/Introduction:*** PET/CT studies with 18F-Choline are mainly performed to localize parathyroid glands adenomas. Scintigraphy with 99mTc-sestamibi is the elective examination to study neoformations and identify abnormal and ectopic parathyroid tissue in the neck area. Occasionally, further investigations with high-resolution methods, such as PET/CT with 18F-Choline, might be necessary. This paper aims to provide our centre's radiographers with a practical guidance on double PET/CT acquisition examinations for parathyroid adenomas after findings with conventional imaging (parathyroid scintigraphy or ultrasonography). ***Materials and Methods:*** In our nuclear medicine unit, PET/CT acquisition protocol for studying parathyroids with Choline-F18 is performed through two different scans executed at standard time intervals in order to assess and evaluate SUV changes.Patients were included in the study based on the following procedure1. Blood glucose level examination showing values below 180 mg/dl;2. Injection of Choline-F18, 3.4 mBq/Kg3.Patients had to wait in a comfortable area before the examination;4.First acquisition, 5 minutes after injection;5.Second acquisition, with the same parameters, 60 minutes after the injection.Both acquisitions started from the vertex to the liver domes; acquisition time was 4' for each bed. ***Results:*** After examining a sample of 30 patients (18M, 12F, age 28-73), a new protocol to optimize parathyroids 18F-Choline PET/CT examination was developed in 2022. This allowed us to best evaluate and compare 18F-Choline absorption in the scanned area with specific and standard time intervals. The results concerning the 2021 study allowed us to standardize two acquisitions performed after 5 and 60 minutes to evaluate the choline washout times at the level of the parathyroid glands. ***Conclusion:*** Our findings show that double acquisition leads to an optimal radiopharmaceutical kinetics evaluation, and the highest Choline-F18 uptake occurs at 60 min after injection. In particular, these acquisition parameters allow us to carry out an accurate qualitative assessment of SUVmax and average over the area of interest. After the completion of this study, an internal acquisition protocol was also drafted. The double acquisition allows us to understand a real data on the parathyroid washout after first acquisition. In order to optimize the procedure, patients that have to undergo this examination are generally scheduled at the end of the F18-choline daily session, so that double scans can be performed without interruption.

### OP-324

**Reduction of scan time in $^{18}$F-FMM PET/CT-scans in the diagnosis of Alzheimer's disease**

***J. Terzic***[1,2], *J. K. Fuglsang*[2], *R. Ismail*[3];
[1]*Vejle Hospital, Vejle, DENMARK,* [2]*Aalborg University, Aalborg, DENMARK,* [3]*Odense University Hospital, Odense, DENMARK.*

***Aim/Introduction:*** Alzheimer's disease (AD) is the most common form of dementia. The protein β-amyloid is a diagnostic biomarker for AD. Patients with AD have an increased accumulation of β-amyloid in cerebrum. $^{18}$F-Flutemetamol ($^{18}$F-FMM) PET/CT scans are used to provide information about the accumulation of β-amyloid in cerebrum. This information is strongly correlated with post mortem findings. The relatively long scan time of 20 minutes may result in cooperation difficulties which can cause movement artifacts. This can affect image quality and the diagnostic accuracy. For this patient group it may be beneficial to reduce the scan time. The aim of this study was to investigate, via visual and quantitative evaluation, whether reduced scan times for $^{18}$F-FMM PET/CT scans affected the diagnostic accuracy in the diagnosis of AD. ***Materials and Methods:*** The $^{18}$F-FMM PET/CT scans were performed at the Department of Nuclear Medicine, Vejle Hospital. 25 patients were included in this study. 185±2.4 MBq $^{18}$F-FMM was injected intravenously 88.9±3.3 minutes prior to the PET scan. PET data was acquired in list mode and CT was used for attenuation correction. The acquisition time for the PET scan was 20 minutes in accordance to international guidelines. The images were reconstructed into periods of 10, 15 and 20 minutes which resulted in three sets of data per patient. A blinded, experienced nuclear medicine physician visually evaluated the

scans as positive, negative or borderline. Standard uptake value ratios for 13 auto segmented regions in cerebrum were used for quantitative evaluation of the scans. Pons was used as the reference region. Friedman's test was used for statistical analysis, to test whether there was a significant difference between the three scan times. For the post hoc analysis a Wilcoxon test with Bonferroni correction was applied. The concordance between visual and quantitative evaluation was furthermore evaluated. ***Results:*** There was no significant difference in the diagnosis between 10, 15 and 20 minutes scan times in the visual evaluations, nor in the quantitative evaluations (p>0.05 in all 13 regions). The concordance between the visual and quantitative evaluations was 80-84%. ***Conclusion:*** Visual and quantitative evaluation showed no significant difference in the diagnosis of AD between 10 or 15 minutes scan times compared to 20 minutes scan time. Based on these findings a reduced scan time may have potential for use in clinical practice. This may reduce cooperation difficulties for patients with AD.

## OP-325

### Optimization of TOF-BPL reconstruction using clinical images in [18F]flutemetamol amyloid PET

***S. Fukuda***[1], *K. Miwa*[2], *K. Wagatsuma*[1,3], *Y. Yakushiji*[1], *T. Yamao*[2], *Y. Kamitaka*[3], *T. Hasegawa*[1];
[1]*Kitasato University Graduate School of Medical Sciences, Kanagawa, JAPAN,* [2]*Fukushima Medical University, Fukushima, JAPAN,* [3]*Tokyo Metropolitan Institution of Gerontology, Tokyo, JAPAN.*

***Aim/Introduction:*** Bayesian penalized likelihood reconstruction with Q.Clear and time-of-flight (TOF-BPL) are useful for oncological, but not brain images acquired using positron emission tomography (PET). The β value controls the global strength of noise suppression, whereas the γ factor in the relative difference penalty (RDP) controls the degree of edge preservation in Q.Clear. Block sequential regularized expectation maximization (BSREM) is applied in Q.Clear as an optimizer. Here, we optimized the γ factor and iteration number in BSREM to acquire amyloid PET images using a phantom. This study aimed to confirm quantitative values in [18F]flutemetamol images and further optimize TOF-BPL reconstruction for amyloid PET. ***Materials and Methods:*** We analyzed imaging data from 30 patients who were positive (n = 13) or negative (n = 17) for amyloid and assessed by [18F]flutemetamolPET. All data were reconstructed using Duetto toolbox (GE HealthCare) running on MATLAB All data were reconstructed under the following algorithms and conditions: the γ factor 2 (β value, 300; iteration, 8; with PSF), γ factor 5 (β value, 500; iteration, 1; without PSF), and γ factor 10 (β value, 800; iteration, 1; without PSF). The β values and iterations of γ factors 5 and 10 were optimized in a previous phantom study. We calculated composite standardized uptake value ratios (SUVr) using the pons as a reference region, then the Centiloid scale (CL). Correlation coefficients were calculated between the composite SUVr and the CL in three γ factors, and areas under receiver operating characteristic (ROC) curves (AUC) were calculated for SUVr and CL. ***Results:*** The SUVr was increased slightly more by γ factor 5, than 2 and 10. The CL of γ factors 5 and 10 were slightly lower than that of γ factor 2. The coefficient correlations were higher for γ factors 5 and 10 than 2. The AUCs for SUVr and CL were almost identical under γ factors 5 and 2, and lower under γ factor 10. ***Conclusion:*** A γ factor > 2 in TOF-BPL was appropriate, and TOF-BPL reconstruction without PSF, γ factor = 5, β = 500, iterations, 1, and PSF OFF were the optimal conditions for [18F] flutemetamol.

## OP-326

### Influence of the number of iterations on image quality and semiquantitative accuracy in [18F]FDG PET imaging using a Long Axial Field-of-View PET/CT system

***M. van der Vegt***, *R. A. J. O. Dierckx, A. W. J. M. Glaudemans, J. van Sluis;*
*University Medical Centrum Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Long Axial Field-of-View (LAFOV) PET/CT systems are characterised by increased sensitivity, resulting in improved image quality. Improved performance characteristics of LAFOV PET have been shown to allow reduction in activity administration and/or shorter scan duration while maintaining image quality in terms of signal-to-noise ratio and semiquantitative accuracy [1, 2]. However, to date, the influence of the number of iterations on image quality using a LAFOV PET/CT has not been evaluated yet. Therefore, the aim of the current study was to explore the influence of the number of iterations on image quality and semiquantitative accuracy in [18F]FDG PET imaging using a LAFOV PET/CT system. ***Materials and Methods:*** So far, six oncological patients underwent a 3-min listmode [18F]FDG PET/CT acquisition and received a weight-based activity injection of 2 MBq/kg. PET data were reconstructed using European Association of Nuclear Medicine Research Ltd. (EARL) 2 compliant settings with various iterations: 2, 4, 6, 8, and 10. Six tumour lesions and liver tissues were segmented [AWJM1] using in-house developed software to obtain Standardized Uptake Values (SUV), Coefficient of Variation (COV) in the liver and Tumour to Background Ratio (TBR). Also the maximum intensity projection (MIP) images were visually assessed on image quality. ***Results:*** Median $SUV_{max}$ of the tumour lesions increased from 9.42 to 9.93 from 2-10 iterations, respectively, with almost no difference between 6-10 iterations. The median $SUV_{peak}$ increased even less. From 2-10 iterations the median COV increased from 4.2% to 8.7%, respectively, with the largest increase between 4 to 6 iterations. The highest TBR was seen in the images reconstructed using 8 and 10 iterations, however there is merely a 5% increase in TBR between from 2-10 iterations. Also, image quality MIPs in all cases are sufficient for diagnostic purposes, but the noise was considered higher when having more iterations. ***Conclusion:*** The number of iterations influence noise levels in the obtained images resulting in the highest COV in the images reconstructed using 10 iterations, whereas TBR improved slightly with the number of iterations. Because of the largest increase in COV between 4-6 iterations, we recommend to use 4 iterations or less to obtain optimal image quality with minimal interference of noise. Future research will determine the influence of the number of iterations on convergence rate. ***References:*** [1] van Sluis J et al. Eur J Nucl Med Mol Imaging. 2022 Nov;49:4652-4660. ## OP-327

### Comparison of the quadratic scheme suggested by EANM guidelines and manufacturer-recommended dose factor for Fluorine-18 FDG imaging on PET-CT system with SiPM detectors: evaluation on image quality

***A. Hurtado de Mendoza***, *M. Yaryes, C. Soza-Ried, H. Amaral;*
*Positronmed, Santiago, CHILE.*

***Aim/Introduction:*** The aim of this study is to compare the Fluorine-18 FDG activity determined by the quadratic scheme suggested by the European Association of Nuclear Medicine (EANM) guidelines with the manufacturer-recommended dose factor for PET-CT imaging. Additionally, we aim to evaluate the impact of these dose factors on image quality, measured by

signal-to-noise ratio (SNR) tumor-to-background ratio (TBR), Coefficient of Variation (COV), and Exposure Internal Dose (EID) in mSv to assess radiation protection. ***Materials and Methods:*** We included 60 oncology patients, divided into two groups of 30 each. The first group underwent FDG PET imaging with the manufacturer-recommended dose factor of 0.06 mCi/kg/body weight, while the second group received activity of 0.08 mCi/kg/body weight, determined using the quadratic linear method following the technical note provided by the EANM. Image acquisition parameters, including 4 iterations, 5 subsets, 4-mm Gaussian filter, OSEM PSF + TOF reconstruction method, and 1 minute per bed, were kept constant for both groups. We measured SNR and COV in the liver and TBR. Lesions were evaluated by nuclear medicine physicians with over 10 years of experience, using VOI isocontour with a threshold of 41% for SUVmax. SNR and TBR were compared between the two groups using Wilcoxon Test. For COV, we used descriptive statistics and considered values under 15% as acceptable for both groups. EID was compared using Student's t-test. ***Results:*** SNR values were significantly higher in the group receiving 0.08 mCi/kg/body weight compared to the group receiving 0.06 mCi/kg/body weight ($p < 0.01$). In contrast,TBR values did not show significant differences between groups ($p = 0.74$). The internal exposure dose was significantly higher in the group receiving 0.08 mCi/kg/body weight compared to the group receiving 0.06 mCi/kg/body weight ($p < 0.05$). The COV values remained below 15% in both groups. ***Conclusion:*** Our study shows that digital PET-CT technology allows the use of the manufacturer-recommended dose factor of 0.06 mCi/kg/body weight for FDG imaging without compromising image quality. Our findings demonstrate that there is no significant impact in TBR between the two dose factors, which is crucial for accurate lesion evaluation. Furthermore, COV values are acceptable for both methods. From a radiation protection perspective, the 0.06 mCi/kg/body weight dose factor may result in lower internal exposure dose (mSv) to patients. Therefore, we recommend using the manufacturer-recommended dose factor for FDG PET imaging to achieve optimal image quality while minimizing radiation exposure to patients. ***References:*** 1. https://doi.org/10.1186/s40658-016-0135-5.

## OP-328

### The Impact of a New Breathing Movement Correction Method On FDG Uptake and Volume Determination of Body Lesions

***M. Schiavini***[1], *F. Buffoni*[1], *M. Bardo*[1], *M. Giavarini*[2], *D. Capolongo*[1], *R. Leo*[1], *M. Rognoni*[1], *C. Sdraiati*[1], *L. Sembele*[3], *M. Castellani*[1];
[1]*IRCCS Fondazione "Cà Granda" Osp. Maggiore Policlinico di MILANO, Milan, ITALY,* [2]*UNIMI, Milan, ITALY,* [3]*Latvian Maritime Medical Center, Riga, LATVIA.*

***Aim/Introduction:*** Patient's respiratory movement is a common problem occurring during whole body PET/CT (WB-PET/CT) images acquisition. Due to overestimation of lesion volume and underestimation of radiotracer concentration, this kind of artefact generates not only an important loss of the image quality but also leads to a change of PET and CT quantitative parameters. ***Materials and Methods:*** [$^{18}$ F] FDG PET/CT (Biograph Vision 450 Siemens) images of sixty-four patients with one or more hyper-enhancing lesions (chest and/or abdomen) were retrospectively analysed over the last four months. Two sets of reconstructed WB images with and without OF respiratory gating were processed. After a visual comparison of the PET/CT fused images quality of two image sets, a manually delineation of an iso-contour volume of interest (VOI) was obtained. Standardized uptake values (SUVs) of the lesions along with their metabolic volumes were calculated. ***Results:*** A more precise correspondence between focal FDG uptake area and CT profile of the lesions was found at WB-OF reconstructed images. An increase of the percent mean variations of SUVmax and SUVmean (13.74% ± 11.44%) and a decrease of volumes (-39.21% ± 45.20%) were respectively calculated at WB-OF images in comparison to standard WB image group. ***Conclusion:*** Our data indicated that the DDG methods and particularly OF-AI may reduce the effects of respiratory artefacts, leading to a better quality of images and to a different FDG uptake values and lesion volumes, in comparison to WB images obtained without OF reconstruction.

## OP-330

### Occupational Radiation exposure from PET/CT during patient positioning

***R. Siyanbola****, M. Coelho, P. Fragoso Costa, A. Moraitis, K. Herrmann, H. Hautzel;*
*Department of Nuclear Medicine, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY.*

***Aim/Introduction:*** Due to increasing PET/CT throughput rates occupational radiation exposure (ORE) to technicians is of major interest. Previously, both tracer injection and patient positioning contributed almost equally to the radiation exposure and accounted for more than 90% of the total dose [1]. Nowadays injection-related exposure is negligible due to automated i.v.-application systems. Therefore, patient handling is now the main ORE source. Aim of this ongoing project is to identify factors leading to increased dose exposure in the course of PET/CT patient positioning. ***Materials and Methods:*** Dose rates using a FH 40 G-L 10 Survey Meter (Thermo Fisher Scientific, USA) and the time being with the patients were collected during (1) accompanying the patient into the scanner room and positioning her/him in the PET/CT (inPET-procedure) and (2) taking the patient out of the scanner/scanner room (outPET-procedure). From these variables total dose per procedure were calculated. Further data collected were: type of disease, injected activity, time point of injection, time point into the scanner, time point out of the scanner. After testing for normality two-sided t-tests and Spearman's Rho correlational analyses were calculated whenever appropriate. ***Results:*** Up to now 44 consecutive patients were included, predominately suffering from lung or prostate cancer. Patients were positioned in the PET/CT 61±17 min after injection of 240±45 MBq [$^{18}$F]-labelled tracers. After 88±17 min patients were removed from the scanner. Measures for inPET-procedure were: time consumption 2.9±1.9 min, dose rate 26.8±11.2 µSv/h, ORE 1384±1623 nSv per procedure. Results for outPET-procedure were: time consumption 1.4±0.8 min, dose rate 14.2±8.0 µSv/h, ORE 413±622 nSv per procedure. outPET-procedure was significantly faster than inPET-procedure. Consequently, ORE was correlated with the type of procedure but not with the injected activity or type of disease. Decay correction of the inPET-procedure dose rate to the time point of the outPET-procedure resulted in 23.2±9.5 µSv/h. Of note, that was still significantly higher than the dose rate of the outPET-procedure. ***Conclusion:*** From our preliminary data one might infer that the inPET-procedure is about twofold more time-consuming than the outPET-procedure. However, its contribution to the total ORE is threefold indicating that not only timing matters but potentially also the distance between the technician and the patient during positioning within the scanner. This assumption is supported by the fact that even the decay corrected dose rate of the inPET-procedure is significantly higher than the corresponding outPET-procedure dose rate. ***References:*** [1] Costa P.F. et al.; Radiat Prot Dosimetry. 2018;179(3):291-298

## OP-331

### Eye lens exposure of nuclear medicine technologists during PET/CT procedures: compliance with dose limits and eye lens vs whole-body dosimetry

***M. Ryser***, *S. Figueiredo, S. Medici, J. O. Prior, N. Cherbuin; CHUV, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** Following the recommendations of the International Commission of Radiological Protection, the Swiss Radiological Protection Regulation drastically decreased the annual equivalent dose limit for the eye lens from 150 to 20 mSv for workers professionally exposed to ionizing radiation. Eye lens exposure can be either measured by dedicated dosimeters worn close to the eye or extrapolated from whole-body dosimeters worn on the chest. The aim of this work was to quantify the annual eye lens dose of nuclear medicine technologists performing different PET/CT-related activities in our department and determine whether the dose extrapolation from the chest-worn dosimeter provides a conservative approximation of the eye lens exposure. ***Materials and Methods:*** This study was performed on a monthly basis using optically-stimulated luminescent (OSL) passive dosimeters: one whole-body worn on the left side of the chest allowing to retrieve $H_p(10)$, $H_p(0.07)$ and $H_p(3)$ and two eye lens (left and right) calibrated in $H_p(3)$. A total of 17 technologists wore two sets of dosimeters during their work routine on a digital PET/CT: one set for the technologist at the console acquisition (T1) and the other for the technologist in charge of patient care, including radiopharmaceutical injection (T2). ***Results:*** According to our preliminary results obtained over a 3-month surveillance period, approximately 85% of the monitored procedures involved F-18 while the remaining were performed with Ga-68. The radionuclides were bond to different vectors and 42% of the injections were performed manually, while 58% were performed using an automatic injector (administered activity 2 MBq/kg). The monthly normalized $H_p(3)$ for T1 were 4.0 µSv/GBq and 4.2 µSv/GBq for the left and right eye respectively, and 5.3 µSv/GBq and 6.5 µSv/GBq for T2. Thus, the predicted annual eye lens doses are significantly below the legal dose limits, with a maximum estimated $H_p(3)$ for T2 of 2.52 mSv for the right eye. For T1, the ratio between $H_p(3)$ provided by the eye lens (left and right) and whole-body dosimeters was 0.67 and 0.70, respectively. For T2, these values were 0.78 and 0.95. ***Conclusion:*** The annual eye lens legal dose limit is unlikely to be exceeded by the technologists for the PET/CT procedures and workload considered during this study. Given the predicted eye lens dose, a dosimetric surveillance based on the whole-body dosimeter is sufficient. The whole-body dosimeter generally provides a conservative estimator of the eye lens dose.

## OP-332

### Radioligand Therapy with [$^{177}$Lu]Lu-PSMA I&T in the Elderly - Safety, Efficacy and Prognosticators of Survival

***S. Weber***[1], *A. Seitz*[2], *H. Kübler*[2], *A. K. Buck*[1], *R. A. Werner*[1,3], *P. E. Hartrampf*[1];
[1]*University Hospital Wuerzburg, Department of Nuclear Medicine, Wuerzburg, GERMANY,* [2]*University Hospital Wuerzburg, Department of Urology and Paediatric Urology, Wuerzburg, GERMANY,* [3]*Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Peak rate of prostate cancer (PC) is above 75 years of age, rendering elder patients as the main target population for novel treatment options. We aimed to evaluate safety and efficacy of prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) using [$^{177}$Lu]Lu-PSMA I&T in individuals of minimum 75 years of age, including predictors of overall survival (OS). ***Materials and Methods:*** We identified 56 men (≥75 years) affected with metastatic castration resistant PC (mCRPC), which were treated with PSMA RLT using [$^{177}$Lu]Lu-PSMA I&T. Adverse events were classified according to the Common Terminology Criteria for Adverse Events (CTCAE) v5.0, by investigating haematological (platelets, leukocytes, haemoglobin) and renal (eGFR, creatinine) parameters. In addition, baseline liver enzymes (aspartate aminotransferase [AST], alkaline phosphatase [AP]), lactate dehydrogenase (LDH), C-reactive protein (CRP), and Gleason-Score were also recorded. PSA response was evaluated by comparing PSA levels from baseline and last available follow-up (n=43). We performed univariable cox regression, followed by multivariable analyses to determine an association with OS. ***Results:*** Median age at 1$^{st}$ cycle was 78 years (range, 75-95 y) with an initial Gleason Score of 8 (5-10). Median 3 (range, 1-9) cycles of RLT were administered using a median cumulative activity of 18.2 GBq (range, 4.9-54.8 GBq) [$^{177}$Lu]Lu-PSMA I&T. Median decrease for platelet counts, leucocytes and haemoglobin was 11.4%, 7.4% and 6.2%, respectively. After RLT, the following grade I/II haematologic CTCAE were recorded: anaemia in 21%, followed by leukocytopenia in 17%, and thrombocytopenia in 7%. eGFR decreased by 2.5%, with respective grade I/II CTCAE in 19% (creatinine increase by 5%; creatinine CTCAE grade I/II, 14%). No CTC grade ≥III occurred. 33/43 (76.7%) exhibited a PSA decrease of median 57% (range, 0.6 - 99%), with the vast majority (22/33 [66.7%]) achieving a decline by more than 50%. Median OS was 11 months, while 32/56 (57.1%) patients died. Univariable analysis provided the following significant parameters: PSA, CRP, LDH, AST, AP, haemoglobin (p<0.05, each). In multivariable cox regression, baseline CRP (per mg/dl, Hazard Ratio [HR], 1.233 [95%CI 1.098-1.373]; P<0.001), PSA (per ng/ml, HR, 1.001 [95%CI, 1.000-1.002]; P<0.01), and LDH (per U/l, HR, 1.001 [95%CI 1.000-1.002]; P<0.02) remained significant, indicative for an independent prognostic value for OS. ***Conclusion:*** RLT with [$^{177}$Lu]Lu-PSMA I&T is safe in elderly patients (above 75 years of age) and showed comparable outcome to previously published data. Initial lower PSA, lower CRP and lower LDH were associated with longer OS in those patients.

## OP-333

### Evaluation of Nephrotoxicity of Extended Lu$^{177}$-PSMA in Patients with Metastatic Castration-Resistant Prostate Cancer

***E. Topal***[1], *B. Kovan*[1], *D. Has Simsek*[1], *C. Civan*[1], *M. Sanli*[2], *M. Basaran*[3], *Y. Sanli*[1];
[1]*Istanbul University, Istanbul Medical Faculty, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University, Istanbul Medical Faculty, Department of Urology, Istanbul, TÜRKIYE,* [3]*Istanbul University, Oncology Institute, Department of Medical Oncology, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** We aimed to investigate the effect of extended Lu$^{177}$-PSMA radioligand treatment (PSMA-RLT) on renal function in patients with metastatic castration-resistant prostate cancer. ***Materials and Methods:*** The cohort included 54 patients who received ≥4 cycles of PSMA-RLT. All patients underwent post-treatment whole body and SPECT/CT images at 4$^{th}$, 24$^{th}$ and 96$^{th}$ hours after each cycles. Renal dosimetry for

each cycles were calculated using the OLINDA/EXM 1.1 program. Pre and post-treatment blood creatinine values were measured and nephrotoxicity was graded according to CTCAE v4.0. Risk factors for nephrotoxicity included pre-existing renal disease, comorbidities and history of chemotherapy and radiotherapy were recorded. ***Results:*** Median of PSMA-RLT cycles was 6 and the number of cycles of PSMA-RLT were 4 in 13 patients, 5-8 in 38 patients and 9-10 in 3 patients. The median age was 71 (range, 54-89) years and the median baseline creatinine value was 0.83 mg/dL (range,0.5-2,19). Median of cumulative renal dose (cRD) of 4 cycles in 54 patients was 12.71 Gy (IQR: 4,83). After 4 cycles, maximum cRD was 20,64 Gy. In 38 patients who received 5-8 cycles, median of cRD was 21.8 Gy (IQR:7,15) and maximum cRD was 35,1 Gy. In 3 patients who received 9-10 cycles, median of cRD was 39.1 Gy (IQR:7,5) and maximum cRD was 44,27 Gy. According to CTCAE v4.0, none of the 54 patients received grade 2 or more than 2 nephrotoxicity. After PSMA-RLT, 13 patients (24%) had grade 1 nephropathy. Of those, 5 patients had grade 1 nephropathy at baseline. In 8 patients, who developed grade 1 nephropathy, median and maximum cRD were 23,25 and 44,27 Gy, respectively. 7 patients (13%) received cRD more than 28 Gy without any severe nephrotoxicity. ***Conclusion:*** Our results showed that extended PSMA-RLT is safe for renal function. PSMA-RLT could be continued in patients who responded treatment with personalized dosimetric evaluation without any severe nephrotoxicity. Maximum cumulative renal doses of PSMA-RLT should be determined in prospective, multi-centric studies.

## OP-334

### Safety and Efficacy of Extended $^{177}$Lu-PSMA Therapy: Multi-Center Retrospective Analysis

***T. Telli***[1,2,3], *R. Seifert*[1,2,3], *C. Lapa*[4], *T. Hekimsoy*[5], *W. Weber*[5], *C. Pfob*[4], *K. Herrmann*[1,2,3], *K. Rahbar*[6], *M. Eiber*[5], *W. Fendler*[1,2,3];
[1]*Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY,* [2]*German Cancer Consortium (DKTK), University Hospital Essen, Essen, GERMANY,* [3]*West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Augsburg, Augsburg, GERMANY,* [5]*Department of Nuclear Medicine, University Hospital of Munich Technical University, Munich, GERMANY,* [6]*Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY.*

***Aim/Introduction:*** Therapy continuation or re-challenge with $^{177}$Lu-PSMA is a viable option for patients with favorable response to $^{177}$Lu-PSMA therapy. This study aims to determine the feasibility, efficacy, and safety of continuous or re-challenge $^{177}$Lu-PSMA extended therapy. ***Materials and Methods:*** In this multicenter study, we retrospectively analyzed 111 patients who were treated with more than six cycles of either continuous (n=43) or re-challenge (n=68) $^{177}$Lu-PSMA therapy at the Nuclear Medicine Departments of Munich Technical University, University Hospitals Essen, Münster, and Augsburg. The primary endpoints of the study were to analyze efficacy with overall survival(OS)and therapy response, as well as the safety of extended therapy options of $^{177}$Lu-PSMA. PSA response was assessed after 8-12 weeks after first therapy cyle. Biochemical partial response(PR) was defined as at least 50% decrease of PSA value, while progression(PD)was defined as any increase from baseline. Any other differences were considered as biochemical stable disease(SD). The severity of adverse events was graded according to Common Terminology Criteria for Adverse Events (CTCAE) v5.0 criteria. ***Results:*** Median cumulative doses for continuous and re-challenge therapy patients were 57.4(IQR: 51.6-59.5) and 60.8(IQR: 54.9-73.1) GBq. The estimated median OS from the beginning of initial therapy of the total cohort was 31.3 months (95% CI: 26.3-36.3) and the projected two-year OS rate was estimated 69%. For the continuous therapy group estimated median OS from the beginning of the first $^{177}$Lu-PSMA administration was 23.2 months(95% CI: 20.4-25.9). For the rechallenge therapy group estimated median OS from the beginning of the first $^{177}$Lu-PSMA administration and from the beginning of rechallenge therapy were 40.2(95% CI: 31.8-48.7) and 20(95% CI: 11.8-28.3) months, respectively. Biochemical PR, SD, and PD 8-12 weeks after the first $^{177}$Lu-PSMA cycle were seen in 10/42(23.8%), 21/42(50%), 11/42(26.2%) in the continuous therapy group, and 37/65(56.9%), 24/65(36.9%), 4/65(6.2%) in re-challenge therapy patient group, respectively. 8-12 weeks after the first re-challenge $^{177}$Lu-PSMA cycle biochemical PR, SD, and PD were seen in 22/63(34.9%), 22/63(34.9%), 19/63(30.2%), respectively. Grade 3 anemia, thrombocytopenia, leukocytopenia, neutropenia, and decrease in GFR occurred in 7/43(16.3%), 3/43(7%), 1/43(2.3%), 1/39(2.6%) 2/43(4.7%) for continuous therapy group and 12/68(17.6%), 2/68(2.9%), 2/67(3%), 0(0%), 5/68(7.4%) for rechallenge group. One patient(1.5%) in the re-challenge group had grade 4 thrombocytopenia. ***Conclusion:*** Patients who received more than 6 cycles of $^{177}$Lu-PSMA therapy presented a median OS of 31.3 months with favourable toxicity . In selected patients with favorable initial response and better response biomarkers, $^{177}$Lu-PSMA treatment continuation or re-challenge is feasible.

## OP-335

### AcTION: A phase 1 study of [$^{225}$Ac]Ac-PSMA-617 in men with PSMA-positive prostate cancer with or without prior [$^{177}$Lu]Lu-PSMA-617 radioligand therapy

***M. Sathekge***[1], *M. Crumbaker*[2], *A. M. Joshua*[2], *F. Bruchertseifer*[3], *T. Kreisl*[4], *S. Emeneni*[5], *J. Wehbe*[6], *M. Korn*[4], *A. Morgenstern*[*3,7], *L. Emmett*[*2,7];
[1]*University of Pretoria and Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA,* [2]*St Vincent's Hospital, Sydney, AUSTRALIA,* [3]*European Commission, Joint Research Centre, Karlsruhe, GERMANY,* [4]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, UNITED STATES OF AMERICA,* [5]*Novartis India, Hyderbad, Telangana, INDIA,* [6]*Novartis Institutes for BioMedical Research, Basel, SWITZERLAND,* [7]**Co-senior author, GERMANY, AUSTRALIA.*

***Aim/Introduction:*** Lutetium ($^{177}$Lu) vipivotide tetraxetan ([$^{177}$Lu]Lu-PSMA-617; $^{177}$Lu-PSMA-617) plus standard of care (SoC) significantly prolongs radiographic progression-free survival (rPFS) and overall survival relative to best SoC alone in patients with prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer (mCRPC). The AcTION study will assess the novel PSMA-targeted radioligand [$^{225}$Ac]Ac-PSMA-617 ($^{225}$Ac-PSMA-617), which delivers PSMA-guided $^{225}$Ac, a high-energy α-emitter able to create DNA double-strand breaks. ***Materials and Methods:*** AcTION (NCT04597411) is an international, open-label, dose-escalation, phase 1 study. The primary endpoint is to determine the recommended phase 2 dose and schedule of administration of $^{225}$Ac-PSMA-617 in men with progressive PSMA-positive mCRPC with or without prior exposure to $^{177}$Lu-PSMA-617. Approximately 60 patients with PSMA-positive disease (determined by [$^{68}$Ga]Ga-PSMA-11 positron emission tomography/computed tomography) will be assigned to one of three groups (20 patients per group): (A) prior chemotherapy/androgen receptor pathway inhibitors (ARPI) received, no prior $^{177}$Lu-PSMA-617; (B) naïve to chemotherapy and novel ARPI; (C) prior $^{177}$Lu-PSMA-617. Enrolled patients will receive intravenous

$^{225}$Ac-PSMA-617 once every 8 weeks (±1 week) for a maximum of 6 cycles. Dose escalation will proceed using a Bayesian logistic regression model with a starting dose of 4 MBq. Subsequent dose levels will increase by 2 MBq increments to a maximum of 10 MBq. The lowest dose tested will be reduced to 2 MBq if required. In each group, at least three patients will be treated at each dose and evaluated for ≥ 6 weeks before consideration of patient enrolment into the next dose. The maximum tolerated dose will be that at which the posterior probability of targeted toxicity exceeds 50% (≥ 6 patients treated at this dose and observed for 6 weeks) or at which a minimum of 15 participants have already been treated in the trial. Patients may also receive supportive care, including palliative radiation therapy, but cannot receive concurrent anti-cancer therapies. Secondary endpoints are overall safety and tolerability, response according to RECIST v1.1 (overall response rate, duration of response, disease control rate), progression-free survival (radiographic disease progression, clinical progression and prostate specific antigen progression), biochemical response, and health-related quality of life (HRQoL). Safety follow-up will be performed approximately 60 days following the final dose of $^{225}$Ac-PSMA-617, or before any subsequent anti-cancer treatment. Long-term follow-up will include HRQoL, survival and treatment update every 3 months (± 1 month) for 12 months.

## OP-336

### Prediction of resistance to PSMA-617 Lu-177 by assessment of circulating tumor DNA biomarkers

***O. Sartor***[1], *E. Ledet*[2], *M. Huang*[1], *J. Schwartz*[2], *A. Lieberman*[2], *B. Lewis*[2], *J. Layton*[2], *A. Jang*[2], *O. Pocha*[2], *S. Lanka*[2], *M. Hawkins*[2], *K. Harris*[2];
[1]*Mayo Clinic, Rochester, MN, UNITED STATES OF AMERICA,*
[2]*Tulane University, New Orleans, LA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Response to radiopharmaceuticals remains incompletely understood despite pre-treatment imaging being a well established biomarker. Herein we explore the possibility of using circulating tumor DNA (ctDNA) as a prognostic biomarker for metastatic castrate resistant prostate cancer (mCRPC) treated with PSMA-617 Lu-177 (PSMA Lu-177) + standard of care (SOC). ***Materials and Methods:*** Blood for ctDNA (Guardant360 assays) was obtained <50 days before treatment with PSMA Lu-177 + SOC. This assay uses deep sequencing to assess mutations in 83 genes, deletions in 7 genes, and amplification in 17 genes. All assessed genes are implicated in cancer growth, progression, and/or metastases. PSMA Lu-177 responses were assessed by PSA declines (>50% decline or not). Patients selection for treatment used VISION criteria for inclusion/exclusion. ***Results:*** Fourty-four patients had baseline ctDNA. Of these 28/44 (63.6%) had a PSA response., whereas 16/44 (36.3%) did not. Unresponsive patients were more likely to have amplifications detected in their ctDNA assays; 75% vs 39.2% (P=0.03). When examining alterations on a gene by gene basis, three genes were distinct. Amplification in CCNE1 and FGFR1 and pathogenic mutations in CDK12 were more frequently detected in patients without a PSA response. A total of 0% of responders had CCNE1 amplification vs 31.2% of non-responders (P=0.004). Responders had 0% FGFR1 amplifications vs 25% of non-responders (P=0.01). For CDK12, 3.6% of responders were pathologically mutated compared to 25% of non-responders (P=0.05). ***Conclusion:*** CCNE1 and FGFR1 amplifications and CDK12 pathogenic mutations are associated with resistance to PSMA Lu-177 therapy in mCRPC patients. Alterations in each of these genes are implicated in other studies of drug resistance, including resistance to DNA damaging agents such as platinum. Limitations include a small sample sizes and a single institution study. In addition, Guardant assays are known to incompletely assess ctDNA alterations in prostate cancer. More and larger studies with more complete ctDNA assessments are needed to confirm these initial findings.

## OP-337

### Implementation of PSMA-PET/CT improves treatment outcomes after salvage radiotherapy for recurrent or persistent prostate cancer after surgery

***C. Zamboglou***[1,2], *P. Staus*[3], *M. Wolkewitz*[3], *N. S. Schmidt Hegemann*[4], *T. Wiegel*[5], *L. Emmett*[6], *S. Fanti*[7], *A. L. Grosu*[2], *S. Koerber*[8], *S. G. C. Kroeze*[9], *F. Ceci*[10], *J. C. Peeken*[11], *S. Hayoz*[12], *D. M. Aebersold*[13], *A. Vrachimis*[1], *P. Ghadjar*[14];
[1]*German Oncology Center, Limassol, CYPRUS,* [2]*Department of Radiation Oncology, University of Freiburg - Medical Center, Freiburg, GERMANY,* [3]*Institute of Medical Biometry and Statistics, Division Methods in Clinical Epidemiology, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany, Freiburg, GERMANY,* [4]*Department of Radiation Oncology, University of Munich, Munich, GERMANY,* [5]*Department of Radiation Oncology, University of Ulm, Ulm, GERMANY,* [6]*St VIncent's Public Hospital Sydney, University of New South Wales, Sydney, AUSTRALIA,* [7]*Department of Nuclear Medicine, University of Bologna, Bologna, ITALY,* [8]*Department of Radiation Oncology, University of Heidelberg, Heidelberg, GERMANY,* [9]*Department of Radiation Oncology, University of Zuerich, Zuerich, SWITZERLAND,* [10]*European Institute of Oncology, Milano, ITALY,* [11]*Department of Radiation Oncology, Technical University of Munich, Munich, GERMANY,* [12]*Swiss Group for Clinical Cancer Research (SAKK), Bern, SWITZERLAND,* [13]*Department of Radiation Oncology, University of Bern, Bern, SWITZERLAND,* [14]*Department of Radiation Oncology, Charite Berlin, Berlin, GERMANY.*

***Aim/Introduction:*** Due to its high diagnostic accuracy and impact on the treatment decision making, prostate-specific membrane antigen positron emission tomography (PSMA-PET) is increasingly used to guide salvage radiotherapy (sRT) for prostate cancer patients with prostate specific antigen (PSA) persistence or relapse after prostatectomy. Whether the implementation of PSMA-PET is leading to improved outcomes in these patients is not answered yet. ***Materials and Methods:*** Patients who underwent sRT from two separate patient cohorts were included. Cohort 1 consists of 344 patients from the phase III SAKK 09/10 trial (no PSMA-guided sRT). Cohort 2 consists of 1201 patients from a retrospective multicentre cohort (12 hospitals, 5 countries, PSMA-guided sRT). Patients with positive lymph nodes in primary surgery, initial cM1 status, cM1 status on PET imaging, PSA>0.5 ng/ml and with missing stratification variables were excluded. Subsequently, the cohorts were balanced (inverse probability of treatment weighting) based on ISUP score, PSA before sRT, PSA recurrence vs. persistence and pT/R status in surgery. Finally, biochemical recurrence-free survival (BRFS) and recurrence patterns were compared. Biochemical recurrence was defined as PSA nadir after sRT +0.2 ng/ml. ***Results:*** In total, 654 patients (cohort 1 and 2: 256 and 398) with median follow-up of 75 and 36 months (cohort 1 and 2) were included. The cohorts were well balanced (standardized mean differences <0.1). The delivered sRT dose to the fossa/local relapse in PET was <66 Gy in 188 (49%) and 41 (10%), 66-70 Gy in 194 (51%) and 201 (51%) and 70 Gy in 0 and 150 (38%) patients of cohort 1 and 2, respectively. In cohort 1 no patient had androgen deprivation therapy (ADT) and no sRT to elective pelvic lymph nodes (PLN) was performed. In cohort 2, 70 (82.2%) patients had PET-positive pelvic LNs, two (0.5%) patients received ADT and in 86 (21.6%) patients PLNs were irradiated.

Three years BRFS rates were 70% (95%CI 64-77%) and 78% (95%CI 73-83%) for cohort 1 and 2 (p=0.012, weighted log-rank test). Recurrence patterns showed that within the first 3 years, 33 (83%) and 14 (58%) of the patients in cohort 1 and 2, respectively, had relapse in regional or distant lymphatics. ***Conclusion:*** Our data suggests a significant improvement in BRFS with the inclusion of PSMA-PET for sRT guidance. One possible reason is the individualized coverage of local and regional disease in the sRT field based on PET . Currently, prospective studies are ongoing to validate this finding.

## OP-338

### LuTectomy: phase 1/2 study evaluating dosimetry, safety and potential benefit of pre-surgery [$^{177}$Lu]Lu-PSMA-617 radioligand therapy in patients with high-risk localised prostate cancer

***M. Hofman***[1], *R. Eapen*[1], *J. P. Buteau*[1], *P. Jackson*[1], *C. Mitchell*[1], *S. Oon*[1], *O. Alghazo*[2], *L. McIntosh*[1], *N. Dhiantravan*[3], *J. O'Brien*[1], *A. McVey*[1], *S. Sandhu*[1], *A. A. Azad*[1], *S. G. Williams*[1], *G. Sharma*[1], *B. Emmerson*[1], *M. B. Haskali*[1], *M. Bressel*[1], *D. Moon*[1], *N. Lawrentschuk*[1], *P. Neeson*[1], *D. G. Murphy*[1];
[1]*Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [2]*Flinders University, Adelaide, AUSTRALIA,* [3]*Royal Brisbane & Women's Hospital, Brisbane, AUSTRALIA.*

***Aim/Introduction:*** High-risk localised prostate cancer (HRCaP) is associated with high chances of local and systemic recurrence. $^{177}$Lu-PSMA-617 (LuPSMA) is effective for patients with metastatic castration-resistant prostate cancer. LuTectomy is a phase I/II study evaluating LuPSMA in men with HRCaP before undergoing radical prostatectomy (RP). The primary objective was to measure tumour radiation absorbed dose. ***Materials and Methods:*** Patients with HRCaP (PSA >20 ng/mL, ISUP grade group (GG) 3-5, ≥cT2c or N1), high tumour uptake (SUVmax≥20) on $^{68}$Ga-PSMA-11 PET/CT and scheduled for RP were eligible. Cohort A (n=10) received 1 cycle of 5GBq LuPSMA and Cohort B (n=10) received 2 cycles of 5GBq LuPSMA followed by RP scheduled 6 weeks after treatment completion. Radiation dose was estimated using post-therapy SPECT/CT at 4, 24 and 96 hours utilising voxel-based 3-phase exponential clearance model with partial-volume correction. Adverse events (AE) [CTCAE v5], surgical safety [Clavien-Dindo], PSA decline≥50% (PSA50-RR) at 6 weeks post-LuPSMA were evaluated. ***Results:*** 20 patients with a median age of 66 and median PSA (IQR) of 18 (11-35) ng/mL were enrolled 5/2020-4/2022. 6/20 (30%) had N1 disease. The median (IQR) baseline SUVmax was 31 (26-36).The median (IQR) highest tumour absorbed dose after cycle 1 for all lesions was 36Gy (20-50) with a median of 20Gy (11-48) for the prostate and 38Gy (33-50) for lymph nodes.PSA50-RR occurred in 9/20 (45%). AE were mainly G1 including fatigue (8), dry mouth (7), nausea (6) and lymphopenia (5). One patient in cohort B developed Grade 1 thrombocytopenia that precluded a 2nd dose of LuPSMA as per protocol. No grade 3/4 toxicities.All patients underwent robotic RP, with PLND in 18/20. Surgical difficulty levels were similar to expected for 15/20 (75%) of men, with minor increase in surgical difficulty in 5 pts. Length of hospitalisation was 1 night in 19/20 (95%) and urinary catheters were removed by day 17 in all patients. No Clavien 3-5 complications were recorded. 16/20 (80%) had evidence of treatment effect on histopathology and one patient had minimal residual disease in the prostate. No complete pathologic responses were seen. ***Conclusion:*** LuPSMA before RP in men with HRCaP delivered high radiation doses with few toxicities and without compromising surgical safety. Significant PSA reductions were achieved. LuPSMA in this setting warrants further evaluation ***References:*** [1] Clinical Trial Protocol: doi: 10.1016/j.euf.2020.09.021

## OP-339

### Lutetium-177-PSMA-617 in oligo-metastatic hormone sensitive prostate cancer (Bullseye)

***B. Privé***[1], *C. H. J. Muselaers*[1], *D. Meijer*[2], *W. A. Van Gemert*[1], *B. Timmermans*[1], *M. J. R. Janssen*[1], *M. A. Jonker*[1], *M. de Groot*[1], *I. M. van Oort*[1], *N. Mehra*[1], *W. R. Gerritsen*[1], *E. Alevroudis*[3], *A. Vrachimis*[3], *J. A. Gietema*[4], *M. Gotthardt*[1], *A. N. Vis*[2], *I. J. de Jong*[4], *A. J. Witjes*[1], *W. Noordzij*[4], *D. E. Oprea-Lager*[2], *J. Nagarajah*[1];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*Amsterdam University Medical Centers, Amsterdam, NETHERLANDS,* [3]*German Oncology Center, Limassol, CYPRUS,* [4]*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-PSMA-617 radioligand therapy (RLT) is a novel treatment for patients with metastatic castration resistant prostate cancer. Previously, we showed that [$^{177}$Lu]Lu-PSMA-617 could be offered to patients with PSMA-expressing oligometastatic hormone-sensitive prostate cancer (HSPC), with encouraging results and minimal toxicity (CCR, 2021). Due to [$^{177}$Lu]Lu-PSMA-617 RLT, androgen deprivation therapy (ADT) could be postponed and thus delaying the time to ADT-related toxicity. We hereby report interim results of a randomized trial analyzing the time without ADT using [$^{177}$Lu]Lu-PSMA-617 RLT versus deferred ADT (current standard of care; SoC). ***Materials and Methods:*** This is an ongoing international, multicenter, open-label, randomized phase 2 trial (NCT04443062). Fifty-eight patients will be randomized in a 1:1 ratio. Eligibility consists of fast-progressing HSPC (PSA doubling time <6 months) following local treatment, with a maximum of 5 metastases on [$^{18}$F]PSMA-PET/CT. Patients can receive 2+2 cycles of 7.4 GBq [$^{177}$Lu]Lu-PSMA-617. The primary outcome is progression-free survival (i.e., ADT free time). Progressive disease (PD) is defined as the initiation of ADT, a 100% increase in PSA since randomization, and radiographic or clinical progression. Secondary outcomes are PSA response and toxicity, following CTCAE v5.0. ***Results:*** To date (April 3rd, 2023), 42 patients were included. Their median PSA at inclusion was 4.5 ng/mL (range: 1.3 - 38). During a median follow-up of 6 months (range 1-20 months), 77% (17/22) and 10% (2/20) of the SoC and [$^{177}$Lu]Lu-PSMA-617 arm, respectively, reached the definition for PD. The median progression-free survival was 4 months in the SoC arm vs. not reached in the [$^{177}$Lu]Lu-PSMA-617 arm (HR 0.03; 95% CI 0.004 to 0.227; p < 0.001). The most common treatment-related adverse events were grade 1 xerostomia (70%), grade 1 fatigue (61%), grade 1 nausea (35%), grade 1 bone marrow toxicity (30%). Grade ≥2 adverse events were observed in less than 10% of patients. One patient developed grade 3 xeropthalmia and grade 2 xerostomia. The median percentage PSA change was +114% vs. -91% in the SoC vs. [$^{177}$Lu]Lu-PSMA-617 arm, respectively. At present, 55% (11/20) of the patients that underwent treatment had a PSA drop exceeding 90%, with five patients having a complete biochemical response. ***Conclusion:*** [$^{177}$Lu]Lu-PSMA-617 RLT shows promising efficacy in oligometastatic HSPC patients to defer from ADT, with minimal and mostly transient side effects. After surgery and external beam radiotherapy, [$^{177}$Lu]Lu-PSMA-617 could become a third metastases-directed therapeutic option for oligometastatic hormone-sensitive prostate cancer patients, to prolong the ADT-free interval.

## OP-340

### Association of baseline quantitative [68Ga]Ga-PSMA-11 PET imaging parameters with clinical outcomes in patients with mCRPC receiving [177Lu]Lu-PSMA-617: a VISION sub-study

***Aim/Introduction:*** In the phase 3 VISION study, patients with PSMA-positive metastatic castration-resistant prostate cancer (mCRPC) benefited from addition of lutetium ($^{177}$Lu) vipivotide tetraxetan ([$^{177}$Lu]Lu-PSMA-617, $^{177}$Lu-PSMA-617) to standard of care (SoC). This sub-study aimed to correlate the pattern and level of PSMA expression at baseline with response to $^{177}$Lu-PSMA-617 targeted radioligand therapy. ***Materials and Methods:*** In VISION, lesion PSMA positivity was visually assessed as greater than liver uptake on $^{68}$Ga-PSMA-11 PET. In this exploratory post hoc analysis, quantitative $^{68}$Ga-PSMA-11 PET parameters were based on standardized uptake values (SUVs) in bone, lymph node, liver, soft tissue and whole body. $SUV_{mean}$, $SUV_{max}$, PSMA-positive tumour volume, tumour load and presence of PSMA-positive lesions by disease site were assessed for associations with efficacy outcomes. All patients randomized were eligible for quantitative analysis, 551 in the $^{177}$Lu-PSMA-617 plus SoC arm and 280 in the SoC alone arm. The study was not powered for post hoc analyses. ***Results:*** Analysable $^{68}$Ga-PSMA-11 PET scans from 826 patients were included. Baseline quantitative $^{68}$Ga-PSMA-11 PET parameters were well balanced between the study arms. rPFS and OS were prolonged with $^{177}$Lu-PSMA-617 plus SoC versus SoC alone in all whole-body $SUV_{mean}$ quartiles. In the highest quartile (rPFS, ≥10.1; OS, ≥9.9), hazard ratio (HR) was 0.34 (95% CI: 0.20-0.56) for rPFS (median: 13.8 vs 3.9 months) and 0.47 (0.32-0.68) for OS (median: 21.4 vs 15.0 months). In the lowest quartile (rPFS, <6.0; OS, <6.0), HR was 0.75 (0.45-1.26) for rPFS (median: 5.8 vs 4.0 months) and 0.87 (0.60-1.27) for OS (median: 14.5 vs 11.3 months). rPFS and OS differed significantly between the treatment and control arms at all $SUV_{mean}$ cut-points and no optimal cut-point was identifiable. Whole-body tumour load and presence of lesions in bone or liver (as compared with node only) on $^{68}$Ga-PSMA-11 PET were associated with increased rPFS and OS event risk in both arms of the study. ***Conclusion:*** Baseline $^{68}$Ga-PSMA-11 $SUV_{mean}$ was predictive of $^{177}$Lu-PSMA-617 efficacy in patients with PSMA-positive mCRPC in the VISION study. Among patients with higher $SUV_{mean}$, addition of $^{177}$Lu-PSMA-617 to SoC resulted in greater improvements in rPFS and OS. Nevertheless, $^{177}$Lu-PSMA-617 improved outcomes across all $SUV_{mean}$ quartiles and at all $SUV_{mean}$ cut-points. Higher $SUV_{mean}$ values indicate higher PSMA expression, which may increase $^{177}$Lu-PSMA-617 tumour dose and enhance anti-tumour activity. These results indicate that the VISION $^{68}$Ga-PSMA-11 PET eligibility criteria identify patients with widely ranging tumour PSMA expression, but who are suitable candidates for $^{177}$Lu-PSMA-617 treatment.

## M2M Track - TROP Session: TME and Therapy: Direct Targeting and Secondary Effects

## OP-355
**Optimisation of FAP-targeted radionuclide therapy through molecular evolution of OncoFAP derivatives and combination with immunocytokines**
***A. Galbiati***[1], *M. Bocci*[1], *E. Gilardoni*[1], *J. Mock*[1], *D. Neri*[2], *S. Cazzamalli*[1];
[1]*Philochem AG, Otelfingen, SWITZERLAND,* [2]*Philogen, Siena, ITALY.*

***Aim/Introduction:*** Fibroblast Activation Protein (FAP) is abundantly expressed on the surface of stromal cells of the majority of solid human cancers. High-affinity small molecule FAP ligands labelled with $^{18}$F or $^{68}$Ga, are excellent diagnostic tools for the detection of lesions in many different types of cancer. [1,2] For therapeutic applications, more stringent requirements on affinity are needed, as ligands need to remain at the tumor site for several days, with negligible uptake in normal organs. We have recently identified OncoFAP, an ultra-high affinity small molecule ligand of FAP whose targeting performance has been validated in patients with a wide variety of solid malignancies.[3,4] Here, we describe the development of novel OncoFAP-based RLTs with enhanced tumor uptake and residence time. Combination therapy with a targeted cytokine (L19-IL2, a clinical-stage tumor-targeted interleukin2) strongly potentiates the anticancer efficacy of OncoFAP-based RLTs. ***Materials and Methods:*** We exploited DNA-encoded chemical libraries and conventional medicinal chemistry approaches to mature OncoFAP affinity. The novel derivatives were coupled to DOTAGA chelator, suitable for radiolabelling with $^{177}$Lu. In vitro characterization was performed using recombinant human FAP and transfected FAP-expressing cell lines. Tumor-targeting properties and therapeutic efficacy of the novel derivatives were investigated in comparative biodistribution and therapy studies, alone and in combination with L19-IL2. ***Results:*** BiOncoFAP, OncoFAP-11 and OncoFAP-23 were identified as promising candidates from chemical engineering activities. $^{177}$Lu-OncoFAP-23 emerged for its superior uptake and residence time in tumors (i.e., ~20% ID/g at 24 h and ~16% ID/g at 96 h) and for its favorable tumor-to-kidney ratio (i.e., ~17-to-1 at 24 h and ~22-to-1 at 96 h). Moreover, when administered at very low doses (e.g., 250 MBq/kg), $^{177}$Lu-OncoFAP-23 exhibited an enhanced anticancer activity compared to other $^{177}$Lu-labeled OncoFAP derivatives. $^{177}$Lu-OncoFAP-23 showed a dose-dependent therapeutic activity and strong synergism with L19-IL2. Mechanistic studies revealed a potent activation of NK cells, with a significant enhancement of the expression of biocidal granzymes and perforin-1 after combination treatment. ***Conclusion:*** Our findings demonstrate the superior tumor uptake and residence time of OncoFAP-23 compared to other FAP-targeted ligands. The combination with L19-IL2 represents an avenue to achieve promising anti-tumor activity at low activities, thus further reducing the radioactive burden. ***References:*** 1.Calais J et al. ## OP-356

### Tumor-targeted Interleukin-2 Boosts the Anti-cancer Activity of FAP-directed Radioligand Therapeutics

***P. Backhaus***[1,2], *P. Dorten*[2], *A. Galbiati*[3], *E. Gilardoni*[3], *F. Gierse*[2], *M. Bocci*[3], *A. Zana*[3], *J. Mock*[3], *M. Claesener*[1], *J. Cufe*[1], *F. Büther*[1], *K. Schäfers*[2], *S. Hermann*[2], *D. Neri*[4,5], *M. Schäfers*[1], *S. Cazzamalli*[3];
[1]*University Hospital Münster, Münster, GERMANY,* [2]*European Institute for Molecular Imaging, University of Münster, Münster, GERMANY,* [3]*Philochem AG, R&D department, Otelfingen, SWITZERLAND,* [4]*Swiss Federal Institute of Technology, Department of Chemistry and Applied Biosciences, Zurich, SWITZERLAND,* [5]*Philogen S.p.A, Siena, ITALY.*

***Aim/Introduction:*** We studied the anti-tumor efficacy of a combination of Lutetium-177-labelled Radio Ligand Therapeutics (RLTs) targeting the Fibroblast Activation Protein (OncoFAP and BiOncoFAP) with the antibody-cytokine fusion protein L19-IL2 providing targeted delivery of Interleukin-2 to tumors. ***Materials and Methods:*** The biodistribution of $^{177}$Lu-OncoFAP and $^{177}$Lu-BiOncoFAP was studied in mice bearing subcutaneous HT-1080.hFAP tumors via SPECT/CT at different molar amounts (3 nmol/kg vs 250 nmol/kg) of injected ligand and self-absorbed tumor and organ doses were calculated. In vivo anti-cancer effect of 5 MBq of the radiolabelled preparations was evaluated as monotherapy or in combination with L19-IL2 in subcutaneously implanted HT-1080.hFAP and SK-RC-52.hFAP tumors. Tumor samples from animals treated with $^{177}$Lu-BiOncoFAP and/or with L19-IL2 were analyzed by mass spectrometry-based proteomics to identify therapeutic signatures on cellular and stromal markers of cancer, and on immunomodulatory targets. ***Results:*** $^{177}$Lu-BiOncoFAP led to significantly higher self-absorbed dose in FAP-positive tumors (0.293 ± 0.123 Gy/MBq) compared to $^{177}$Lu-OncoFAP (0.157 ± 0.047 Gy/MBq, p=0.01), and demonstrated favorable tumor-to-organ ratios at high molar amounts of injected ligand. Administration of L19-IL2 or $^{177}$Lu-BiOncoFAP as single agents led to cancer cures only in a limited number of treated animals. In $^{177}$Lu-BiOncoFAP + L19-IL2 combination therapy, complete remissions were observed in all injected mice (7/7 C.R. for the HT-1080.hFAP model, and 4/4 C.R. for the SK-RC-52.hFAP model), suggesting therapeutic synergy. Proteomic studies revealed a mechanism of action based on the activation of NK cells, with a significant enhancement of the expression of granzymes and perforin-1 in the tumor microenvironment after combination treatment. ***Conclusion:*** The combination of OncoFAP-based RLTs with concurrent targeting of interleukin-2 shows synergistic anti-cancer effects in the treatment of FAP-positive tumors. This experimental finding should be corroborated by future clinical studies.

## OP-357

### FAP directed target modules for UniCAR T cell therapy and radionuclide-based tumour theranostics

***C. Neuber****, L. Loureiro, L. Hoffmann, M. Kubeil, C. Arndt, A. Feldmann, M. Bachmann;*
*Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY.*

***Aim/Introduction:*** Expression of fibroblast activation protein (FAP) is restricted to activated fibroblasts. In line with this, there is very limited FAP expression on healthy adult tissue. As FAP is mainly found on cancer-associated fibroblasts (CAFs) in the tumour stroma, it is a widespread tumour target and a variety of attempts have been made to address FAP using radiotracers. Our aim is to use FAP not only as a target for radionuclide-based tumour theranostics but also to address this protein via UniCAR T cell therapy. The modular universal chimeric antigen receptor (UniCAR) platform is a promising immunotherapeutic approach that reduces the risk for on-target/off-tumour toxicities and cytokine release syndrome since the UniCAR T cells are exclusively activated in the presence of a target module (TM) that specifically establishes the crosslinking between target cells and UniCAR T cells. ***Materials and Methods:*** We established TMs by fusing the single-chain variable fragment (scFv) of an anti-human FAP mAb to the peptide epitope E5B9 that is recognized by UniCAR T cells. In addition to this low molecular weight TM (αFAP scFv) that is rapidly eliminated, a TM based on the human IgG4 Fc-domain with an extended half-life was developed (αFAP IgG4). TMs were charcterized for their potetial in UniCAR T cell therapy and as FAP-directed radiotracers. ***Results:*** Both αFAP TMs bind to FAP-expressing cells with a $K_d$ in the low nanomolar range and enabled specific killing of FAP-positive tumour cells by UniCAR T cells both in vitro and in vivo. In addition, αFAP TMs were conjugated to different chelators, e.g. Bispidines, NODAGA, and CHX-A-DTPA to allow for radiolabelling with either Copper-64 or Lutetium-177 for PET and SPECT imaging, respectively. PET and SPECT imaging in NMRI nude mice bearing both FAP-negative and FAP-overexpressing HT1080 tumours revealed an excellent FAP-specific tracer enrichment at the FAP-positive tumour site, especially for αFAP IgG4, resulting in $SUV_{mean}$ up to 25 with almost no background. Considering the results found with $^{177}$Lu-radiolabelled αFAP IgG4, also regarding tumour growth, this TM is a promising candidate for not only diagnostic imaging but also targeted radionuclide therapy. ***Conclusion:*** We demonstrated suitability of novel FAP specific TMs with different molecular weights not only for immunotherapeutic approaches using UniCAR T cells but also for diagnostic PET and SPECT imaging as well as targeted radionuclide therapy. Given their immunotherapeutic as well as radionuclide-based theranostic potential these TMs might be able to improve individualized cancer therapy.

## OP-358

### Evaluation of Therapeutic and Immunological Action of CAIX-Targeted Lutetium-177 Radionuclide Therapy Combined with Immune Checkpoint Inhibition

***S. Kleinendorst***[1], *M. Konijnenberg*[1], *G. Franssen*[1], *J. Molkenboer-Kuenen*[1], *S. Wenker*[1], *D. Boreel*[1], *D. Kroon*[1], *M. Gloudemans*[1], *K. Twumasi-Boateng*[2], *M. Wheatcroft*[2], *E. Oosterwijk*[3], *S. Heskamp*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Telix Pharmaceuticals Ltd., Melbourne, AUSTRALIA,* [3]*Department of Urology, Radboud University Medical Center, Nijmegen, NETHERLANDS.*

***Aim/Introduction:*** Treatment response to immunotherapy differs widely among tumours, which is often reliant on their immunogenicity. Shifting this immunogenic phenotype towards a more responsive one is an attractive approach to enhance tumour sensitivity to immune checkpoint inhibition (ICI). This is exemplified by the in situ vaccination effect that can result from ionizing radiation, releasing neo-antigens and triggering inflammatory signalling. We aim to evaluate therapeutic action of combined targeted radionuclide therapy (TRT) and ICI in mouse tumour models of distinct immunogenicity. ***Materials and Methods:*** Renca-hCAIX or CT26-hCAIX tumour cells were injected subcutaneously in the flank of Balb/c mice. Tumour PD-L1 and

CD3 expression was characterized by immunohistochemistry. For therapeutic experiments, treatment was initiated when tumours reached 50-100mm$^3$. Subsequently, tumour-bearing mice were randomized as follows: (1) control, (2) ICI, (3) TRT ([$^{177}$Lu]Lu-DOTA-hG250, recognizing hCAIX), (4) TRT+ICI combination. Each tumour growth curve was quantified as mean tumour volume (MTV) and reported as median with interquartile range. Mice with complete tumour regressions were re-challenged with hCAIX-positive and hCAIX-negative tumour cells. In a follow-up experiment, Renca-hCAIX tumour-bearing mice will be sacrificed at 0, 5, or 8 days after treatment and immunological TME changes will be characterized by flow cytometry, immunohistochemistry, and transcriptional profiling. ***Results:*** Renca-hCAIX tumours were classified as poorly immunogenic with homogeneous PD-L1 expression and poor T cell infiltration, whereas CT26-hCAIX tumours showed heterogeneous PD-L1 expression and extensive T cell infiltration, thus were classified as highly immunogenic. The pharmacokinetic and pharmacodynamic behaviour of [$^{177}$Lu]Lu-DOTA-hG250 was comparable for both tumour models. Therapy studies demonstrated significantly reduced tumour growth after combined treatment regimens (11 or 32 Gy TRT with aPD1+aCTLA4 for Renca-hCAIX and 11 Gy TRT with aPD1 for CT26-hCAIX) compared with control groups ($MTV_{11Gy+ICI}$="58(70)"mm$^3$ and $MTV_{32Gy+ICI}$="55(61)"mm$^3$ vs $MTV_{control}$="270(320)"mm$^3$, $p<0.01$ for Renca-hCAIX, and $MTV_{11Gy+ICI}$="23(42)"mm$^3$ vs $MTV_{control}$="344(161)"mm$^3$, $p<0.05$ for CT26-hCAIX). Only for Renca-hCAIX, tumour control was significantly better after combination therapy compared with TRT alone ($MTV_{11Gy}$="414(280)"mm$^3$, $p<0.05$ and $MTV_{32Gy}$="166(179)"mm$^3$, $p<0.05$). Furthermore, complete tumour regression was most frequent after combination treatments (80% for Renca-hCAIX and 78% for CT26-hCAIX) and re-challenge of these mice resulted in 100% rejection of hCAIX-positive cells and 94% and 17% rejection of parental Renca and CT26 cells, respectively. Preliminary immunohistochemistry experiments suggest increased DNA damage and neutrophil infiltration after TRT compared to control, and further TME characterization is ongoing. ***Conclusion:*** Combined TRT and ICI resulted in significant tumour control in both Renca-hCAIX and CT26-hCAIX models and complete tumour responses were abundantly observed.

## OP-359

### RAYZ-15170, a novel small-molecule binder to carbonic anhydrase IX (CA9) for targeted radiopharmaceutical therapy of clear cell renal cell carcinoma and other CA9 expressing tumors

***N. Smith****, J. Tran, A. Lai, Y. Bravo, A. Cieniewicz, P. Mondala, R. Clift, T. Lo, G. Chen, G. Li, K. Lidberg, L. Nyiranshuti, S. Richardson, A. Hudson;*
*RayzeBio, Inc., San Diego, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Carbonic anhydrase IX (CA9) is a cell surface enzyme that plays a key role in microenvironmental pH regulation, cell growth, survival and migration, with limited expression in normal tissues. In up to 95% of clear cell renal cell carcinoma (ccRCC), loss of Von Hippel Lindau function results in overexpression of CA9 and is associated with worse prognosis. Compared to the long circulating half-life of antibodies, a small-molecule, CA9-targeting radiopharmaceutical therapy (RPT) with selectivity over related CA isozymes such as CA12 that are more widely expressed in normal tissues, would provide a valuable way to treat ccRCC and other CA9 expressing tumors. ***Materials and Methods:*** RAYZ-15170 is comprised of a small-molecule CA9 binder attached to a DOTA chelator that is used to complex different radioisotopes. The affinity of RAYZ-15170 to mouse, monkey and human CA9 and CA12 was determined by surface plasma resonance (SPR), and cell-based potency was determined in a HT-29 cell-line in which CA12 had been knocked out. In vivo biodistribution of RAYZ-15170 was examined using both SPECT imaging and ex-vivo cut/count techniques in SK-RC-52 tumor bearing mice (ccRCC tumor line). Anti-tumor efficacy studies were also performed in SK-RC-52 tumor-bearing mice with both $^{225}$Ac and $^{177}$Lu constructs. ***Results:*** $^{175}$Lu-RAYZ-15170 showed potent binding affinity to human CA9 with a $K_D$ of 0.094 nM and high selectivity over human CA12 of >1,500x. Binding affinity was maintained across mouse, monkey and human CA9. Potent cell-binding of $^{175}$Lu-RAYZ-15170 was confirmed in a HT29 cell line ($IC_{50}$ = 1.6 nM). In vivo biodistribution of $^{177}$Lu-RAYZ-15170 in SK-RC-52 tumor bearing mice using SPECT imaging showed sustained tumor uptake of 10, 8.1, 8.0 and 5.4 %ID/g at 2, 24, 48, and 96 hours, respectively. Uptake was low in kidney, stomach and intestines from the 24 hour time-point onward (%ID/g < 3%). Biodistribution measured by ex-vivo cut/count gave a similar result with tumor uptake of 19, 5.7 and 5.7 %ID/g at the 2, 24 and 48 hr time-points, and kidney, stomach and intestines wall <3% ID/g from 24 hours onward. Minimal uptake was observed in other normal tissues. Efficacy studies with $^{225}$Ac and $^{177}$Lu constructs showed significant tumor-growth regression and survival benefit in SK-RC-52 tumor-bearing mice. ***Conclusion:*** Preclinical in-vitro potency and selectivity together with biodistribution and efficacy data demonstrate the potential of RAYZ-15170 as a RPT agent for the treatment of patients with clear cell renal cell carcinoma (ccRCC) and other CA9 expressing tumors.

## OP-360

### [$^{225}$Ac]Ac-DPI-4452, a new peptide radioligand targeting Carbonic Anhydrase IX, displays strong anti-tumoral activity in colorectal cancer and clear cell renal cell carcinoma mouse models

***N. Wiedemann****, A. Attinger, E. Da Costa Branquinho, U. Andersson;*
*Debiopharm International SA, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** The transmembrane metalloenzyme Carbonic Anhydrase IX (CAIX) is an attractive diagnostic and therapeutic target with expression in hypoxic tumor types such as colorectal cancer (CRC) and clear cell renal cell carcinoma (ccRCC) and a limited number of healthy organs. The cyclic peptide DPI-4452 selectively binds CAIX and its DOTA cage allows labelling with different radionuclides for diagnostic and therapeutic purposes. Previously, promising theranostic potential of [$^{68}$Ga]Ga-DPI-4452 and [$^{177}$Lu]Lu-DPI-4452 has been demonstrated in CRC and ccRCC xenograft mouse models. Here we characterized the ex vivo biodistribution and the in vivo efficacy of [$^{225}$Ac]Ac-DPI-4452 in CRC and ccRCC xenograft mouse models. ***Materials and Methods:*** CAIX-positive human cancer cell lines HT-29 (CRC) or SK-RC-52 (ccRCC) were subcutaneously implanted in immunodeficient mice. Treatments were initiated at a mean group tumor volume of 140-180 mm$^3$, and tumor volume and tolerability monitored. Groups of 7-10 mice received a single intravenous administration of either 15 kBq, 45 kBq or 135 kBq of [$^{225}$Ac]Ac-DPI-4452. Efficacy was assessed at 14 days post-treatment by one-way ANOVA and p-values below 0.05 deemed significant. Radioactivity uptake (as % of injected dose/gram tissue; %ID/g) in tumors, kidney, stomach, small and large intestine at secular equilibrium was assessed in separate groups of 4-5 mice 4h upon a single administration of 15 kBq of [$^{225}$Ac]Ac-DPI-4452 using an automated gamma counter.

***Results:*** Mice displayed high radioactivity uptake in tumors 4h after administration of 15 kBq of [$^{225}$Ac]Ac-DPI-4452 as analyzed by ex vivo gamma counting, with SK-RC-52 tumors (39.1 %ID/g) showing more than 3-fold higher uptake than HT-29 tumors (11.3 %ID/g). Kidneys showed the highest non-target organ uptake with tumor-to-kidney ratios remaining above 1 in both models, whereas tumor-to-organ ratios were above 10 for the other organs. All [$^{225}$Ac]Ac-DPI-4452 treatments were well tolerated in both models as indicated by stable or increasing body weights. Significant dose-dependent tumor growth inhibition (TGI) was observed 14 days post-treatment in the 45 kBq (56% TGI) and 135 kBq (78% TGI) groups in the HT29 model, and for all 3 dose levels in the SK-RC-52 model (TGI of 57%, 64% and 67% for 15 kBq, 45 kBq and 135 kBq groups, respectively). ***Conclusion:*** [$^{225}$Ac]Ac-DPI-4452 displays promising therapeutic potential in CAIX-expressing CRC and ccRCC xenograft mouse models demonstrating that DPI-4452 is a versatile peptide radioligand suitable for use with the alpha-emitting radionuclide Ac-225 for efficacious treatment of CAIX-expressing tumors.

## OP-361

### Extracellular Matrix-Targeted Radionuclide Therapy Remodels Tumor Microenvironment Landscape and Enhances Immunotherapy in Triple-Negative Breast Cancer

***L. Li***, *Z. Zeng, F. Liu, X. Ma, B. Jia, Z. Yang;*
*Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** Although immunotherapy has significantly impacted triple-negative breast cancer (TNBC) treatment, its benefits remain confined to a small patient subset, emphasizing the urgent need for immunomodulatory approaches that overcome resistance. In this study, we examined the potential of a targeted radionuclide therapy (TRT) method employing a novel nanobody-based therapeutic tracer ($^{177}$Lu-HMI02-ABD035) targeting the fibronectin, a key component of tumor extracellular matrix, as an immunomodulator to reshape the TNBC microenvironment and enhance immunotherapy effectiveness. ***Materials and Methods:*** We analyzed TCGA data to compare fibronectin expression in TNBC tumors and normal breast tissues. A novel nanobody (HMI02) was acquired by immunizing llama with fibronectin protein and fused with albumin binder ABD030 (HMI02-ABD035) to extend its blood half-life. $^{177}$Lu radiolabeling was achieved via the chelator DOTA that was site-specifically attached to the C terminus of HMI02-ABD035. Micro SPECT imaging, biodistribution studies and TRT monotherapy were conducted in mice bearing syngeneic EMT-6 TNBC tumors. Combination therapy with $^{177}$ Lu-HMI02-ABD035 and anti PD-1 was assessed in EMT-6 and 4T1 xenografts that were resistant to immunotherapy. Post-treatment immune cells infiltration was analyzed using multiplex immunohistochemistry. ***Results:*** The TCGA analysis of TNBC data revealed significantly higher fibronectin expression in tumor regions compared to normal tissues. Fibronectin overexpression occurred frequently (67.3%) in TNBC patients. SDS-PAGE and MALDI-TOF analysis confirmed the high purity and accurate fusion of HMI02-ABD035, respectively. Excellent uptake and retention of $^{177}$Lu-HMI02-ABD035 were observed in EMT-6 tumors (28.24 ± 1.65%ID/g at 48 h p.i. and 11.20 ± 2.23%ID/g at 120 h p.i.). The normal tissues showed low uptakes of tracer, and the tumor to muscle ratios were as high as 31 ± 3.24 at 48 h p.i. Low-dose $^{177}$Lu-HMI02-ABD035 (9.3 MBq per mouse) significantly inhibited tumor growth and extended overall survival in EMT-6 xenografts. $^{177}$Lu-HMI02-ABD035 monotherapy reduced the cancer-associated fibroblast population in tumor and enhanced dendritic cell infiltration. Combining TRT with anti PD-1 improved antitumor efficacy compared to either monotherapy in both tested tumor models, resulting in complete tumor regression in most EMT-6 tumor-bearing mice (4/7). Combination therapy also induced tumor-specific memory, as demonstrated by protection against tumor rechallenge and induction of effector and memory T cells. ***Conclusion:*** Our results suggest that fibronectin-targeted $^{177}$Lu-HMI02-ABD035 TRT holds potential for treating TNBC and sensitizing treatment-resistant tumors to immunotherapy. This indicates that combining $^{177}$Lu-HMI02-ABD035 with anti-PD-1 therapy may be a promising approach to treating TNBC patients in the clinic.

## OP-362

### Profiling the influencing factors of radiopharmaceutical therapy: spatial transcriptomics and computational modeling in microenvironment

***J. Hong***[1], *S. Bae*[2], *L. Cavinato*[3], *M. Ryhiner*[1], *A. Rominger*[1], *H. Choi*[2], *K. Shi*[1];
[1]*University of Bern/Inselspital, Bern, SWITZERLAND,*
[2]*Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [3]*Politecnico di Milano, Milan, ITALY.*

***Aim/Introduction:*** Computational modeling of radiopharmaceuticals in microenvironment has contributed to the investigation of dosimetry in radiopharmaceutical therapy (RPT). Recently, a novel technique, Spatial Transcriptomics (ST), has been introduced which counts the number of transcripts of a gene at distinct spatial locations in a tissue. We used a novel approach that combines computational modeling with ST which profiles the distribution of the influencing factor of RPT. In particular, we incorporated ST of hypoxia M10508 (Harris hypoxia) and Folate Hydrolase 1 (FOLH1) expression, which are associated with hypoxia and prostate tumor, respectively, to modeling spatiotemporal distribution as well as dosimetry of both $^{177}$Lu-PSMA and $^{225}$Ac-PSMA. ***Materials and Methods:*** We employed a prostate cancer single-cell transcriptomic dataset to fingerprint Harris hypoxia and FOLH1 expression in each spot composing the ST data. We then calculated the proportion of cell types that included endothelial cells in the same spatial ST domain, which was used to contour the vessel. To generate an arterial input function (AIF) of each $^{177}$Lu-PSMA and $^{225}$Ac-PSMA within those vessels, we used a well-established physiological-based-pharmacokinetic-modeling (PBPK) model where the injected amount was determined to deposit 10Gy in the prostate tumor 20 days post-injection. We established convection-reaction-diffusion (CRD) model to simulate spatiotemporal distribution, assuming that once radiopharmaceutical enters the tumour interstitium from the vessels, it is transported through the interstitial volume by diffusion down concentration gradients and convection from regions of high to low interstitial fluid pressure, finally exiting the compartment via a cellular uptake and backflow into the vasculature. ST of FOLH1 was integrated into the simulation to serve as parameter associated with receptor density, and all other parameters were taken from the previous literature. Dose-voxel kernel (DVK) method was utilized to derive the dosimetry using MIRD cell. Cell survival rate was derived in each ST locations using hypoxia information from Harris hypoxia ST and linear quadratic model. ***Results:*** The average simulated dose in PSMA abundant area was 15.02 Gy and 10 Gy for $^{177}$Lu-PSMA and $^{225}$Ac-PSMA, respectively. On the other hand, in PSMA depleted area, the absorbed dose was 0.48 Gy and 0.06 Gy for $^{177}$Lu-PSMA and $^{225}$Ac-PSMA, respectively. However, cell survival rate was largely

decreased in the PSMA depleted area in $^{225}$Ac-PSMA compared to $^{177}$Lu-PSMA, indicating that $^{225}$Ac-PSMA therapy outcome is more sensitive to hypoxia than $^{177}$Lu-PSMA. ***Conclusion:*** This pilot study confirmed the feasibility of ST to enhance the computational modelling in the investigation of RPT dosimetry.

### OP-363

**Fast Penalized Maximum Likelihood Method for Positron Lifetime Image Reconstruction Using Adaptive Time Framing**

***J. Qi***, *B. Huang;*
*UC Davis, Davis, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Positronium lifetime imaging (PLI) has attracted growing interest due to its potential for examining tissue microenvironment and identifying hypoxia regions. However, it has been commonly believed that the spatial resolution of PLI is limited by the time-of-flight (TOF) resolution of a PET scanner. A previous study has shown a spatial resolution of 3 cm with 460 ps TOF resolution and that achieving 5 mm spatial resolution would require 50 ps TOF resolution [1], which is far beyond the capability of current state-of-the-art scanners. Previously we developed a list-mode based penalized maximum likelihood method for reconstructing high-resolution positronium lifetime images using an existing TOF PET [2], but the method was computationally intensive for practical use. Here we present a new fast penalized maximum likelihood method for positronium lifetime image reconstruction using adaptive time framing. ***Materials and Methods:*** List-mode coincidence events are adaptively divided into frames based on their measured delay times between positron annihilation and prompt gamma. In each frame, the coincidence data follow a Poisson distribution with the expectation of events in each LOR related to the lifetime of each voxel through a positron decay model and the system matrix of the PET scanner. Using the optimization transfer method, we decoupled the reconstruction of positron decay curve in each voxel and lifetime estimation. The proposed method allows for the use any positron lifetime model in the fitting procedure. For the mono-exponential decay model, a closed form update equation is obtained. ***Results:*** Simulation studies demonstrate that the proposed method can reconstruct positronium lifetime images at much better spatial resolution than the limit set by the TOF resolution of the PET scanner. The new method substantially reduced the computation time by more than a factor of 10 compared to the list-mode maximum likelihood method without sacrificing the accuracy of lifetime estimation. Additionally, the proposed penalized maximum likelihood method achieves lower variance than methods that perform reconstruction and lifetime estimate in two separate steps. ***Conclusion:*** The proposed fast and efficient method for positronium lifetime image reconstruction enables high-resolution PLI using existing PET scanners. This method opens opportunities of using PLI for studying tissue microenvironment in various diseases in human and animal models. ***References:*** [1] Moskal et al., "Performance assessment of the 2γ positronium imaging with the total-body PET scanners," EJNMMI Physics, 7(1):44, 2020. ### OP-364

**Direct versus indirect parametric whole body [$^{18}$F]FDG Patlak imaging using a LAFOV PET/CT system**

***J. van Sluis***[1], *L. Providência*[1], *J. H. van Snick*[1], *A. W. J. M. Glaudemans*[1], *R. H. J. A. Slart*[1], *R. A. J. O. Dierckx*[1], *C. Tsoumpas*[1], *R. Boellaard*[1,2];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Amsterdam University Medical Centers, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Whole body axial coverage and high sensitivity of long axial field-of-view (LAFOV) PET systems allow whole body dynamic acquisition and precise measurements of image-derived input functions (IDIF). Commonly, estimation of kinetic parameters derived from dynamic PET data is done indirectly following individual frame reconstruction. However, because of the use of an approximated noise model and high noise levels, especially in shorter time frames, indirect parametric images may be noisy. Alternatively, parametric images can be estimated directly from raw dynamic PET data, hereby taking into account all acquired dynamic data instead of per frame. This allows more precise modelling of the noise distribution resulting in improved image quality. Here, we aimed to compare the quality of parametric images obtained with indirect and direct [$^{18}$F]FDG Patlak reconstruction using a LAFOV PET/CT system. Dynamic PET data were acquired using a maximum ring difference (MRD) of 85 (high sensitivity mode) which equals a photon acceptance angle of 18 degrees, and using an MRD of 322 (ultra-high sensitivity mode) equivalent to a photon acceptance angle of 52 degrees. ***Materials and Methods:*** Eleven oncological patients received a weight-based injection of [$^{18}$F]FDG and underwent a 65-min dynamic PET acquisition. First, dynamic PET data frames were reconstructed individually. From these dynamic frames, an IDIF from the ascending aorta was extracted and used for Patlak parametric image generation (indirectly); this IDIF also served as input for the direct Patlak reconstructions. For both Patlak methods (t* = 30 min) [$^{18}$F]FDG influx rate constant ($K_i$) images were obtained. Herein, tumour lesions as well as liver tissues were segmented to derive $K_i$ and information regarding image noise levels. All reconstructions were performed offline using prototype research software (Siemens Healthineers). Indirect parametric image conversion and all image segmentations were performed using in-house developed software. ***Results:*** Lesion $K_i$ differed minimally (~3%) between indirectly and directly reconstructed parametric images and applied MRDs. However, large differences between the liver coefficient of variation (COV) between the indirect and direct reconstruction methods were found: indirect MRD85 and MRD322 mean COV were 37.1% and 32.3%, direct MRD85 and MRD322 mean COV were 10.5% and 9.1%. ***Conclusion:*** Direct reconstruction of parametric Patlak images results in similar $K_i$ but a substantial decrease in noise levels compared with indirect Patlak analysis. Improved signal-to-noise ratio and increased image quality is obtained with direct Patlak reconstruction which may enable future reduction of dynamic imaging duration for a more feasible clinical implementation.

## OP-365

### O-15 water in acceptance angle comparison high sensitivity vs ultra-high sensitivity

***H. Merisaari***[1], *N. Ono*[2], *T. Tolvanen*[3,4], *V. Saunavaara*[3,4], *J. Knuuti*[3], *L. Nummenmaa*[3], *P. Nuutila*[3], *H. Iida*[3];

***Aim/Introduction:*** The acceptance angle during PET reconstruction determines the spatial resolution and sensitivity of the PET scanner. A larger acceptance angle means that more gamma ray pairs are detected. This can improve the sensitivity of the scanner, allowing use of lower injected activity in PET acquisition, and shorter acquisition times [1]. However, a larger acceptance angle can also lead to a lower spatial resolution, as the position of the annihilation event along the LOR may be less accurately determined. The purpose of this study was to evaluate potential benefits of higher acceptance angle in full body water O-15 PET acquisition with large FOV PET scanner. ***Materials and Methods:*** One patient underwent full body water O-15 PET scan with Biograph Vision Quadra (Siemens Healthineers), with four injected activity amounts (50, 100, 300, and 700 MBq activities), with one subject. To evaluate the effect of injected activity to image quality, we applied bootstrapping approach taking 50% of activations 10 times for each acquisition. We evaluated high sensitivity mode with maximum ring difference (MRD) of 85 and ultra high sensitivity mode with MRD 322 in the image reconstruction, with PSF-TOF as reconstruction method. The image quality was evaluated with Coefficient of Variation (CoV=SD/mean) across the 10 bootstrap permutations for each frame of dynamic series. We used 38 Volumes of Interest including brain, heart, lungs, artery, pancreas, kidney, and bone marrow. We evaluated time activity curves and modelled K1 and k2 parameters. ***Results:*** The CoV across bootstraps in ROI mean values were significantly lower for the higher acceptance angle, giving up to 20% average reduction. In K1 and k2 parameters, the K1 and k2 parameter CoVs were generally improved in the heart left ventricle, pancreas, kidney and bone marrow, with CoV improvements being dependent on the ROI in question. As expected, biggest improvements were observed with lowest dose acquisitions (50 and 100 MBq). ***Conclusion:*** Increased acceptance angle provided promising image data quality, and may allow to reduce injected dose in clinical acquisitions in the future. ***References:*** [1] Mingels, C., Weidner, S., Sari, H., Buesser, D., Zeimpekis, K., Shi, K., Alberts, I. and Rominger, A., 2023. ### Impact of different collimator response models on quantitative $^{177}$Lu-SPECT reconstructions

***W. Claeys***[1], *W. Deckers*[2], *V. Nuttens*[3], *C. Deroose*[1,2], *K. Goffin*[1,2], *K. Baete*[1,2], *M. Koole*[1];
[1]*KU Leuven, Leuven, BELGIUM,* [2]*UZ Leuven, Leuven, BELGIUM,* [3]*OLV Aalst, Aalst, BELGIUM.*

***Aim/Introduction:*** $^{177}$Lu-DOTATATE and $^{177}$Lu-PSMA are increasingly used for radiopharmaceutical therapy. For these therapies, post-therapy SPECT-CT is important to estimate the absorbed dose to tumor and organs at risk. However, quantitative $^{177}$Lu-SPECT-CT reconstruction protocols are not standard yet. Therefore, our aim was to investigate the impact of different collimator response models on the quantitative properties of $^{177}$Lu-SPECT imaging. ***Materials and Methods:*** Quantitative SPECT acquisitions were performed on a Siemens Intevo Bold SPECT-CT system with medium energy collimators. The NEMA IEC PET body phantom comprising hot spheres (2MBq/ml) on a cold background was used. The standard 10mm diameter sphere was replaced by a 60mm sphere, resulting in diameters between 13 and 60mm. Reconstructions were performed using the vendor neutral reconstruction software MIM Encore (MIM Inc., Cleveland, OH, USA) with and without a simple geometric resolution model, and with Siemens Flash3D and xSPECT Quant software, including a Gaussian model and measured collimator response respectively. Number of subsets was set to 2 while the number of iterations was varied between 5 and 80. Reconstructed data were smoothed with a Gaussian kernel and varying Full Width Half Maximum (FWHM) from 0 to 25mm. Quantitative accuracy was evaluated based on the recovery coefficients (RC) for different sphere sizes while Gibbs artefacts (GA) were quantified as the relative difference between the central minimum and sphere maximum of the activity concentration. ***Results:*** Reconstruction without collimator modeling gives poor quantitative accuracy ($RC_{max}$ = 64% for the 60mm sphere). With collimator model, increasing the number of updates increases the RC for all spheres up to approximate convergence at 80 updates. Using a more advanced model further increases quantitative accuracy, but only moderately at convergence ($RC_{max}$ of the 60mm sphere is 88%, 91% and 94% for MIM, Flash3D and xSPECT respectively). In the largest sphere, Gibbs artefacts are present, which increase with number of updates and are amplified with the inclusion of a more advanced collimator model ($GA_{max}$ = 28%, 38% and 50% for MIM, Flash3D and xSPECT). In the smaller spheres, visual heterogeneities were observed for MIM and Flash3D, but not for xSPECT. Increasing the smoothing level decreases Gibbs artefacts and hotspots, at the cost of lower RC. Varying the number of subsets while maintaining the number of updates does not affect RC nor Gibbs artefacts. ***Conclusion:*** Quantitative $^{177}$Lu-SPECT-reconstructions with a more advanced collimator response model provide better quantitative accuracy at the expense of larger Gibbs artefacts.

## OP-367

### Towards the clinical implementation of quantitative$^{177}$Lu SPECT/CT with a ring-shaped CZT-based camera: comparison of OSEM and Q.Clear reconstruction algorithms

***R. Danieli***[1], *M. Stella*[2], *J. Leube*[3], *J. Tran Gia*[3], *H. Levillain*[1], *C. Marin*[1], *B. Vanderlinden*[1], *N. Reynaert*[1], *P. Flamen*[1];
[1]*Institut Jules Bordet, Brussels, BELGIUM,* [2]*GE HealthCare, Diegem, BELGIUM,* [3]*University Hospital Würzburg, Würzburg, GERMANY.*

***Aim/Introduction:*** Dosimetry after radiopharmaceutical therapy with $^{177}$Lu ($^{177}$Lu-RPT) relies on quantitative SPECT/CT, for which suitable reconstruction algorithms are required. Q.Clear is a reconstruction algorithm that has recently been made available for a CZT ring-shaped SPECT/CT camera (StarGuide, GE HealthCare), as alternative to the well-established OSEM. This study represents a first step towards the definition of an optimal reconstruction protocol for dosimetry after $^{177}$Lu-RPT and compares the performance of three different algorithms (OSEM and Q.Clear with and without RDP regularization). ***Materials and Methods:*** The six spherical inserts of a NEMA phantom (diameter range: 10-37mm) and a cylindrical phantom (filling volume: 5.4L) were filled with

1.6MBq/ml and 700MBq of $^{177}$Lu, respectively. Each phantom was scanned on a StarGuide for 15 minutes, with emission and scatter windows centred at 208keV (±6%) and 185keV (±5%), respectively. Acquired projections were reconstructed with OSEM and Q.Clear, both including resolution recovery, attenuation and scatter correction, with 1 subset and a number of iterations varying from 12 to 576. In addition, Q.Clear reconstructions including RDP regularization were performed (Q.ClearRDP). The noise was quantified as the coefficient of variation of the counts in a volume of interest drawn inside the cylindrical phantom. The spatial resolution was calculated by a matched-filter analysis based on the NEMA phantom [1]. ***Results:*** Visually, OSEM reconstructions presented more evident Gibbs-like artefacts compared to Q.Clear and Q.ClearRDP. After 12 iterations, all algorithms provided similar noise (~10%) and spatial resolution (~20 mm). Increasing the number of iterations, however, OSEM exhibited a faster noise build-up than Q.Clear and Q.ClearRDP (63%, 22% and 14%, respectively, after 576 iterations). After 72 iterations, a resolution of 9 mm, 11 mm and 12 mm was determined for OSEM, Q.Clear and Q.ClearRDP, respectively. From 72 to 576 iterations, minor improvements down to 7 mm, 8 mm and 10 mm were observed. Similar trade-offs between noise build-up and resolution improvement were found after 48, 96 and 192 iterations for OSEM, Q.Clear and Q.ClearRDP, respectively. ***Conclusion:*** When imaging $^{177}$Lu on a StarGuide system, Q.ClearRDP succeeds considerably better than OSEM in reducing the accumulation of noise for a growing number of iterations, while also reducing Gibbs-like artefacts. However, when the reconstruction parameters are chosen with care, similar quality, noise and spatial resolution can be obtained with all considered algorithms (OSEM, Q.Clear and Q.ClearRDP). ***References:*** [1] Tran-Gia, Lassmann. Characterization of Noise and Resolution for Quantitative $^{177}$Lu SPECT/CT with xSPECT Quant. J Nucl Med. 2019;60(1):50-59. doi:10.2967/jnumed.118.211094

## OP-368

### Positron-Range Correction for an On-Chip PET Scanner using Deep Learning

***C. Clement***[1], *G. Birindelli*[1], *F. Pagano*[2,3], *M. Pizzichemi*[2,3], *M. Kruithof-De Julio*[1], *S. Ziegler*[4], *A. Rominger*[1], *E. Auffray*[2], *K. Shi*[1];

***Aim/Introduction:*** Organs-on-Chips (OOCs) are an innovative technology designed to replicate human organ functions in vitro. OOCs provide a promising alternative to traditional in vitro and animal models for drug development, disease modeling, and toxicity testing [1]. As OOCs emerge as a potent tool for studying human physiology and drug responses, there is an increasing demand for dedicated PET scanners that can precisely and effectively image these microfabricated devices. However, the spatial resolution of existing small-scale PET systems is inadequate for OOC imaging. One key factor limiting PET scanner spatial resolution is the positron range, which refers to the distance a positron travels before colliding with an electron. In prior work, we introduced a dedicated On-Chip PET scanner capable of imaging OOCs [2]. In this study, we present enhanced performance results of the scanner by implementing a deep learning-based positron-range correction algorithm. ***Materials and Methods:*** We generated a dataset comprising pairs of non-corrected and corrected images using a Monte-Carlo simulation of a realistic OOC phantom and a fully three-dimensional Maximum-Likelihood Expectation-Maximization (MLEM) iterative reconstruction algorithm. We then developed and trained an image-to-image deep learning (DL) model that accepts a non-positron-range corrected reconstructed image as input and outputs a positron-range corrected image. ***Results:*** The mean full-width at half-maximum (FWHM) values of the non-positron-range corrected, ground truth, and DL-corrected reconstructed images of the test set are 0.260 mm, 0.169 mm, and 0.177 mm, respectively. These values were calculated using line profiles in the x-, y-, and z-directions drawn through the four sources in each compartment of the OOC phantom. Moreover, we compared the quality of the predicted images and ground truth images using the Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM) metrics. The reconstructed test images achieved a PSNR of 48.9 dB and an SSIM of 0.994. ***Conclusion:*** Our findings demonstrate the effectiveness of the DL-based positron-range correction algorithm in enhancing the overall quality of the reconstructed images. This approach has the potential to serve as a valuable tool for advancing the study of 3D models in radiopharmaceutical research. Overall, this study highlights the potential of using a deep learning-based positron-range correction algorithm to improve the performance of a dedicated PET scanner for imaging OOCs. ***References:*** [1] L. A. Low et al., Nature Reviews Drug Discovery 20.5 (2021). [2] C. Clement et al., EJNMMI Physics 9.1 (2022).

## OP-369

### Implementation and performance evaluation of artificial intelligence based SPECT attenuation correction on clinical SPECT images

***M. Szolikova***[1], *A. Kovacs*[1], *B. Husztik*[1], *N. Meszaros*[1], *F. Nagy*[2], *I. Garai*[2], *S. Barna*[2];
[1]*Mediso Ltd., Budapest, HUNGARY,* [2]*ScanoMed Nuclear Medicine Centers, Debrecen, HUNGARY.*

***Aim/Introduction:*** Accurate attenuation correction (AC) is essential for precise quantification and improved image quality in single-photon emission computed tomography (SPECT) imaging. While non-uniform AC through computed tomography (CT) is the standard method in clinical practice, it may produce artifacts due to patient movement, misalignment between SPECT and CT images, presence of metal implants and contrast agents in the body. Additionally, CT scans expose patients to higher levels of radiation. SPECT-only systems are still widely used, which do not allow transmission imaging, therefore CT-based AC is not available. We aimed to develop an artificial intelligence (AI) assisted method that generates synthetic CT images from bone SPECT measurements. This novel technique enables SPECT imaging comparable to CT-based correction, without requiring an actual CT scan. ***Materials and Methods:*** Our team developed a convolutional neural network solution that employs supervised and unsupervised techniques. The objective was to produce a synthetic CT-like image from SPECT data and a corresponding attenuation map. Retrospective study involved 1300 clinical subjects injected with $^{99m}$Tc-MDP, images were acquired using 3-headed SPECT/CT system. The clinical sample was heterogeneous in terms of sex, age, BMI, disease, and regions examined. We randomly selected 900 images for network training, 200 for testing, 200 for evaluation. SPECT projection data was reconstructed three ways: AC using the original CT volume (CT-AC), AC using the synthetic CT volume (SCT-AC), non-attenuation-corrected (Non-AC). Both the attenuation maps and the reconstructed SPECT images were compared by considering the original CT-based method as reference. Image-derived metrics

such as mean absolute error, structural similarity index (SSI), peak signal-to-noise ratio (SNR), Dice coefficient, and region-based clinically relevant values such as activity concentrations were evaluated. ***Results:*** Evaluation of 200 independent samples (noninvolved in neural network learning and hyperparameter optimization) indicated that the synthetic attenuation maps were both qualitatively and quantitatively consistent with the CT-based attenuation maps. There were no significant differences in terms of SNR and activity concentration between the SPECT volumes reconstructed using CT-AC and SCT-AC methods. Both CT-AC and SCT-AC methods outperformed the Non-AC method in terms of SNR. Furthermore, when using SCT-AC, misregistration error is excluded due to the main principle of our method. ***Conclusion:*** Our study has shown that accurate attenuation maps can be generated exclusively from the emission data for bone SPECT imaging. Our proposed method offers several clinical benefits, including reduced radiation exposure to the patient and elimination of CT and motion artifacts from SPECT images.

## OP-370

### Deep-Learning-based Partial Volume Correction in SPECT

***T. Kaprélian****, A. Extebeste, D. Sarrut;*
*Université de Lyon, CREATIS; CNRS UMR5220; Inserm U1044; INSA-Lyon; Université Lyon 1; Centre Léon Bérard, France., Lyon, FRANCE.*

***Aim/Introduction:*** Image resolution and quantification on SPECT is limited by Partial Volume Effects (PVE) [1]. PVE are dominated by collimator response and depend on source-to-detector distance and source size, making lesions smaller than the system's resolution volume hard to detect. A widely used Partial Volume Correction (PVC) method is the Resolution Modeling (RM) during reconstruction, which improves spatial resolution but generates Gibbs artifacts. We propose a deep learning framework (PVCNet) to compensate for the collimator's PSF on projections, before reconstruction. ***Materials and Methods:*** We generated an analytical database counting 5000 sources containing a cylindrical background and 1 to 8 ellipsoidal lesions with background-to-source activity ratios between $10^{-3}$ and 1/8. Each source was then projected twice for each angle on a $256^2$ pixels detector with ray-tracing using RTK [2]: once without RM ($P_{noPVE}$ projection) and once with RM corresponding to a realistic SPECT system followed by Poisson noise ($P_{PVE,noise}$ projection). We then trained a UNet taking $P_{PVE,noise}$ projections as input and corresponding projections from $P_{noPVE}$ as targets. The UNet takes six projections as input: the projection to correct, the two adjacent angles, the two orthogonal and the opposite ones. It contains a convolutional layer followed by 4 encoding/decoding blocks. We used L1 loss, Adam optimizer, and learning rate starting from $4x10^{-4}$. PVCNet method was tested on a simulated IEC phantom containing 6 spheres of 10, 13, 17, 22, 28 and 37mm radius, with source-to-background activity ratio of 40. Recovery Coefficients (RC) were compared on three reconstructed images: the image reconstructed with $P_{noPVE}$ without PVC (Rec_noPVE_noPVC), with $P_{PVE,noise}$ and RM (Rec_PVE_RM) and with PVCNet-corrected projections (Rec_PVE_PVCNet). All reconstructions were made with RTK's OSEM algorithm (5 iterations, 10 subsets), except for Rec_PVE_RM (20 iterations). ***Results:*** Training PVCNet took 20 hours, on 4 GPUs. RCs on Rec_noPVE_noPVC image were close to 1 while RCs on Rec_PVE_PVCNet were always at least 12% higher than Rec_PVE_RM (on the 17mm radius sphere 0.649 (PVCNet) / 0.531 (PVC-RM)) although the smallest sphere was more affected by artifacts. RMSE was divided by a factor of 1.46 and CNR by 1.36. ***Conclusion:*** PVCNet shows encouraging results reducing PVE on synthetic data compared to standard PVC-RM method. Increased realism of the training dataset and further testing of the PVCNet on real data are necessary. ***References:*** [1] Erlandsson et. al 2012 Phys. Med. Biol. vol. 57, no. 21, pp. R119-R159, 2012[2] Rit et al. 2014 Phys: Conf. Ser., vol. 489, p. 012079

## OP-371

### Deep-learning based partial volume correction for $^{177}$Lu SPECT/CT imaging based on a large Monte Carlo simulated dataset

***J. Leube****[1], J. Gustafsson[2], M. Lassmann[1], M. Salas Ramirez[1], J. Tran-Gia[1];*
*[1]University Hospital Würzburg, Würzburg, GERMANY,*
*[2]Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** The partial volume effect is a major obstacle in quantitative SPECT/CT imaging and image-based dosimetry. In this work, a deep-learning based method for partial volume correction (PVC) of $^{177}$Lu SPECT/CT imaging is presented. The method was developed and tested based on a large dataset of randomly shaped SPECT images generated by Monte Carlo (MC) simulations. ***Materials and Methods:*** A dataset of 10,000 activity distributions was generated by randomly placing random voxelized shapes [1] inside artificially generated XCAT body phantoms. Using the SIMIND MC program [2] low-noise ("noisefree") SPECT projection sets (120 projections, 128x128 matrices, 0.48x0.48 cm2 pixels, 20% energy window at 208 keV) were simulated for a Siemens Intevo bold SPECT/CT system (MELP collimator, 3/8" crystal). SPECT reconstructions were performed based on noisefree and noisy (created by adding Poisson noise) projections using standard OSEM without (CASToR [3], 2 iterations, 10 subsets, AC, SC) and with PSF modeling (STIR [4], 6 iterations, 6 subsets, AC, SC). Based on these four different sets of SPECT reconstructions, four different u-shaped convolutional neural networks (u-nets) were trained (input: SPECT reconstructions, output: original activity distributions, 60 epochs, L1 loss function). The dataset was divided in 9000/500/500 for training/validation/testing. For quantitative analysis, SSIM, NRMSE and volume activity accuracy (VAA, a new metric describing the percentage of voxels with activity in which the determined activity concentration deviates from the true activity concentration by less than 5%) between original activity distributions and SPECT reconstructions without / after PVC were calculated for all test data. ***Results:*** For CASToR, the PVC resulted in significant improvements (paired Wilcoxon test, $p<0.01$) in the quality parameters for noisefree (no PVC: 0.852/1.15%/10.7%, PVC: 0.960/0.66%/38.4% [SSIM/NRMSE/VAA]) and noisy reconstructions (no PVC: 0.816/1.29%/7.8%, PVC: 0.942/0.81%/30.7%). For STIR, the same behavior was found for noisefree (no PVC: 0.903/0.99%/11.7%, PVC: 0.965/0.64%/41.4%) and noisy reconstructions (no PVC: 0.893/1.04%/11.5%, PVC: 0.944/0.80%/32.9%). PVC based on STIR performed significantly better ($p<0.01$) than based on CASToR. ***Conclusion:*** In this work, the great potential of deep-learning based PVC is presented. A simulated data set was used to demonstrate the functionality of the presented method for different standard reconstructions (OSEM with and without PSF modeling). Overall, the method could help to alleviate the major problem of poor spatial resolution in SPECT. ***References:*** [1] Leube et al., EJNMMI Phys, 2022(9) [2] Ljungberg et al., Comput Meth Prog Bio, 1989(29) [3] Merlin et al., Phys Med Biol, 2018(63) [4] Thielemans et al., Phys Med Biol, 2012(57)

**Dual-phase $^{68}$Ga-FAPI-04 PET/CT: the pancreatic FAPI uptake characteristics and differentiation of pancreatic diseases**
***H. Wu****, C. Li, Y. Tian, Z. Xiao, Y. Jiang, Y. He;*
*Zhongnan Hospital of Wuhan University, Wuhan, Hubei Province, CHINA.*

***Aim/Introduction:*** This study aims to evaluate the diagnostic performance of dual-phase $^{68}$Ga-FAPI-04 PET/CT in differentiation of pancreatic disease and explore the factors affecting pancreatic $^{68}$Ga-FAPI-04 uptake. ***Materials and Methods:*** We retrospectively analyzed patients who received dual-phase point $^{68}$Ga-FAPI-04 PET/CT scan from May 2022 to October 2022. PET/CT scans were performed in at 30~60 minutes (rang from the base of the skull to mid-thigh). and at 2 hours (from the lower chest to mid abdomen for full coverage of pancreas). Multiple clinical data were collected to analyze its relationship with pancreatic $^{68}$Ga-FAPI-04 uptake. Quantitative parameters including the maximum standardized uptake (SUVmax), tumor to mediastinal blood pool ratio (TBR) at both time points for the pancreas were measured or calculated to evaluate the diagnostic performance for pancreatic diseases. The threshold of SUVmax to differentiate between malignant and non-malignant pancreas was determined by receiver operating characteristic (ROC) analysis. The reference standard was based on histopathological findings, clinical data typical imaging data (CT, MRI, ultrasound and $^{18}$F-FDG PET/CT) and imaging follow-up. ***Results:*** A total of 98 patients (63/98 males; median age, 56 years) were evaluated. The pancreatic FAPI uptake was significantly correlated with age ($P = 0.032$). There was no significant correlation between pancreatic FAPI uptake and body mass index (BMI), blood glucose, bilirubin, serum amylase, lipase, tumor markers, abdominal surgery ($P > 0.05$). Meanwhile, the SUVmax and TBR of malignant pancreas at dual-phases were significantly elevated than those of benign or normal pancreas ($P < 0.05$). The SUVmax and TBR of dual-phase $^{68}$Ga-FAPI-04 PET/CT scans performed excellent diagnostic performance in differentiating malignant and non-malignant condition of the pancreas. The optimal cut-off level of early SUVmax= 13.6 and delayed SUVmax=9.8 were associated with sensitivity of 91.7% and 66.7%, specificity of both was 90.7%. And the cut-off level of early TBR= 9.8 and delayed TBR=7.1 were associated with sensitivity of 100% and 66.7%, specificity of 88.4% and 84.9 respectively. ***Conclusion:*** The pancreatic $^{68}$Ga-FAPI-04 uptake was age-dependent, with older individuals more likely to experience pancreatic FAPI uptake. More importantly, the dual-phase $^{68}$Ga-FAPI-04 PET/CT scan can be used to distinguish between malignant, benign disease and normal pancreas.

### OP-374
**$^{68}$Ga-labeled Fibroblast Activation Protein Inhibitor PET/CT in the clinical diagnosis and management of breast cancer: Comparison with [$^{18}$F]FDG PET/CT**
***W. Guo***[1]*, W. Xu*[1]*, H. Fu*[1]*, Y. Pang*[1]*, L. Zhao*[1]*, L. Sun*[1]*, H. Chen*[2]*;*
[1]*The first affiliated hospital of Xiamen University, Xiamen, CHINA,* [2]*The first affiliated hospital of Xiamen University, Xiamen city, CHINA.*

***Aim/Introduction:*** Quinoline-based fibroblast activation protein inhibitors (FAPIs) have shown promising results in the diagnosis of cancer. PET imaging using $^{68}$Ga-FAPI shows a greater tumour-to-background ratio (TBR) than [$^{18}$F]FDG in various types of cancer, particularly in breast cancer. However, the further clinic role of [$^{68}$Ga]Ga-FAPI in the detection, staging/re-staging, and cancer management of breast cancer have not been systematically investigated. In this study, we investigated the diagnostic accuracy and clinical impact of [$^{68}$Ga]Ga-FAPI PET/CT in primary and metastatic breast cancer and compare the results with those of standard-of-care imaging (SCI) and [$^{18}$F]FDG PET/CT. ***Materials and Methods:*** This was a single-centre post-hoc retrospective study of a sub-cohort of patients from a previously acquired database. Patients with diagnosed or suspected breast cancer who underwent concomitant [$^{68}$Ga]Ga-FAPI (FAPI-46) and [$^{18}$F]FDG PET/CT scans from October 2019 to March 2022 were retrospectively analysed. Breast ultrasound (US) imaging was performed in all treatment-naïve patients as SCI. The maximum standard uptake value (SUVmax),TBR, lesion detection rate, and tumour-node-metastasis (TNM) classifications between [$^{68}$Ga]Ga-FAPI and [$^{18}$F]FDG PET/CT were evaluated and compared. ***Results:*** Thirty female patients (median age, 52 y; range, 28-80 y) were included. Among them, 5 patients underwent evaluation for a definitive diagnosis of suspected breast lesions, 9 underwent initial staging, and 16 were evaluated for the detection of recurrence. The sensitivities of breast US, [$^{18}$F]FDG, and [$^{68}$Ga]Ga-FAPI PET/CT for detecting primary breast tumours were 80%, 70%, and 100%, respectively. Regarding the diagnosis of recurrent/metastatic lesions, the per-lesion detection rate of [$^{68}$Ga]Ga- FAPI PET/CT was significantly higher than that of [$^{18}$F]FDG, which including local and regional recurrence (129 vs. 88), neck lymph node(LN) metastases (33 vs. 15), abdomen LN metastases (28 vs. 3), bone metastases (146 vs. 59), and liver metastases (28 vs. 11). Compared with [$^{18}$F]FDG, [$^{68}$Ga]Ga-FAPI PET/CT upstaged eight patients' TNM staging/re-staging (8/29, 28%) and changed six patients' clinical management (6/29, 21%). Compared to SCI, [$^{68}$Ga]Ga-FAPI changed eleven patients' TNM staging/re-staging (11/29, 33%) and eight patients' therapeutic regimens(8/29, 28%). There was no significant association between FAPI-derived SUVmax and receptor status/histologic type in both primary and metastatic lesions. ***Conclusion:*** [$^{68}$Ga]Ga-FAPI PET/CT was superior to [$^{18}$F]FDG in diagnosing primary and metastatic breast cancer, with higher radiotracer uptake and TBR, especially in the detection of primary/recurrent tumour, abdominal LN metastases, liver, and bone metastases. [$^{68}$Ga]Ga-FAPI PET/CT is superior to [$^{18}$F]FDG and SCI in TNM staging and may improve tumour staging, recurrence detection, and implementation of necessary treatment modifications.

## OP-375

### Role of PET/CT using [68Ga]Ga-DOTA-FAPI-04 in the Detection of Lesions and Staging of Various Malignancies, Excluding Gastrointestinal Tract Malignancies with Non-FDG Avid Lesions.

***G. Beydagi***[1], *N. Alan-Selcuk*[1], *K. Akcay*[1], *E. Demirci*[1], *O. Sonmez*[1], *M. Ocak*[2], *T. Toklu*[1], *S. Celik*[3], *B. Oven*[3], *L. Kabasakal*[4,1];
[1]*Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University, Faculty of Pharmacy, Department of Pharmaceutical Technology, Istanbul, TÜRKIYE,* [3]*Yeditepe University, Department of Medical Oncology, Istanbul, TÜRKIYE,* [4]*Istanbul Unıversity-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The emergence of 68Ga-labeled FAP ligands, also known as 68Ga-FAPI, has provided a promising alternative for cancer patients with FDG-negative lesions. Various studies have demonstrated the effectiveness of FAPi PET/CT in detecting digestive system malignancies. This study aims to evaluate the potential effectiveness of 68Ga-FAPI PET/CT in detecting, staging, and restaging different malignancies, excluding digestive system malignancies, which are characterized by low FDG uptake or FDG-negativity. ***Materials and Methods:*** After obtaining approval from the Clinical Research Ethics Committee, we prospectively enrolled patients with primary tumors or metastases confirmed by pathology. All participants underwent 68Ga-FAPI and 18F-FDG PET/CT scans within one week for either initial assessment (detection and staging) or recurrence detection (restaging). Two senior nuclear medicine physicians reviewed all studies by consensus. ***Results:*** A total of 52 patients with suspicious lesions on FDG PET/CT underwent 68Ga-FAPI PET/CT imaging. Of these, 15 had ovarian cancer, 11 had breast cancer, 7 had pancreatic cancer, 4 had hepatocellular carcinoma, 4 had renal cell carcinoma, 2 had lung cancer, 2 had leiomyosarcoma, 1 had thyroid papillary carcinoma, 1 had gastrointestinal stromal tumor, 1 had endometrium cancer, 1 had squamous cell carcinoma, and 2 had unknown primary. Compared to FDG PET/CT, FAPi PET/CT showed an increase in the primary malignancy stage in 16 patients (31%). Specifically, 75% of patients (n=3/4) diagnosed with lobular carcinoma of the breast had an increase in primary malignancy stage. Peritoneal metastases were detected in 28 patients (68%). Although 10 patients had FDG-negative peritoneal metastases, FAPi PET/CT could detect them in all but one patient with a gastrointestinal stromal tumor diagnosis. As a result, major treatment changes were made for 11 patients (21%) and minor changes for 5 patients (10%) in the entire patient cohort. ***Conclusion:*** 68Ga-FAPI PET/CT has demonstrated superiority in the detection, staging, and restaging of low FDG-avid tumors, not only in gastrointestinal malignancies but also in other malignancies where the tumor background ratio in FDG-PET/CT is unfavorable.

## OP-376

### Impact of $^{68}$Ga-FAPI PET/CTimaging in the diagnosis and management of primary and recurrent epithelial ovarian cancer

***K. Xu***, *J. Chen, C. Li, Y. Tian, L. Li, Y. Jiang, Z. Xiao, D. Xing, B. Wen, Y. He;*
*Zhongnan Hospital of Wuhan University, Wuhan, China, CHINA.*

***Aim/Introduction:*** Gallium-68-labeled fibroblast activation protein inhibitor ($^{68}$Ga-FAPI) has showed promising application prospects in many malignant tumors. This study aims to evaluate the diagnostic performance and impact on the clinical management of $^{68}$Ga-FAPI PET/CT in epithelial ovarian cancer (EOC) compared with conventional imaging (CI). ***Materials and Methods:*** Forty-one patients with EOC were retrospectively recorded between October 2021 and January 2023. All participants underwent both CI and [$^{68}$Ga]Ga-FAPI-04 PET/CT. PET images were analyzed for judging complete resectability according to SUIDAN scoring system(PET scores). The associations between the PET score, peritoneal cancer index (PCI) score, and Esienkop score of preoperative [$^{68}$Ga]Ga-FAPI-04 PET/CT imaging were also evaluated. A receiver operating characteristic (ROC) curve analysis was performed to assess the accuracy of the PET score in predicting complete postoperative resection and guide therapeutic management. The recommended treatment was determined by imaging according to the NCCN guidelines. The final diagnosis and treatment were determined by pathological criteria and a dedicated multidisciplinary team. The diagnostic performance according to [$^{68}$Ga]Ga-FAPI-04 PET/CT was compared with CI and changes in oncologic management were recorded. ***Results:*** [$^{68}$Ga]Ga-FAPI-04 PET/CT significantly outperformed CI in diagnostic accuracy (86.5% vs. 51.2%, respectively, p< 0.001), especially in the stage III to IV. The PET score had a significant positive correlation with tumor burden (Eisenkop: r=0.768, P< 0.001; PCI: r=0.777, P< 0.001). The ROC showed that preoperative PET score ≥ 6 and score≥ 3 predicted a high risk of incomplete resection for primary and secondary debulking surgeries, respectively. Based on the final treatment, the coincidence rate of PET score guided treatment was significantly higher than that of CI (90.2% vs. 62.5%, p<0.001). Compared with CI, [$^{68}$Ga]Ga-FAPI-04 PET/CT modified the diagnosis in 34.6% of patients. [$^{68}$Ga]Ga-FAPI-04 PET/CT led to an upgrade in 45.0% and 33.3% of treatment-naive and relapse participants, resulting in management changes in 30.0% and 28.6% of patients compared with CI. ***Conclusion:*** [$^{68}$Ga]Ga-FAPI-04 PET/CT is a promising imaging modality for the diagnosis performance and therapeutic management. The preoperative PET score can noninvasively reflect tumor burden and helps predict complete resection after surgery in EOC patients.

## OP-377

### Fibroblast activation protein and glycolysis in lymphoma diagnosis: comparison of$^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT

***X. Chen***, *S. Wang, Y. Lai, G. Wang, M. Wei, X. Jin, J. Ding, Y. Zhang, Y. Shi, F. Wang, H. Zhu, Z. Yang, X. Wang;*
*Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** o compare the diagnostic performances of gallium 68 ($^{68}$Ga)-labeled fibroblast activation protein inhibitor (FAPI) and fluorine 18 ($^{18}$F)-labeled fluorodeoxyglucose (FDG) PET/CT in diagnosing lymphomas and to characterize the influences of fibroblast activation protein (FAP) and glycolytic markers on tracer uptake by involved lesions. ***Materials and Methods:*** Participants with different lymphoma subtypes, who were prospectively recruited from May 2020 to December 2021, underwent $^{68}$Ga-FAPI and $^{18}$F-FDG PET/CT. Immunohistochemistry was performed to evaluate FAP, hexokinase 2 (HK2), and glucose transporter 1 (GLUT1) expression, and paired samples t-test and Wilcoxon signed-rank test were used to compare parameters. Correlation between the immunochemistry results and tracer uptake was determined by Spearman's rank correlation coefficient. ***Results:*** In total, 186 participants (median age: 52 years [interquartile range: 41-64 years]; 95 women) were included. Dual-tracer imaging produced three types of imaging profiles. $^{18}$F-FDG PET possessed a higher staging accuracy (98.4%) than $^{68}$Ga-FAPI PET (86.0%). In 5980 lymphoma lesions, $^{18}$F-FDG PET/

CT detected more nodal (4624 vs. 2196) and extranodal lesions (1304 vs. 845) than $^{68}$Ga-FAPI PET/CT. Additionally, 52 FAPI+/FDG− lesions and 2939 FAPI−/FDG+ lesions were observed. In many lymphoma subtypes, semiquantitative evaluation revealed no significant differences in maximum standardized uptake values ($SUV_{max}$) and target-to-liver ratios between $^{68}$Ga-FAPI and $^{18}$F-FDG PET/CT (P > .05). Interestingly, GLUT1 and HK2 were overexpressed in both lymphoma cells and the tumor microenvironment, while FAP was only expressed in stromal cells. FAP and GLUT1 expression were positively correlated with $SUV_{max\text{-}FAPI}$ (r = 0.622, P = .001) and $SUV_{max\text{-}FDG}$ (r = 0.835, P < .001), respectively. ***Conclusion:*** $^{68}$Ga-FAPI PET/CT was inferior to $^{18}$F-FDG PET/CT in diagnosing lymphomas with low FAP expression. However, the former may supplement the latter and help reveal the molecular profile of lymphomas.

## OP-378

### [68Ga]GaFAPI-RGD PET/CT in the evaluation of renal carcinoma: comparison with [18F]FDG/[68Ga]Ga-PSMA PET/CT

***R. Lin***[1], *J. Zang*[1], *C. Wang*[1], *S. Chen*[1], *J. Zhang*[1], *Y. Yang*[1], *F. Xu*[1], *J. Zhang*[2], *X. Chen*[2], *W. Miao*[1];
[1]*Department of Nuclear Medicine, the First Affiliated Hospital, Fujian Medical University, Fuzhou, Fujian Province, CHINA,*
[2]*National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** To compare the potential efficiency of [$^{68}$Ga]Ga-FAPI-RGD with that of [$^{18}$F]FDG/[$^{68}$Ga]Ga-PSMA PET/CT for detecting renal cell carcinoma (RCC) and to explore parameters derived from [$^{68}$Ga]Ga-FAPI-RGD PET/CT for discriminating pathological characteristics in RCC. ***Materials and Methods:*** Twenty-five RCC patients confirmed by pathology with a total of 28 lesions were enrolled in this prospective study. 16 patients underwent paired [$^{68}$Ga]Ga-FAPI-RGD and [$^{18}$F]FDG PET/CT, and the other 9 patients underwent paired [$^{68}$Ga]Ga-FAPI-RGD and [$^{68}$Ga]Ga-PSMA PET/CT. The activity of tracer accumulation in lesions was assessed by maximum standardized uptake value (SUVmax) and tumor-to-background (TBR). Pathological characteristics included WHO/ISUP grade and adverse pathology (tumor necrosis or sarcomatoid or rhabdoid feature). Values of radiological parameters were compared within subgroups of pathological characteristics. ***Results:*** [$^{68}$Ga]Ga-FAPI-RGD PET/CT showed a higher detection rate for primary lesions than those of [$^{18}$F]FDG and [$^{68}$Ga]Ga-PSMA (FAPI-RGD vs. FDG: 76.5% [13/17] vs. 23.5% [4/17], P < 0.001; FAPI-RGD vs. PSMA: 81.8% [9/11] vs. 54.5% [6/11], P = 0.361). [$^{68}$Ga]Ga-FAPI-RGD showed higher SUVmax (6.6 vs. 3.7, P = 0.005) and TBR (2.6 vs. 1.7, P = 0.011) in RCC compared with [$^{18}$F]FDG, and it also showed higher TBR (2.9 vs. 0.5, P = 0.003) and TBR-delay (2.8 vs. 0.3, P = 0.003) compared with [$^{68}$Ga]Ga-PSMA PET/CT. The SUVmax, TBR and TBR-delay significantly differed by WHO/ISUP grade and adverse pathology (all P < 0.05), the TBR significantly differed by clinical grade and M stage (P = 0.018, P = 0.002), and the SUVmax-delay significantly differed by pT stage (P = 0.019). SUVmax and TBR could effectively differentiate WHO/ISUP grade (3-4 vs. 1-2) and adverse pathology (positive vs. negative) (SUVmax: AUC 0.81, P = 0.04, cutoff 9.1, sensitivity 80%, and specificity 93% for WHO/ISUP grade; AUC 0.80, P = 0.033, cutoff 10.5, sensitivity 67%, and specificity 100% for adverse pathology; TBR: AUC 0.84, P = 0.026, cutoff 4.0, sensitivity 80%, and specificity 87% for WHO/ISUP grade; AUC 0.85, P = 0.014, cutoff 3.8, sensitivity 67%, and specificity 94% for adverse pathology). ***Conclusion:*** [$^{68}$Ga]Ga-FAPI-RGD is a promising new diagnostic PET tracer for RCC imaging and can effectively identify aggressive pathological features of RCC.

## OP-379

### Diagnostic Accuracy of $^{68}$Ga-FAPI and $^{18}$F-FDG PET/CT for Localizing Primary Tumor in the Head and Neck Cancer of Unknown Primary

***B. Gu***, *X. Du, Z. Yang, S. Song, Z. Yang;*
*Fudan University Shanghai Cancer Center, Shanghai, CHINA.*

***Aim/Introduction:*** To investigate the diagnostic accuracy of gallium 68 ($^{68}$Ga)-labeled FAP inhibitor (FAPI) PET/CT for the detection of primary tumor of head and neck cancer of unknown primary (HNCUP), compared with fluorine 18 ($^{18}$F)-labeled fluorodeoxyglucose (FDG). ***Materials and Methods:*** A total of 91 patients (18 females, 73 males; median age: 60 years, range: 24-76 years) with negative or equivocal findings of primary tumor by comprehensive clinical examination comprehensive clinical examination and conventional imaging were prospectively enrolled from June 2020 to September 2022. Images from paired $^{18}$F-FDG and $^{68}$Ga-FAPI PET/CT underwent within 1 week were analyzed. Suspected primary sites were further verified by biopsy or histopathologic examination. Paired t test and Wilcoxon signed-rank test were used to compare the differences of maximum of standardized uptake value ($SUV_{max}$) and tumor-to-liver blood pool ratio (TLR) between $^{18}$F-FDG and $^{68}$Ga-FAPI in primary tumor and metastatic lesions. The survival analyses were performed using Kaplan-Meier method. ***Results:*** Of the 91 patients, primary tumor was detected in 46 patients (50.55%) after a thorough diagnostic workup. Compared to $^{18}$F-FDG, $^{68}$Ga-FAPI PET/CT detected more primary lesions (17 vs. 46, P < 0.001) and outperformed in sensitivity, positive predictive value and accuracy for the locating the primary tumor (25% vs. 51.11%, 42.50% vs. 97.87%, and 18.68% vs. 50.55%, respectively). Furthermore, $^{68}$Ga-FAPI PET/CT led to T upstaging in 22 of 91 (24.18%) patients compared with $^{18}$F-FDG. Moreover, in terms of $SUV_{max}$ and TLR, primary tumors demonstrated significantly higher semiquantitative uptake values of $^{68}$Ga-FAPI than $^{18}$F-FDG ($SUV_{max}$: 6.11 ± 4.30 and 3.16 ± 5.11, P < 0.001; TLR: 10.85 ± 6.81 and 1.45 ± 2.31, P < 0.001). Kaplan-Meier curve illustrated that patient with unidentified primary tumor had a significant worse prognosis than patient with identified primary tumor (Hazard rate (HR) = 5.77, 95% confidence interval (CI): 1.86-17.94, P = 0.0097). ***Conclusion:*** $^{68}$Ga-FAPI PET/CT outperforms $^{18}$F-FDG in detecting primary lesions, and could serve as a sensitive, reliable and reproducible imaging modality for HNCUP patients.

## OP-380

### Head-to-head comparison of$^{68}$Ga-FAPI46 PET/CT,$^{18}$F-FDG PET/CT, and contrast-enhanced CT in patient with various solid tumors

***M. Watanabe***, *H. Grafe, N. Hirmas, R. Hamacher, H. Lanzafame, K. M. Pabst, M. Nader, J. T. Siveke, W. P. Fendler, K. Herrmann, M. Weber;*
*Essen University Hospital, Essen, GERMANY.*

***Aim/Introduction:*** FAPI-PET/CT is characterized by visualization of high tumor specific uptake and low background accumulation, enabling the detection of tumor lesions with high sensitivity. We aimed to compare the diagnostic performance of $^{68}$Ga-FAPI46 PET/CT vs. $^{18}$F-FDG PET/CT vs. contrast-enhanced CT (CE-CT) in patients with solid tumors. ***Materials and Methods:*** 241 patients underwent $^{68}$Ga-FAPI46 PET/CT,$^{18}$F-FDG PET/CT, and CE-CT within 4 weeks from October 2018 to September 2022. Detection rates were assessed by a blinded reader, with at least 2 weeks between scans of the same patient to avoid recall bias, per-lesion, per-region and per-patient. In addition, the highest SUVmax in each region

was measured. A separate sub-analysis was carried out for 629 histopathologically validated lesions to calculate sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV) and accuracy. Detection rates among different modalities were compared using McNemar's test. ***Results:*** The total lesion-based detection rates in $^{68}$Ga-FAPI46 PET/CT, $^{18}$F-FDG PET/CT, and CE-CT were 91.5% (1635/1787), 82.7% (1477/1787) and 60.2% (1075/1787). Separate for regions, the lesion-based analyses were 95.4% (185/194), 88.7% (172/194) and 78.9% (153/194) for primary lesions, 82.7% (335/405), 88.4% (358/405), 51.6% (209/405) in cervicothoracic nodal metastases, 93.1% (338/363), 72.7% (264/363) and 47.7% (173/363) in abdominopelvic nodal metastases, 96.2% (178/185), 93.0% (172/185) and 93.0% (172/185) in lung metastases, 95.6% (215/225), 73.3% (165/225) and 58.7% (132/225) in liver metastases, 92.1% (176/191), 76.4% (146/191) and 43.5% (83/191) in other visceral metastases, 92.9% (208/224), 89.3% (200/224) and 68.3% (153/224) in bone metastases, respectively. Per-region detection rates were 95.7% (441/461), 84.8% (391/461) and 70.3% (324/461), and per-patient analysis was 99.5% (210/211), 92.9% (196/211) and 90.5% (191/211), respectively. As well as the per-region and per-patient analyses, per-lesion detection rates were significantly higher in $^{68}$Ga-FAPI46 PET/CT than $^{18}$F-FDG PET/CT for total, primary, abdominopelvic nodal, liver, and other visceral lesions ($p<0.05$). There were no significant differences of SUVmax between $^{68}$Ga-FAPI46 PET/CT and $^{18}$F-FDG PET/CT.In the sub-analysis, sensitivity, specificity, PPV, NPV and accuracy were 75.7%, 94.9%, 85.4%, 90.9% and 89.5% in$^{68}$Ga-FAPI46 PET/CT, 71.2%, 94.0%, 82.4%, 89.3% and 87.6% in $^{18}$F-FDG PET/CT, and 65.5%, 96.2%, 87.2%, 87.7% and 87.6% in CECT, respectively. ***Conclusion:*** $^{68}$Ga-FAPI46 PET/CT outperforms $^{18}$F-FDG PET/CT and CE-CT in a variety of solid tumors with regards to the detection rate, while also lowering the risk of false-positive findings, especially for primary, abdominopelvic nodal, liver, and other visceral lesions. Further studies on which entities draw particular benefit from $^{68}$Ga-FAPI46 PET/CT are warranted to aid appropriate diagnostic workup.

### OP-381

**Cardiac one stop shop: Performance of a Rapid Diagnostic Outpatient Clinic using Rubidium-82 PET-CT Imaging.**

***J. Boer***, *M. Ros, P. Bot;*
*Spaarne Gasthuis, Haarlem, NETHERLANDS.*

***Aim/Introduction:*** Atherosclerotic vascular disease is a major cause of death worldwide, and in the Netherlands, coronary heart disease affects a large number of people.To speed up the diagnosis of myocardial ischemia due to severe atherosclerotic narrowing of coronary arteries, a one-stop-shop (OSS) was introduced that utilizes rubidium-82 myocardial perfusion PET-CT imaging (Rb-82 PET-CT). The aim of this clinic is to analyze patients within a week and all appointments on the department of cardiology and nuclear medicine take place on the same day. The study aims to determine whether the use of the OSS results in shorter throughput times, thus decreasing the risk for patients with severe coronary artery disease without compromising efficiency and healthcare costs. ***Materials and Methods:*** The study was conducted by retrospectively comparing the throughput times between the OSS and the traditional outpatient clinic. The date of referral and the date of the follow-up appointment after the examination for all patients referred for examination at the OSS were recorded, as well as the number of patients who actually underwent an examination. The Duke score was calculated, and a pre-test likelihood of >15% indicated the need for additional testing according to the guideline of the European Society of Cardiology (ESC). The study's main outcome was the potential reduction in days of the diagnostic process through the use of the OSS compared to the control group. ***Results:*** In total, 152 patients were analyzed, and the results showed that the throughput times in the OSS were on average 9 days compared to 68 days in the control group. Ischemia was found in 25% of patients in the OSS and 10% of controls. Six percent of patients dropped out of the OSS because the indication was rejected by the cardiologist, and 8% of patients in the OSS had a pretest likelihood of below 15%. Examinations with a Duke score below 15% or with non-specific complaints were considered not useful and deemed as over diagnosis. ***Conclusion:*** The implementation of a OSS utilizing Rb-82 PET-CT imaging has the potential to dramatically expedite the diagnosis of myocardial ischemia in patients with suspected coronary artery disease with an average reduction of 59 days. The OSS was more effective in selecting patients with ischemia, where 25% of patients had ischemia compared to 10% in the control group. Dropout rates and overdiagnosis occurred in 14% of cases.

### OP-382

**Prognostic value of coronary flow capacity by rubidium-82 PET/CT in patients with suspected CAD and normal myocardial perfusion imaging**

***A. D'Antonio***[1], *E. Zampella*[1], *R. Assante*[1], *T. Mannarino*[1], *V. Gaudieri*[1], *P. Buongiorno*[1], *M. Falzarano*[1], *R. Lepre*[1], *F. Reina*[1], *M. Panico*[2], *P. Arumugam*[3], *A. Cuocolo*[1], *W. Acampa*[1];
[1]*Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY,* [2]*Institute of Biostructure and Bioimaging, CNR, Naples, ITALY,* [3]*Department of Nuclear Medicine, Central Manchester Foundation Trust, Manchester, UNITED KINGDOM.*

***Aim/Introduction:*** Vasodilator capacity of coronary circulation is an important diagnostic and prognostic tool in patients with suspected and known coronary artery disease (CAD). Non-invasive assessment of myocardial blood flow (MBF) and myocardial perfusion reserve (MPR) is able to evaluate both epicardial disease and microvascular dysfunction. Coronary flow capacity (CFC) has been evaluated as comprehensive of the coronary circulation, integrating both MBF and MPR measurements. We aimed to assess the prognostic value of impaired CFC, evaluated by Rubidium-82 positron emission tomography/computed tomography (PET/CT), in patients with suspected CAD and normal myocardial perfusion imaging (MPI) ***Materials and Methods:*** We evaluated 2454 patients with suspected CAD who underwent stress/rest Rubidium-82 cardiac PET/CT. Patients with normal MPI (n=2005), defined as a total perfusion defect <5%, were included. Hyperemic MBF and MPR were calculated and considered abnormal when < 1.8 ml/min/g and <2, respectively. In order to evaluate CFC, four patient groups were identified based on the concordant or discordant impairment of MBF or MPR. CFC was considered impaired in the presence of both abnormal MBF and MPR. End- points were defined as major adverse cardiovascular

events (MACEs), such as cardiovascular death, nonfatal myocardial infarction, unplanned hospitalization for any cardiac reasons, and unplanned coronary revascularization. Annualized event rates (AER) were calculated. A parametric survival model was also used to identify how the variables influenced time to event and to estimate risk-adjusted event rates during the follow-up ***Results:*** Follow-up was available in 1896 (95%) patients (median age 59±13 years). During a median time of 44 months (range 3-111), 72 events occurred (cumulative rate 4%, AER 0.8%). Both MBF and MPR were concordant abnormal in 141 (7%) subjects with impaired CFC, concordant normal in 1402 (74%), discordant with impaired MBF in 112 (6%) and discordant with impaired MPR in 241 (13%). According to MBF and MPR categories, AER was higher in patients with impaired CFC (AER 3.2%) as compared to concordant normal (AER 0.4%), discordant patients with impaired MBF (1.3%) and those discordant with impaired MPR (AER 0.9%) (p for trend <0.001). At Weibull parametric survival analysis, the highest probability of cardiac events and the major risk acceleration were observed in patients with both impaired MBF and MPR ***Conclusion:*** In patients with suspected CAD and normal MPI, impaired CFC was associated with a higher risk of MACEs. The CFC evaluation can help identify patients candidates to additional therapies in order to prevent future events

## OP-383

### Quantitative relationship between coronary artery calcium and myocardial blood flow by hybrid rubidium-82 PET/CT imaging in heart transplanted patients

***T. Mannarino***[1], *R. Assante*[1], *E. Zampella*[1], *A. D'Antonio*[1], *F. Cacciatore*[2], *C. Amarelli*[3], *M. Falzarano*[1], *F. Reina*[1], *R. Lepre*[1], *I. Mattucci*[3], *R. Chiappetti*[2], *V. Gaudieri*[1], *P. Buongiorno*[1], *M. Panico*[1], *C. Maiello*[3], *A. Cuocolo*[1], *W. Acampa*[1];
[1]*Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [2]*Department of Translational Medical Sciences, University of Naples "Federico II", Naples, ITALY,* [3]*Department of Cardiac Surgery and Transplantation, Monaldi, Azienda Ospedaliera dei Colli, Naples, Naples, ITALY.*

***Aim/Introduction:*** Cardiac myocardial perfusion imaging (MPI) by positron emission tomography (PET)/ computed tomography (CT) represents a noninvasive method used for an integrated measurement of myocardial blood flow (MBF), myocardial flow reserve (MFR) and coronary calcium content. No study has investigated the relationship between coronary atherosclerotic burden and vascular function in heart transplanted patients. Thus, we assessed the relationship between CAC score, MBF and MFR in heart transplant patients undergoing hybrid $^{82}$Rb positron emission tomography (PET)/computed tomography (CT) imaging. ***Materials and Methods:*** We enrolled a total of 100 (mean age 60±13 years) consecutive patients referred to hybrid $^{82}$Rb PET/CT myocardial perfusion imaging for evaluation of myocardial ischemia. CAC score was measured according to the Agatston method and patients were categorized into 4 groups (0, 0.01-99.9, 100-399.9, and ≥400). Baseline and hyperemic MBF were automatically quantified. MFR was calculated as the ratio of hyperemic to baseline MBF and it was considered reduced when <2. The Spearman correlation coefficient was assessed between continuous CAC score and MBF or MFR values. Univariable and multivariable logistic regression analyses were used to determine the variables associated with reduced MFR. ***Results:*** Global CAC score showed a significant inverse correlation with hyperemic MBF (r=-0.28, P < .05) and MFR (r=-0.40, P < .001), while no correlation between CAC score and baseline MBF was found (P = 0.9). CAC score was zero in 71 (71%) patients, 0.1-99.9 in 8 (8%), 100-399.9 in 12 (12%), and ≥400 in 9 (9%). Global baseline MBF was comparable among the four groups of patients at different levels of CAC score (F = 0.040, P = 0.989). Whereas hyperemic MBF (F = 2.897) and CFR (F = 4.344) progressively decreased with increasing CAC levels (P for trend <0.05). Univariable analysis demonstrated that age, diabetes, and CAC score (all P < .05) were associated with reduced MFR. At multivariable logistic regression analysis only age and CAC score (both P < .05) were independently associated with reduced MFR. The addition of CAC score to clinical data, increased the global chi-square value for predicting reduced MFR from 18.79 to 25.66 (P < .01). ***Conclusion:*** In heart transplanted patients there was an inverse relationship between CAC score and MFR. The evaluation of calcium content might be helpful for identifying patients with a reduced MFR, at high risk to develop cardiac allograft vasculopathy.

## OP-384

### MPI - from Rb to [$^{15}$O]water with a dedicated cyclotron

***M. Lonsdale****, S. Fuglsang, M. Krakauer, A. Larsen, I. Rasmussen, U. Talleruphuus, P. Hovind;*
*Bispebjerg Hospital, Copenhagen, DENMARK.*

***Aim/Introduction:*** [$^{15}$O]water PET is considered the reference for non-invasive in vivo measurement of myocardial blood flow[1]. Advantages over $^{82}$Rb include metabolical inertness and a linear relationship between tracer uptake and myocardial blood flow. The main disadvantages are the need for an on-site cyclotron due to the half-life of $^{15}$O and software to calculate parametric images as no static uptake images can be acquired. We present our experiences transitioning perfusion studies from $^{82}$Rb to [$^{15}$O]water with a dedicated mini-cyclotron at a hospital with no previous cyclotron installation. ***Materials and Methods:*** Supply chain disruptions, economic uncertainties, and the ambition to provide state-of-the-art myocardial perfusion imaging (MPI) services initiated the transition from $^{82}$Rb to [$^{15}$O]water. A self-shielded cyclotron dedicated to the production of $^{15}$O was installed in a technical building without radiation shielding features. Production of $^{15}$O, synthesis to [$^{15}$O]water and i.v. administration is performed using standard procedures which are exclusively performed by the departments' technologists - without other cyclotron staff. Initial training included physicists (cyclotron troubleshooting), technologists (production of $^{15}$O and [$^{15}$O]water, QC - all according to GMP) and medical doctors (software, reading of images). All patient handling and scanning procedures could be easily translated 1:1 from $^{82}$Rb. ***Results:*** Economics: The return-of-investment is less than 5 years, with the extra advantage of greater flexibility. For $^{82}$Rb generators, the cost is driven by the number of $^{82}$Rb-generators, regardless of utilization. In contrast, cyclotron running costs are dominated by its actual use. No extra staff was necessary apart from a part-time consulting radiochemist acting as QP for GMP. Clinical: After 12 months of exclusive use of [$^{15}$O]water for MPI, the impact on the referral pattern was the most notable change. Patient referrals decreased from 125 per months to around 100. During implementation of [$^{15}$O]water, the interprofessional collaboration with cardiology was improved significantly (teaching sessions, more frequent multidisciplinary conferences and continuous case-oriented dialogue) leading to increased awareness and knowledge in pearls and pitfalls in MPI studies in general - all in all leading to more clinically appropriate and relevant referrals. "Stress-only" studies for selected populations offer extra patient comfort. As a minor positive side-effect

radiation dose to patients and exposed staff was reduced to about 50%. ***Conclusion:*** We have demonstrated the possibility to offer high-volume, state-of-the-art MPI studies at a hospital with no prior cyclotron installation. Clinical experience is positive. ***References:*** [1] R Sciagrà et al: EANM procedural guidelines for PET/CT quantitative MPI, EJNMMI. 2021;48:1040-69.

## OP-385

### $^{82}$Rb and [$^{15}$O]$H_2O$ Myocardial perfusion PET imaging - a prospective head to head comparison

***L. Marner***[1], *M. Krakauer*[1], *A. Ismail*[1], *U. Talleruphuus*[1], *A. C. Henriksen*[1], *M. N. Lonsdale*[1], *I. L. Rasmussen*[1], *S. Fuglsang*[1], *E. Prescott*[2], *P. Hovind*[1], *L. Marner*[1];
[1]*Copenhagen University Hospital Bispebjerg, Department of Clinical Physiology and Nuclear Medicine, Copenhagen NV, DENMARK,* [2]*Copenhagen University Hospital Bispebjerg, Department of Cardiology, Copenhagen NV, DENMARK.*

***Aim/Introduction:*** $^{82}$Rb PET and [$^{15}$O]$H_2O$ PET are both validated tracers for myocardical perfusion imaging but have not previously been compared in a prospective cohort of patients in diagnosing possible myocardial ischemia. During our site's clinical transition from $^{82}$Rb PET to [$^{15}$O]$H_2O$ PET, we performed a head-to-head comparison measuring myocardial perfusion in a mixed population with suspected ischemic heart disease. ***Materials and Methods:*** A total of 37 patients were examined with both $^{82}$Rb and [$^{15}$O]$H_2O$ PET on the same day in rest and during adenosine-induced stress. Significant regional perfusion defects were suspected in $^{82}$Rb PET if a relative defect was >10% and in [$^{15}$O]$H_2O$ PET if two segments had perfusion ≤ 2.3 mL/(g·min). Significant global reduction was suspected in $^{82}$Rb PET if the perfusion reserve (relative increase) was ≤ 1.8 and in [$^{15}$O]$H_2O$ PET if all segments were ≤ 2.3 mL/(g·min). Further, a less sensitive assessment of total perfusion defects of 10% (TPD) was evaluated for [$^{15}$O]$H_2O$ PET. Results were rated by two blinded readers to assess agreement between methods and interrater agreement. ***Results:*** Agreement between methods was 59% as [$^{15}$O]$H_2O$ PET identified more patients compared to $^{82}$Rb PET with regional perfusion defects during pharmacological stress. Using the less sensitive TPD, the agreement increased to 84% corresponding to a Cohen's kappa of 0.57 [95% C.I.: 0.25 - 0.87]. Interrater agreement was 95% corresponding to a kappa of 0.89 [95% C.I.: 0.74 - 1.00]. ***Conclusion:*** In conclusion, [$^{15}$O]$H_2O$ myocardial perfusion PET is a sensitive imaging modality with a high interrater agreement. However, we found a moderate agreement between methods as [$^{15}$O]$H_2O$ PET identifies more patients with signs of ischemia than $^{82}$Rb PET especially in patients with previous heart disease. When performing a clinical transition from $^{82}$Rb PET to [$^{15}$O]$H_2O$ PET, the higher sensitivity for perfusion defects should be taken into account.

## OP-386

### Splenic switch-off as marker of adenosine response in myocardial perfusion imaging with O-15-H2O PET

***M. Jochumsen***[1,2], *L. C. Gormsen*[1,2], *L. P. Tolbod*[1,2], *J. Brorson*[1,2];
[1]*Dept of Nuclear Medicine and PET-Centre, Aarhus University Hospital, Aarhus, DENMARK,* [2]*Department of Clinical Medicine, Aarhus University, Aarhus, DENMARK.*

***Aim/Introduction:*** Surrogate markers of sufficient adenosine response during positron emission tomography (PET) myocardial perfusion imaging (MPI) are important for discriminating between adenosine non-responders and patients with severe balanced ischemia. These results is part of a larger study to validate splenic switch-off as a marker of sufficient adenosine response on $^{15}$O-$H_2O$-PET MPI using both qualitative and quantitative analysis and examines the splenic switch-off in a cohort with verified sufficient adenosine response. ***Materials and Methods:*** A cohort of patients with sufficient adenosine response was identified (n=90), including patients with normal MPI (n=30), regional ischemia (n=30), and global/balanced ischemia (n=30). To determine whether the adenosine response was sufficient, two criteria were used: (1) a 1.5-fold increase in myocardial blood flow in at least two adjacent segments following adenosine administration, and (2) at least two of the following: hemodynamic response, side effects, and ECG changes. All patients were scanned according to facility standards and international guidelines on a GE Discovery MI Digital Ready PET/CT (GE Healthcare, Waukesha, Wisconsin, USA). Since $^{15}$O-$H_2O$ is not a retention tracer, images of summed activity and parametric blood flow images are used for visual assessment of splenic switch-off. Furthermore, spherical VOIs of the spleen, liver, and blood were drawn on both summed activity and parametric blood flow images for quantitative analysis. ***Results:*** Summed activity images: Visual splenic switch-off: positive (71%), inconclusive (16%), negative (13%). Spleen signal: >10% decrease (84%), 0-10% decrease (6%), increase (10%). Hepatic signal: >10% increase (30%), 0-10% increase (27%), decrease (43%). Spleen-liver-ratio: >10% decrease (81%), 0-10% decrease (11%), increase (8%). Parametric blood flow images: Visual splenic switch-off: positive (86%), inconclusive (6%), negative (8%). Spleen signal: >10% decrease (92%), 0-10% decrease (5%), increase (3%). Hepatic signal: >10% increase (66%), 0-10% increase (15%), decrease (19%). Spleen-liver-ratio: >10% decrease (91%), 0-10% decrease (4.5%), increase (4.5%). When comparing stress-rest-ratios for splenic switch-off, hepatic switch-on and decrease in spleen-liver-ratio, parametric images highly significantly outperformed summed images on all parameters (p<0.0001). ***Conclusion:*** The presence of splenic switch-off, and decrease in spleen-liver-ratio are reliable markers of sufficient adenosine response on $^{15}$O-$H_2O$-PET MPI, whereas the absence of these does not necessarily indicate a lack of adenosine response. For both visual and quantitative assessment, parametric blood flow images should be preferred; however, summed images can serve as a convenient alternative in clinical routine.

## OP-387

### RV to LV Myocardial Blood Flow Ratio With $^{15}$O-water PET as a Risk Marker for Cardiac Events in Patients With Left Ventricular Hypertrophy

***P. Svanström***, *J. Sigfridsson, H. J. Harms, T. Kero, K. Eggers, N. Regula, M. Lubberink, J. Sörensen;
Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** Left ventricular hypertrophy (LVH) is a well-established cardiac risk factor. Increased risk in LVH is associated with microvascular dysfunction, but LVH might also increase poor outcome by diastolic dysfunction and subsequent pulmonary hypertension (PH), which is less well studied. LVH is diagnosed as increased septal wall thickness (WT) or left ventricular mass (LVM), which can be measured with $^{15}$O-water PET [1]. Using $^{15}$O-water PET, a ratio of right ventricle (RV) and LV resting myocardial blood flow ($MBF_{RV/LV}$) larger than 67% diagnosed PH and predicted poor outcome with high accuracy in cardiac amyloidosis patients [2]. This study aimed to determine the prognostic value of $MBF_{RV/LV}$ in a clinical cohort of patients with LVH. ***Materials and Methods:*** We retrospectively identified LVH from a single-centre cohort of 500 consecutive patients with suspected coronary artery disease

referred for routine rest/adenosine-stress $^{15}$O-water PET. LVH was determined from resting PET according to standard criteria (LVM >85g/m$^2$ or WT >12 mm). Cardiac events were defined as cardiac death, acute heart failure or acute myocardial infarction. The prognostic value of $MBF_{RV/LV}$ was compared to LV stress-MBF, coronary flow reserve (CFR), WT and LVM using Cox hazards ratio (HR[95% confidence interval]). ***Results:*** LVH was diagnosed in 105 patients (21%), in which 24 cardiac events were registered (median follow-up 4.1 years). Significant prognostic value in univariate analysis was found for $MBF_{RV/LV}$ (HR 1.61[1.20-2.12] per 10%), stress-MBF (HR 0.93[0.87-0.98] per 0.1 ml/min/g) and CFR (HR 0.43[0.25-0.71]), but not WT (HR 1.00[0.84-1.19] per mm) or LVM (HR 1.01[0.99-1.03] per g/m$^2$). In multivariate analysis $MBF_{RV/LV}$ and CFR remained independently significant. Using receiver-operating characteristic analysis $MBF_{RV/LV}$ > 67.7% was the best cut-off (HR 5.2[2.2-12], P < 0.001). ***Conclusion:*** A $MBF_{RV/LV}$-ratio from $^{15}$O-water PET was independently prognostic in patients with LVH. Surprisingly, the best predictive cut-off for $MBF_{RV/LV}$ in generic LVH equalled the best cut-off previously shown in cardiac amyloidosis patients. Prospective trials to establish $MBF_{RV/LV}$ as a clinical risk marker are warranted. ***References:*** 1. ## OP-388

### Evaluation of DOTA as a marker of myocardial blood flow by comparison of $^{68}$Ga-DOTA to$^{15}$O-water-PET

***M. Lubberink***[1], *S. Kvernby*[1], *C. Rischpler*[2], *K. Azarbar*[1], *J. Sörensen*[1], *I. Velikyan*[1], *T. Kero*[1];
[1]*Uppsala University, Uppsala, SWEDEN,*
[2]*Klinikum Stuttgart, Stuttgart, GERMANY.*

***Aim/Introduction:*** Gd-DOTA (DOTAREM) and similar MRI contrast agents are often suggested as non-invasive markers for myocardial blood flow (MBF). Accurate quantification of MBF with MR contrast agents requires (1) correct conversion of the MR signal to Gd concentration which is challenging; (2) analysis with an appropriate kinetic model; and (3) correction for the limited extraction of Gd-DOTA using the relationship between the uptake rate of the contrast agent and true MBF. Contrary to MRI, the PET signal is directly proportional to radioactivity concentrations and hence a PET analogue of DOTAREM, $^{68}$Ga-DOTA, could be used to assess the kinetics of DOTA without the challenge of converting MR signal to Gd concentration. The aim of the present work was to assess the kinetics of DOTA by comparing $^{68}$Ga-DOTA to the gold standard for non-invasive measurement of MBF, $^{15}$O-water PET. ***Materials and Methods:*** Twenty-five patients referred for assessment of ischemia using $^{15}$O-water-PET underwent 4 min dynamic $^{15}$O-water-PET scans during rest and adenosine stress followed by 10 min dynamic $^{68}$Ga-DOTA-PET scans during rest and adenosine stress on a Signa PET/MR scanner. $^{15}$O-water PET was analysed automatically using aQuant software, and volumes of interest were transferred to the co-registered $^{68}$Ga-DOTA-PET images. $^{68}$Ga-DOTA-PET was analysed using single- and two-tissue irreversible compartment models and the uptake rate constant $K_1$ of $^{68}$Ga-DOTA was compared to that of $^{15}$O-water. Permeability-surface area product for $^{68}$Ga-DOTA was estimated using the Renkin-Crone equation. ***Results:*** Kinetics of $^{68}$Ga-DOTA were well described by a single-tissue compartment model. Correlation between $^{68}$Ga-DOTA and $^{15}$O-water $K_1$ values was moderate (Spearman rho 0.82 at the global and 0.71 at the regional level, P < 0.005). Extraction of $^{68}$Ga-DOTA was low with average whole myocardium $^{68}$Ga-DOTA $K_1$ values ranging from 0.22 to 0.80 mL/cm$^3$/min compared to 0.72 and 4.2 mL/cm$^3$/min for $^{15}$O-water. The permeability surface area product of $^{68}$Ga-DOTA was 0.41 (CI 0.30-0.53) mL/cm$^3$/min. ***Conclusion:*** Extraction of DOTA is low, and lower than for $^{82}$Rb or even $^{99m}$Tc-sestamibi, resulting in a high uncertainty in hyperemic MBF and coronary flow reserve values. Based on these results, DOTA cannot be considered a suitable agent for accurate measurement of MBF.

## OP-389

### The Second Phase-3 Multi-Center Trial of$^{18}$F-Flurpiridaz PET Myocardial Perfusion Imaging for Coronary Artery Disease Evaluation

***Aim/Introduction:*** $^{18}$F-flurpiridaz (flurpiridaz) is a novel PET myocardial perfusion imaging tracer. The aim of this study was to further assess the diagnostic efficacy and safety of flurpiridaz PET for the detection and evaluation of coronary artery disease (CAD) defined as >50% stenosis by quantitative invasive coronary angiography (ICA) in a multi-center prospective international clinical trial. The primary end point was to assess the diagnostic sensitivity and specificity of flurpiridaz for the detection of significant CAD. The secondary end points were to compare the diagnostic performance of flurpiridaz vs. Tc-99m SPECT MPI in the detection of CAD in all patients and in the clinically important subgroups of women, patients with BMI≥30 kg/m$^2$, and those with diabetes. The safety of flurpiridaz was also evaluated. ***Materials and Methods:*** 730 patients with suspected CAD from 48 clinical sites in US, Canada and Europe were enrolled. Patients underwent 1-day rest/stress (pharmacological or exercise) flurpiridaz PET and rest-stress Tc-99m labeled SPECT before ICA. PET and SPECT images were read by 3 experts blinded to clinical and ICA data. ICA was quantified by a core laboratory expert blinded to clinical and image data. ***Results:*** 578 patients (age, 63.7+9.5 years) were evaluable. Flurpiridaz met the prespecified primary endpoint of the study; sensitivity and specificity were significantly higher than the prespecified threshold value of 60% by two of the three readers. Analysis of the secondary endpoints showed that flurpiridaz sensitivity and specificity met the predefined criterion of being significantly higher than SPECT by two of three readers in the overall population as well as in women, in patients with

BMI≥30 kg/m$^2$, and in diabetic patients. Sensitivity and specificity of flurpiridaz were 80.3% and 63.8% that were significantly higher (p<0.0004) than those of SPECT 63.8% and 61.7%. Furthermore, ROC area under the curves were significantly higher than SPECT in the overall population (0.80 vs 0.68, p<0.0001), in women and in patients with BMI≥30 kg/m$^2$. Flurpiridaz was also superior to SPECT for assessment of defect extent/severity (p<0.0001). Image quality (% excellent or good) was significantly better than SPECT for rest images, pharmacological stress images and treadmill exercise images. Radiation exposure was less for flurpiridaz than SPECT. ***Conclusion:*** This second flurpiridaz MPI multicenter trial demonstrates that flurpiridaz has promise as a new tracer for detection and evaluation of CAD. This is particularly so in women and patients with BMI≥30 kg/m$^2$.

### OP-391

**Radioactive Iodine Therapy for Low-risk Papillary Thyroid Cancer: Long-term Recurrence Risk Reduction in a Matched Cohort Study**

***S. Bilgic***[1], *R. C. Meral*[2], *M. S. Sağer*[3], *K. Sönmezoğlu*[3];
*[1]Sirnak State Hospital, Sirnak, TÜRKIYE, [2]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study was to investigate the factors associated with the recurrence of low-risk papillary thyroid cancer patients as defined by the American Thyroid Association (ATA) guidelines and the effect of radioactive iodine (RAI) therapy on long-term treatment success(1). ***Materials and Methods:*** Patients with papillary thyroid carcinoma or papillary microcarcinoma who were classified as low risk and underwent total or near-total thyroidectomy, treated at Nuclear Medicine Department of Cerrahpaşa Medical Faculty between 2004 and 2016 were included in the study. Risk groups were determined according to the 2015 ATA guidelines. Patients who did not have a complete set of postoperative data, interim evaluation results, and follow-up data for more than 40 months were excluded. Age at diagnosis, gender, pathology reports, and scintigraphic findings were analyzed. ***Results:*** Our patient cohort predominantly comprises women (85.0%; n=495), with a median follow-up duration of 76.5 (40-189) months. Low-risk patients who received RAI therapy (n=396) and those who did not (n=196) were matched using 1:1 Mahalanobis distance matching. In order to make the distribution of low-risk patients more homogeneous, women with no high anti-tg levels (<135 IU/ml) and tumor diameter less than 16 mm were matched in the analysis. After matching, 173 patients were obtained from both groups. Static results for up to 6 months, dynamic results for up to 24 months, and long-term outcomes were evaluated. RAI therapy reduced the risk of late recurrence by 13-fold in patients with low-risk papillary thyroid carcinoma and papillary microcarcinoma (p=0.0014). Unsuccessful initial RAI ablation, and high postoperative thyroglobulin levels were predictors of disease recurrence in this cohort. ***Conclusion:*** Due to the latent nature of low-risk papillary thyroid cancer, observing the effectiveness of RAI treatment is only possible through long-term follow-ups. Factors associated with recurrence in papillary thyroid cancer patients differ considerably depending on whether they receive RAI therapy. ***References:*** 1. Haugen BR, Alexander EK, Bible KC, et al. 2015 American Thyroid Association Management Guidelines for Adult Patients with Thyroid Nodules and Differentiated Thyroid Cancer: The American Thyroid Association Guidelines Task Force on Thyroid Nodules and Differentiated Thyroid Cancer. Thyroid : official journal of the American Thyroid Association 2016; 26:1-133

### OP-392

**Comparison of 1.1 gbq and 2.2 gbq$^{131}$I activities in patients with low-risk differentiated thyroid cancer requiring postoperative iodine-131 therapy.**

***A. Campenni'***[1], *R. Ruggeri*[1], *M. Garo*[2], *A. Raffa*[1], *M. Siracusa*[1], *G. Restuccia*[1], *A. Rappazzo*[1], *H. Rosarno*[1], *A. Nicocia*[1], *D. Cardile*[1], *P. Petranović Ovčariček*[3], *S. Baldari*[1], *L. Giovanella*[4];
*[1]Ospedale Gaetano Martino, Messina, ITALY, [2]Mathsly Research, Roma, ITALY, [3]University Hospital Center Sestre Milosrdnice, 10 000 Zagreb, CROATIA, [4]Clinic for Nuclear Medicine and Competence Centre for Thyroid Diseases, Imaging Institute of Southern Switzerland, Ente Ospedaliero Cantonale, 6500 Bellinzona, SWITZERLAND.*

***Aim/Introduction:*** Thyroid surgery followed by risk-adapted postoperative $^{131}$I therapy (RIT) is considered the current standard of care for many DTC patients, leading to an excellent response in >80% of them. This study was aimed to compare the efficacy of low and moderate $^{131}$I activities in low-risk DTC patients requiring postoperative RIT in a real-world clinical setting. ***Materials and Methods:*** We reviewed the records of 299 (F=225, M=74; female-to-male ratio=3:1; median age=52, range=18-81) low-risk DTC patients [pT1-T2, Nx(0),Mx]. Papillary thyroid cancer was carried in 246/296 (82%) patients while 47 (16%) had a follicular thyroid carcinoma and 6 (2%) had a Hurthle cell carcinoma. All patients had undergone (near)-total thyroidectomy followed by RIT, using either low (1.1 GBq) or moderate (2.2 GBq) radioiodine activities. A post-therapy whole body scintigraphy coupled with SPECT-CT (pT-imaging) was obtained 2-5 days after RIT. Finally, the response to initial treatments was evaluated 8-12 months after RIT using basal and rhTSH-stimulated Tg measurements, neck-ultrasound and $^{123}$I-Diagnostic whole body scintigraphy associated to SPECT/CT imaging. Then, patients were classified according to 2015 American Thyroid Association guidelines (2015 ATA). ***Results:*** At the time of pT-imaging, 246 (82.3%) patients showed thyroid remnants alone, while 53 (17.7%) patients showed thyroid remnants and metastases (i.e., loco-regional lymph-node metastases, n=51; lung metastases, n=1; lymph-node and lung metastases, n=1). Among patients carrying metastases, 22 (41.5%) received low $^{131}$I activity (Group A), while 31 (58.5%) moderate one (Group B) (p= not significant).An excellent response (ER) to initial treatments was observed in 274/299 (91.6%) patients, specifically, in 119/139 (85.6%) and 155/160 (96.9%) patients treated with low and moderate $^{131}$I activities, respectively (p=0.029). The

biochemical indeterminate or incomplete response was observed in 17 (22.2%) patients treated with low $^{131}$I activities and 3 (1.8%) patients treated with moderate $^{131}$I activities (p=0.001). Five patients showed a structural incomplete response, among them 3 and 2 received low and moderate $^{131}$I activities, respectively (p=0.654). Notably, 25/53 (47.2%) patients carrying metastatic disease at pT-imaging showed less than ER at follow-up [20/22 Group A (91%) and 5/31 Group B (16%), p<0.0001]. No differences were found between these patients before RIT. ***Conclusion:*** The incidence of metastatic disease may be unexpectedly high in low-risk DTC patients in real life settings. When $^{131}$I therapy is indicated, we encourage the use of moderate instead of low activities, in order to reach an ER in a significantly larger patients' proportion, including patients with unexpected persistence of disease.

## OP-393

### Integrating $^{131}$I SPECT-based RPT dosimetry into stereotactic external beam treatment planning for patients with metastatic radioiodine-refractory thyroid cancer, preliminary clinical trial results

***I. Marsh***[1], *H. Quon*[1], *P. Santhanam*[1], *P. Ladenson*[1], *B. He*[2], *D. Kaplin*[1], *K. Lowe*[1], *H. Wang*[1], *G. Sgouros*[1], *R. F. Hobbs*[1];
[1]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [2]*RAPID LLC, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Treatment of well differentiated thyroid cancer with radioiodine ($^{131}$I) has a long and successful history. However, tumor uptake of $^{131}$I can be diminished in patients with recurrent metastatic disease resulting in sub-therapeutic absorbed doses (AD) to the tumors. Here we present results from an ongoing clinical trial combining $^{131}$I with stereotactic radiotherapy (SRT), using personalized dosimetry. ***Materials and Methods:*** Four patients have been enrolled in the trial to date. Patients are simulated for external beam treatment planning and then administered a tracer amount of $^{131}$I, with multiple time point whole body probe and blood activity measurements aquired. These measurements are used in a two source compartment S-value dosimetry model to determine the patient-specific maximum tolerated therapeutic activity based on bone marrow constraints. Following administration of the therapeutic $^{131}$I, three SPECT/CT images are acquired using the patient-specific immobilization devices from the SRT simulation, which improves the registration of images across time and reduces the uncertainty in $^{131}$I AD calculations. SPECT images undergo quantitative reconstruction and are registered to the simulation CT where target lesion(s) are delineated. S-value dosimetry is used to determine mean lesion AD, which is then converted to EQDX, where X is the dose per fraction of the SRT treatment, determined as the amount needed to deliver a cumulative 80 Gy EQD2 to the target lesion(s). ***Results:*** In the case of the first patient, two lesions were identified and treated, the $^{131}$I portion was calculated to have delivered ADs of 16.6 and 12.5 Gy (14.7 and 11.0 Gy EQDX), respectively, to lesion PTVs. The lesions were then treated with five fractions of SRT of 9.0 Gy and 9.5 Gy (66.0 Gy and 71.3 Gy EQD2), respectively. Following treatment, the patient experienced tumor volume reduction and pain relief. Thyroglobulin levels fell from 89,000 to 55,000 ng/ml three months post-treatment and TSH increased to 9.0 mU/L, indicating reduction in overactive thyroid tissue. The other patients have received similar treatments with follow-up data to come. ***Conclusion:*** Personalized dosimetry-based combination radiopharmaceutical therapy (RPT)-SRT is feasible, allows for effective AD delivery to target lesions that is unachievable through either modality alone, and may benefit from reduced toxicity. The low level of AD from $^{131}$I observed in this work may indicate a need for a more quantitative triage approach and a wider application of this methodology. This work sets the groundwork for more generalized routine clinical RPT-external beam combinations.

## OP-394

### Is radio iodine therapy really as bad as it is made out to be? A look at secondary neoplasms using the SEER database.

***B. Schemmer****;*
*Uniklinik Bonn, Bonn, GERMANY.*

***Aim/Introduction:*** It is frequently noted that radio iodine therapy (RIT) is associated and causal for secondary primary neoplasms. Our goal was to find evidence in support of the induction of secondary neoplasms due to RIT. ***Materials and Methods:*** We searched the SEER Research Plus Data 12 Registries (excl AK), Nov 2021 Sub (1992-2019) database for cases of papillary thyroid carcinoma (only ICD-O-3 8260/3) using the MP-SIR tool. We used the Radioisotopes(1988+) variable and the system supplied Summary Stage 2000 to analyze both cumulative observed to expected ratios (O/E) as well as latency. p<0.05 was considered statistically significant(#). ***Results:*** For localized, regional and distant papillary carcinomas the O/E was 1.22#, 1.24# and 1.1 for non-iodine and 1.14#, 1.41# and 1.71# for RIT. In total 23461/21335 (non iodine/RIT) patients were considered, 381/439 died and 23080/20896 were lost to follow-up @ 360 months post diagnosis. The total number of observed/expected events was 1018/834, 205/165 and 18/16 for non-iodine and 590/518, 704/501 and 83/48 events for RIT. Confidence intervals of non-iodine and RIT patients overlaped for localized (1.15-1.30 vs 1.05-1.23), regional (1.08-1.42 vs 1.30-1.51) and distant stages (0.65-1.73 vs 1.37-2.13). The latency from exposure to event (secondary primary tumor) was 14 years (mean age at exposure 48.9 years, mean age at event 62.9), 16.6 (45.3,61.9) and 10 (60.2,70.4) years for localized, regional and distant for non-iodine and 15.6 (46.3,61.9), 16.5 (44.2,60.7) and 14.7 (51.4,66.1) years for RIT. The most common cancers out of 6030 neoplasms for 2785 patients in the case files treated with radio iodine (non-iodine) were 348(356) breast, 145(98) prostate, 121(150) lung and bronchus, 113(95) melanomas, 81(81) kidney, 75(67) corpus uteri, 45(36) urinary bladder, 33(19) ovary, 30(48) pancreatic, 79(63) NHL, 60(39) leucemias (acute and chronic), 17(20) myelomas, 6(3) hodgkin. ***Conclusion:*** Using the SEER Research Data Plus database we did not find evidence that RIT causes any one specific cancer. We did not find a significant difference between patients treated with radio iodine and non-iodine patients regarding type and onset of secondary primary neoplasms, the most common types of cancers do correspond to those also most common in the general population. Due to the rarity of thyroid carcinomas, even if the relative risk may appear large, the absolute risk of leukemia potentially induced by RIT appears to be minuscule (on the order of 0.1%).

## OP-395

### Radioguided Occult Lesion Localization (ROLL) in patients with persistence/recurrence of differentiated thyroid cancer: a 10-years single-centre experience

***C. Manni***[1], *G. Follacchio*[1], *G. Gesuelli*[2], *R. Scibè*[2], *G. Ferrara*[3], *M. Capponi*[4], *G. Ciccioli*[4], *F. Capoccetti*[1];
[1]*Nuclear Medicine Unit, Macerata Hospital, Italy, Macerata, ITALY,* [2]*Surgery Unit, Macerata Hospital, Italy, Macerata, ITALY,* [3]*Anatomic Pathology and Cytopathology Unit, Istituto Nazionale Tumori di Napoli, IRCCS "G. Pascale", Naples, ITALY,* [4]*Radiology Unit, Macerata Hospital, Italy, Macerata, ITALY.*

***Aim/Introduction:*** Surgery is the elective treatment in cervical recurrence from differentiated thyroid cancer (DTC), but it is burdened by risk of failure and morbidity. We report results of 10-years single-center experience with Radioguided Occult Lesion Localization (ROLL) in this setting. ***Materials and Methods:*** Patients with DTC persistence/recurrence who underwent ROLL procedure in our Institution between 2012 and 2022 were considered. All patients were previously treated with thyroidectomy and at least one radiometabolic therapy with 131-Iodine. DTC persistence/recurrence was diagnosed by neck ultrasonography (US), PET/CT and Fine-Needle Aspiration Citology (FNAC) on suspect lesions associated to Thyroglobulin Wash Test (Thy-WT). On the day before surgery, target lesions were marked by intralesional injection of 99mTc-radiolabelled human albumin macroaggregates (99mTc-MAA - mean activity 11.1 MBq) under US guidance. During tracer injection, Thy-WT was repeated. SPECT/CT neck scan was then performed. For locoregional recurrence, a mini-invasive ROLL-guided excision was performed; for nodal metastases, ROLL-guided lymph-node excision was associated to a modified neck dissection. A hand-held gamma-probe was employed for intraoperative lesion detection. Thy-WT was performed on all radioactive surgical specimens. First follow-up evaluation was performed 3 months after surgery with serum Thyroglobulin measurement and neck US, then repeated every 6 months. ***Results:*** 23 patients were included in the study. DTC persistence/recurrence was localized in thyroid bed in 4 patients and in loco-regional lymph-nodes in 19 patients. A total of 26 lesions was identified and marked with 99mTc-MAA. SPECT/CT scan confirmed in every case a correct lesion localization. Intraoperatively all radioactive areas were correctly localized and resected without surgical complications.Final histology showed DTC persistence/recurrence in 22/26 lesions, in accordance with Thy-WT on surgical specimens. In 4/26 lesions, characterized by highly suspect cytology and a slight increase in Thy-WT, malignancy was not confirmed. At 3-months follow-up, patients were classified in complete response (n=16/23), partial response due to biochemical disease persistence (n=5/23) and no evidence of structural disease (n=2/23). During complete follow-up (mean 52 months, range 3-115), 11/23 patients remained in complete response, 5/23 patients with biochemical disease persistence underwent radiometabolic treatment, 7/23 developed disease progression: in 3 patients ROLL was repeated and 4 patients underwent external-beam radiotherapy. ***Conclusion:*** Radioguided surgery in DTC persistence/recurrence can be a useful tool to optimize radical surgical treatment minimizing local morbidity due to repeated neck surgery.

## OP-396

### High Ki-67 LI is an Important Factor for Good Early Outcomes After Radioiodine Therapy in Patients with Intermediate to High-Risk Papillary Thyroid Cancer

***X. Luo***, *W. Ouyang;*
*Department of Nuclear Medicine, Zhujiang Hospital of Southern Medical University, Guangzhou, Guangdong Province, CHINA.*

***Aim/Introduction:*** This study aims to correlate Ki-67 expression with outcomes after radioiodine (RAI) therapy in papillary thyroid cancer (PTC) with different risk stratifications. ***Materials and Methods:*** Samples from 221 patients with PTC were studied for expression of Ki-67 labelling index (LI) between January 2015 and December 2019. Ki-67 LI was determined immunohistochemically. Samples were divided into low (≤4) and high (>4) groups according to mean value. Then correlations of Ki-67 LI with clinicopathological variables were analyzed by Chi-square test, and survival curves were evaluated by Kaplan-Meier methods. Furthermore, univariate and multivariate analysis were performed to assess the diagnostic values of Ki-67 LI by the Cox regression model. ***Results:*** Ki-67 LI was considered low in 54.3% and high in 45.7%. High Ki-67 LI was associated with vascular invasion (OR=3.684,95%CI:1.463-9.276,P=0.006), distant metastases (OR=8.089, 95%CI: 1.690-38.706, P=0.009), and central lymph node ratio (LNR) >0.28 (OR=0.427, 95%CI: 0.230-0.794, P=0.007), and was an independent prognosticator of disease-free survival (DFS) in multivariate analysis (HR=0.523, 95%CI: 0.319-0.858, P=0.010). Moreover, intermediate and high-risk patients with high Ki-67 LI had decreased risk for DFS (P=0.018, P=0.396). On contrary, low-risk patients with high Ki-67 LI had increased risk for DFS (P=0.067). ***Conclusion:*** In summary, our data show that high Ki-67 LI in intermediate to high-risk PTC is associated with good early outcomes after RAI therapy compared with patients with low Ki-67 LI, so the high radioiodine activities may change the initial poor outcomes caused by high Ki-67 LI to some extent. ***References:*** 1. ### Redifferentiation Therapy for RAI-Refractory Differentiated Thyroid Cancers Based on Tumor Genomic Assay

***D. Shen***[1,2], *H. Chan*[1], *F. Tsai*[1], *Y. Chiu*[1], *T. Liang*[1], *Y. She*[1], *S. Li*[1];
[1]*Kaohsiung Veterans General Hospital, Kaohsiung, TAIWAN,* [2]*Tri-Service General Hospital, Taipei, TAIWAN.*

***Aim/Introduction:*** Radioiodine (RAI)-refractory thyroid cancers (RR-DTCs) are usually treated with tyrosine kinase inhibitors (TKIs) and certain TKIs might offer advantage of re-differentiation effect, i.e. restoration of tumor RAI avidity, allowing for further RAI therapy. Such strategy is based on the salvage of cancer-related aberrant mechanism to re-induce $Na^+/I^-$ sympoter (NIS) by targeting oncogene-involved signaling pathways. We intend to investigate whether the use of TKIs specific to cancer-related

genes for RR-DTC patients based on the oncogene identified can lead to effective redifferentiation effects. ***Materials and Methods:*** RR-DTC patients without RAI-avid lesion were recruited and their tumor tissues were subjected for next generation sequencing to identify driver-genes; then they were treated with different TKIs to inhibit mutated bRAF, RET fusion, NTRK fusion, or ROS-1 fusion, according to genomic assay results. Since the start of TKI treatment, serum markers, i.e. thyroglobulin (Tg) and anti-Tg antibody (ATA) were monitored monthly. FDG PET/CT was used to assess tumor response and RAI therapy (120~150 mCi) was administered in week 16~22 after TKIs treatment. Post-RAI whole body scans were checked to see any lesion RAI avidity. ***Results:*** Totally 57 patients with RR-DTCs in progression were included for tumor genomic assay. 23 (10 females; age: 56.3+/- 15.5, 23~79) of them received > 16 weeks of TKIs specifically to target their tumor-related gene alterations, i.e. bRAFV600E (n=18), RET fusion (n=3), NTRK fusion (n=1), and ROS-1 fusion (n=1). In week 16~22 post TKIs treatment, decreased tumor lesion FDG avidity was noticed (16~99% decrease of SUVmax). With PET-based therapeutic response criteria, there were 8(35%), 12(52%) and 3(13%) patients classified as complete, partial and stable metabolic response, respectively. Post-RAI whole body scans demonstrated significant tumor I-131 uptake in 20 (87.0%) patients; among them, four of 20 cases showed unexpected extra-cervical lesion I-131 uptake, i.e. pulmonary metastases. Tumor marker assay after TKI treatment showed a decrease of ATA level in 3/3 of RR-DTC patients with positive ATA while significant increment (up to >200%) of serum Tg level in 19/20 of ATA-negative patients during the TKI therapy. ***Conclusion:*** In our study, we demonstrated the potential of using oncogene-specific TKIs to restore RAI uptake for RR-DTCs and 16 weeks of TKI therapy might be sufficient to induce redifferentiation effect. The findings of unexpected pulmonary metastases shown on post-RAI scans and opposite-direction change of serum marker between ATA and Tg post TKI treatment warrant for further study.

## OP-398

### Radioligand Therapy with $^{177}$Lu-EB-FAPI for the Treatment of Metastatic Radioiodine Refractory Thyroid Cancer: First-in-Human Dose-Escalation Clinical Trial

***H. Fu***, *J. Huang, W. Guo, L. Sun, H. Wu, H. Chen;*
*The First Affiliated Hospital of Xiamen University, Xiamen, CHINA.*

***Aim/Introduction:*** This study is designed to explore the safety, tolerability, dosimetry, recommended dose, and preliminary effects of administration of $^{177}$Lu-EB-FAPI with 3+3 escalating doses in metastatic radioiodine refractory thyroid cancer (mRAIR-TC) patients suffer from disease progression after tyrosine kinase inhibitors (TKIs) treatment. ***Materials and Methods:*** 12 mRAIR-TC patients were recruited, divided into 3 groups, and treated with escalating doses. Group A received 1.85-2.22GBq/cycle; Group B, 3.33-3.7GBq/cycle, and Group C, 4.44-4.81GBq/cycle. The treatment was planned for up to 2 cycles. All the patients underwent serial whole-body planar scans at 1, 4, 24, 48, 72, 96, and 168 h and SPECT/CT at 72h after the first treatment. Treatment-related adverse events were graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), version 5.0. The dosimetry was calculated using the Hermes system and OLINDA/EXM 1.1 software. ***Results:*** Administration of $^{177}$Lu-EB-FAPI was well tolerated, without life-threatening adverse events. None of 3 patients experience dose-limiting toxicity (DLT) in Group A. CTCAE grade 4 thrombocytopenia was recorded in one patient in Group B, hence, another 3 patients enrolled in Group B, and none of these patients experienced DLT. CTCAE grade 3 hematotoxicity (thrombocytopenia) was recorded in 2 patients in Group C. No hepatotoxicity and nephrotoxicity were observed. All the patients recovered within a short period after drug intervention. The whole-body effective dose (mean±SD) was 0.16±0.02 mSv/MBq. The mean absorbed organ doses for kidney and red marrow were 1.32±0.69 mSv/MBq and 0.11±0.03 mSv/MBq, respectively. Intense uptake and prolonged tumor retention of $^{177}$Lu-EB-FAPI resulted in high absorbed tumor doses (7.55±6.68 Gy/GBq). The effective half-lives (mean±SD) for whole body and tumor were 90.20±7.68 h and 96.91±8.54 h, respectively. Up to now evaluation results were obtained in 10 of the 12 patients, three patients showed partial response, one patient showed progressive disease and the other 6 patients showed stable disease. ***Conclusion:*** $^{177}$Lu-EB-FAPI was well tolerated in all patients, and demonstrated increased uptake and prolonged tumor retention. At the dose of 3.33-3.7GBq/cycle, $^{177}$Lu-EB-FAPI displayed acceptable side effects. Prospective clinical studies are warranted.

### The Probability of Prostate Cancer Metastases within different Prostate-Specific Antigen ranges using Primary Staging Prostate-Specific Membrane Antigen PET/CT in Patients with Newly Diagnosed Prostate Cancer

***W. Luining***[1], *M. J. Hagens*[2], *D. Meijer*[1], *S. Srbljin*[3], *J. C. C. Koppes*[1], *R. J. J. Knol*[4], *P. J. van Leeuwen*[2], *A. N. Vis*[1], *D. E. Oprea-Lager*[1];
[1]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital (NCI-AVL), Amsterdam, NETHERLANDS,* [3]*Zaans Medisch Centrum, Zaandam, NETHERLANDS,* [4]*Northwest Clinics, Alkmaar, NETHERLANDS.*

***Aim/Introduction:*** Prior research on prostate-specific membrane antigen (PSMA) positron emission tomography/computed tomography (PET/CT) has predominantly focused on patients with biochemical recurrence following curative treatment for prostate cancer (PCa), whereas data on outcomes of primary staging at the time of initial diagnosis is limited (1-3). This is the first study to investigate, in a large patient cohort, the association between the serum prostate specific antigen (PSA) levels and the findings on PSMA PET/CT for primary staging, regarding the proportion and site of prostate cancer metastases. ***Materials and Methods:*** Patients with newly diagnosed PCa, in whom a PSMA PET/CT was performed for primary staging between January 2017 and April 2022, were retrospectively studied. The primary objective of this study was to evaluate the risk of metastatic disease on PSMA PET/CT, based on stratification by PSA levels. Additionally, the study aimed to investigate the proportion of PSMA-positive lesions in different anatomical locations (miN1, miM1a-c). A logistic regression analysis was performed to investigate the association between iPSA levels and the findings on PSMA PET. ***Results:*** Overall, 1306 patients were included with a median PSA of 16.5 ng/mL (IQR 8.4-40.4). Of these, 42% (548/1306) were found to have metastatic disease (miN1, and/or miM1a-c) on PSMA PET/CT. The proportion of patients with metastatic disease increased with

rising PSA levels, with PSMA PET/CT detecting metastases in 19%, 30%, 39%, 41%, 60%, 73%, and 89% of patients with PSA levels <10, 10-15, 15-20, 20-35, 35-50, 50-100, and >100 ng/mL, respectively. On PSMA PET/CT, 37% (477/1306) of patients had miN1, 16% (208/1306) miM1a, 22% (283/1306) miM1b, and 2.5% (33/1306) had miM1c PCa. The PSA level was a significant predictor for the presence of metastases on PSMA PET/CT (p<0.05). ***Conclusion:*** Metastatic disease was found in 42% of patients at primary staging using modern PSMA PET/CT imaging. The initial PSA level was a significant predictor of the presence of metastases on PSMA PET/CT. These findings support the use of PSMA PET/CT in the initial staging of PCa. The current results might have important implications for the counseling and treatment of patients with PCa. ***References:*** 1. HofmanMS,LawrentschukN,Fran isRJ, Tang-C,Velal,ThomasP,et al. ## EPS-106

### A systematic review and meta-analysis of the diagnostic test accuracy of PSMA PET for tumor staging in newly diagnosed prostate cancer patients, compared to histopathology

***F. Gossili***[1,2], *A. W. Mogensen*[1,2], *T. C. Konnerup*[3], *K. Bouchelouche*[4], *I. L. Alberts*[5], *A. Afshar-Oromieh*[5], *H. D. Zacho*[1,2];
[1]*Department of Nuclear Medicine and Clinical Cancer Research Center, Aalborg University Hospital, Aalborg, DENMARK,* [2]*Department of Clinical Medicine, Aalborg University, Aalborg, DENMARK,* [3]*Unit of Clinical Biostatistics, Aalborg University Hospital, Aalborg, DENMARK,* [4]*Department of Nuclear Medicine & PET-Centre, Aarhus University Hospital, Aarhus, DENMARK,* [5]*Department of Nuclear Medicine. Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** The current clinical guidelines suggest the utilization of PSMA-PET tracers for identifying metastatic prostate cancer in the primary staging. However, their efficacy in localizing the index tumor and tumor stage is not well-defined. This study aims to determine the diagnostic accuracy of PSMA-PET tracers for tumor-staging in newly diagnosed prostate cancer patients using histological confirmation as the reference standard. ***Materials and Methods:*** We conducted a systematic literature search of the PubMed, Embase, Web of Science, and Cochrane Library databases using a set of specific search terms, which included 'PSMA PET', 'primary staging', and 'prostate cancer'. Two reviewers independently evaluated all the studies based on predetermined inclusion criteria; one of the main inclusion criteria was the use of histopathology as reference standard. The reviewers extracted relevant data, and assessed the quality of evidence, with the aid of a third reviewer to resolve any discrepancies. The random-effects Sidik-Jonkman model was utilized to perform a meta-analysis and estimate the diagnostic accuracy on a per-patient basis, along with 95% confidence intervals. Furthermore, an assessment of potential publication bias and small-study effect was conducted through both Egger's test and visual analysis of the funnel plot. ***Results:*** The analysis encompassed a total of twenty-three papers, consisting of 969 patients, which were examined using both qualitative and quantitative approaches. The findings revealed that the estimated diagnostic accuracy of PSMA PET/CT and PSMA PET/MRI, regardless of PSMA-tracer type, for intraprostatic tumor detection was 86% (95% CI: 76-96%) and 97% (95% CI: 94-100%), for extraprostatic extension detection was 73% (95% CI: 64-82%) and 77% (95% CI: 69-85%), and for seminal vesicle involvement detection was 87% (95% CI: 80-93) and 90% (95% CI: 82-99%), respectively. ***Conclusion:*** The present analysis has demonstrated that PSMA PET/MRI exhibits greater diagnostic accuracy than the currently recommended mpMRI, while PSMA PET/CT displays comparable diagnostic accuracy in the detection of intra-prostatic tumors, when compared to mpMRI. Nonetheless, the analysis uncovered potential limitations, such as small study effects, and a risk of publication bias, which may influence the overall conclusions drawn from the study.

## EPS-107

### A multi-center European study to explore the detection of oligometastatic disease by PSMA-PET/CT in intermediate to high-risk Prostate Cancer

***G. Zuccotti***[1], *F. Mattana*[1], *A. Barone*[1], *L. Muraglia*[1], *R. Mei*[2], *A. Farolfi*[2], *P. Rajwa*[3], *M. Miszczyk*[4], *V. Kasivisvanathan*[5], *F. Zattoni*[6], *G. Gandaglia*[7], *A. Briganti*[7], *S. Shariat*[3], *P. Castellucci*[2], *S. Fanti*[2], *F. Ceci*[1];
[1]*Division of Nuclear Medicine, IEO European Institute of Oncology IRCCS, Milano, ITALY,* [2]*Service of Nuclear Medicine, Sant'Orsola-Malpighi University Hospital IRCCS, Bologna, ITALY,* [3]*Department of Urology, University of Vienna, Vienna, AUSTRIA,* [4]*Department of Nuclear Medicine, Narodowy Instytute Onkologii, Gliwice, POLAND,* [5]*Department of Urology, Imperial College of London, London, UNITED KINGDOM,* [6]*Department of Urology, University of Padova, Padova, ITALY,* [7]*Department of Urology, San Raffaele Hospital, Milano, ITALY.*

***Aim/Introduction:*** The accurate staging of prostate cancer (PCa) prior to primary therapy is crucial, as metastatic disease is related to less favorable outcome compared to locally confined ones. Recently, the addition of metastasis-directed therapy to conventional radical therapy (surgery or radiotherapy) has been proposed. Nevertheless, evidences about the incidence of oligo-metastatic disease (OMD) detected by PSMA-PET are still limited.The primary objective was to compare the positivity rate of PSMA-PET vs. conventional imaging (CI) (CT and bone scan) to identify OMD. Secondary objectives were: a) to assess the overall detection of OMD in intermediate vs high-risk PCa; b) to assess the overall detection of OMD in M1a/M1b vs. M1c; c) the intention-to-treat analysis to evaluate potential changes in clinical management. ***Materials and Methods:*** This is a retrospective, multicenter, head-to-head comparative analysis involving seven high-volume centers in Europe. All patients were affected by a biopsy proven intermediate to high-risk PCa, and performed PSMA-PET and CI (CT and/or bone scan) prior radical therapy within four months each other. According to literature, the proportion of OMD detected with CI was in the 5-10% range. We hypothesized that PSMA-PET was able to identify a higher proportion of OMD compared to CI. The Mc-Nemar test for paired proportions was used. ***Results:*** Overall, 359 patients met the inclusion criteria (high-risk=260/359; intermediate-risk=99/359). PSMA-PET identified metastatic disease in 88/359 (24,5%) and disease confined to the pelvis in 47/359 (13%), while CI identified

metastatic disease in 39/359 (10,8%) and disease confined to the pelvis in 33/359 (9,2%).The primary end-point analysis was performed in 256 patients who performed both CT and bone scan. PSMA-PET detected OMD in 29/256 patients (11,3%), while CI in 17/256 patients (6,6%). In 6/256 (2,3%) patients PSMA-PET and CI were concordant in the identification of OMD, 6/256 patients (2,3%) were considered OMD by CI and upstaged as multi-metastatic by PSMA-PET, 23/256 patients (9%) showed OMD in PSMA-PET while were negative on CI.In the overall population (n=359), PSMA-PET detected OMD in 41/359 patients (11,4%) all M1a/M1b. In the intermediate-risk sub-cohort, PSMA-PET detected OMD in 9/99 patients (9%), while CI in 3/99 patients (3%). In the high-risk sub-cohort, PSMA-PET detected OMD in 32/260 patients (12,3%), while CI in 22/260 (8,4%). ***Conclusion:*** PSMA-PET identified a higher proportion of metastatic disease compared to CI, as expected. Accordingly, the proportion of patients presenting with OMD at PSMA-PET was approximately the double compared to CI.

## EPS-108

### Role of AL$^{18}$F-labeled prostate specific membrane antigen (PSMA-BCH) PET/CT in detecting extracapsular extension of localized prostate cancer.

***Z. Jie***[1], *Y. Zhi*[2], *L. Chen*[2];
[1]*Shanxi Cancer Hospital, Taiyuan, CHINA,* [2]*Peking University Cancer Hospital and Institute, Bejing, CHINA.*

***Aim/Introduction:*** In this study, we evaluated the usefulness of AL$^{18}$F-PSMA-BCH PET/CT in detecting extracapsular extension before radical prostatectomy for localized prostate cancer. ***Materials and Methods:*** The study consisted of thirty patients with localized prostate cancer who underwent AL$^{18}$F-PSMA-BCH PET/CT befor either open or laparoscopic radical prostatectomy between January 2018 and August 2022. Intraprostatic tumor extent, maximum diameter of the index tumor, SUVmean, SUVmax were evaluated on the PET/CT scans in the thirty patients and compared with postoperative histopathology to analyze the detectability of AL$^{18}$F-PSMA-BCH in localized prostate cancer using one sample t-test and ROC curve by SPSS 25.0. ***Results:*** In the thirty patients with localized prostate cancer were diagnosed age at 55-81 years and the median age was 69 years; Gleason score in preoperative biopsy was 6-10, median Gleason score was 7; Gleason score was 6-9 in postoperative pathology, median Gleason score was 7; the range of tumor volume was 1227.5-36891.6 mm3, the median volume was 9289.25 mm3;maximum diameter of the index tumor was 20.4-62.3mm, the maximum diameter was 38.5mm; the range of SUVmean was 2.19-4.95, the median SUVmean was 3.585; the range of SUVmax was 3.41-29.33, and the median SUVmax was 9.04. In AL18F-PSMA-BCH PET/CT images, there were significant differences in tumor volume, the maximum diameter , SUVmean and SUVmax between prostate cancer patients with and without extracapsular invasion ($P < 0.05$). When the cutoff value of tumor volume is 12805.9mm3, tumor extracapsular invasion AL18F-PSMA-BCH has better diagnostic value in tumor extracapsular invasion. The AUC value was 0.638 and the Youden index was 0.286. The sensitivity and specificity of detecting tumor extracapsular invasion were 50% and 78.6% respectively. ***Conclusion:*** The tumor volume in AL$^{18}$F-PSMA-BCH PET/CT can detective tumor extracapsular invasion in localized prostate cancer effectively, which can guide the treatment plan for patients with localized prostate cancer helpfully .

## EPS-109

### Exploring the Correlation between Multiparameters Detected in Primary Prostate Cancer using 18F-PSMA-1007 PET/MRI and thier Potential for Predicting Lymph Node and Bone Metastatses

***S. Cheewadhanaraks***[1], *K. Sereeborwornthanasak*[2], *C. Chotipanich*[1], *D. Siripongsatian*[1], *C. Promteangtrong*[1], *A. Kunawudhi*[1], *P. Kiatkittikul*[1], *A. Jantarato*[1], *N. Boonsingma*[1], *N. Boonkawin*[1];
[1]*National Cyclotron and PET Centre, Chulabhorn Hospital, Bangkok, THAILAND,* [2]*Bhumibol Adulyadej Hospital, Bangkok, THAILAND.*

***Aim/Introduction:*** Prostate cancer is the second most common cancer in men. A novel tool so called PSMA PET/MRI has emerged as having a better diagnostic performance than mpMRI alone. To further enhance the value of PET/MRI, there have been studies of quantitative parameters, including ADC value, SUVmax, PSMA-TLU, and PSMA-TV of the primary cancer. This is the first study evaluating the correlation of those parameters using 18F-PSMA-1007 PET/MRI and their potential for predicting lymph node and bone metastases. ***Materials and Methods:*** This retrospective study was performed in 51 patients with primary prostate cancer who underwent initial staging at National Cyclotron and PET Centre (NCPC), Chulabhorn Hospital, Thailand between September 2020 and September 2022. The SUVmax, PSMA-TLU, and PSMA-TV were automatically calculated in primary prostate tumors. The ADC value was then measured in the darkest area of the primary tumor. The metastases were recorded by locations. Bone metastases were further divided into two groups based on the exclusion of the non-specific bone lesion (NSBL). ***Results:*** There was a significant inverse correlation between ADC value and other quantitative parameters. ADC value was significantly lower in patients with lymph node metastasis ($p = 0.0342$). Whereas, PSMA-TLU, PSMA-TV, SUVmax/ADC, PSMA-TLU/ADC, and PSMA-TV/ADC ratios were significantly higher ($p = 0.0479$, 0.0006, 0.0044, 0.0252, 0.006, and 0.0026, respectively). From ROC analysis, PSMA-TLU ratio was the best predictor of lymph node metastasis with sensitivity and specificity of 76.47% and 79.41%, respectively. No significant correlation was noted between the presence of bone metastases with NSBL and those parameters. After excluding NSBL, ADC value was significantly lower in patients with bone metastasis ($p = 0.0053$). While, SUVmax, PSMA-TLU, PSMA-TV, SUVmax/ADC, PSMA-TLU/ADC, and PSMA-TV/ADC ratios were significantly higher ($p = 0.0137$, 0.0129, 0.0111, 0.0089, 0.0108, and 0.0089, respectively). From ROC analysis, PSMA-TLU/ADC and PSMA-TV/ADC ratios could be the best predictors of bone metastasis with sensitivity of 76.92% and 61.54%, as well as specificity of 60.53% and 97.37%, respectively. ***Conclusion:*** There is a significant inverse correlation between ADC values and other quantitative parameters in primary prostate cancer using 18F-PSMA-1007 PET/MRI. Moreover, a strong correlation is noted between such parameters and the presence of metastases in lymph nodes and bones without NSBL. PSMA-TLU/ADC ratio can be the best predictor of lymph node metastasis. Meanwhile, both PSMA-TLU/ADC and PSMA-TV/ADC ratios are the best predictors of bone metastasis.

## EPS-110

### The Updated Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE V2.0) Framework for Standardized Reporting of PSMA-PET

***R. Seifert***[1], *L. Emmett*[2], *K. Herrmann*[1], *B. Hadaschik*[1], *J. Calais*[3], *S. Fanti*[4], *T. A. Hope*[5], *M. S. Hofman*[6], *M. Eiber*[7], *W. P. Fendler*[1];
[1]*University Hospital Essen, Essen, GERMANY,* [2]*St Vincent's Hospital, Sydney, AUSTRALIA,* [3]*David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES OF AMERICA,* [4]*IRCCS AOU di Bologna, Bologna, ITALY,* [5]*University of California, San Francisco, San Francisco, CA, UNITED STATES OF AMERICA,* [6]*University of Melbourne, Melbourne, AUSTRALIA,* [7]*Technical University of Munich, Munich, GERMANY.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) targeting PET imaging is becoming the reference standard examination for patients with prostate cancer. It is widely used for early stages with localized treatment options, for staging advanced disease undergoing systemic treatment, and to assess eligibility for PSMA-targeting radioligand therapy. Therefore, the PROMSIE framework has been introduced to standardize the reporting of PSMA-PET derived findings. However, new applications for PSMA-PET have emerged, such as prostate imaging in biopsy-naïve patients as well as to response monitoring to systemic anti-cancer therapy. Therefore, a comprehensive and updated version of the PROMISE framework is needed. ***Materials and Methods:*** To address this need, the updated and expanded PROMISE V2.0 framework is introduced. It now comprises three layers of assessment: certainty of the diagnosis (expressed by the PRIMARY score for local tumors or by the harmonized PSMA-expression score), extent of the tumors or metastases (expressed by a revised miTNM score), and tumor volume as exploratory endpoint for clinical trials. ***Results:*** A literature review of the currently used PROMISE framework confirmed the association of PSMA-PET derived parameters with clinically relevant outcomes, such as overall survival or progression-free survival. In addition, there is growing evidence that PSMA-PET has an important role in measuring response. Especially total tumor volume changes may be associated with the outcome in advanced stages (response evaluation criteria in PSMA PET, RECIP framework). However, a lesion-based reporting approach might be more suited for earlier stages of the disease (PSMA PET Progression Criteria, PPP criteria). To facilitate the assessment with already proposed response frameworks like PPP or RECIP, but also enable new response frameworks, a standardized reporting template is proposed by PROMISE 2.0. In this way, all PSMA-PET derived characteristics that are of relevance for response assessment or outcome prognostication are clearly defined. ***Conclusion:*** The updated and extended PROMISE V2.0 framework provides a comprehensive basis for standardized PSMA-PET reporting. In addition, novel parameters are proposed to facilitate the use of PSMA-PET for response monitoring in clinical trials. ***References:*** Gafita, Andrei, et al. ### PRIMARY scores on PSMA PET/CT and MpMRI: Role in initial evaluation of prostate cancer.

***S. Kumar****, Y. Mathur, H. Singh, B. Mittal, R. Kumar;*
*PGIMER, Chandigarh, INDIA.*

***Aim/Introduction:*** Multiparametric MR (MpMR) with the PIRADS (Prostate Imaging Reporting and Data Systems) forms the cornerstone of non-invasive modalities used in the initial evaluation of prostate cancer. PSMA PET/CT is a well-established modality for extent assessment, but its ability for initial evaluation of patients is less explored. The PRIMARY score provides a hierarchical approach to prostatic PSMA uptake pattern determination. The study aims to evaluate the ability of PIRADS and primary scores to identify patients with cs PC (clinically significant prostate cancer). ***Materials and Methods:*** 101 patients who underwent diagnostic MpMR and presented to PGIMER, for initial staging and/or patients suspected to have Ca prostate referred for initial evaluation were retrospectively reviewed. PRIMARY scoring of the PSMA PET/CT was done by two independent nuclear medicine physicians and compared with the PIRADS score on MpMRI. The patients were followed up for confirmation of diagnosis (Malignant vs Benign) based on TRUS/PET guided biopsy findings and/or follow-up serum PSA levels. ***Results:*** Of the 101 men with a mean age of 66.5 years included in the study, 15 %(15/101) were lost to follow up and 50% (51/101) patients had csPC. PRIMARY score 1-5 was seen in 22% (22), 12% (12), 10% (10), 11% (11), and 45% (46) of the patients. PIRADS SCORE 1-5 were seen in 0%(0), 13%(13), 15%(15), 32%(32) and 40%(41) of the patients. SUV max values respectively among the PRIMARY score 1-5 were score 1 (4.7), score 2 (6.5), score 3 (6.9), score 4 (9.6), and score 5 (24.6). Sensitivity, specificity, PPV, and NPV for PRIMARY score 1,2 (low-risk patterns) vs PRIMARY score 3-5 (high-risk patterns) were 92, 73, 84, and 86 %. Sensitivity, specificity, PPV, and NPV for PIRADS score 1,2,3 (low-risk patterns) vs score 4-5 (high-risk patterns) was 90, 63, 78 and 81% respectively. PIRADS and PRIMARY score were discordant in 6 (PIRADS - and PSMA +) and 18(PIRADS - and PSMA +) patients. ***Conclusion:*** PRIMARY Score was able to accurately identify patients who were seen to have csPC. MpMRI and PSMA PET/CT at the time of initial evaluation may act as complementary tools in the initial assessment for csPC. ***References:*** Emmett LM, Papa N, Buteau J, Ho B, Liu V, Roberts M, et al. ## EPS-112

### European Association of Urology Biochemical Recurrence (EAU BCR) Risk Groups after radical prostatectomy in the era of PSMA PET/CT

***C. Artigas****, C. Leplat, Q. Shagera, T. Jabbour, R. Diamand, P. Flamen;*
*Institut Jules Bordet, Université Libre de Bruxelles, Brussels, BELGIUM.*

***Aim/Introduction:*** After radical prostatectomy about a third of patients present with biochemical recurrence (BCR). The European Association of Urology (EAU) BCR risk grouping relies on data from historical cohorts that used conventional imaging techniques. Assessing the pattern of recurrence is essential to distinguish local relapse, oligometastatic disease or extended metastatic disease, as treatments and prognosis differ. The aim of this study was to compare the rate and patterns of positivity of $^{68}$Ga-PSMA-11 PET/

CT across EAU-BCR risk groups and to provide insight on positivity predictors. ***Materials and Methods:*** From a local database of 1185 $^{68}$Ga-PSMA-11 PET/CT performed for BCR, we analyzed a homogenous population of 435 patients. All patients were treated by radical prostatectomy, with or without adjuvant or salvage radiotherapy and presenting BCR as defined by the EAU. Patients that were in biochemical persistence or under androgen deprivation therapy (ADT) were excluded. PSA and PSA kinetics were measured at the time of PSMA-PET/CT. Oligometastasis was defined as ≤ 5 lesions according to ESTRO-ASTRO consensus. The Mann-Whitney U-test was used to compare continuous variables, and chi-squared test for categorical variables. Univariate and multivariable logistic regressions were performed searching for predictive factors of positivity. Cut-offs were defined using ROC curves. ***Results:*** $^{68}$Ga-PSMA-11 PET/CT detected at least one lesion suspicious for prostate cancer recurrence in 236 (54%) patients. In 51% of cases with a positive PET/CT, lesions were limited to the pelvis. 43 (18,2%) patients were cM1a, 59 (25%) cM1b and 14 (5,9%) cM1c respectively. In the EAU-BCR Low-risk group, the positivity rate was 36% (n=35), compared to 59% (n=201) in the High-risk group (p<0,001). Among the BCR Low-risk patients with a positive PSMA-PET/CT, 100% had oligometastatic disease, compared to 89% in the High-risk group (p<0.001). In addition, EAU-BCR High risk patients had an increased risk for PSMA-PET/CT positive extra-pelvic lymph node (p=0,008) and bone (p=0,007) lesions. Multivariable logistic regression analysis showed that EAU-BCR risk groups (OR 2,2; CI 95% 1,3-3,8; p=0,004) and PSA at PET/CT (OR 2,7; CI 95% 1,7-4,4; p<0,001) were independent predictive factors of PSMA-PET/CT positivity. ***Conclusion:*** This study confirms that the EAU-BCR risk groups have different rates of PSMA-PET/CT positivity. We highlight the high rate of oligometastatic disease in EAU-BCR Low risk patients with a positive PSMA-PET/CT. Such patients may benefit from metastasis directed therapy, delaying ADT and its toxicities. Future prospective studies are still needed to validate the above findings and assumptions.

## EPS-113

### Multispectral fluorescence imaging as a means to separate healthy from diseased lymphatics during radioguided robotic surgery

***F. van Leeuwen***[1], *A. Berrens*[2], *M. van Oosterom*[1], *P. van Leeuwen*[2], *I. Slof*[1], *t. buckle*[1], *h. van der Poel*[2];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,*
[2]*NETHERLANDS cancer institute, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Within the management of prostate cancer with a 5% chance of lymph node invasion, it is common practice to perform an (extended) pelvic lymph node (LN) dissection (ePLND) during (robot-assisted) radical prostatectomy (RARP). This, however, often comes at the cost lymph edematous complications. A previous preclinical proof-of-concept studies in porcine surgery [1], suggests that not all LNs within the ePLND template are related to the prostate. In this clinical study we aimed to categorize LNs within the ePLND template by employing multispectral fluorescence imaging to intraoperatively differentiate the lymphatic drainage pathway from the prostate (and tumor) to that of non-disease related anatomies such as the leg and the abdominal wall. ***Materials and Methods:*** Thirteen patients with elevated risk of LN involvement were prospectively included and underwent RARP + ePLND. All men underwent a sentinel node (SN) procedure by intraprostatic administration of indocyanine green (ICG)-99mTc-nanoscan and preoperative SPECT/CT imaging. Prior to RARP, Fluorescein was injected intradermally with two deposits into the upper leg (group 1; n=8) or the abdominal wall (group 2; n=5). Multicolor fluorescence imaging was performed in and ex vivo using a Firefly (da Vinci Xi; ICG only) camera and Image 1 HUB HD + D-light P (Karl Storz; ICG and Fluorescein) fluorescence laparoscope. Imaging data was correlated to histopathological findings. ***Results:*** A median of 4 SNs (interquartile range [IQR] 3-6, n=13) were identified per patient on both SPECT/CT and intraoperative ICG imaging. The additional Fluorescein did not result in discomfort at the site of injection or abnormal postoperative recovery. In group 1, in 5/8 patients (63%) fluorescein was clearly visible within the ePLND template. In group 2, this increased to 5/5 patients (100%). There was a discordance in nodal staining for Fluorescein and ICG, suggesting separate drainage routes of the prostate (and cancer) vs. the lower limbs or the abdominal wall. Of the 11 tumor positive LNs, 91% (10) were ICG-positive SNs and 0% was fluorescein positive. Damage to fluorescein positive lymphatic ducts revealed leakage and fluorescein containing urine was shown to contaminate the surgical field during prostatectomy. ***Conclusion:*** For the first time, discordance of lymph drainage patterns of the leg and prostate, or the abdominal wall and prostate, was presented in humans. Thereby providing a first step towards lymph node sparing ePLND strategies. ***References:*** [1] Meershoek et al., J Nucl Med, 2018

## EPS-114

### Significance of interim $^{18}$F-PSMA-1007 PET/CT for early prediction of $^{177}$Lu-PSMA-I&T treatment effect in metastatic castration-resistant prostate cancer patients

***S. Cheung****, S. Chen, Y. Wong, Y. Yip, C. Ho;*
*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

***Aim/Introduction:*** A common approach for monitoring the efficacy of $^{177}$Lu-PSMA radionuclide therapy is by serial evaluation of serum PSA (PSA Response) and a PSMA-targeted PET/CT (Imaging Response) after completion of 4 treatment cycles. However, serum PSA dynamics are known to be affected by a number of inherent factors such as cytological heterogeneity, tumor grade and differentiation, free-to-protein-bound ratios and treatment flare effects. We aimed to investigate whether an interim $^{18}$F-PSMA-1007 PET/CT after 2 cycles of $^{177}$Lu-PSMA-I&T treatment in mCRPC patients could provide early prediction of response to guide further treatment decisions. ***Materials and Methods:*** Between Aug-2020 and Dec-2022, we recruited mCRPC patients who completed 4 cycles of $^{177}$Lu-PSMA-I&T therapy (~7.4 GBq at six-week intervals). They all had serum PSA bioassay and $^{18}$F-PSMA-1007 PET/CT: (1) baseline (bPET), (2) after 2 cycles of treatment (interim PET, iPET), (3) 3 months after 4 cycles (fPET). We used a "PSA Response" criterion proposed by PCWG3 with "PSA decline≥50%" from baseline as positive response. Whereas, we followed the RECIP-1.0 proposal to calculate Total PSMA-avid tumor volume (PSMA-VOL, automatically by MIMContouring) as a tumor burden parameter for gauging "Imaging Response" on 3 sets of PET/CT. "Imaging Response" was defined as complete (CR), partial (PR) or nonresponse (NR) based on iPET and fPET changes compared with bPET. CR: all PSMA-1007-avid lesions normalized; PR: decline≥30% in PSMA-VOL with no emergence of new lesions; NR: progressive or decline<30% in PSMA-VOL or emergence of new lesions. Final therapeutic outcome was judged by the combined "PSA+imaging responses" 3 months after 4 cycles. ***Results:*** This study recruited 24 patients (mean age=73.5±11.1 years, range:54-92 years). After the 2$^{nd}$ cycle of treatment, interim "PSA Response" rate was 79% (19/24); while interim "Imaging Response" rate was significantly lower, only 46% (11/24: 1 CR+10 PR). After

the 4th cycle, "PSA Response" rate was 46% (11/24); while "Imaging Response" rate was 42% (10/24: 10 PR). The primary outcome based on combined "PSA+imaging responses" identified 11/24 patients (46%) as responders. Interim "Imaging Response" was consistent with the primary outcome for all patients classified as Response/Nonresponse, while interim "PSA Response" misclassified 8/19 (42%) patients as positive response, who were found to have new tumors on iPET and confirmed on fPET, with rebounded PSA after 4 cycles of treatment. ***Conclusion:*** Interim $^{18}$F-PSMA-1007 PET/CT after the 2nd cycle of $^{177}$Lu-PSMA-I&T treatment in mCRPC patients has prognostic value as a surrogate biomarker for monitoring treatment and predicting final therapeutic outcome.

## EPS-115

### Absorbed dose prediction for subsequent therapy cycles from 1st cycle of $^{177}$Lu-PSMA-617 therapy of mCRPC patients

***J. Brosch-Lenz***[1], *N. Colpo*[2], *I. Bloise*[1], *X. Hou*[1], *W. R. Parulekar*[3], *C. Dellar*[3], *F. Saad*[4], *K. Chi*[2], *D. Wilson*[2], *F. Bénard*[2], *A. Rahmim*[1], *C. Uribe*[2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA,* [3]*Canadian Cancer Trials Group, Queen's University Kingston, Kingston, ON, CANADA,* [4]*Prostate cancer research, Montreal Cancer Institute / CRCHUM, Montreal, QC, CANADA.*

***Aim/Introduction:*** $^{177}$Lu-PSMA-617 was approved as a radiopharmaceutical for patients suffering for metastatic, castration-resistant prostate cancer (mCRPC) that is administered using fixed activities. However, mCRPC patients may present with very different tumor burden and extent of disease besides natural differences such as age, weight, height, and pre-therapy history. Consequently, a personalized activity prescription approach based on dosimetry is advisable to maximize the therapeutic effect, while minimizing the radiation exposure to healthy tissues. The aim of this study was to estimate the accuracy of dose predicted for subsequent therapy cycles based on the first therapeutic administration. This work is based on early experience from the Canadian Cancer Trials Group PR21 trial (NCT 04663997). ***Materials and Methods:*** Four patients with six therapy cycles each were included in this study. Healthy organs (kidneys, liver, spleen) were segmented on the CT images using an AI-model and salivary glands were segmented using a threshold-based approach on the quantitative $^{177}$Lu-SPECT. Organ-specific time-activity-curves were fitted to a mono-exponential function for the first therapy cycle, while a single time point dosimetry approach was used for the subsequent therapy cycles. Monte Carlo simulations were used for 3D dosimetry in GATE using the patients' organ time-integrated activity images and CT per cycle. The organ absorbed doses (ADs) per injected activity from first cycle were extrapolated to subsequent therapy cycles and compared with the actual calculated ADs per cycle. ***Results:*** Median injected activity was 7718±205MBq across patients and cycles. Kidney ADs increase by +37%, liver ADs by +21%, spleen ADs by +20%, while salivary gland ADs decreased by -9% from cycle 1 to 6. Percentage differences between predicted AD and actual AD per cycle was -9%, -12%, -22%, -26%, and -19% for kidneys (cycle 2 to 6); 0%, -13%, -19%, -28%, and -16% for liver (cycle 2 to 6); -8%, -16%, -23%, -31%, and -26% for spleen (cycle 2 to 6); and 0%, -3%, -8%, -1%, and -6% for salivary glands (cycle 2 to 6). ***Conclusion:*** The results of this preliminary analysis indicate that a simple extrapolation of healthy organ ADs from the cycle 1 to 2 to 6 is not advisable. We observed large AD underestimation up to -31% compared to individual dosimetry per cycle. The differences increased towards higher cycles, which may be related to the tumor sink effect. It is planned to expand this analysis to a larger patient cohort of the PR21 trial.

## EPS-116

### Pre-treatment$^{68}$Ga-PSMA PET/CT Parameters Could Predict Response to$^{177}$Lu-PSMA Treatment and Overall Survival in Metastatic Castration Resistant Prostate Carcinoma Patients Treated with$^{177}$Lu-PSMA

*E. Özkan*[1], ***B. Demir***[1], *M. Ozturk*[1], *M. Araz*[1], *C. Soydal*[1], *B. Dursun*[2], *Y. Urun*[2], *N. O. Kucuk*[1];
[1]*Ankara University School of Medicine Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara University School of Medicine Department of Medical Oncology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Response to $^{177}$Lu-PSMA treatment is highly variable and the factors that can be useful in predicting response to $^{177}$Lu-PSMA treatment and their correlation to overall survival of the patients have not been clearly established yet. In this study we aimed to determine parameters that are contributing to predict therapy response and overall survival, derived from pre-treatment $^{68}$Ga PSMA PET/CT. ***Materials and Methods:*** We analysed a total number of 55 patients treated with $^{177}$Lu-PSMA therapy in this retrospective study. Baseline PET/CT of all patients were segmented and total tumour metabolic volume (TT-MV), SUVmax, SUVmean, SUVpeak and total tumour PSMA uptake (TT-PSMA) values were noted. Also, overall survival time after PET/CT imaging and PSA response based on a decline of at least 50% for responders were determined for available patients. ROC analysis for PET/CT parameters was performed in predicting PSA response. For overall survival, Kaplan-Meier survival analysis between PSA responders/non-responders and the groups generated from PET/CT parameters based on median values was performed. ***Results:*** PSA responder and non-responder groups median SUVmax, SUVmean, SUVpeak, TT-MV and TT-PSMA values were 47.78 vs. 26.80, 13.62 vs. 8.47, 32.25 vs. 16.96, 162.12 vs. 168.61 and 839.68 vs 1627 respectively. Between two groups SUVmax (p=0.002), SUVmean (p=0.038) and SUVpeak (p=0.007) values were significantly higher in responder group. In ROC analysis AUC for SUVmax, SUVmean and SUVpeak were 0.772, 0.681 and 0.736 respectively. A high specificity cut-off were determined for SUVmax value to predict PSA response was 50.70 (sensitivity: 47.1%, specificity: 87.9%). In survival analysis overall median survival time after PET/CT for PSA responder group (513 days) was significantly (p=0.003) longer than non-responder group (305 days). Also, the patients with TT-MV smaller than 162.12 cm3 had longer median overall survival time (567 days) than TT-MV>162.12cm3 (279 days) group (p<0.001). ***Conclusion:*** SUVmax, SUVmean and SUVpeak values in pre-treatment $^{68}$Ga-PSMA PET/CT were significantly higher in PSA responder group. Also, PSA responder patients to $^{177}$Lu-177 PSMA treatment and the patients with lower TT-MV values had significantly longer overall survival. Understanding of contributing factors to predict response in $^{177}$Lu-PSMA treatment may help better selection of suitable patients to $^{177}$Lu-PSMA treatment.

## EPS-117

### Changes in PSA levels after two cycles of radioligand therapy appear superior to changes in PSMA PET for outcome prediction

***P. Hartrampf***[1], *T. Hüttmann*[1], *A. K. Seitz*[2], *H. Kübler*[2], *T. Higuchi*[1], *S. E. Serfling*[1], *W. Schlötelburg*[1], *K. Michalski*[1], *A. K. Buck*[1], *R. A. Werner*[1];
[1]*Klinik und Poliklinik für Nuklearmedizin, Würzburg, GERMANY,* [2]*Klinik und Poliklinik für Urologie, Würzburg, GERMANY.*

***Aim/Introduction:*** In patients with prostate carcinoma (PC) undergoing PSMA-directed radioligand therapy (RLT), current guidelines recommend restaging using PSMA-directed PET/CT after two cycles of treatment along with monitoring of PSA levels. We aimed to determine whether changes of quantitative parameters on molecular imaging are superior for prediction of overall survival (OS) when compared to alterations of PSA levels. ***Materials and Methods:*** In this retrospective study, 73 PC patients were imaged with [$^{18}$F]-PSMA-1007 PET prior to and after two cycles of RLT using [$^{177}$Lu]Lu-PSMA I&T. By analyzing the whole tumor burden on both scans, we recorded changes (provided as delta [Δ]) of quantitative PET-based parameters (including mean/maximum SUV, PSMA-avid tumor volume [PSMA-TV], and total lesion PSMA [TL-PSMA, defined as PSMA-TV * mean SUV). We also determined PSA levels at baseline and after the second cycle. Moreover, subjects were stratified according to biochemical PCWG3 criteria (with progressive disease [PD] defined as PSA increase ≥ 25%) and PET-based RECIP 1.0 (PD defined as increase ≥ 20% in PSMA-TV and appearance of new lesions). We performed univariable cox regression analysis, followed by multivariable and Kaplan Meier analyses for survival prediction. ***Results:*** Median OS was 17 months [mo], while 28 patients died. On univariable analysis, ΔPSMA-TV, ΔTL-PSMA and ΔPSA were associated with OS (P<0.01, each). Multivariable cox regression revealed only ΔPSA (per unit, HR, 1.003, 95% CI 1.001-1.005; P<0.001) as prognosticator for OS, while ΔPSMA-TV (P=0.06) narrowly failed to reach significance. On Kaplan Meier analysis, we observed significant segregation between individuals with (21 mo) vs. without any PSA response (13 mo, HR 0.4, 95% CI 0.2-1.0; P=0.02). Using PD classification according to RECIP (no PD, 21 mo vs. PD, 11 mo [HR 2.5, 95% CI 1.0-6.3; P=0.008]) or PCWG3 criteria (no PD, 21 mo vs. PD, 11 mo [HR 3.0, 95% CI 1.2-7.2; P=0.001]) showed shorter OS for patients with PD. Combination of RECIP 1.0 and PCWG3 criteria provided improved segregation (no PD, 21 mo vs. PD, 11 mo [HR 3.6, 95% CI 1.6-8.3; P<0.001]). ***Conclusion:*** After two cycles of RLT, changes in PSA levels may better identify patients prone to shorter survival when compared to alterations on PSMA-PET. Standardized frameworks combining biochemical (PCWG3 criteria) and PET-based changes (RECIP 1.0) may further refine response evaluation.

## EPS-118

### Analysing the Tumour Transcriptome of Prostate Cancer to Predict Efficacy of Lu-PSMA Therapy

***A. Handke***[1], *C. Kesch*[1], *W. Fendler*[1], *T. Telli*[1], *Y. Liu*[2], *A. Hakansson*[2], *E. Davicioni*[2], *J. Hughes*[2], *H. Song*[3], *K. Lückerath*[1], *K. Herrmann*[1], *B. Hadaschik*[1], *R. Seifert*[1];
[1]*Universitätsklinikum Essen, Essen, GERMANY,* [2]*Decipher Bioscience, Vancouver, BC, CANADA,* [3]*Stanford University, Stanford, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Radioligand therapy with $^{177}$Lu-PSMA is a promising treatment option for patients with PSMA-positive mCRPC. However, treatment failure is seen frequently and the interplay of immune-related features and efficacy of177Lu-PSMA therapy is poorly understood. Therefore, the analysis of the immune tumour microenvironment could help identifying patients who are best candidates for $^{177}$Lu-PSMA radioligand therapy. ***Materials and Methods:*** Between March 2018 and December 2021, we screened a total of 168 patients who were referred to $^{177}$Lu-PSMA therapy in our department and received a mean dose of 21.9 GBq (3 cycles in mean). All patients underwent a baseline PSMA PET. Of this group of patients, primary pathology was requested from the primary pathology institutes; a total of 34 samples were successfully retrieved. Sufficient RNA passing quality for subsequent analysis was available in n = 23 patients. In this subset, tumour RNA transcriptomic analyses measured 74 immune-related features. From these features, n=24 signatures were not co-correlated and therefore investigated further for outcome prognostication. Univariable and multivariable Cox proportional hazards models were used for the OS analysis; Bonferroni correction was used to minimize the risk of alpha error accumulation. Kaplan Meier plots were used to visualize survival difference between patients; for that, signature scores were dichotomized by their median value and log-rank tests were used to investigate the statistical significance of differences in OS. ***Results:*** PD-L1 was not significantly associated with OS (hazard ratio (HR) per standard deviation (SD) change [95% confidence interval (CI)] 0.74 [0.42-1.30]; p=0.29) in patients who received $^{177}$Lu-PSMA therapy. However, PD-L2 was positively associated with longer OS (HR per SD change 0.46 [0.29-0.74]; p=0.001; median OS 17.2 vs. 5.7 months in higher vs. lower PD-L2 patients). Furthermore, PD-L2 levels correlated with PSA-response ($\varrho$ = -0.46; p=0.04). The ability of PD-L2 for OS prognostication was significantly associated with LDH levels (Cox model interaction p=0.01). ***Conclusion:*** The presented preliminary evidence suggests a crosstalk between the tumor immune microenvironment and the outcome of patients treated with Lu-PSMA therapy. Higher PD-L2 expression seems to be associated with improved outcome of patients treated with $^{177}$Lu-PSMA therapy by a currently unknown relationship of radiation efficiency and immune environment.

## EPS-119

### Initial clinical study results of $^{68}$Ga/$^{177}$Lu-NYM032, a new generation of PSMA-targeting theranostic radiopharmaceuticals, in patients with metastatic prostate cancer

***H. He***[1], *Y. Wang*[1], *Y. Mi*[1], *C. Yan*[2], *P. Fang*[2], *W. Eng*[2], *H. Fu*[1], *C. Yu*[1];
[1]*Affiliated Hospital of Jiangnan University, Wuxi, CHINA,* [2]*Norroy bioscience Co. Ltd., Wuxi, CHINA.*

***Aim/Introduction:*** The current study was aimed at developing a new generation of prostate specific membrane antigen (PSMA)-targeting radiopharmaceuticals that have the characteristics of longer tumor uptakes and faster circulatory elimination. $^{68}$Ga/$^{177}$Lu-NYM032 is a novel small-molecule theranostic radiopharmaceutical targeting PSMA. This study adopted a clinical design of a head-to-head comparison with the well-known radiopharmaceutical, PSMA617, to mainly investigate and analyze the diagnostic imaging capability and biodistribution of $^{68}$Ga/$^{177}$Lu-NYM032 in patients with metastatic prostate cancer. ***Materials and Methods:*** Through several iterations of structural optimization and preclinical studies, the small-molecule lead derivative with an optimized structure, NYM032, was obtained. In the current head-to-head comparative study, the radiation doses of $^{68}$Ga-NYM032 and $^{68}$Ga-PSMA617 for each patient, were maintained the same, i.e., with an intravenous injection dose of about 2-4 mCi of both radiopharmaceuticalsto each patient, and the repeated PET scanning time points were at 1 and 2 h after injection. In the imaging studies of $^{177}$Lu-NYM032 (with SPECT) and $^{68}$Ga-NYM032 (with PET) in each patient, the injected radioactive dose of $^{177}$Lu-NYM032 was about 15-30 mCi, and multiple (tomographic SPECT) scanning time points between 0.5 h and 504 h were selected; while the radioactive dose of $^{68}$Ga-NYM032 at injection, which was about 24-96 h prior to the administration

of $^{177}$Lu-NYM032, was about 3-5 mCi, with a PET scanning time point at 1 h after $^{68}$Ga-NYM032 injection. ***Results:*** Among the 10 patients with metastatic prostate cancer who have completed the entire research study, the results of $^{68}$Ga-NYM032, as compared to $^{68}$Ga-PSMA617, showed higher tumor radiation uptakes and a lower uptake in the heart blood pool, thus demonstrating a high tumor target-to-background ratio. The SPECT scanning results of in three patients who have received $^{177}$Lu-NYM032 showed a prolonged residence time of radioactivity in tumors (persisted more than 504 h, with an average $t_{1/2\ eff}$ >150 h in most tumor lesions) and a low uptake in the circulation, thus supporting the notion that $^{177}$Lu-NYM032 has stronger therapeutic and higher safety potential. ***Conclusion:*** $^{68}$Ga/$^{177}$Lu-labeled versions of the small-molecule radiopharmaceutical, NYM032, with an optimized structure exert a high specificity for PSMA-positive tumor lesions, leading to higher lesion uptakes, and a prolonged and persistent residence time of radioactivity in the target tissues. Therefore, $^{68}$Ga/$^{177}$Lu-NYM032 have a great potential as a novel and powerful theranostic for prostate cancer.

## EPS-120

### Detection Rate of $^{64}$Cu-SAR-Bombesin-PET/CT in Men with Biochemically Recurrent Prostate Cancer and Negative or Equivocal $^{68}$Ga-PSMA-11-PET/CT

***S. Li***[1], *A. Nguyen*[1,2], *W. Counter*[1], *N. John*[1], *J. De Leon*[3], *G. Hruby*[4,3,5], *A. M. Joshua*[6,7,8], *P. Stricker*[9,5,10], *K. Wong*[1], *V. Liu*[1], *E. Lengyelova*[11], *S. Agrawal*[1,6,7], *L. Emmett*[1,7,2];
*[1]Department of Theranostics and Nuclear Medicine, St Vincent's Hospital, Sydney, AUSTRALIA, [2]St Vincent's Clinical School, University of New South Wales, Sydney, AUSTRALIA, [3]Genesis Cancer Care, Sydney, AUSTRALIA, [4]Department of Radiation Oncology, Royal North Shore Hospital, Sydney, AUSTRALIA, [5]Faculty of Medicine, University of Sydney, Sydney, AUSTRALIA, [6]The Kinghorn Cancer Care Centre, St Vincent's Hospital, Sydney, AUSTRALIA, [7]Garvan Institute of Medical Research, Sydney, AUSTRALIA, [8]St. Vincent's Clinical School, University of New South Wales, Sydney, AUSTRALIA, [9]Department of Urology, St Vincent's Hospital, Sydney, AUSTRALIA, [10]Faculty of Medicine, University of New South Wales, Sydney, AUSTRALIA, [11]Clarity Pharmaceuticals, Sydney, AUSTRALIA.*

***Aim/Introduction:*** Despite a high detection rate of $^{68}$Ga Prostate-specific Membrane Antigen (PSMA) PET/CT in biochemical recurrence (BCR) of prostate cancer (PCa), a significant proportion of men have negative $^{68}$Ga-PSMA-11 PET/CT. Identifying sites of disease recurrence is critical in better targeting salvage treatment (sRT) post radical prostatectomy (RP). Gastrin-releasing peptide receptor, targeted by $^{64}$Cu-SAR-BBN PET/CT is also overexpressed in PCa. In this Phase IIa, prospective, single-site study, we investigate the added diagnostic value of PET/CT imaging with the copper-chelated analogue $^{64}$Cu-labelled-Bombesin ($^{64}$Cu-SAR-BBN) in patients with $^{68}$Ga-PSMA-11 PET/CT that is negative or equivocal in BCR (NCT 0561384) ***Materials and Methods:*** 20 men with BCR (defined as PSA >0.2ng/mL) with negative or equivocal $^{68}$Ga-PSMA-11 PET/CT underwent $^{64}$Cu-SAR-BBN PET/CT within 3 months (median 1.0). $^{64}$Cu-SAR-BBN median dose was 211MBq (IQR 186-225) with scans acquired at 1 and 3 hours. Delayed 24-hour imaging was undertaken in 13/20. All images were reviewed, with site, intensity of tracer uptake and certainty of disease involvement recorded. PET results were released to referring clinicians, and any further treatments or investigations undertaken to confirm imaging findings were obtained. ***Results:*** Median age 71 (range 58-81). Prior RP in 19/20, RP and sRT in 12/20. Median PSA at imaging 0.73 (IQR 0.50-2.28). Median PSA doubling time of 4.6 months (IQR 2.5-7.3). 15/20 had negative $^{68}$Ga-PSMA-11 PET studies and 5/10 reported as equivocal probably negative. $^{64}$Cu-SAR-BBN PET avid disease was identified in 6/20 (30% detection rate). These comprised 2/20 with local recurrence, 2/20 with nodal disease (pelvic) and 2/20 with distant disease (lung). 40% (8/20) of all patients underwent subsequent treatment, 7/8 targeted and 1/8 systemic. On follow-up, 2/8 had targeted treatment response (pelvic node) or biopsy confirmation (lung biopsy), considered true positive disease on$^{64}$Cu-SAR-BBN PET/CT. Physiological uptake was noted in mediastinal lymph nodes in 7 patients. No adverse events from $^{64}$Cu-SAR-BBN administration were reported. ***Conclusion:*** $^{64}$Cu-SAR-BBN PET/CT demonstrates sites of disease recurrence in 30% of BCR cases with negative or equivocal $^{68}$Ga-PSMA-11 PET/CT. Further evaluation to confirm diagnostic benefit is warranted.

## EPS-121

### Impact of $^{68}$Ga-PSMA-11 PET/CT on salvage radiation treatment concept in males with early biochemical relapse of prostate cancer after radical prostatectomy

***M. Dyankova***[1,2], *T. Stoeva*[1], *Z. Dancheva*[1], *S. Chausheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
*[1]Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Imaging Diagnostics, Interventional Radiology and Radiotherapy, Varna, BULGARIA, [2]St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA.*

***Aim/Introduction:*** Salvage radiation treatment (SRT) is well settled in males with biochemical recurrence (BCR) after radical prostatectomy (RP) in the absence of distant metastases. The aim of this study was to assess the impact of 68Ga-PSMA-11-PET/CT on SRT concept in males with early biochemical relapse in the low-range values up to prostate-specific antigen (PSA) ≤ 0.5 ng/ml after RP. ***Materials and Methods:*** We performed a retrospective analysis in 85 consecutive patients with BCR (up to PSA ≤ 0.5 ng/ml) after RP. The patients were planned for SRT after PSMA PET/CT scan. An experienced radiation therapists defined the concept of upcoming SRT by two different approaches: first based on the clinical and pathological characteristics hypothetically, where after based on the obtained PET/CT scans. ***Results:*** The mean age of the patients was 69.3 years. The mean ISUP grade group was 3 and the mean PSA level was 0.354 ng/mL (0.2-0.5). Without taking into account the results of the PSMA PET/CT, all 85 patients would have been referred for RT: 65 (76.5%) to the prostate bed and seminal vesicles fossa only, and 20 (23.5%) furthermore to the regional pelvic lymph nodes due to high-risk histopathologic features. A total of 44 patients (51.8%) showed at least one positive lesion. $^{68}$Ga-PSMA PET/CT detection rate varied according involved regions as follows: local recurrence- 21.2% (18) : in the prostate bed- 11.8% (10) in the seminal vesicle fossa- 9.4% (8), lymph node metastases: regional- 12.9% (11), distant- 9.4% (8); bone metastases- 20.0% (17), distant metastases as a whole- 23.5% (20). Additional data from 68Ga-PSMA-11-PET/CT guide to alter of RT planning in 28 (32.9%) males. There were modification with mild adaptation of RT, included the supplementary inclusion in the irradiated area of seminal vesicle fossa in 8 patients (9.4%). The significant differences in the target volume included the supplementary RT of lymph nodes or the added or particular RT of bone metastatic lesions in 20 patients (23.5%). PSA response was achieved in 47 (92%) patients from the available PSA levels in 65 patients 6 months after accomplishment of SRT. ***Conclusion:*** $^{68}$Ga-PSMA-11-PET/CT showed a high impact on SRT concept in

males with early biochemical relapse of PC after RP. A change in the treatment planning was indicated in 32.9% of patients with BCR at PSA levels ≤ 0.5 ng/ml. Thus, PSMA PET/CT can significantly contribute to a personalized approach in RT planning, which may improve progression-free survival.

## EPS-122

### Effects of novel androgen receptor signaling inhibitors on PSMA PET signal intensity in patients with castrate-resistant prostate cancer: a prospective exploratory serial imaging study

***I. Sonni***[1,2], *A. Gafita*[1,3], *R. M. Alano*[1], *S. Lira*[1], *L. Unterrainer*[1,4], *J. Shen*[1], *A. Drakaki*[1], *T. Grogan*[1], *M. B. Rettig*[1], *J. Czernin*[1], *J. Calais*[1];
[1]*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Università Magna Graecia, Catanzaro, ITALY,* [3]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [4]*Ludwig-Maximilians-University, Munich, GERMANY.*

***Aim/Introduction:*** PSMA expression on prostate cancer (PCa) cells is influenced by hormonal status. Studies investigating the effects of androgen-receptor (AR) targeting treatments on PSMA expression produced unclear results. Aim of this study was to evaluate changes on serial whole-body (WB) PSMA PET parameters and PSA levels in patients with metastatic castrate-resistant prostate cancer (mCRPC) in response to AR-signaling inhibitor (ARSI). ***Materials and Methods:*** This was a single-center, exploratory, prospective study designed to enroll 30 patients. Inclusion criteria were known mCRPC and planned initiation of treatment with a new ARSI. Patients underwent serial serum PSA measurements and 68Ga-PSMA-11 PET/CT (PSMA PET) at baseline (pre-ARSI - visit #1), 1-week (visit #2) and 3-months (visit #3) post-ARSI. Follow-up with PSA was conducted every 3 months after visit #3 (at 6, 9, and 12-months post-ARSI). The imaging analysis was conducted using qPSMA by a board-certified nuclear medicine physician who contoured all PSMA-avid lesions to extract WB quantitative parameters (SUVmean, SUVmax and tumor volume). We assessed changes in PSA and WB-PSMA PET parameters at all time-points. Changes ≤10% were considered stable and >10% as clinically significant. We correlated PSA and WB-PSMA PET changes to outcome at 1-year post-ARSI. PSA levels and WB-PSMA PET changes were considered concordant with outcome in case of an increase with unfavorable outcome or in case of a decrease, or stable with favorable outcome. ***Results:*** Nine patients/30 were prospectively enrolled between 02/2020 and 11/2021. All patients underwent PSA and PSMA PET at visit #1 and #2, 6/9 patients had PSA and PSMA PET at visit #3. Changes in PSA, PSMA-VOL, SUVmean and SUVmax were -12%, +5%, +3%, and +10% at 1-week in 9/9 patients, -42%, -16%, -15% and -17% at 3-months in 5/9 patients, respectively. Six/9 patients had unfavorable outcome, 2/9 died and 4/6 experienced biochemical recurrence during the 1-year follow-up. 1-week PSA changes were discordant with 1-year outcome in 4/6 patients. Three/9 patients had favorable outcome with stable or decreasing PSA at 1-year, and none had increase in any of the PSMA PET metrics at 1-week or 3-months post-ARSi initiation. ***Conclusion:*** In this prospective study we found a heterogeneous response to the AR pathway modulation, and in most cases discordance between PSA kinetics and whole-body PSMA PET measurements. The modulation induced by ARSI to the PSMA expression of the whole tumor burden of mCRPC patients was not observed at 1- week.

## EPS-123

### Comparison of SUV and tumour net uptake rate values using dynamic whole-body $^{68}$Ga-PSMA-11 PET/CT in patients with metastatic castrate-resistant prostate cancer

***N. Payan***[1], *J. M. Vrigneaud*[1,2], *A. Cochet*[1,2];
[1]*George François Leclerc Centre, Department of Nuclear Medicine, Dijon, FRANCE,* [2]*ICMUB Laboratory, UMR CNRS 6302, University of Burgundy, Dijon, FRANCE.*

***Aim/Introduction:*** $^{68}$Ga-PSMA-11 PET ligand targeting the prostate specific antigen (PSMA) is widely used in patients with prostate cancer. This radiopharmaceutical has also recently gained popularity in assessing patients' eligibility for $^{177}$Lu-PSMA therapy. However, there is a paucity of data focused on the complementarity of $^{68}$Ga-PSMA-11 PET SUV and parametric images-based values. The aim of this study was to assess whether SUV-based values in tumour lesions do correlate with the net influx rate Ki as a representation of the PSMA receptor expression in patients with metastatic castrate-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Ten patients with mCRPC who underwent diagnostic $^{68}$Ga-PSMA-11 PET scans were prospectively included. Immediately after $^{68}$Ga-PSMA-11 injection, a 6-min chest-centered static acquisition was used to generate the bolus part of the image-derived input function (IDIF) extracted from descending aorta. Then, six dynamic whole-body PET/CT acquisitions were performed in continuous bed motion, for one hour. Parametric Ki images were computed with the graphical Patlak method, using a fully-automated IDIF extracted from the static and dynamic acquisitions. Five lesions per patient were delineated using isocontours of 40% of the SUV_max and were transferred on the Ki parametric images. Correlation analyses were carried out between SUV, Tumour-to-Blood Ratio (TBR) and Ki (mL/min/mL) mean values. Correlations of Tumour-to-Liver (TLR) and Tumour-to-Spleen (TSR) ratios were analysed between both, SUV and Ki parameters (TLR_SUV, TLR_Ki, TSR_SUV and TSR_Ki respectively). Linear and non-linear regressions were tested. R squared were calculated for linear regressions and the goodness of the fits was evaluated using residual standard error. ***Results:*** A total of 50 malignant lesions were included. Strong correlations between SUV-based and Ki-based parameters' values were noted using linear relationships, with the highest correlations observed between TBR and Ki values (adjusted $R^2$=0.92, 0.95, 0.97 and 0.97 with p-values <0.001, for SUV/Ki, TLR_SUV/TLR_Ki, TSR_SUV/TSR_Ki and TBR/Ki respectively). Slightly lower residual standard errors were noted using non-linear regressions except for TBR/Ki (7.6 vs 8.2, 0.95 vs 1.01, 0.96 vs 0.97 and 2.54 vs 2.39 using non-linear and linear regressions, between SUV/Ki, TLR_SUV/TLR_Ki, TSR_SUV/TSR_Ki and TBR/Ki respectively). ***Conclusion:*** Strong correlations between Ki and SUV-based values were observed, including when SUV and Ki parameters were corrected by liver or spleen mean values, reflecting a good agreement between the SUV extracted from $^{68}$Ga-PSMA-11 PET scans and the lesions' PSMA receptor density. A stronger correlation between TBR and Ki would suggest that TBR reflects lesions' PSMA receptor density slightly better than SUV_mean.

## EPS-124

### Predictive $^{18}$F-rhPSMA 7.3 PET parameters for outcome assesssment of $^{177}$Lu-PSMA RLT

***K. Hansen***, *C. Fütterer, T. Langbein, M. Heck, W. A. Weber, M. Eiber, I. Rauscher;*
*Klinikum rechts der Isar, Munich, GERMANY.*

***Aim/Introduction:*** Several clinical/laboratory parameters as well as 68Ga-PSMA-11 PET-based imaging parameters have been proposed as predictors for outcome of PSMA-radioligand therapy (RLT) in patients with metastatic castration-resistant prostate

cancer (mCRPC). Increasingly, 18F-labelled PSMA-targeting agents are used in preference to 68Ga-PSMA-11. The aim of this retrospective analysis was to evaluate the use of a 18F-rhPSMA-7.3 in conjunction with clinical/laboratory parameters as prognostic marker of outcome in patients receiving 177Lu-PSMA RLT. ***Materials and Methods:*** A total of 188 mCRPC patients were included. Prognostic factors included clinical parameters, routine laboratory parameters and findings on baseline 18F-rhPSMA-7.3 PET. For each patient, all tumor lesions were semi-automatically delineated using aPROMISE software and different quantitative parameters were calculated (e.g., SUV mean/max/peak, total lesion number, total tumor volume (TTV)). Overall survival (OS) was calculated and uni- and multivariable Cox regression analyses were performed to determine the association with OS. Further, the Kaplan-Meier method was used for estimation of event time distributions and log rank tests were used for group comparisons. ***Results:*** Overall, OS was 11.8 months (95% CI, 10.0 to 13.0). Univariable Cox regression analysis revealed total lesion number, TTV, rising levels of AP, LDH, PSA, decreasing hemoglobin, prior chemotherapy, and the presence of visceral metastases at baseline as negative prognostic factors for OS. In multivariable analysis, total lesion number on 18F-rhPSMA-7.3 PET, rising levels of LDH and the presence of visceral metastases were identified as significant prognosticators. Further, patients presenting with a higher TTV (≥ median of 394 ml) and a higher number of metastatic lesions (≥ median of 127 lesions) on 18F-rhPSMA-7.3 PET presented with a significant reduced OS (10.1 vs. 15.9 months for TTV and 9.7 vs. 16.3 months for lesion number; p<0.001 each, respectively). ***Conclusion:*** Our results indicate that 18F-rhPSMA-7.3 PET increasingly replacing 68Ga-PSMA-11 yields prognostic value in patients undergoing 177Lu-PSMA RLT. In addition to clinical and laboratory parameters, the total number of metastatic lesions on baseline 18F-rhPSMA-7.3 PET prior to 177Lu-PSMA RLT is an independent prognosticator of OS.

## EPS-125

### Associations between antihormonal-treatment status and $^{68}$Ga-PSMA-HBED-CC PET biodistribution

***K. Kluge***[1], *D. Haberl*[1], *H. Einspieler*[1], *D. Muin*[1], *L. Shiyam Sundar*[2], *S. Gutschmayer*[2], *L. Kenner*[3], *A. Haug*[1], *M. Hacker*[1]; [1]*Medical University of Vienna - Dept. of Nuclear Medicine, Vienna, AUSTRIA,* [2]*Medical University of Vienna - Dept. of Medical Physics, Vienna, AUSTRIA,* [3]*Medical University of Vienna - Dept. of Pathology, Vienna, AUSTRIA.*

***Aim/Introduction:*** Androgen deprivation therapies (ADT) are known to influence the prostate-specific membrane antigen (PSMA) expression of prostate cancers, potentially complicating the interpretation of PSMA ligand positron-emission tomography (PET) findings and affecting PSMA radioligand therapy (RLT). However, the impact of ADT on the PSMA ligand biodistribution in non-tumorous organs is not well understood. ***Materials and Methods:*** Fifty men with histological-proven prostate cancer who underwent $^{68}$Ga-PSMA-HBED-CC PET/computed tomography (CT) between March 2019 and July 2021 at the Medical University Vienna with known ADT status were retrospectively recruited. 25 patients were on ADT at the time of imaging (treatment group), while 25 patients with no history of ADT served as a control group. Patients on androgen-receptor, 5α-reductase or CYP17A1 (1) inhibitors were excluded.Physiologically PSMA-expressing organs (salivary glands, kidneys, liver, spleen) were delineated (2,3) and their uptake values were compared according to their data distributions. Multivariate regression analysis was performed to assess the relationship between renal as well as salivary gland SUVmean values and the explanatory variables metabolic tumour volume (MTV), glomerular filtration rate (GFR) and ADT status. ***Results:*** ADT was associated with lower levels of PSMA uptake in the kidneys (SUVmean Δ[ADT - Control]=-6.46; CI=[-10.26;-2.66]; p=0.002) and salivary glands (SUVmean - Δ[ADT - Control]=-2.45; CI=[-4.03;-0.86]; p=0.004), but no significant differences were observed in hepatic or splenic PSMA uptake between the control and treatment groups. In a multivariate analysis, ADT was found to be associated with lower renal SUVmean values (β=-7.84, CI=[-11.32; -4.36], p= <0.0001), while GFR was associated with higher levels of renal SUVmean values (β=0.279, CI=[0.152; 0.405], p <0.0001). Salivary glandular SUVmean levels were only associated with ADT (β=-2.83, CI=[-4.67; -0.991], p= 0.0034), but not with GFR or MTV. ***Conclusion:*** These findings suggest that long-term ADT modulates PSMA expression in a systemic fashion, which may have implications for treatment-optimizing and side-effect minimizing strategies of PSMA radioligand therapies, particularly those using more potent but toxic $^{225}$Actinium labelled PSMA-conjugates.

### OP-427
**Clinical Evaluation of $^{68}$Ga-FAPI-RGD for Imaging of Fibroblast Activation Protein and Integrin $\alpha_v\beta_3$ in Various Cancer Types**
***Y. Pang****, l. zhao, w. xu, j. cai, l. sun, h. chen;*
*Department of Nuclear Medicine & Minnan PET Center, Xiamen Cancer Center, The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, China, xiamen, CHINA.*

***Aim/Introduction:*** Radiolabeled fibroblast activation protein (FAP) inhibitors (FAPIs) and Arg-Gly-Asp (RGD) peptides have been extensively investigated for imaging of FAP- and integrin $\alpha_v\beta_3$-positive tumors. In this study, a FAPI-RGD heterodimer was radiolabeled with $^{68}$Ga and evaluated in patients with cancer. We hypothesized that the heterodimer, recognizing both FAP and integrin $\alpha_v\beta_3$, would be advantageous because of its dual-receptor-targeting property. ***Materials and Methods:*** The effective dose of $^{68}$Ga-FAPI-RGD was evaluated in 3 healthy volunteers. The clinical feasibility of $^{68}$Ga-FAPI-RGD PET/CT was evaluated in 22 patients with various types of cancer, and the results were compared with those of $^{18}$F-FDG and $^{68}$Ga-FAPI-46. ***Results:*** $^{68}$Ga-FAPI-RGD was tolerated well, with no adverse events in any of the healthy volunteers or patients. The effective dose from $^{68}$Ga-FAPI-RGD PET/CT was 1.01 x $10^{-2}$ mSv/MBq. In clinical investigations with different types of cancer, the radiotracer uptake and tumor-to-background ratio (TBR) of primary and metastatic lesions in $^{68}$Ga-FAPI-RGD PET/CT were significantly higher than those in $^{18}$F-FDG PET/CT (primary tumors: SUVmax, 18.0 vs. 9.1 [P<0.001], and TBR, 15.2 vs. 5.5 [P<0.001]; lymph node metastases: SUVmax, 12.1 vs. 6.1 [P<0.001], and TBR, 13.3 vs. 4.1 [P<0.001]), resulting in an improved lesion detection rate and tumor delineation, particularly for the diagnosis of lymph node (99% vs. 91%) and bone (100% vs. 80%) metastases. $^{68}$Ga-FAPI-RGD PET/CT also yielded a higher radiotracer uptake and TBR than $^{68}$Ga-FAPI-46 PET/CT did. ***Conclusion:*** $^{68}$Ga-FAPI-RGD exhibited improved tumor uptake and TBR compared with $^{18}$F-FDG and $^{68}$Ga-FAPI PET/CT. This study demonstrated the safety and clinical feasibility of $^{68}$Ga-FAPI-RGD PET/CT for imaging of various types of cancer.

### OP-428
**Quantitative SPECT/CT Imaging of the Radiation Dosimetry of $^{99m}$Tc-Labeled FAPI Tracer in Healthy Subjects, and Compared with $^{68}$Ga-PET/CT in Gastrointestinal Tumor**
***C. ZHOU****, G. Li, F. Kang, J. Wang;*
*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, China, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is a potential target for tumor diagnosis and treatment because it is selectively expressed on the cell membrane of Cancer-associated fibroblasts (CAFs) in most solid tumor stroma. Professor Zhang's team from Beijing Normal University previously reported a new $^{99m}$Tc-labeled FAPI imaging agent([$^{99mTc}$]Tc-DP-FAPI), and they have verified the effect and stability of this agent in cell and animal experiments. The research reported the dosimetric profile of [$^{99mTc}$]Tc-DP-FAPI in healthy volunteers, and gastrointestinal solid tumors, to assess its diagnostic accuracy for gastrointestinal tumor imaging, and to evaluate the prognosis. ***Materials and Methods:*** Five healthy individuals were included for dosimetric studies based on their physical examination. Ten patients with different types of cancer (pancreatic cancer (n=5), gastric cancer (n=3), liver cancer(n=1), cholangiocarcinoma (n=1)) were included. The patients underwent quantitative SPECT/CT 2 h after the intravenous application of [$^{99mTc}$]Tc-DP-FAPI (740MBq). $^{68}$Ga-FAPI PET/CT image acquisition was performed on the second day after the completion of [$^{99mTc}$]Tc-DP-FAPI quantitative SPECT/CT image acquisition. Tumor/background ratios (T/B) were calculated by delineating volumetric regions of interest (VOIs) (3D) around tumor areas (T) and healthy tissue as background (B), including: liver (T/Bl).In the [$^{99mTc}$]Tc-DP-FAPI and $^{68}$Ga-FAPI images, the maximum standardized uptake value (SUV max) was quantified. ***Results:*** The equivalent dose received by the five healthy subjects was 3.8 mSv. The calculated effective dose for [99mTc]Tc-DP-FAPI is safety. Visual comparison between [$^{99mTc}$]Tc-DP-FAPI quantitative SPECT/CT and $^{68}$Ga-FAPI PET/CT molecular imaging techniques revealed that both radiotracers accumulated in the same primary tumor lesions, with an excellent image quality. And that is [$^{99mTc}$]Tc-DP-FAPI quantitative SPECT/CT detected primary tumor (100%) and the SUVmax was 3.22-11.33 and the T/Bl (tumor/background liver) was range from 1.58 to 3.58, which reflect significant contrast. ***Conclusion:*** In conclusion, [$^{99mTc}$]Tc-DP-FAPI for the tumor imaging of FAP showed high tumor uptake and target to non-target ratios. The calculated effective dose and biodistribution for [$^{99mTc}$]Tc-DP-FAPI is safe, and there are no obvious toxic and side effects were observed, and it had the high sensitivity for the identification of several primary tumors. ***References:*** 1. Qi, N.; Meng, Q.; You, Z.; Chen, H.; Shou, Y.; Zhao, J., Standardized uptake values of 99mTc-MDP in normal vertebrae assessed using quantitative SPECT/CT for differentiation diagnosis of benign and malignant

bone lesions. BMC Medical Imaging 2021, 21 (1).2. Armstrong, I. S.; Hoffmann, S. A., Activity concentration measurements using a conjugate gradient (Siemens xSPECT) reconstruction algorithm in SPECT/CT. Nucl Med Commun 2016, 37 (11), 1212-7.

## OP-429

### Preclinical evaluation of a novel $^{18}$F-labeled probe for fibroblast activation protein-targeted imaging and side by side comparison with FAPI-04

***F. Elvas***, *N. Filippi, Y. Van Rymenant, S. Grintsevich, L. Cianni, I. De Meester, P. Van der Veken;*
*University of Antwerp, Wilrijk, BELGIUM.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is an abundant, practically universal biomarker of cancer that is expressed on the surface of cancer-associated fibroblasts in >90% of carcinomas. Currently, great attention goes to the use of FAP as a tumoral anchor point for cancer diagnostics and therapeutics. $^{68}$Ga-labeled FAPI-04 is one of the most clinically investigated FAP-radioligands, showing excellent lesion visualization in a variety of cancers(1). Soon after, $^{18}$F-labeled derivatives were developed to benefit from the larger batch size, longer half-life and better image quality. However, there are only a few suboptimal examples available. With the aim of improving pharmacokinetics and tumor targeting, we have developed and evaluated a novel $^{18}$F-labeled FAP radioligand for PET imaging in cancer. ***Materials and Methods:*** A lead compound structurally derived from our FAP inhibitor - UAMC1110 - and having a polar linker between the pharmacophore and the radiolabel, was synthesized and characterized in vitro, comprising affinity and selectivity determination(2). The precursor was synthesized and radiolabeled with fluorine-18 using a fluoroalkylation strategy yielding [$^{18}$F]UAMC-4522. The reference radioligand, FAPI-04, was radiolabeled with gallium-68 as described before(3). A series of in vitro assays were performed to characterize radioligands' lipophilicity and stability. The pharmacokinetic profile of [$^{18}$F]UAMC-4522 was evaluated by micro-PET imaging and ex vivo biodistribution in nude mice. In addition, PET imaging and biodistribution studies were conducted in U87MG xenografts to evaluate in vivo FAP targeting. Ex vivo validation of radiotracer uptake in the tumors was performed by autoradiography and histological analysis of FAP expression. ***Results:*** UAMC-4522 showed excellent affinity for FAP (0.32±0.02 nM) and excellent selectivity with respect to PREP (> 10 μM), when compared to the reference compounds UAMC1110 and FAPI-04. [$^{18}$F]UAMC-4522 was radiolabeled with a 2.6±1.2% isolated radiochemical yield (decay-corrected) and a high radiochemical purity of >99%. The $^{18}$F-labeled FAP ligand showed a less polar profile when compared to [$^{68}$Ga]Ga-DOTA-FAPI-04 (logD=-1.77 vs -3.46, respectively), which led to mixed renal-hepatobiliary excretion of [$^{18}$F]UAMC-4522. Compared to the reference radiotracer, [$^{68}$Ga]Ga-DOTA-FAPI-04, [$^{18}$F]UAMC-4522 showed high in vivo stability. Micro-PET imaging of U87MG xenografts revealed higher specific tumor uptake of [$^{18}$F]UAMC-4522 compared to [$^{68}$Ga]Ga-DOTA-FAPI-04 (10.98±1.73%ID/g vs 3.67±0.73%ID/g), in accordance with FAP expression in the tumors. ***Conclusion:*** [$^{18}$F]UAMC-4522 showed excellent FAP affinity and selectivity, favourable in vivo pharmacokinetics, and high and specific tumor uptake. These results suggest that [$^{18}$F]UAMC-4522 has potential clinical usefulness in oncology. ***References:*** 1.Giesel FL, et al. JNM.2019;60(3):386-92. 2.Jansen K, et al. JMC.2014;57(7):3053-74. 3.Lindner T, et al. JNM.2018;59(9):1415-22.

## OP-430

### Enhancing the tumor-to-background ratio of FAP-positive PET/CT scans with the novel $^{61}$Cu-Kalios derivatives: synthesis, in vitro and in vivo characterization

***J. Millul***[1], *T. Basaco Bernabeu*[1], *R. H. Gaonkar*[1], *F. De Rose*[2], *L. Jaafar-Thiel*[2], *R. Mansi*[1], *M. Fani*[1];
[1]*University Hospital Basel, Basel, SWITZERLAND,*
[2]*Nuclidium AG, Basel, SWITZERLAND.*

***Aim/Introduction:*** Fibroblast Activation Protein (FAP)-targeting ligands labeled with the positron-emitters Ga-68 and F-18 have gained increased attention for imaging of solid tumors and fibrotic diseases. Nevertheless, due to the relatively short half-life and the logistic of the clinically-used radionuclides, delayed time-points PET/CT scans are rarely doable. We propose the use of Kalios, a class of novel FAP-targeting ligands bearing the NODAGA chelator and radiolabeled with the cyclotron-produced Copper-61 ($t_{1/2}$ = 3.33 h), as an alternative to $^{68}$Ga- and $^{18}$F-based FAP PET/CT imaging. ***Materials and Methods:*** Four new ligands, Kalios-01, Kalios-02, Kalios-01M and Kalios-02M were synthesized, conjugated with NODAGA, and radiolabeled with Cu-61 in high yield and radiochemical purity. In vitro affinity against the isolated protein, log D, and cellular distribution on human fibrosarcoma cell line HT-1080 transduced with hFAP were evaluated for all four radioligands. In vivo PET/CT imaging and ex vivo biodistribution were assessed at different time points in mice bearing FAP-positive and FAP-negative tumors after the intravenous administration of $^{61}$Cu-labeled ligands. ***Results:*** All Kalios derivatives were radiolabeled with Cu-61 at room temperature in quantitative yields and >95% radiochemical purity at apparent molar activity of 24 MBq/nmol. All four $^{61}$Cu-Kalios showed high hydrophilicity (log D range from -3.32 to -3.09) and high affinity (KD from 1.50 nM to 3.44 nM and IC50 from 26.2 pM to 232 pM) against FAP. The radioligands were mainly internalized after incubation with FAP-positive cells. PET/CT images performed at 0-1h (dynamic scans) and 4h p.i. (static scans) illustrated the ability of all radioligands to visualize the tumors. Quantitative biodistribution studies confirmed the feasibility and advantage of delayed time-point imaging, with tumor-to-background ratios increasing at 4h, especially for two out of 4 radioligands, $^{61}$Cu-NODAGA-Kalios-02 and $^{61}$Cu-NODAGA-Kalios-01M. ***Conclusion:*** $^{61}$Cu-Kalios ligands are a new class of FAP-targeting PET tracers. Kalios ligands can be easily labeled with $^{61}$Cu and allow delayed time-point imaging due to the physical half-life of Cu-61 and the improved signal-to-noise ratio. The selection of the best candidate for clinical translation is planned after direct comparison with $^{68}$Ga-FAPI-46.

## OP-431

### Effects of Linker and Attachment Position on Binding Affinity, Tumor Uptake and Tumor-to-background Contrast of $^{68}$Ga-labeled Pyridine-based Fibroblast Activation Protein Inhibitors

***A. Verena***, *H. Kuo, H. Merkens, N. Colpo, P. Ng, F. Bénard, K. Lin;*
*BC Cancer Research Centre, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Most of the emerging fibroblast activation protein (FAP)-targeted tracers incorporate a quinoline-based pharmacophore. Recently, we reported two FAP-targeted tracers containing a pyridine-3-carbonyl- ([$^{68}$Ga]Ga-AV02053) or pyridine-4-carbonyl-based pharmacophore ([$^{68}$Ga]Ga-AV02070), and a 1,2-dimethylethylenediamine linker attached to the pyridine ring at the ortho position to the pyridine nitrogen. Both tracers showed significantly better tumor-to-background image contrast than the

clinically validated [$^{68}$Ga]Ga-FAPI-04 (Verena A, et al. Pharmaceuticals 2023;16:449), making the pyridine-based pharmacophore a promising candidate for the design of FAP-targeted tracers. Here, we aim to investigate the effects of linker and the position to attach the linker to the pyridine ring on FAP binding affinity, tumor uptake and tumor-to-background uptake ratios. ***Materials and Methods:*** AV02093, a DOTA-conjugated ligand containing a 3-(piperazin-1-yl)propan-1-ol linker (the same one in [$^{68}$Ga]Ga-FAPI-04) attached to the meta position (to the pyridine nitrogen) of the pyridine-4-carbonyl-based pharmacophore, was synthesized in 5 steps: coupling methyl 3-hydroxyisonicotinate with Boc-protected 3-(piperazin-1-yl)propan-1-ol via Mitsunobu reaction, hydrolysis of the methyl ester, coupling with (S)-1-(2-aminoacetyl)-4,4-difluoropyrrolidine-2-carbonitrile, Boc-deprotection with trifluoroacetic acid, and the final coupling with the DOTA chelator. Gallium ($^{nat}$Ga and $^{68}$Ga) complexation was conducted in acetate (0.1 M, pH 4.5) and HEPES (2 M, pH 5.0) buffers, respectively. FAP binding affinity was determined by enzyme-based competition binding assay. PET imaging and biodistribution studies were conducted in HEK293T:hFAP tumor-bearing mice at 1h post-injection. ***Results:*** AV02093 was obtained in 5.4% overall yield over 5 steps. Ga-AV02093 was obtained in 38% yield. The decay-corrected radiochemical yields of [$^{68}$Ga]Ga-AV02093 were 46-50% with >57 GBq/µmole molar activity and >99% radiochemical purity. The binding affinity of Ga-AV02093 ($IC_{50}$=72.9±4.16 nM) was lower than Ga-AV02070 ($IC_{50}$=17.1±4.60 nM), but higher than Ga-AV02053 ($IC_{50}$=187±52.0 nM). The HEK293T:hFAP tumor xenografts were clearly visualized with good contrast on PET images acquired at 1h post-injection. The tumor uptake of [$^{68}$Ga]Ga-AV02093 (5.33±0.87 %ID/g) was comparable to [$^{68}$Ga]Ga-AV02070 (7.93±1.88 %ID/g) and [$^{68}$Ga]Ga-AV02053 (5.60±1.12 %ID/g). The tumor-to-background (blood, muscle and bone) uptake ratios of [$^{68}$Ga]Ga-AV02093 (7.00±1.35, 16.9±5.84 and 4.66±1.35, respectively) were significantly lower than [$^{68}$Ga]Ga-AV02070 (22.9±10.1, 45.7±9.88 and 34.3±7.35, respectively) and [$^{68}$Ga]Ga-AV02053 (25.2±1.97, 51.2± 19.8 and 38.1±5.03, respectively). ***Conclusion:*** Replacing the 1,2-dimethylethylenediamine linker with a 3-(piperazin-1-yl)propan-1-ol linker and changing its attachment position (ortho to meta of the pyridine nitrogen) on the pyridine-4-carbonyl-based pharmacophore generated [$^{68}$Ga]Ga-AV02093 with retained tumor uptake, but significantly decreased tumor-to-background contrast ratio. Our data suggest that attaching the linker to the ortho position to the pyridine nitrogen is more preferable for the design of pyridine-4-carbonyl-based FAP-targeted tracers.

## OP-432

### Preclinical side by side comparison of two [$^{177}$Lu]Lu-labeled FAP-based inhibitors: A promising therapeutic approach for targeted radionuclide therapy of stromal tumors

***T. Läppchen***[1], *A. Bilinska*[1], *E. Pilatis*[1], *E. Menéndez*[1], *S. Imlimthan*[1], *E. S. Moon*[2], *F. Rösch*[2], *A. Rominger*[1], *E. Gourni*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, 3010 Bern, SWITZERLAND,*
[2]*Department of Chemistry – TRIGA site, Johannes Gutenberg - University Mainz, 55128 Mainz, GERMANY.*

***Aim/Introduction:*** Cancer-Associated Fibroblasts (CAFs) account for approximately 80% of all fibroblasts in tumor microenvironment and are identified by several biomarkers with Fibroblast Activation Protein (FAP) being one of them. FAP is highly expressed on the surface of CAFs and promotes tumor growth invasion, metastasis and immunosuppression and its inhibition may increase the antitumor biological response. It also appears to be an appealing target in the nuclear medicine field, since it has the potential to be used for non-invasive radionuclide-based in vivo tumor imaging and therapy. Herewith, we report a side-by-side comparison of the in vitro and in vivo performance of two FAP-based inhibitors, the monomer DOTA.SA.FAPi and the dimer DOTAGA.(SA.FAPi)2, labeled with lutetium-177 for SPECT imaging and potential therapeutic applications. ***Materials and Methods:*** DOTA.SA.FAPi and DOTAGA.$(SA.FAPi)_2$ were labeled with lutetium-177. Their lipophilicity and tendency to bind to human plasma proteins was investigated. The human hTERT PF179T CAF cells which overexpress FAP as proven by western blot and immunofluorescence staining, was used for their further in vitro (saturation, internalization and efflux studies studies) evaluation. In addition, biodistribution and SPECT imaging studies were performed in PC3 xenografts. ***Results:*** [$^{177}$Lu]Lu-DOTA.SA.FAPi and [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ were prepared in >95% radiochemical purity and apparent molar activities between 8 and 12 GBq/µmol exhibiting a $logD_{octanol/PBS}$ of -2.86, and -1.71, respectively. The % of the radioactivity bound to human serum proteins was 9 for [$^{177}$Lu]Lu-DOTA.SA.FAPi and 25 for [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ after 30 min of incubation. $^{177/nat}$Lu-DOTA.SA.FAPi and $^{177/nat}$Lu- DOTAGA.$(SA.FAPi)_2$ exhibited high affinity for the CAF cells, with $K_d$ values of 0.82±0.22, and 1.35±0.68 nM, respectively. After 60 min of incubation with the stromal cells, approximately 20% of the total added activity was internalized for [$^{177}$Lu]Lu-DOTA.SA.FAPi and about 15% for [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$. The efflux studies revealed the superiority of [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ compared to [$^{177}$Lu]Lu-DOTA.SA.FAPi with regard to their residency in CAFs. After 24 h, 51% of the internalized [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ activity was released from CAFs, versus 87% in case of [$^{177}$Lu]Lu-DOTA.SA.FAPi. Biodistribution studies revealed specific tumor uptake of 8.9±0.3 %IA/g for [$^{177}$Lu]Lu-DOTA.SA.FAPi and 8.6±0.7 %IA/g for [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ at 1h p.i. Over time, the accumulated activity in the tumor was faster washed out for [$^{177}$Lu]Lu-DOTA.SA.FAPi compared to [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$, with values of 1.1±0.3 %IA/g and 3.9±0.5 %IA/g, respectively, at 72h p.i. These findings were also illustrated by SPECT imaging. ***Conclusion:*** The superior in vitro and in vivo behaviour of [$^{177}$Lu]Lu-DOTAGA.$(SA.FAPi)_2$ compared to [$^{177}$Lu]Lu-DOTA.SA.FAPi paves the way towards improved FAP-directed therapy of stromal tumors.

## OP-433

### Novel Co-culture Model of Pancreatic Cancer to Accurately Predict the Efficacy of Fibroblast Activation Protein Targeted Radionuclide Therapy using [$^{161}$Tb]Tb-FAP-2286 and [$^{177}$Lu]Lu-FAP-2286

***C. D. van der Heide***[1], *A. Lak*[1], *R. McMorrow*[1,2,3], *L. Mezzanotte*[1,2], *S. U. Dalm*[1];
[1]*Department of Radiology & Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS,* [2]*Department of Molecular Genetics, Erasmus MC, Rotterdam, NETHERLANDS,* [3]*Percuros B.V, Leiden, NETHERLANDS.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is almost exclusively expressed by cancer-associated fibroblasts (CAFs). When targeting FAP on CAFs for targeted radionuclide therapies (TRT), the neighboring cancer cells will be irradiated via cross-radiation, unlike conventional TRT in which the radiation is being delivered to the cancer cells themselves. Improved in vitro models that accurately mimic this indirect irradiation are necessary for a more accurate evaluation of FAP-directed TRT. Therefore, we aim to develop a co-culture system that mimics the stromal disposition of pancreatic tumors and that can be used to correctly

evaluate the efficacy of FAP-TRT. Moreover, we are evaluating the binding and cytotoxicity of both [$^{161}$Tb]Tb-FAP-2286 and [$^{177}$Lu]Lu-FAP-2286 using this novel system. ***Materials and Methods:*** The human pancreatic cancer cell line PANC-1, transduced to express GFP and near-infrared click beetle luciferase (λ=740 nm) (PANC-1-CBR2), and the pancreatic stellate cell line PS-1 were used. Co-cultures were optimized by seeding different ratios of PANC-1-CBR2 and PS-1 cells. Images of the co-cultures were obtained with fluorescence microscopy and compared to three pancreatic cancer patient samples on which FAP immunohistochemistry staining was performed. The correlation between the bioluminescent signal and the number of PANC-1-CBR2 cells was evaluated by seeding the cells in increasing numbers in monoculture or co-culture. Uptake studies on PS-1 cells were performed by incubating cells with 1 nM [$^{161}$Tb]Tb-FAP-2286 or [$^{177}$Lu]Lu-FAP-2286 for 45 minutes, with and without 1 µM of UAMC-1110 for blocking. ***Results:*** Fluorescent microscopy images demonstrated that in a ratio of 1:1 and 1:2 PS-1 cells densely collect and surround clusters of the PANC-1-CBR2 cell, which resembles the FAP-positive fibroblast density observed in patient samples. The bioluminescent signal of PANC-1-CBR2 correlated with the number of cells for both monoculture and co-culture ($R^2$ of 0.91 and 0.97 respectively). A FAP-specific uptake of 2.5% and 3.0% added dose/200,000 cells was measured for [$^{161}$Tb]Tb-FAP-2286 and [$^{177}$Lu]Lu-FAP-2286, respectively, with 75% of the radionuclide being membrane-bound. ***Conclusion:*** The developed co-culture system presents a relatively simple method to combine fibroblasts and cancer cells to resemble the patient's situation more closely. The bioluminescent signal of PANC-1-CBR2 allows for cell death quantification of cancer cells and fibroblasts separately which is relevant for cytotoxicity studies. The first uptake studies demonstrate no big difference in uptake between [$^{161}$Tb]Tb-FAP-2286 and [$^{177}$Lu]Lu-FAP-2286 on PS-1 cells. How this affects cytotoxicity in the co-culture system is currently still being determined.

## OP-434

### Radioligand Therapy in GBM: Fibroblast Activation Protein (FAP) Promises

***P. Jeanjean***[1,2], *S. Kwock*[1,2], *T. Cloughesy*[1], *J. Calais*[1,2], *J. Czernin*[1,2], *G. Carlucci*[1,2], *D. Nathanson*[1,2], *C. Mona*[1,2], *E. Besserer-Offroy*[1,2];
[1]*Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, University of California - Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Ahmanson Translational Theranostics Division, David Geffen School of Medicine, University of California - Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Glioblastomas (GBM) are grade IV gliomas, and, with a dismal 5-year survival rate of 4%, are the most aggressive and fatal type of brain cancer. Despite intensive research efforts leading to various pharmacological approaches, cure has remained elusive. Recently, Fibroblast Activation Protein (FAP) has emerged as a new therapeutic target. Expressed both by Cancer-Associated Fibroblasts (CAFs) and GBM cells[1], FAP has been targeted by radiolabeled small molecules used as pan-cancer theranostics agents[2]. This study aims to evaluate the relevance of FAP inhibitor-46 (FAPi-46) as a molecular probe for Positron Emission Tomography (PET) imaging and Radioligand Therapy (RLT) in GBM models. ***Materials and Methods:*** U87MG and U138MG, human glioblastoma-derived cell lines reported to express FAP, were used as xenograft models. NSG mice were inoculated with U87MG or U138MG cells subcutaneously. FAP expression was assessed by $^{68}$Ga-FAPi-46 PET imaging. Mice were subsequently randomized into four groups: vehicle, 5mg/kg temozolomide (TMZ), 60kBq $^{225}$Ac-FAPi-46, and 5mg/kg TMZ + 60kBq $^{225}$Ac-FAPi-46. Tumor growth and overall survival were evaluated. Additionally, DNA-damage and FAP expression were assessed by immunohistochemistry (IHC) on resected tumors, respectively, 24h after $^{225}$Ac-FAPi-46 treatment or at sacrifice endpoints. ***Results:*** FAP-targeted RLT was first performed on U87MG model. Following confirmation of FAP expression by $^{68}$Ga-FAPi-46 PET imaging (SUVmax=6.1±1.2), mice treated with a single $^{225}$Ac-FAPi-46 injection showed tumor growth delay compared to vehicle-treated animals (median survival of 30 and 23 days, respectively). Treatment with TMZ induced a significant delay in tumor growth of 23 days. Finally, the combination of $^{225}$Ac-FAPi-46 and TMZ significantly improve the survival rate compared to TMZ alone (median survival of 67 and 46 days, respectively). IHC confirmed FAP expression and DNA-damage after $^{225}$Ac-FAPi-46 treatment. FAP-targeted RLT on U138MG tumors is ongoing and preliminary results are promising. ***Conclusion:*** Since FAP is expressed by both tumor cells and microenvironment in GBM, FAP-targeted RLT can act on these two tumor compartments. Our results suggest that $^{225}$Ac-FAPi-46 has a real theranostics potential on subcutaneous GBM tumors combined with TMZ. As observed with many GBM therapeutic agents, FAPi-46 is not able to cross the blood brain barrier to reach orthotopic tumors at a therapeutic concentration. Subsequent conjugation of FAPi-46 with a cell penetrating peptide moiety[3] will be required to improve brain uptake and recapitulate therapeutic effects observed on subcutaneous models. ***References:*** 1.Fitzerald, A. et al. ## OP-435

### Targeted Covalent Radiopharmaceutical (TCR) Could be a Promising Modality for Delivering Radionuclides to Tumour

***X. Cui***[1], *Z. Liu*[2,1];
[1]*Changping Lab, Beijing, CHINA,* [2]*Peking University, Beijing, CHINA.*

***Aim/Introduction:*** The success of therapeutic radiopharmaceutical requires perfect tumour targeting, rapid blood clearance, and sufficiently long tumour retention. Yet, balancing blood clearance and tumour retention of a drug is often a dilemma. A general technology platform that irreversibly fixes radiopharmaceuticals to cancer targets in a tumour-selective manner, if successfully developed, would ideally solve the above dilemma but has not been established. Herein, we aimed to develop a Targeted Covalent Radiopharmaceutical (TCR), installing radiopharmaceutical molecule with a suitable covalent warhead rationally, to gain the function of irreversible ligation but avoid loss of affinity. ***Materials and Methods:*** The rational engineering was started with an unprecedentedly accurate docking of metal-chelated FAPI, which is targeting fibroblast activated protein (FAP). A covalent-engineered FAPI derivative (TCR-FAPI) was designed and synthesized. TCR-FAPI with DOTA is compatible for $^{68}$Ga or $^{177}$Lu-radiolabelling and quality control was performed by radio-HPLC. The stability of $^{177}$Lu-TCR-FAPI was assessed both in vitro and in vivo. An SDS-PAGE-autoradioluminography tandem assay was developed to detect the irreversible covalent binding of TCR-FAPI with FAP protein. The PET-CT imaging studies of $^{68}$Ga-TCR-FAPI were performed in mice bearing HT-1080-FAP xenografts on shoulder. ***Results:*** The molecule docking provided a solid basis for computer-assisted design. $^{68}$Ga-TCR-FAPI and $^{177}$Lu-TCR-FAPI

can be labelled with high radio-yield and radio-purity. The autoradioluminography shows $^{177}$Lu-TCR-FAPI presented efficient (over 90% ligation yields) and robust (at least 144 h) covalent binding with FAP in an irreversible manner. In HT-1080-FAP tumour-bearing mice, the maximum standard uptake value in the tumour of $^{68}$Ga-TCR-FAPI is increased to 10.5±1.3 ID%/g at 1-hour post-injection, which is doubled that of $^{68}$Ga-labelled original FAPI. ***Conclusion:*** A covalent-engineered TCR-FAPI was developed and evaluated for delivering radionuclides to FAP-expressed tumour. The administration of $^{68}$Ga-TCR-FAPI allowed for higher uptake of tumor xenografts in mice, with only slightly higher uptake in the normal tissues. The irreversible covalent interaction of TCR-FAPI and FAP was validated at molecule level, which should be the root cause for the improved pharmacokinetics. The chemical modification of this hit to leading molecule is underway. ***References:*** 1. Verdonk, M.L., et al . Improved protein-ligand docking using GOLD. ## OP-436

### Bone Marrow Dosimetry in Radioligand Therapy using AI-Enabled Whole Body Spongiosa Segmentation and Complementary Marrow/Lesion Maps from $^{99m}$Tc-Sulfur Colloid SPECT/CT and [$^{68}$Ga]Ga-PSMA-11 PET/CT

***A. Peterson***[1,2], *S. J. Wilderman*[1], *J. Blakkisrud*[1,3], *K. Wong*[1], *K. A. Frey*[1], *Y. K. Dewaraja*[1];
[1]*University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,* [2]*Wayne State University, Detroit, MI, UNITED STATES OF AMERICA,* [3]*Oslo University Hospital, Oslo, NORWAY.*

***Aim/Introduction:*** In metastatic castrate resistant prostate cancer (mCRPC) patients treated with [$^{177}$Lu]Lu-PSMA-617 radioligand therapy, lesion infiltration of bone causes heterogeneous distributions of hematopoietically active (red) bone marrow making dosimetry challenging. We present a methodology for patient-specific Monte Carlo (MC)-based bone marrow dosimetry which uses [$^{177}$Lu]Lu-PSMA-617 SPECT/CT in combination with complementary information from $^{99m}$Tc-sulfur colloid (SC) SPECT/CT and [$^{68}$Ga]Ga-PSMA-11 PET/CT for red marrow and lesion localization. ***Materials and Methods:*** [$^{68}$Ga]Ga-PSMA-11 PET/CT, $^{99m}$Tc-SC SPECT/CT, and sequential cycle 1 [$^{177}$Lu]Lu-PSMA-617 2-bed-SPECT/CT were rigidly coregistered for seven mCRPC patients. Using open-source AI-based segmentation tools[1], the skeletal anatomy in the field-of-view (FOV) was delineated on CT and processed to extract spongiosa ("FOV spongiosa"). A "reference spongiosa" region was defined as a vertebra with little $^{68}$Ga-PET uptake but strong, uniform $^{99m}$Tc-SPECT uptake and assigned an age-based cellularity according to [2]. This allowed for patient-specific conversions from $^{99m}$Tc-SPECT images to red marrow mass maps. $^{177}$Lu time-integrated activity (TIA) maps were generated by voxel-level time-activity fitting. Lesion voxels were determined by a 3 SUV threshold on the $^{68}$Ga-PET map that was transferred to the $^{177}$Lu-TIA map with partial volume correction. Voxels with active marrow were determined by applying a threshold to the red marrow mass map. Where lesion and marrow thresholds overlapped, voxels were randomly assigned to lesion or marrow and red marrow mass was displaced from lesion voxels while TIA was displaced from marrow voxels. Dose to red marrow in the FOV spongiosa was computed using an in-house MC code with routines for marrow voxels that apportion energy while accounting for material composition (bone fraction/cellularity/lesion fraction) of each voxel given TIA, CT-derived density, and red marrow mass maps. ***Results:*** Cycle 1 absorbed dose to red marrow in the FOV spongiosa ranged from 0.14-4.24 Gy (0.02-0.59 Gy/GBq) and was significantly correlated with percent change at 6 weeks post-cycle 1 relative to baseline for platelets (Spearman r=-0.79,P=0.036) and neutrophils (r=-0.93,0.003) indicating a potential dose-toxicity trend. Correlation with other toxicity measures was not significant (white blood cells: r=-0.75,P=0.052; hemoglobin: r=-0.61,P=0.148; lymphocytes: r=0.00,P=1.000). ***Conclusion:*** Absorbed dose to red marrow was calculated with MC using $^{99m}$Tc-SC and [$^{68}$Ga]Ga-PSMA-11 imaging for marrow and lesion localization/quantification. Dosimetry correlates with toxicity markers motivating studies with larger cohorts to establish robust dose-toxicity relationships. ***References:*** [1] Wasserthal J, et al. ***Aim/Introduction:*** [$^{177}$Lu]Lu-PSMA is an effective therapy for men with metastatic castration-resistant prostate cancer (mCRPC). Terbium-161 ($^{161}$Tb) offers comparable beta emission to $^{177}$Lu with the addition of Auger electrons which have high linear energy transfer and very short range. [$^{161}$Tb]Tb-PSMA has shown superior in-vitro and in-vivo results in comparison with [$^{177}$Lu]Lu-PSMA. We calculated radiation absorbed dose to normal organs in patients with mCRPC who were treated with [$^{161}$Tb]Tb-PSMA-I&T. ***Materials and Methods:*** VIOLET (NCT05521412) is a single-center, single-arm, phase I/II trial recruiting 30 to 36 men with progressive mCRPC. The phase I dose-escalation is designed with a 3+3 design to establish the maximum tolerated dose of [$^{161}$Tb]

Tb-PSMA-I&T using initial administered radioactivities of 4.4, 5.5 and 7.4 GBq. Dose calibration was performed for local vial and syringe geometry using supplier activity as reference and verified using high-purity germanium gamma spectroscopy. [$^{161}$Tb]Tb-PSMA-I&T was produced using an automated radiochemistry module with extensive process validation. Quantitative SPECT/CT sensitivity was derived from serial phantom imaging with activity ranging from 50-5400 MBq. Three time-point SPECT/CT from vertex to mid-thigh were acquired at 2-6h, 18-24h and 72-120h. Acquisitions were obtained on low energy high resolution collimators, using a triple energy window peaked at 74keV with upper and lower scatter limits. Retention of [$^{161}$Tb]Tb-PSMA-I&T was estimated from voxel-based time-activity curves based on a multi-phase exponential clearance model and convolved using a GATE-derived voxel dose kernel based on decay of $^{161}$Tb in ICRP soft tissue to yield three-dimensional absorbed dose maps. ***Results:*** Nine patients received their first cycle of [$^{161}$Tb]Tb-PSMA-I&T; three patients each receiving 4.4, 5.5 and 7.4 GBq. The mean absorbed dose per GBq (standard deviation) for parotid glands, submandibular glands, kidneys, liver and spleen was 0.14 (± 0.03), 0.14 (±0.06), 0.35 (± 0.10), 0.07 (±0.03), 0.07 (± 0.03) Gy/GBq, respectively. The highest dose cohort potentially receiving 40 GBq cumulative activity over 6 cycles are estimated to receive 5.60 (± 1.20), 5.60 (±2.40), 14 (±4.00), 2.8 (±1.2), 2.8 (±1.2) Gy/GBq for the same organs in above order. The dosimetry owing to beta emission are inline with known dose estimates for [$^{177}$Lu]Lu-PSMA. However, we did not apply additional radiation weighting factor for Auger electrons as subcellular distribution knowledge is required to determine Auger biological effects. ***Conclusion:*** Radiation absorbed doses following [$^{161}$Tb]Tb-PSMA-I&T are within a safe and expected range for normal organs with physiological uptake.

## OP-438

### Evaluation of a Phantom-Independent Dual-Energy Quantitative Computed Tomography (PI-DEQCT) Method for Selecting Bone-Site Specific S-Values in Bone Marrow Dosimetry in Molecular Radiotherapy

***J. Pereira-Cubillo***[1], *E. Mora-Ramirez*[2], *M. Salas-Ramirez*[3];
[1]*University of Costa Rica, Escuela de Física, San José, COSTA RICA,* [2]*University of Costa Rica, Escuela de Física, CICANUM, San José, COSTA RICA,* [3]*University Hospital of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY.*

***Aim/Introduction:*** Accurately quantifying the volume fraction of cortical bone, fat, and water is crucial for applying bone site-specific S-Values for active bone marrow absorbed dose quantification. This study aims to evaluate a DEQCT method [1] for quantifying the volume fraction of cortical bone, fat, and water by investigating the impact of kVp, quality reference mAs (QRM), pitch, and beam hardening on the acquired images. ***Materials and Methods:*** Several CT scans of the Advanced Electron Density Phantom (Sun Nuclear) were obtained using various combinations of kilovoltage (70 kVp, 80 kVp, 100 kVp, 120 kVp, and 140 kVp), QRM (35 mAs, 45 mAs, and 55 mAs), and pitch values (1.2 and 1.4) in a PET/CT (Biograph Vision, Siemens Healthineers). The scans were performed with and without the phantom head and external shell (attenuation medium). For each combination, the attenuation coefficients were parameterized relative to water using a method described in [2], and lookup tables (F(Z)) were generated to parametrize the effective atomic number (Zeff) and effective mass density (ρeff) of the material mixture. Finally, a three-material decomposition using a phantom-dependent DEQCT [3] (PD-DEQCT) and a phantom-independent DEQCT (PI-DEQCT) [1] method was performed in a section of a bone sample of a pig inside a NEMA IEC PET body phantom, with and without water filling (attenuation). The volume fractions of cortical bone, fat, and water were quantified using low-dose (80 kVp, 55 mAs; 120 kVp, 35 mAs) and high-dose (100 kVp, 45 mAs; 140 kVp, 35 mAs) kVp-combinations. ***Results:*** The steepness of the F(Z) curves depends on the selected kVp-combination and attenuation conditions. Moreover, the kVp-combinations with the 70 keV data were found to be inapplicable for clinical purposes. The relative error quantifying the volume fraction of cortical bone, fat, and water between the PD-DEQCT (reference) and PI-DEQCT methods were 30.9%, 14.3%, and 36.2% for 80/120 kVp and 12.5%, 8.1%, and 51.8% for 100/140 kVp combinations without attenuation, and 2%, 20%, and 4.1% for 100/140 kVp with attenuation. The quantification using 80/120 kVp with attenuation was not feasible. ***Conclusion:*** The PI-DEQCT method shows promise for accurate quantification of the volume fraction of cortical bone, fat, and water using a commercial hybrid (PET/)CT system, but its accuracy is affected by the kVp-combination and beam hardening. ***References:*** [1] Salas-Ramirez M. et al. ZMedPhys. 2022. [2] Martines L. et al. PhysMed. 2012.[3] Goodsitt M. et al. MedPhys. 2014

## OP-439

### Hematological Toxicity Correlates with Monte Carlo-derived Absorbed Dose to the Red Marrow in Patients Treated with [$^{177}$Lu]Lu-DOTA-TATE

***J. Blakkisrud***[1,2], *G. Kingkiner*[1], *A. B. Peterson*[1,3], *S. J. Wilderman*[1], *K. Wong*[1], *K. A. Frey*[1], *Y. K. Dewaraja*[1];
[1]*University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,* [2]*Oslo University Hospital, Oslo, NORWAY,* [3]*Wayne State University, Detroit, MI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Observed toxicities in peptide receptor radionuclide therapy (PRRT) of neuroendocrine tumours (NET) have been primarily hematological. In this work we investigate the relationship between absorbed dose to the red marrow and hematological toxicity in patients treated with PRRT. ***Materials and Methods:*** Nineteen patients with somatostatin-positive NETs who were treated with four cycles of [$^{177}$Lu]Lu-DOTA-TATE and underwent multi-timepoint post cycle 1 SPECT/CT-imaging were included in this study. Vertebrae in the field of view (FOV) were segmented on CT by an AI-segmentation tool [1] with manual fine-tuning when necessary. Vertebrae time-integrated activity (TIA) maps were generated following exponential and trapezoidal fitting of time-activity. Absorbed dose to the red marrow was calculated coupling TIA-maps with an in-house developed Monte Carlo (MC) code. The code allows for specification of the fraction of red marrow cells, the location of the activity within each skeletal site (i.e. red and yellow marrow and trabecular bone) and a CT-based density correction for the trabecular bone fraction. The patient level absorbed dose to red marrow was calculated as the median of the red marrow dose in all vertebrae in the FOV, excluding those with focal uptake in metastatic disease. Hematological toxicity was monitored with neutrophil (ANC), thrombocyte (Plt), white blood cell (WCC) and lymphocyte (ALC) count. The change in values compared to baseline before cycle two as well as three and six months after the last treatment cycle were used for dose-toxicity correlation and tested with the Spearman rank test. The absolute values at the sampling times were also investigated. ***Results:*** The vertebrae-median absorbed dose (absorbed dose per administered activity in parenthesis) of cycle 1 ranged from 0.16 (0.02 Gy/GBq) to 0.79 (0.11 Gy/GBq) with an average of 0.38 Gy (0.053 Gy/GBq). Of the evaluated toxicity markers, a significant dose-toxicity correlation was identified

for relative platelet counts before the second cycle (r = -0.51, p = 0.026) and after six months (r = -0.57, p = 0.041). ***Conclusion:*** A correlation between the absorbed dose to red marrow and toxicity markers was found, suggesting that dosimetry can be used to manage and potentially predict treatment-related toxicities for dosimetry-guided treatment in the future. ***References:*** 1) Wasserthal et. al. TotalSegmentator: robust segmentation of 104 anatomical structures in CT images, 2022. arXiv: 2208.05868

## OP-440

### Dosimetry estimates of $^{177}$Lu-PNT2002 in oligorecurrent prostate cancer: preliminary dosimetry results from a randomized phase 2 trial (LUNAR)

***Z. Ells***[1], *L. Unterrainer*[1,2], *D. Sennung*[1], *R. Alano*[1], *K. Booker*[1], *C. Felix*[1], *A. Daley*[1], *A. Farolfi*[1,3], *J. Czernin*[1], *M. Dahlbom*[1], *A. Kishan*[1], *J. Calais*[1];
[1]*University of California - Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Ludwig Maximilian University of Munich, Munich, GERMANY,* [3]*Universita di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** The phase II trial LUNAR (NCT05496959) randomizes oligo-recurrent prostate cancer patients with 1-5 lesions visible by PSMA-PET to neo-adjuvant $^{177}$Lu-PSMA-I&T (PNT2002) and stereotactic body radiotherapy (SBRT) versus SBRT alone (no ADT). Here we report preliminary dosimetry data of PNT2002 in these patients. ***Materials and Methods:*** Patients randomized to the intervention group received 2 cycles (6.8GBq/cycle) of neo-adjuvant PNT2002. Quantitative SPECT images were obtained with Siemens Intevo 6 at 4, 24, and 72-96 hours after the injection of the first cycle (3 bed positions, 120 views, 10s per view, 256x256 pixels (2.4 mm)^2). Siemens quantitative image reconstruction (xSPECT) was completed using 48 iterations, 1 subset, and 0mm Gaussian filter. The CT from the second and third timepoint was deformably registered to the first, creating a voxel wise dose map in which SPECT voxels at each timepoint represent the same volumes using HERMES (2.15.0). Tumor lesions and organs of interest (kidneys, parotids, submandibular glands, liver) were manually delineated with HERMES Affinity Viewer. Time integrated activity curves were created for each segmentation. The absorbed dose calculations were done on a voxel-level basis (electrons considered absorbed locally, photons modeled using semi-monte-carlo modeling). ***Results:*** By March 2023, 14 patients were randomized to the PNT2002 group and were included in the analysis. Patients received an average of 6.97 GBq ± 0.31 (SD) of PNT2002 for their first cycle. The average dose to the right and left, kidneys, parotid and submandibular glands, and liver were 3.51 ± 1.33; 3.51 ± 1.35; 0.96 ± 0.34; 1.09 ± 0.53; 1.04 ± 0.28; and 0.97 ± 0.15, 0.29 ± 0.20 Gy/cycle, respectively. The average dose to and volume of the 9 bony and 22 lymph node lesions were 0.51 ± 0.61 Gy/cycle, 1.20 ± 0.87 mL and 1.90 ± 1.51 Gy/cycle, 0.63 ± 0.63mL respectively. ***Conclusion:*** For organs at risk the absorbed dose estimates remained within the same range as in a higher burden of disease setting. There was significant interpatient absorbed dose variation. Due to the small size of the tumor lesions partial volume corrections will need strong consideration. ***References:*** Support: Point Biopharma

## OP-441

### Modelling the effect of daughter migration on dosimetry estimates for actinium-225 in targeted alpha therapy

***S. Tronchin***[1], *J. C. Forster*[1,2], *K. Hickson*[2,3], *E. Bezak*[1,4];
[1]*Department of Physics, The University of Adelaide, Adelaide, AUSTRALIA,* [2]*Medical Physics & Radiation Safety, South Australia Medical Imaging, Adelaide, AUSTRALIA,* [3]*Allied Health & Human Performance, University of South Australia, Adelaide, AUSTRALIA,* [4]*Cancer Research Institute, University of South Australia, Adelaide, AUSTRALIA.*

***Aim/Introduction:*** Actinium-225 ($^{225}$Ac) has demonstrated promising results in Targeted Alpha Therapy. A concern with $^{225}$Ac is that the decay energy can break the bond to the targeting vehicle, releasing free daughter radionuclides in the body. Daughter migration is generally not considered in clinical dosimetry. The effect of daughter migration needs to be studied to assess the reliability of dose estimates which do not account for daughter migration. The aim of this work is to develop a compartment model that includes individual biokinetics for the daughter isotopes of $^{225}$Ac. ***Materials and Methods:*** A multilevel compartment model for $^{225}$Ac and its daughters was developed, where the daughter isotopes of $^{225}$Ac are assigned their own unique transfer coefficients between compartments. The developed compartment model was used to build a program in Python. Computer simulations were performed for $^{225}$Ac-DOTATATE. The initial distribution of $^{225}$Ac-DOTATATE was obtained from the literature for patients with meningioma and neuroendocrine tumours. Each decay of $^{225}$Ac was assumed to release the daughter isotope from the DOTATATE peptide. Simulations were performed for scenarios where: 1) the daughters have unique biokinetics, and 2) the daughters decay at the site of $^{225}$Ac-DOTATATE. Absorbed doses to the tumour and normal organs were determined in each case. The impact of tumour cell internalisation was also studied in the following way: If $^{225}$Ac-DOTATATE was internalised, then the daughters remained internalised. For non-internalised $^{225}$Ac-DOTATATE in the tumour, the decay released the daughter into the plasma. ***Results:*** When the daughter isotopes had unique biokinetics and no $^{225}$Ac-DOTATATE was internalised in tumour cells, the kidneys and tumour received doses of 0.79 Gy/MBq and 7.11 Gy/MBq, respectively. This is a change in dose of +12% for the kidneys and decrease in tumour dose by a factor of almost 5 compared to when the daughter isotopes decayed at the site of $^{225}$Ac-DOTATATE. When 100% of $^{225}$Ac-DOTATATE was internalised in tumour cells, the kidneys and tumour received doses of 0.75 Gy/MBq and 33.76 Gy/MBq, respectively. This is a change in dose of +6% for the kidneys and 0% for the tumour compared to when the daughter isotopes decayed at the site of $^{225}$Ac-DOTATATE. ***Conclusion:*** When the daughter isotopes have unique biokinetics, there is a 6-12% increase in kidney dose compared to when the daughters decayed at the site of $^{225}$Ac-DOTATATE. Tumour cell internalisation had a minor effect on normal organ dose but a substantial effect on tumour dose.

## OP-442

### Image Quantification and Quality Assessment of Dual-Isotope $^{99m}$Tc and $^{177}$Lu SPECT for Bone Marrow Dosimetry: a Simulation Study

***C. Miller***, *X. Hou, J. Brosch-Lenz, A. Rahmim, C. Uribe;*
*BC Cancer Research Institute, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Bone marrow (BM) is the organ-at-risk in metastatic castration-resistant prostate cancer (mCRPC) treatment with $^{177}$Lu-PSMA. Although $^{177}$Lu-SPECT imaging enables dosimetry, the active BM distribution is not necessarily known as BM is considered a non-imageable organ and bone metastases might change the BM distribution. The aim of this work is to test the feasibility for localization and quantification of active BM activity distributions by performing a $^{99m}$Tc-sulphur colloids (SC) scan simultaneously with one of the $^{177}$Lu dosimetry scans. This can lead to improved image-based BM dosimetry in radiopharmaceutical therapies. ***Materials and Methods:*** We tested two phantom configurations: i) a cylindrical phantom containing three spheres filled with $^{99m}$Tc, $^{177}$Lu, or both, with hot

background and varying ratios of $^{177}$Lu:$^{99m}$Tc up to 50:1 and ii) the XCAT anthropomorphic phantom, with four $^{177}$Lu-PSMA and two $^{99m}$Tc-SC biodistributions. $^{177}$Lu biodistributions were based on 14 SPECT images of 8 mCRPC patients treated at our institution and scanned at 4, 24, and 48 hours post-injection of $^{177}$Lu-PSMA. The $^{99m}$Tc-SC cases represented patients with high/low BM uptakes (5% and 25% of administered activity, respectively) based on $^{99m}$Tc-SC biodistribution data. All the phantoms were imaged with a medium energy collimator using the Simind Monte-Carlo code. The projections of each radionuclide were combined to replicate dual-isotope scans. Seven energy windows were used to estimate the counts for the photopeaks and scatter of $^{99m}$Tc and $^{177}$Lu and remove the $^{177}$Lu scatter from the $^{99m}$Tc photopeak. Images were reconstructed using our PyTomography software with 10 subsets, 6 iterations, attenuation and scatter correction (using our 7-energy windows). Spherical ROIs were placed in the spheres or pelvic bones to assess quantitative accuracy of $^{99m}$Tc. Images were assessed qualitatively to determine if BM localization could be determined. ***Results:*** For the spheres in the water cylinder, quantification of $^{99m}$Tc was acceptable (within 12% of baseline ($^{99m}$Tc alone)) up to a 10:1 ratio of $^{177}$Lu:$^{99m}$Tc. For the XCAT phantom, when BM uptake was high, quantitative accuracy was always within 10% of baseline. When uptake was low, accuracy was within 17% of baseline 4-24 hours post-injection and within 3% at 48 hours. Qualitatively, dual-isotope $^{99m}$Tc images appeared identical to images of $^{99m}$Tc alone and BM could be identified. ***Conclusion:*** Active BM localization in mCRPC patients could be possible with a $^{99m}$Tc-SC scan in the presence of $^{177}$Lu. Best quantification for $^{99m}$Tc-SC was achieved when the scan was performed 48 hours post-injection of $^{177}$Lu.

## OP-443

### Uncertainty analysis for Lu-177-PSMA in clinical routine

***V. Nuttens***[1], *M. Koole*[2], *O. De Winter*[1], *P. De Bondt*[1];
[1]*OLVZ, Aalst, BELGIUM,* [2]*KU Leuven, Leuven, BELGIUM.*

***Aim/Introduction:*** There is a large interest in performing personalized post-therapy dosimetry for patients treated with Lu-177-PSMA as this allows to determine dose-response relationships and adapt dosing schemes for each patient individually. But is Lu-177-PSMA dosimetry feasible with acceptable uncertainties using current state-of-the-art SPECT/CT systems? How will a new generation 360° CZT SPECT/CT camera impact these uncertainties? Current clinical routine uses the validated protocol for a DH (dual-head) Anger-type SPECT/CT. [1] ***Materials and Methods:*** Uncertainty analysis was performed according to EANM recommendations [2] with a model implemented in Python. The mean absorbed dose D= Ã*S (with Ã the cumulated activity) as defined in the MIRD model, gives the following: $[u(D)/D]^2 = [u(Ã)/Ã]^2+[u(S)/S]^2+2u(Ã,S)/(ÃS)$ The last term considers the covariance as specified by the law of propagation of uncertainty (LPU). The uncertainty of Ã consists of its different subcomponents; A0 administered activity (as the uncertainty of the dose calibrator), λ effective decay constant, Q calibration factor, R recovery coefficient ($=C_{observed}/C_{true}$), C count rate, φ error function and $c_2$ a fitting constant of the S-factor. This analysis was done for a kidney volume of 176 mL, a tumour volume of 13 mL, with measured values for DH and datasheet values for the 360° CZT SPECT/CT. ***Results:*** The volume has the largest fractional uncertainty in DH with 51.1% and 21.4% for tumour and kidney volumes respectively. For the 360° CZT these are lower and correspond to 33.1% and 13.9%. The large volume error propagates through the total chain as R, C and the S-factor are all directly influenced by it. This leads for the DH to dose uncertainties of 36.4% and 14.1% for tumour and kidney volumes. For the 360° CZT the corresponding uncertainties are 22.9% and 10.7% respectively. Additionally, a 25% uncertainty corresponds to an 11 mL lesion for the 360° CZT while this is 30 mL for the DH. ***Conclusion:*** Volume is a dominating factor in the total uncertainty chain. Findings demonstrated that a SPECT/CT system with smaller pixel size and better spatial resolution such as these newly 360° CZT SPECT/CT's drastically decreases the dose uncertainty, especially for smaller lesions. ***References:*** [1] Marin G et al. ## OP-444

### Tumour dosimetry after $^{177}$Lu-RPT with a ring-shaped CZT-based camera requires inclusion criteria based on volume and activity concentration

***R. Danieli***[1], *C. Marin*[1], *M. Stella*[2], *B. Vanderlinden*[1], *H. Levillain*[1], *N. Reynaert*[1], *P. Flamen*[1];
[1]*Institut Jules Bordet, Brussels, BELGIUM,* [2]*GE HealthCare, Diegem, BELGIUM.*

***Aim/Introduction:*** Partial volume effect (PVE) corrections based on recovery coefficients (RC) are widely adopted to enhance the accuracy of tumour dosimetry after radiopharmaceutical therapy (RPT) with $^{177}$Lu. This study aims to maximise the confidence in our RC-based PVE correction by assessing the RC accuracy and repeatability at different levels of activity concentration. ***Materials and Methods:*** The six spherical inserts of a NEMA phantom (volume range: 1.2-113.1ml) were filled with 1.8MBq/ml of $^{177}$Lu. Nine acquisitions of 60 minutes each were performed over one month (activity concentration range: 0.1-1.8MBq/ml) on a ring-shaped CZT-based camera (StarGuide, GE HealthCare), with emission and scatter windows centred at 208keV(±6%) and 185keV(±5%), respectively. Acquired projections were reframed with the Lister tool to obtain 5 independent sets of projections of 12 minutes each (total: 45 sets). These resulting projections, as well as the 60-minutes projections corresponding to the highest activity level, were reconstructed with the protocol suggested by the manufacturer. For each sphere and reconstructed image, volumes of interest (VOI) were obtained by a region-growing tool based on the nominal volume. RC were determined by dividing the measured activity concentration inside each VOI by the nominal activity concentration. RC obtained with the first 60-minutes acquisition were taken as reference (RC_ref). All the other RC were normalized by the corresponding RC_ref (RC_norm). For each sphere, the median and range (maximum-minimum) of RC_norm on all the reconstructed images were computed to assess the RC accuracy and repeatability, respectively. To investigate the dependency of the RC accuracy and repeatability on the activity concentration, the same analysis was repeated including only the 30 reconstructed images corresponding to activity concentrations arbitrarily >0.3MBq/ml. ***Results:*** RC_ref ranged from 19% (1.2ml sphere) to 73% (113.1ml sphere). Median(range) RC_norm were 1.07(1.96), 0.99(0.62), 1.03(0.34), 1.04(0.16), 1.05(0.15), 1.05(0.16) for the 1.2, 2.6, 5.6, 11.5, 26.5 and 113.1ml sphere, respectively. When considering activity concentrations higher than 0.3MBq/ml, RC_norm were 1.04(1.13), 1.00(0.22), 1.02(0.21), 1.03(0.12),

1.03(0.13), 1.03(0.10). ***Conclusion:*** For all spheres and activity concentrations, high RC accuracy was measured with respect to the chosen reference (median RC_norm < 1.07). Low repeatability was found in the RC of the three smallest spheres (RC_norm range between 0.34 and 1.96). Limiting the analysis to activity concentrations >0.3MBq/ml and to volumes >11.5mL improved both accuracy and repeatability (<1.04 and <0.13, respectively). Our results suggested that inclusion criteria based on volume and activity concentration should be considered for accurate tumour dosimetry after $^{177}$Lu-RPT with StarGuide.

**Predictive value of baseline quantitative parameters of 2-[$^{18}$F]FDG-PET/CT for brain metastases in melanoma patients**

***F. Kalantari***[1,2], *L. Hehenwarter*[1], *G. Rendl*[1], *G. Schweighofer-Zwink*[1], *W. Hitzl*[3], *P. Koelblinger*[4], *C. Pirich*[1], *M. Beheshti*[1];

***Aim/Introduction:*** Malignant melanoma represents a public health challenge due to its increasing incidence over the last decades, its aggressive nature, and its high tendency for brain metastases. Therefore, accurate identification of patients at higher risk of developing brain metastases (BM) is crucial for effective surveillance and optimal treatment management. In this study, we assessed the predictive value of baseline organ-specific metabolic parameters of 2-[$^{18}$F]FDG-PET/CT for brain metastases free survival (BMFS) in malignant melanoma. ***Materials and Methods:*** 159 patients with malignant melanoma (45.3% female, 54.7% male; mean age: 71 ± 14 years) who underwent primary staging by 2-[$^{18}$F]FDG-PET/CT and brain MRI and had available clinical and imaging follow-up data. Semi-quantitative 2-[$^{18}$F]FDG-PET parameters as well as clinical and histopathological variables were collected for survival analysis. Exclusion criteria were undefined disease stage, infection, atypical histopathological findings, brain metastases at initial diagnosis, and second primary malignancies. Predictive value of organ-specific semi-quantitative 2-[$^{18}$F]FDG-PET parameters (i.e. SUVmax, SULpeak, MTV, TLG) of the primary tumor, lymph nodes-, bone-, liver-, and lung-metastases were analyzed. ***Results:*** Median patient follow-up time was 6.3 years, and BM were found in 59 patients (37%) with a median time to brain metastasis-free survival (BMFS) of 60.58 months (range: 2-221 months). A negative 2-[$^{18}$F]FDG-PET/CT scan at the initial staging was significantly associated with BMFS, irrespective of the initial stage, gender, and BRAF mutation. The significant clinical predictors of BMFS were tumor thickness and the primary stage of the disease. No significant correlation was observed between the metabolic tumor burden on 2-[$^{18}$F]FDG-PET/CT and BMFS. There was significant correlation between SULpeak and SULmax of the prominent lymph node metastasis (P value 0.02), and SULpeak of the primary tumor with BMFS (P value 0.009). Patients were classified into low-risk (<20% probability of BM in mean-time of 10 years), intermediate-risk (>50% probability of BM in mean-time of 5 years) and high-risk (>75% probability of BM in mean-time of 1 year) based on a survival curve derived by SULpeak of <2, between ≥2 and 14.6, and > 14.6, respectively. ***Conclusion:*** Baseline organ-specific metabolic parameters of 2-[$^{18}$F]FDG-PET/CT showed promising markers for independent prediction of brain metastases in patients with melanoma. Furthermore, such quantitative metabolic imaging parameters could potentially be incorporated into existing clinical survival prediction models for accurate stratification of high-risk melanoma patients, who may benefit from further imaging surveillance and prophylactic treatment approaches.

***Aim/Introduction:*** The aims of the present study were to assess if the changes of mean SLR, bone marrow uptake and the site of new metabolic lesions at 2-[18F]-FDG PET/CT can predict patients' outcomes. ***Materials and Methods:*** From August 2013 to December 2020, data about [18F]FDG PET/CT obtained for 92 consecutive patients with malignant melanoma were collected. The following inclusion criteria were adopted: 1) a confirmed diagnosis of malignant melanoma; 2) age >18 years; and 3) a follow-up of at least 12 months after the first PET/CT scan. The scans were named as following: baseline PET when performed before starting immuno-therapy (within 3 months), PET1, PET2 and PET, respectively made after 6, 18 and 36 months from starting immunotherapy. Mean standardized uptake value (SUVmean) of the liver (SUVmean_L) and the spleen (SUVmean_spleen) were

measured. The Spleen Liver Ratio (SLR) was calculated as the ratio between SUVmean_spleen and the SUVmean_L. Bone marrow uptake was visually quantified by using a scale system from 1 to 5. ***Results:*** Data for both baseline PET and PET1 was available in all 92 patients, while 70 (76%) and 34 (37%) patients underwent PET2 and PET3 scans, respectively. Median values of SLR across the scans were similar, there was a slight increase in the bone marrow uptake between the baseline PET and PET1 (the score 4/5 moved from 2.2% to 6.5%, respectively in the baseline and PET1 scan), while it was substantially stable in PET2 an PET3. After a median follow-up period of 41 (4-312 months), 41 (44.6%) patients had a progressive disease. Moreover, 32 (34.8%) died after 61 (range 5-342) months. At baseline PET and PET3, median values of SLR were slightly higher in patients with a good prognosis (0.83 vs. 0.70 and 0.78 vs. 0.72, respectively in alive vs. dead patients), while they were substantially similar in PET1 and PET2 (0.79 vs. 0.76 and 0.75 vs. 0.74, respectively in alive vs. dead patient). Bone marrow uptake tended to be higher (score > 2) in PET1, PET2 and PET3 in patients with a worse prognosis, although not statistically significant. ***Conclusion:*** FDG uptake in lymphoid organs would be useful as a prognostic parameter in patients with malignant melanoma undergoing immunotherapy. Larger study population is mandatory to accertain this evidence. ***References:*** Cancers (Basel). 2023 Jan 31;15(3):878.Cancer Biother Radiopharm. 2023 Apr 25. doi: 10.1089/cbr.2022.0092.

## OP-448

### First-in-human PET imaging and evaluation of melanin-targeted $^{18}$F-DMPY2 in malignant melanoma patients.

***Y. Yang***[1], *M. Zhou*[1], *N. Chen*[1], *J. Su*[2], *X. Chen*[2], *S. Hu*[1];
[1]*Department of Nuclear medicine, Xiangya Hospital, Central South University, Changsha City, Hunan Province, CHINA,*
[2]*Department of Dermatology, Xiangya Hospital, Central South University, Changsha City, Hunan Province, CHINA.*

***Aim/Introduction:*** Early diagnosis and accurate staging of malignant melanoma (MM) have significant and decisive value in clinical practice. $^{18}$F-DMPY2 is a promising PET tracer in vivo with high affinity and selectivity for melanin. The study aims to investigate biodistribution and radiation dosimetry in healthy volunteers and the potential clinical application of $^{18}$F-DMPY2 in MM patients. ***Materials and Methods:*** $^{18}$F-DMPY2 was synthesized via a one-pot reaction. The biodistribution, radiation dosimetry, and safety of the new probe were estimated in 3 healthy volunteers. 31 MM patients underwent $^{18}$F-DMPY2 and/or $^{18}$F-FDG PET/CT scans to explore the clinical use in the early detection of melanoma metastasis. Besides, we studied its diagnostic performance in 51 lymph node basins of 27 MM patients after node dissection by comparing PET uptake with the postoperative pathological results. ***Results:*** $^{18}$F-DMPY2 was well tolerated by healthy volunteers and MM patients. The calculated effective dose of $^{18}$F-DMPY2 was 0.0122 mSv/MBq. In MM patients, we observed prominent $^{18}$F-DMPY2 tumor uptake and high tumor-to-background ratios in primary tumors. Diagnostic Performance of $^{18}$F-DMPY2 in Lymph Node Metastases is significantly better than $^{18}$F-FDG. The sensitivity, specificity, accuracy, and positive and negative predictive values of $^{18}$F-DMPY2 were 66.7%, 100%, 88.9%, 100%, and 85.7% respectively. Nevertheless, those of $^{18}$F-FDG were 50%, 42.8%, 46.6%, 50%, and 42.8%. Some distant metastases were detected in $^{18}$F-DMPY2, but not in $^{18}$F-FDG PET, such as brain and bone. Additionally, $^{18}$F-DMPY2 PET imaging had a unique advantage in distinguishing $^{18}$F-FDG false-positive lesions. ***Conclusion:*** $^{18}$F-DMPY2 is a safe and well-tolerated melanin PET tracer. $^{18}$F-DMPY2 PET/CT is a powerful imaging tool in the early detection and clinical staging of MM patients. ***References:*** Pyo A, Kim DY, Kim H, Lim D, Kwon SY, Kang SR, Kim HS, Bom HS, Min JJ. Ultrasensitive detection of malignant melanoma using PET molecular imaging probes. Proc Natl Acad Sci U S A. 2020 Jun 9;117(23):12991-12999. doi: 10.1073/pnas.1922313117.

## OP-449

### The prognostic value of [$^{18}$F]FDG PET/CT based response monitoring in metastatic melanoma patients undergoing immunotherapy: comparison of different metabolic criteria

***C. Sachpekidis***[1], *V. Weru*[1], *A. Kopp-Schneider*[1], *J. C. Hassel*[2], *A. Dimitrakopoulou-Strauss*[1];
[1]*German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [2]*National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** To investigate the prognostic value of [$^{18}$F]FDG PET/CT as part of response monitoring in metastatic melanoma patients treated with immune checkpoint inhibitors (ICIs). ***Materials and Methods:*** Sixty-seven patients underwent [$^{18}$F]FDG PET/CT before start of treatment (baseline PET/CT), after two cycles (interim PET/CT) and after four cycles of ICIs administration (late PET/CT). Metabolic response evaluation was based on the conventional EORTC and PERCIST criteria, as well as the newly introduced, immunotherapy-modified PERCIMT, imPERCIST5 and iPERCIST criteria. Metabolic response to immunotherapy was classified according to four response groups (complete metabolic response [CMR], partial metabolic response [PMR], stable metabolic disease [SMD], progressive metabolic disease [PMD]), and further dichotomized by response rate (responders= [CMR] + [PMR] vs. non-responders= [PMD] + [SMD]), and disease control rate (disease control= [CMR] + [PMR] + [SMD] vs. [PMD]). The spleen-to-liver SUV ratios ($SLR_{mean}$, $SLR_{max}$) and bone marrow-to-liver SUV ratios ($BLR_{mean}$, $BLR_{max}$) were also calculated. The results of PET/CT were correlated with patients' overall survival (OS). ***Results:*** Median patient follow up [95% CI] was 61.5 months [45.3 - 66.7 months]. On interim PET/CT, the application of the novel PERCIMT demonstrated significantly longer survival for metabolic responders, while the rest criteria revealed no significant survival differences between the different response groups. Respectively on late PET/CT, both a trend for longer OS and significantly longer OS were observed in patients responding to ICIs with metabolic response and disease control after application of various criteria, both conventional and immunotherapy-modified. Moreover, patients with lower $SLR_{mean}$ values demonstrated significantly longer OS. ***Conclusion:*** In patients with metastatic melanoma PET/CT-based response assessment after four ICIs cycles is significantly associated with OS after application of different metabolic criteria. The prognostic performance of the modality is also high after the first two ICIs cycles, especially with employment of novel criteria. In addition, investigation of spleen glucose metabolism may provide further prognostic information.

## OP-450

### Early monitoring of immunotherapy using $^{18}$F-FDG-PET-CT in patients with stage IV melanoma treated with PD-1 inhibitors

***D. Hochmuth***[1], *C. Sachpekidis*[1], *J. Hassel*[2], *L. Pan*[1], *A. Dimitrakopoulou-Strauss*[1];
[1]*German Cancer Research Center, CCU Nuclear Medicine, Heidelberg, GERMANY,* [2]*Department of Dermatology, University Hospital Heidelberg and NCT Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** The aim of the present study is to evaluate the value of $^{18}$F-FDG-PET-CT in patients with metastatic melanoma treated with PD-1 inhibitors and to find out at what point in therapy an initial follow-up examination provides a predictive value in terms of survival. Furthermore, the intention is to find out what additional information can be gained from dynamic PET-CT, which has been used until now primarily within research purposes. ***Materials and Methods:*** The study group included twenty-three patients with unresectable, metastatic melanoma treated with PD-1 inhibitors. PD-1 inhibitors were administered either as monotherapy or as combination treatment with a CTLA-4 inhibitor. Therapy monitoring was performed before the start of treatment (baseline), after two treatment cycles (interim) and after four treatment cycles (late) and consisted of dynamic PET-CT of the thorax and upper abdomen as well as static whole-body PET-CT. Patterns of physiological $^{18}$F-FDG uptake and irAEs were documented and distinguished from actual tumor lesions. Treatment response was assessed based on the application of the EORTC criteria and the PERCIMT. Patients' response to treatment was classified as either MB (metabolic benefit), including CMR, PMR and SMD, or no-MB (no metabolic benefit) in case of PMD. The actual clinical response was determined individually by the patients' PFS (progression-free survival) which was measured from the start of treatment until disease progression or death from any cause. ***Results:*** Tumor lesions and irAEs could be assessed in all planes and clearly differentiated from normal tissue due to the high $^{18}$F-FDG uptake. Survival analysis showed that both late and interim PET-CT were able to provide predictive value regarding PFS. Based on both follow-ups, patients with predicted MB showed significantly longer PFS compared to patients with predicted PMD. This significant survival benefit was seen when both criteria were used, with lower p-values and higher hazard ratios expressing superiority of the EORTC criteria (interim: $p = 0.021$, hazard ratio = 3.36; late: $p = 0.022$, hazard ratio = 5.25) over the PERCIMT (interim: $p = 0.048$, hazard ratio = 2.82; late: $p = 0.049$, hazard ratio = 4.23). ***Conclusion:*** The results show that $^{18}$F-FDG-PET-CT has predictive value in the early course of treatment with ICIs and is suitable for identifying early on which patients will benefit from therapy. The additional use of dynamic PET-CT enables a better understanding of the pathophysiology of malignant and inflammatory processes as well as the mechanism of action of ICIs.

## OP-451

### FDG PET/CT Biomarker Dissemination Features In Metastatic Melanoma Patients Treated With Immunotherapy: Association With Survival

***H. Saadani***[1,2], *E. A. Aalbersberg*[1], *M. T. Kayembe*[1], *J. B. A. G. Haanen*[1], *O. S. Hoekstra*[2], *R. Boellaard*[2], *M. P. M. Stokkel*[1];
[1]*NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** In metastatic melanoma treated with immunotherapy, patient risk stratification to determine treatment benefit remains an unsolved clinical problem. FDG Positron Emission Tomography/Computed Tomography ([$^{18}$F]FDG PET/CT) is an established technique for staging malignant melanoma. Melanoma shows heterogeneous metastatic patterns, with certain distributions associated with worse prognosis. Advanced PET dissemination features can quantify malignant spread in a simplified manner. However, the additional value of advanced image analysis and quantification is unknown yet. The aim of this study was to evaluate the association of [$^{18}$F]FDG PET/CT uptake metrics and dissemination features with overall survival (OS) in metastatic melanoma patients treated with immunotherapy. ***Materials and Methods:*** Consecutive metastatic melanoma patients who received first-line immunotherapy from 2016 to April 2021 were eligible. Inclusion criteria were histopathological confirmed metastatic/unresectable melanoma, a baseline [$^{18}$F]FDG PET/CT scan and initiation of immunotherapy within a maximum 12 weeks of baseline scan. Exclusion criteria included aggressive concurrent malignancies within 5 years prior to the baseline scan, brain metastasis and less than two lesions. On a patient level, 18 dissemination features and 5 conventional PET metrics (SUVmax, SUVpeak, SUVmean, TLG, TMTV) were extracted. From the 18 dissemination features, 5 provide quantitative measures for spatial distribution over the body, 10 for the variability in SUV across lesions and 3 for the variability in tumor volume across all lesions. Clinical baseline characteristics were collected including: age, sex, stage, tumour type, immunotherapy type, mutations, LDH, performance status and metastasized organ sites. Univariate and multivariate Cox regression analyses were used to assess association between PET features and OS. The Spearman's rank correlation (rho) between predictor variables was used to test for potential multicollinearity. ***Results:*** Eighty five patients were included, and their mortality rate was 60%. At current follow-up, the median OS time was 33 months. Patients were mostly treated with pembrolizumab, nivolumab and ipilimumab/nivolumab. Two spatial dissemination features and one volume dissemination feature, were significantly associated with OS in the univariate analysis. Conventional PET metrics were not associated with OS. In the multivariate analysis, one spatial dissemination feature remained significantly associated with OS. ***Conclusion:*** Spatial dissemination measuring the distance between the largest and any other lesion within metastatic melanoma patients was associated with worse OS, whereas the conventional PET metrics were not. We showed a first exploratory independent association between spatial dissemination and OS, however we're working on further in-depth examination and validation necessary before clinical implementation can be considered.

## OP-452

### Correlation of thyroid FDG uptake on 18F-FDG PET/CT with response to immunotherapy in metastatic melanoma patients

***K. Zevnik***[1,2], *N. Hribernik*[1,2], *K. Strašek*[3], *A. Studen*[3,4], *A. Doma*[1,2], *K. Škalič*[1], *M. Reberšek*[1,2];
[1]*Oncology Institute Ljubljana, Ljubljana, SLOVENIA,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA,* [3]*Faculty of Mathematics and Physics University of Ljubljana, Ljubljana, SLOVENIA,* [4]*Experimental Particle Physics Department, Jožef Stefan Institute, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** Previous studies showed conflicting results about the occurrence of immune-related (IR) thyroiditis in cancer patients on immunotherapy (ICI) and clinical benefit. Positive correlation between higher thyroid metabolic activity on PET/CT and IR thyroiditis has been shown in previous studies. Our aim was to analyse whether the increase of thyroid metabolic activity on 18F-FDG PET/CT in metastatic melanoma (MM) patients on ICI correlates with clinical outcome ***Materials and Methods:*** In this prospective single-arm, one-centre clinical study, 67 MM patients on ICI were included. Patients were monitored with 18F-FDG PET/CT at the baseline, 1, 4 and 8 months (M1, M4, M8) after ICI treatment initiation. Thyroid gland was segmented on PET/CT scans using a convolutional neural network (CNN). To quantify 18F-FDG thyroid uptake a novel quantitative biomarker was

used - 75th percentile of SUV distribution (SUV75%), which was proven to be optimal for detection of IR-thyroiditis in one of our previous studies. We determined clinical best overall response (BOR) status of patients up to 8 months. We divided the patients into two groups based on their BOR, with progressive patients (PD) being in the non-clinical response group (non-CB) and all the other patients (CR, PR, SD) being in the clinical benefit group (CB). We analysed the correlation of SUV75% on M1 and M4 PET/CT scans with clinical BOR of the patients subdivided into the before mentioned CB and non-CB groups using the Pearson correlation method. Secondarily we analysed the correlation of grade 2 (G2) thyroiditis and any grade thyroiditis (AG), diagnosed in the follow-up period of 8 months, with SUV75% and with BOR. ***Results:*** Clinical BOR status of 67 patients was defined as CR (16 patients), PR (18 patients), SD (7 patients) and PD (26 patients). 41 patients were categorized in the CB group and 26 in the non-CB group. There was no correlation of SUV75% from either M1 or M4 PET/CT with BOR. No threshold was found to distinguish between the two groups (CB and non-CB). G2 thyroiditis was present in 11 pts. and AG thyroiditis in 13 pts. There was no correlation of G2 thyroiditis and AG thyroiditis with BOR. M4 SUV75% had high correlation with G2 thyroiditis and AG thyroiditis. ***Conclusion:*** Our prospective study showed no statistical correlation between higher 18F- FDG PET/CT thyroid uptake and clinical response to immunotherapy. PET/CT seems to be a good diagnostic tool for detection of IR -thyroiditis.

## OP-453

### Prediction of Additional Regional Lymph Node Metastases in Cutaneous Melanoma Patients With Positive Sentinel Lymph Node Biopsy

***L. Radosavcev***[1], *M. Rajovic*[2], *M. Radulovic*[1], *N. Petrov*[3], *L. Kandolf Sekulovic*[4];
[1]*Institute of Nuclear Medicine, Military Medical Academy, Belgrade, SERBIA,* [2]*Clinic for Plastic and Reconstructive Surgery , Military Medical Academy, Belgrade, SERBIA,* [3]*Institute of Pathology and Forensic Medicine , Military Medical Academy, Belgrade, SERBIA,* [4]*Department of Dermatology and Venerology, Military Medical Academy, Belgrade, SERBIA.*

***Aim/Introduction:*** Sentinel lymph node (SLN) biopsy is the standard of care for nodal staging in clinically node-negative melanoma patients. The impact of complete lymph node dissection (CLND), after a positive SLN biopsy is still debatable. Examining the factors associated with increased risk of metastases in non-sentinel lymph node (NSLN) is important to identify patients who could still benefit from CLND. ***Materials and Methods:*** We retrospectively analyzed clinicopathologic and lymphoscintigraphic characteristics in 420 cutaneous melanoma patients who underwent lymphoscintigraphy and SLN biopsy. Univariate and multivariate logistic regression analysis was performed using (non) SLN metastasis (yes/no binary outcome), with odds ratios representing effect size. ***Results:*** The overall detection rate of SLNs was 97.6. Metastatic SLNs were found in 81 patients (19.7%) and CLND was recommended. Among patients who underwent CLND at our institution, additional metastatic nodes (positive CLND) were shown in 26 (32.1 %) patients, while negative CLND was found in 55 (67.9%) patients. Positive NSLN was no associated with a gender, age, localization, presence of ulceration, regression, hystopathological type and mitotic rate of primary melanoma. Breslow thickness in patients with positive NSLN tended to be higher (median 4.8mm ) versus 4.4 mm in NSLN negative group, but without reaching statistical significance. In addition, characteristics on lymphoscintigraphy like the time to procedure, number of draining basins, number of SLN visualized on scintigraphy and excised for patients were no associated with NSLN positivity. ***Conclusion:*** Patients and primary tumor characteristics as well as the lymphoscintigraphy imaging characteristics were not significant predictors of metastatic involvement of additional lymph node(s) in regional basins.

## OP-454

### Effects Of Medications On Dopamine Transporter Imaging Using $^{123}$I-FP-CIT SPECT In Routine Practice

***Y. Piatkova***[1], *M. Doyen*[1], *S. Frismand*[2], *L. Hopes*[2], *L. Imbert*[1], *A. Verger*[1];
[1]*Université de Lorraine, Department of Nuclear Medicine and Nancyclotep Imaging Platform, CHRU Nancy, Nancy, FRANCE,* [2]*Université de Lorraine, Department of Neurology, CHRU Nancy, Nancy, FRANCE.*

***Aim/Introduction:*** Dopamine transporter (DAT) imaging is used as a diagnostic tool to support the diagnosis of neurodegenerative parkinsonian disorders. Medications have been described as potentially influencing the interpretation of $^{123}$I-FP-CIT SPECT scan, but with limited data. The aim of the current study was to evaluate in routine practice the potential effects of medications on interpretation of $^{123}$I-FP-CIT SPECT scan. ***Materials and Methods:*** Consecutive patients undergoing a $^{123}$I-FP-CIT SPECT/CT scan on a 360° CZT camera between September 2019 and December 2022 were included. An exhaustive interrogation of medications (antidepressants,antipsychotics,anti-epileptics,anti-parkinsonians, benzodiazepines, lithium, opioids and stimulants) taken by each patient was performed. Two experienced nuclear physicians, blinded to the report of medications, interpreted the $^{123}$I-FP-CIT SPECT scans visually as well as semi-quantitatively through striatal and occipital masks obtained after a Montreal National Institute spatial normalization of each CT scan registered to the SPECT. ***Results:*** Three hundred and five patients (71.0 ± 10.4, 135 women) were included with 145 (47.5%) of visually interpretated normal scans. In normal scans, the striatum/occiput ratio was decreased by noradrenergic and specific serotonergic antidepressant (n=15, average decrease of 15%) and opioid (tramadol, n=6, average decrease of 12%) medications in association with a lower age in a multivariate analysis. In the overall population, the striatum/occiput ratio was not influenced by these medications since only consensual visual analysis associated with age, sex, and anti-parkinsonian medications, were significant predictors. ***Conclusion:*** This study confirms the potential impact of antidepressant (noradrenergic and specific serotonergic) and opioid (tramadol) medications on semi-quantitative analysis of $^{123}$I-FP-CIT SPECT scans. However, the impact of these medications did not influence the interpretation of $^{123}$I-FP-CIT SPECT scans, based on visual analysis associated with the already known factors of age, sex and parkinsonian disease status.

## OP-455

### Disease-tailored z-score cut-offs for striatal binding ratio of DaT SPECT for the diagnosis of Dementia with Lewy Bodies (DLB): a multicenter study

***F. Lanfranchi***[1,2], *D. Arnaldi*[2,3], *V. Garibotto*[4], *C. Boccalini*[4], *L. Bonanni*[5], *M. V. Mattoli*[6], *V. Costa*[2,3], *S. Raffa*[1,2], *S. Chiola*[1,2], *F. Massa*[2,3], *M. Losa*[2,3], *M. Pardini*[2,3], *G. Frisoni*[7], *N. Nicastro*[8], *G. Sambuceti*[1,2], *M. Bauckneht*[1,2], *S. Morbelli*[1,2];
[1]*Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY,* [2]*IRCCS Ospedale Policlinico San Martino, Genoa, ITALY,* [3]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY,* [4]*Division of Nuclear Medicine and Molecular Imaging, University Hospitals and NIMTLab, Geneva University, Geneva, SWITZERLAND,* [5]*Department of Neuroscience, Imaging and Clinical Sciences, University G. d'Annunzio, Chieti-Pescara, ITALY,* [6]*Nuclear Medicine Unit, Presidio Ospedaliero Santo Spirito, Pescara, ITALY,* [7]*Laboratory of Neuroimaging of Aging (LANVIE), University of Geneva, Geneva, SWITZERLAND,* [8]*Division of Neurorehabilitation, Department of Clinical Neurosciences, Geneva University Hospitals, Geneva, SWITZERLAND.*

***Aim/Introduction:*** There's an emerging evidence about the need to identify disease-specific Z-score (ZS) cut-off for striatal binding ration (SBR) for DLB diagnosis. In a cohort of DLB patients from Genoa, a ZS of -1 for the putamen was identified as the most accurate cut-off to support the differential diagnosis with Alzheimer's Disease (AD). We aimed to assess the accuracy of -1 ZS to support the diagnosis of DLB in an independent sample and in a multicenter setting. ***Materials and Methods:*** Two-hundred patients (150 DLB and 50 AD; age 74.8±8.3 vs. 76.9±6.1; females 48 vs. 27) underwent DaT SPECT in three different European centers. Patients' final clinical diagnosis served as gold-standard (regardless of DaT SPECT results). Age-adjusted ZS of striatum and substriatal regions for both hemispheres were computed with Datquant®, a commercially available software. ROC curve was used to test the accuracy of the previously identified cut-off (-1 ZS) in an independent sample of patients (Chieti and Geneva, 100 DLB and 30 AD) and then in the whole population. Sensitivity (Se), specificity (Sp), positive and negative predictive values (PPV and NPV, respectively), and Youden's index (YI) were calculated and compared to the widely used cut-off of -2 ZS. ***Results:*** In the independent population, the whole putamen of both hemispheres was confirmed as the most accurate parameter for the discrimination between DLB and AD (AUC=0.95 and AUC=0.94 for left and right hemisphere, respectively; p<0.0001 for both), and -1 ZS showed a higher accuracy (Se=0.84, Sp=0.90, PPV=0.97, NPV= 0.63, YI=0.74) with respect to -2 ZS (Se=0.65, Sp=0.93, PPV=0.97, NPV=0.44, YI=0.58). Similarly, the bilateral putamen remained the most accurate parameter to discriminate between DLB and AD (AUC=0.95 and AUC=0.94 for left and right hemisphere, respectively; p<0.0001 for both) in the whole group. Again, a cut-off very close to -1 ZS (-0.96 ZS) resulted more accurate (Se=0.87, Sp=0.92, PPV=0.97, NPV= 0.70, YI=0.79) than -2 ZS (Se=0.69, Sp=0.94, PPV=0.97, NPV=0.51, YI=0.63). ***Conclusion:*** In an independent multi-centric sample, -1 ZS for SBR of both putamen was confirmed as an accurate cut-off to tell apart DLB from AD patients. The experimental exploration of the whole multicenter cohort showed -0.96 ZS for bilateral putamen SBR as the most accurate cut-off for the differential diagnosis between DLB and AD. The use of this less conservative cut-offs provided higher sensitivity than -2 ZS without a measurable loss in specificity.

## OP-456

### Dopamine dysregulation in depression: a 123I-FP-CIT SPET study

***D. Pizzuto***[1], *E. Perrone*[1,2], *F. Cocciolillo*[1], *F. Pesaresi*[3,4], *L. Di Benedetto*[3,4], *A. D'Onofrio*[3,4], *G. Camardese*[3,4], *D. Di Giuda*[1,2];
[1]*Nuclear Medicine Unit, Diagnostic Imaging, Radiation Oncology and Hematology Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [2]*Nuclear Medicine Institute, University Department of Radiological and Hematological Sciences, Università Cattolica del Sacro Cuore, Rome, ITALY,* [3]*Institute of Psychiatry and Psychology, Department of Geriatrics, Neuroscience and Orthopedics, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [4]*Department of Psychiatry, Università Cattolica del Sacro Cuore, Rome, ITALY.*

***Aim/Introduction:*** A decrease in dopamine (DA) transmission has long been thought to be involved in the pathophysiology of depression. Preclinical data suggest plastic changes in Dopamine Transporter (DAT) availability depending on striatal DA levels. However, in-vivo evidence from neuroimaging studies in Major Depressive Disorder (MDD) is inconclusive. The aim of this study was to investigate the relationships between striatal DAT availability and psychopathological dimensions of MDD in a large cohort of patients using 123I-FP-CIT SPET. ***Materials and Methods:*** A retrospective study was conducted on 120 drug-free patients (M: 66; mean age: 66±12 years) with a current Major Depressive Episode (MDE) in MDD (DSM-5 criteria) and 62 healthy subjects (M: 29; mean age: 64±14 years) from a previous 123I-FP-CIT SPET database. All depressed patients showed no DAT-SPET alterations and no neurological diseases were diagnosed in the subsequent three-year clinical follow-up. On the same day as SPET, patients underwent a psychiatric interview and psychometric evaluation: the severity of depression symptoms, levels of anxiety, anhedonia and psychomotor retardation were assessed by the Hamilton Depression Rating Scale (HAMD), Hamilton Anxiety Rating Scale (HAMA), Snaith Hamilton Pleasure Scale (SHAPS) and Depression Retardation Rating Scale (DRRS), respectively. SPECT was carried out 3 hours after 148 MBq 123I-FP-CIT intravenous injection. A semiquantitative assessment was performed using SPM and VOI analysis. Specific to non-specific 123I-FP-CIT binding ratios (SBRs) were calculated. ***Results:*** There were no differences in age and gender between patients and healthy subjects. Depressed patients showed decreased DAT availability in the left caudate (p=0.006), right putamen (p=0.001) and left putamen (p=0.008) in comparison with healthy subjects. Inverse correlations were found between the severity of depression symptoms (HAMD total scores) and DAT availability in the right putamen (p=0.042) and left putamen (p=0.003). Anxiety levels (HAMA total scores) inversely correlated with DAT availability in the right putamen (p = 0.042) and left putamen (p = 0.023). Similarly, psychomotor impairment (DRRS total scores) was associated with lower DAT availability in the right putamen (p = 0.032) and left putamen (p = 0.006), whereas levels of anhedonia (SHAPS total scores) inversely correlated with DAT availability in the left putamen (p=0.015). ***Conclusion:*** This study provided evidence for decreased striatal DAT availability in a large cohort of depressed patients, hypothesising a compensatory down-regulation of DAT in response to blunted DA transmission. Our findings are consistent with prior reports of negative associations between striatal DAT availability and psychopathological dimensions of MDD.

## OP-457

### Comparison of $^{123}$I-FP-CIT SPECT and $^{18}$F-FE-PE2I PET in patients with parkinsonism and persistent diagnostic uncertainty

***M. Dhadamus***[1,2], *A. Delva*[3], *W. Vandenberghe*[3], *K. Van Laere*[1,2];
[1]*Division of Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM,* [2]*Nuclear Medicine and Molecular Imaging, KU Leuven, Leuven, BELGIUM,* [3]*Neurology, University Hospitals Leuven, Leuven, BELGIUM.*

***Aim/Introduction:*** Imaging of dopamine transporters (DAT) in the brain has shown to be a highly performant tool in the diagnostic work-up of clinically uncertain parkinsonism. DAT SPECT radioligands such as $^{123}$I-FP-CIT are widely used in daily clinical practice. Recently, $^{18}$FFE-PE2I was introduced as a highly specific alternative for PET. In several patients, despite $^{123}$I-FP-CIT imaging, diagnostic uncertainty remains. In this study, we have compared follow-up $^{18}$FFE-PE2I PET to previous $^{123}$I-FP-CIT SPECT in patients with parkinsonism and persistent diagnostic uncertainty. ***Materials and Methods:*** All subjects who had a $^{18}$F-FE-PE2I PET scan between 02/2017 and 03/2023 because of persistent diagnostic difficulties and had already previously undergone $^{123}$I-FP-CIT SPECT imaging at our tertiary referral centre were included in this retrospective study. All images were visually assessed by experienced nuclear medicine physicians and classified as normal or abnormal striatal binding. Concordances and discrepancies between both imaging modalities were analysed. ***Results:*** In our database, 46 subjects (26F/20M, 69.1 ± 10.4 years) underwent $^{123}$I-FP-CIT SPECT and subsequent $^{18}$F-FE-PE2I PET. $^{123}$I-FP-CIT SPECT was performed between 2008 and 2022. The average time between $^{123}$I-FP-CIT SPECT and $^{18}$F-FE-PE2I PET imaging (ΔT) was 2.3 ± 2.3 years (range 0.1 - 11.4 years). Thirty-three subjects (72%) had a concordant result for $^{18}$F-FE-PE2I PET and $^{123}$I-FP-CIT SPECT, i.e., both modalities classified 24 and 9 participants as abnormal and normal, respectively. By contrast, the results were discrepant in 13 subjects (28%). In 6 subjects (13%), $^{123}$I-FP-CIT SPECT was judged to be abnormal, but subsequent $^{18}$F-FE-PE2I PET was normal (ΔT= 0.4-7.2 years). In 7 subjects (15%) $^{123}$I-FP-CIT SPECT was normal, but $^{18}$F-FE-PE2I PET abnormal, which may reflect conversion over the time course (ΔT= 0.5-4.7 years). Visual $^{18}$F-FE-PE2I PET assessments agreed with a semiquantitative age-adjusted comparison to an in-house normal dataset in 93% of cases. ***Conclusion:*** In our sample of parkinsonism patients with persistent uncertain clinical diagnosis, 6 out of 30 cases with an abnormal $^{123}$I-FP-CIT SPECT scan had qualitatively and quantitatively normal $^{18}$F-FE-PE2I PET at follow-up. A semiquantitative correlation analysis of both DAT imaging modalities is underway, but this visual analysis already suggests additional clinical value of $^{18}$F-FE-PE2I PET. ***References:*** 1. Delva, A. et al. Quantification and discriminative power of 18F-FE-PE2I PET in patients with Parkinson's disease. EJNMMI 47, 1913-1926 (2020) 2. Marner, L et al. [18F]FE-PE2I PET is a feasible alternative to [123I]FP-CIT SPECT for dopamine transporter imaging in clinically uncertain parkinsonism. EJNMMI Res 12, 56 (2022).

## OP-458

### Within-subject comparison of $^{11}$C-PE2I and $^{18}$F-FE-PE2I PET for dopamine transporter availability and relative blood flow measures

***M. Jonasson****, L. Appel, S. Roslin, G. Antoni, D. Nyholm, T. Danfors, M. Lubberink;*
*Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** PE2I is a PET ligand with high affinity and sensitivity to the dopamine transporter (DAT). It can be labelled with either carbon-11 ($^{11}$C-PE2I) or fluorine-18 ($^{18}$F-FE-PE2I) to measure DAT availability in vivo. Relative tracer delivery, as a measure of relative cerebral blood flow (rCBF), can be estimated as well based on a dynamic scan with either of these tracers. At Uppsala University Hospital, $^{11}$C-PE2I is used as clinical routine investigation using both DAT-availability and rCBF for differential diagnosis of patients with parkinsonism [1], and so far, more than 1200 patients has been investigated. However, the short half-life of carbon-11 can be a disadvantage making fluorine-18 a more clinically feasible alternative. The aim of this study is to compare $^{11}$C-PE2I and $^{18}$F-FE-PE2I, regarding DAT-availability and rCBF measures, in the same individuals. ***Materials and Methods:*** Ten healthy controls have been included so far in this ongoing study. They each received an 80 min dynamic $^{11}$C-PE2I PET scan and a 60 min dynamic $^{18}$F-FE-PE2I scan within one week. Parametric images were generated using a basis function implementation of the simplified reference tissue model, showing binding potential ($BP_{ND}$) as a measure of DAT-availability, and rCBF. In addition, DAT availability was estimated as the standardized uptake value ratio (SUVR) at a 30-40 min interval. Grey matter cerebellum was used as the reference region. Average regional voxel values were extracted from the parametric images in striatal VOIs (caudate and putamen) and in cortical VOIs (frontal, temporal, parietal and occipital). ***Results:*** High corelation was found for DAT availability between $^{11}$C-PE2I and $^{18}$F-FE-PE2I in striatum; r=0.85 and 0.79 for $BP_{ND}$ and SUVR-1 respectively. Both $BP_{ND}$ and SUVR-1 values were significantly lower for $^{18}$F-FE-PE2I than for $^{11}$C-PE2I ($p<0.0001$). Mean $BP_{ND}$ values were 3.16 ± 0.90 for $^{18}$F-FE-PE2I and 6.56 ± 1.39 for $^{11}$C-PE2I, and mean SUVR-1 values were 3.73 ± 1.05 and 4.84 ± 1.20, respectively. Correlation and agreement were high for rCBF in both striatal VOIs (r=0.95, slope=1.09) and cortical VOIs (r=0.98, slope=1.10). ***Conclusion:*** A strong correlation was seen between the two tracers regarding both DAT availability and rCBF. However, both $BP_{ND}$ and SUVR-1 were significantly lower for $^{18}$F-FE-PE2I than $^{11}$C-PE2I, which may reduce discrimination between patients with parkinsonism and healthy subjects. More data (controls and Parkinson's disease patients) will be included in the near future. ***References:*** [1] Appel et al. Use of $^{11}$C-PE2I PET in differential diagnosis of parkinsonian disorders. J Nucl Med. 2015;56(2), 234-242

## OP-459

### Relationship between cerebral blood flow and dopamine transporter availability in healthy individuals

***M. Jonasson****, L. Appel, S. Roslin, D. Nyholm, T. Danfors, M. Lubberink;*
*Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** A dual-biomarker approach with PET, where both blood flow and receptor or transporter availability is assessed from the same scan, can be used for differential diagnosis of patients with neurodegenerative disorders. PE2I is a PET ligand that binds to the dopamine transporters (DAT) and can be label with either carbon-11 or fluorine-18. In a recent study we found a significant correlation between dopamine transporter (DAT) availability and relative tracer delivery ($R_1$) as a measure of relative cerebral blood flow (rCBF) in striatum with both $^{11}$C-PE2I and $^{18}$F-FE-PE2I PET [1]. This suggests that a more active dopamine system requires a higher striatal perfusion, or that the activity of the dopamine system is flow limited. However, to date, the relation between DAT availability and absolute blood flow has not been investigated. The aim of this study is to investigate the relation between cerebral blood flow (CBF) and both DAT availability and tracer delivery using $^{15}$O-water and $^{18}$F-FE-PE2I PET. ***Materials and Methods:*** Ten healthy controls have been included so far in this ongoing study. Each subject underwent a 6-minute dynamic

$^{15}$O-water PET scan and a 60-minute dynamic $^{18}$F-FE-PE2I PET scan. Parametric images showing $^{15}$O-water CBF were generated using a single tissue compartment model and rCBF was calculated relative to cerebellar grey matter. $^{18}$F-FE-PE2I $BP_{ND}$ and $R_1$ were generated using a basis function implementation of the simplified reference tissue model using cerebellar grey matter as reference tissue. Average regional voxel values were extracted from striatal VOIs (caudate and putamen) as well as cortical VOIs (frontal, temporal, parietal and occipital). ***Results:*** A significant positive relationship was found between $^{15}$O-water CBF and $^{18}$F-FE-PE2I $BP_{ND}$ in striatum (r=0.68, p<0.0001). A strong correlation was also seen between $^{15}$O-water rCBF and $BP_{ND}$ (r=0.78, p<0.0001). When comparing the relative measures $^{15}$O-water rCBF and $^{18}$F-FE-PE2I $R_1$, the correlation in the striatal region was high (r=0.87, p<0.0001) but only moderate in the cortical regions (r=0.65, p<0.0001) due to the narrow range of the cortical $R_1$ values. ***Conclusion:*** These results indicate an association between DAT availability and absolute blood flow in striatum and confirms that relative tracer delivery correlates to relative blood flow. More data (controls and Parkinson's disease patients) will be included in the near future. ***References:*** [1] Jonasson et al. Striatal dopamine transporter and receptor availability correlate with relative cerebral blood flow measured with [$^{11}$C]PE2I, [$^{18}$F]FE-PE2I and [$^{11}$C]raclopride PET in healthy individuals. ### FDG-PET related pattern expression and survival in Parkinson's disease

***G. Martí-Andrés***[1], *V. Betech*[2], *E. Prieto*[2], *C. Espinoza-Vinces*[2], *M. Riverol*[2], *M. Luquin*[2], *J. Arbizu*[2];
[1]*Hospital Universitario de Navarra, Pamplona, SPAIN,*
[2]*Clínica Universidad de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** Aim: To assess FDG-PET metabolic findings as a possible risk factor of mortality in a cohort of patients with a clinical diagnosis of Parkinson's disease (PD). Background: Many studies have revealed clinical factors associated with a higher risk of mortality in PD patients however, it is less known about the impact of FDG-PET findings on survival. ***Materials and Methods:*** We performed a retrospective cohort study and included a total of 114 patients with a final clinical diagnosis of PD according to the MDS-PD criteria, who were referred for an FDG-PET scan throughout the disease course. We performed a systematic review of medical charts and obtained clinical and FDG-PET variables, including the date of death or last follow-up visit date in subjects who were alive in December 2022. We included the individual expression of a predefined PD-related pattern (PDRP)[1] obtained using a multivariate Scaled Subprofile Model/Principal Component Analysis (SSM/PCA) into FDG-PET scans. A Kaplan-Meier test was performed to calculate the median of survival. The risk of death in PD patients was calculated using a Cox proportional hazard model in univariate analysis. Moreover, we analyzed the impact on the risk of death at the time of onset of preselected clinical milestones. ***Results:*** PD patients were followed up for a median of 13 years when a total of 30 PD patients died. The median survival was 26.9 years. Higher PET-FDG PDRP expression, increased age at disease onset, presence of dysphagia in the first 5 years, and lower disease duration at PET were independent risk factors of mortality [Table 1]. ***Conclusion:*** A more severe FDG-PET PDRP, older age at onset, and early appearance of dysphagia have a negative impact on survival in PD patients. ***References:*** [1] Martí-Andrés, G., et al. Clinical correlates of Parkinson's disease metabolic pattern: not only a diagnostic tool. 25th international congress of Parkinson´s disease and movement disorders. MDS virtual congress 2020.

## OP-461

### Identification of Synaptic Alterations in Idiopathic REM Sleep Behavior Disorder: A Preliminary Study using $^{18}$F-SynVesT-1 PET/CT Imaging

***J. Li***[1], *J. Huang*[2], *J. Guo*[2], *S. Hu*[1];
[1]*1.Department of Nuclear Medicine (PET Center), Xiangya Hospital Central South University, Changsha, CHINA,* [2]*1.Department of Neurology, Xiangya Hospital Central South University, Changsha, CHINA.*

***Aim/Introduction:*** Idiopathic Rapid Eye Movement (REM) Sleep Behavior Disorder (RBD) is a parasomnia characterized by abnormal motor movements during REM sleep, which has been linked to neurodegenerative diseases such as Parkinson's Disease (PD), Dementia with Lewy bodies (DLB), and Multiple System Atrophy (MSA). Previous research shows that individuals with idiopathic RBD demonstrate disruptions in brain regions associated with sleep-wake regulation and motor control. Synaptic loss is an early indication of many neurodegenerative conditions, and Positron Emission Tomography (PET) imaging of synaptic vesicle glycoprotein 2A (SV2A) could serve as a promising biomarker of synaptic density. This study aims to use $^{18}$F-Synaptic Vesicles Transporter-1 ($^{18}$F-SynVesT-1) PET/CT imaging to determine whether synaptic loss occurs in patients with idiopathic RBD. ***Materials and Methods:*** In this study, we recruited 7 participants diagnosed with idiopathic RBD (mean age 57 years, range 41-68 years; 6 males, 1 female) and 10 healthy controls (mean age 57 years, range 47-69 years; 5 males, 5 females). All subjects underwent $^{18}$F-SynVesT-1 PET imaging and 3D-T1-weighted structural magnetic resonance imaging (MRI). The T1-weighted images were used for accurate PET spatial normalization, and regions of interest (ROIs) were defined using the Anatomical Automatic Labeling (AAL) 3 template in Montreal Neurological Institute (MNI) standard space. The standardized uptake value ratio (SUVR) relative to centrum semiovale was computed and used to compare the SUVRs of the RBD and healthy control groups using a two-sample t-test. ***Results:*** Compared with healthy individuals, RBD patients demonstrated significant decreases in $^{18}$F-SynVesT-1 uptake in regions of the brain involved in sleep regulation, such as the locus coeruleus (mean SUVR 1.66 versus 1.80, p=0.049), ventral tegmental area (mean SUVR 1.44 versus 1.66, p=0.008), and pons (mean SUVR 1.15 versus 1.25, p=0.039). The nigrostriatal pathway, which is associated with the motor symptoms of Parkinson's disease, also exhibited reduced 18F-SynVesT-1 uptake in RBD patients, including the substantia nigra (mean SUVR 1.53 versus 1.69, p=0.03) and Putamen (mean SUVR 4.40 versus 4.78, p=0.036). ***Conclusion:*** This study provides the first evidence of synaptic loss in brain regions that regulate sleep and motor control in living patients with idiopathic RBD. Our findings suggest that $^{18}$F-SynVesT-1 PET imaging could serve as a new biomarker for early detection and monitoring of neurodegeneration in this population. However, larger sample size studies

## OP-462

### Neurobiological dysfunctional substrates for the self-medication hypothesis in adult individuals with ADHD and cocaine use disorder: an18F-FDG PET study

***A. Martini***[1], *G. Carli*[2], *M. Bruscoli*[3], *L. Presotto*[4], *C. Mazzeo*[1], *S. Sestini*[1], *D. Perani*[5];

Stefano, U.S.L. Toscana Centro, Prato, ITALY,* [4]*Department of Physics G. Occhialini, Università degli Studi di Milano Bicocca, Milano, ITALY,* [5]*In vivo human molecular and structural neuroimaging Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute;*
*NuclearMedicine Unit, San Raffaele Hospital, Milano, ITALY.*

***Aim/Introduction:*** Attention-deficit hyperactivity disorder (ADHD) in adulthood shows high co-occurrence rates with cocaine use disorder (CoUD). The self-medication hypothesis (SMH) provides a theoretical explanation for this comorbidity. This study investigates the neurobiological mechanisms that could support SMH in adult patients with ADHD-CoUD. ***Materials and Methods:*** We included 19 ADHD-CoUD (84.2% male; age: 32.11 [7.18]) and 16 CoUD (68.7% male; age: 36.63 [8.12]). All subjects underwent an $^{18}$F-FDG-PET brain scan. We tested brain metabolism differences between ADHD-CoUD and CoUD patients using voxel-based and regions of interest (ROIs)-based analyses. The correlation between dependence/abstinence duration and regional brain metabolism was also assessed in the two groups. Lastly, we investigated the integrity of brain metabolic connectivity of mesocorticolimbic and nigrostriatal dopaminergic systems, and large-scale brain networks involved in ADHD and addictions. ***Results:*** The voxel-wise and ROIs-based approaches showed that ADHD-CoUD patients had a lower metabolism in the thalamus and increased metabolism in the amygdala and parahippocampus, bilaterally, compared to CoUD subjects and HC. Metabolism in the thalamus negatively correlated with years of dependence in ADHD-CoUD patients. Moreover, connectivity analyses revealed that ADHD-CoUD had a more preserved metabolic connectivity than CoUD in the dopaminergic networks and large-scale networks involved in self-regulation mechanisms of attention and behaviours (i.e., ADMN, ECN, SAN). ***Conclusion:*** We demonstrated distinct neuropathological substrates underlying substance-use behaviours in ADHD-CoUD and CoUD. Furthermore, we provided neurobiological evidence in support of SMH, demonstrating that ADHD-CoUD might experience short-term advantages of cocaine assumption (i.e., compensation of dopaminergic deficiency and related cognitive-behavioural deficits).

*[1]Department of Clinical Physiology and Nuclear Medicine, University Hospital Copenhagen – Rigshospitalet, Copenhagen, DENMARK, [2]Cluster for Molecular Imaging, Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK, [3]Image X Institute, Faculty of Medicine and Health, The University of Sydney, Sydney, AUSTRALIA, [4]QIMP Team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [5]Siemens Medical Solutions UNITED STATES OF AMERICA, Inc, Knoxville, TN, UNITED STATES OF AMERICA, [6]National Cardiac PET Centre, University of Ottawa Heart Institute, Ottawa, ON, CANADA.*

***Aim/Introduction:*** To assess the feasibility of applying a positron-range (PR) correction (PRC) method for routinely acquired myocardial perfusion imaging (MPI) employing $^{82}$Rb PET. ***Materials and Methods:*** The PRC was implemented into the vendor-based image reconstruction algorithm as a blurring kernel applied to the image estimate during iterative reconstruction. A spatially variant and tissue-dependent PR-kernel was generated for every voxel. The PR-kernels were composed of simulated uniform PR distributions (within lung, water, and bone densities) based on the underlying tissue compositions derived from the attenuation correction map. The PRC method was evaluated in 25 healthy volunteers (11F/14M, mean age 23-y) who underwent serial rest/stress $^{82}$Rb MPI sessions on the Siemens Biograph mCT system. Static and 8-ECG gated reconstructions (employing a 400x400x109 matrix, PSF+TOF + 5mm post-filter), with and without PRC (PRC (3iterations, 21 subsets) and Standard (2iterations, 21 subsets), respectively; of note, PRC was optimized to compare the results), were evaluated in this study. We report changes in the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) for the static images. Further, for the ECG-gated reconstructions, we evaluated the changes introduced in end-diastolic and systolic volumes (EDV and ESV, respectively), the stroke volume (SV), the left ventricular ejection fraction (LVEF), and the LVEF reserve (stress-rest LVEF) in QPET (Cedars-Sinai). Finally, we evaluate the test-retest repeatability coefficients (Bland-Altman method) for the volumetric assessments. ***Results:*** Image quality of static

reconstructions improved for both rest and stress MPI following PRC (%-change (Rest/Stress): (25±22)%/(34±30)% (SNR) and (35±27)%/(41±34)% (CNR), all p<0.05. When correcting for the PR, EDV and ESV increased (EDV change (Rest/Stress) [mL]: (9±5) / (4±3), (PRC volumes = (110±32) / (131±37)); ESV change (Rest/Stress) [mL]: (9±7) / (9±3), (PRC volumes = (53±24) / (47±22)), all p<0.0001). However, PRC did not change SV during resting conditions (SV change (Rest/Stress) [mL]: (-1±5) / (-5±9), (PRC volumes = (57±10) / (84±17)), p=0.61 and 0.015, respectively). PRC significantly reduced the LVEF without affecting the LVEF reserve (LVEF [%] (Rest/Stress): Standard = (58±7) / (72±7), PRC = (54±9) / (66±7), both p< 0.001, LVEF Reserve: Standard = (13±3), PRC = (12±4), p=0.05). Excellent repeatability coefficients are reported for all volumetric assessments with test-retest variations <7% for both the standard and PRC reconstructions. ***Conclusion:*** In a cohort of healthy volunteers, PRC significantly improves SNR and CNR and changes the majority of the volumetric assessments without affecting the repeatability measures. Follow-up studies in patient cohorts are planned.

## EPS-127

### Metabolic pretest calculator to improve cardiac FDG PET/CT imaging

***S. Hartikainen***[1], *T. Tompuri*[1], *T. M. Laitinen*[1], *T. Laitinen*[1,2];
[1]*Kuopio University Hospital, Kuopio, FINLAND,*
[2]*University of Eastern Finland, Kuopio, FINLAND.*

***Aim/Introduction:*** Poor myocardial glucose metabolism suppression (MGS) may hamper differentiation between cardiac inflammatory manifestations and physiological 18F-FDG uptake. Even a strict one or two-day ketogenic diet (KD) and prolongated fasting with or without heparin premedication doesn't always induce adequate MGS. This may lead to additional imaging or myocardial biopsies. The aim of our study was to develop a pretest probability calculator of adequate MGS based on medical history, body composition and β-hydroxybutyrate (BHB) level. ***Materials and Methods:*** We recruited 193 adults (95 female), median age 66 years (19-87), with any clinical indication for whole body 18F-FDG-PET/CT. 62 patients followed KD 1-2 days before scan and had fasted for at least 12 hours. Blood glucose and β-hydroxybutyrate (BHB) level were measured with a point-of-care device. Electronic health record was searched for the presence of previously diagnosed diseases, including diabetes and hypertension, and use of sodium-glucose transport 2 inhibitor (SGLT2i) medication. Liver and spleen attenuation in a low-dose CT were measured to assess the presence of fatty liver. Adequate MGS was defined as myocardial uptake below left ventricular blood pool. Correlations between MGS and metabolic factors were calculated. Logistic regression analysis was performed using the variables that showed statistically significant correlation. The ability of BHB test and pretest calculator to predict MGS was evaluated with ROC analysis. ***Results:*** Median BMI was 26.9 (range 17.0-55.2), median SUV 1.75 (0.72-19.10) and BHB 0.2 (0.0-5.1) mmol/l. Youden index suggested a cut-off of 0.35 mmol/l for BHB. For patients with low BHB, adequate MGS was seen more often in patients with diabetes (p = 0.003), obesity (p = 0.002) or fatty liver (p = 0.002). Using information attainable before imaging and logistic regression analysis, the most prominent variables to predict MGS were BHB (B = -2.463, p < 0.001) and KD (B = -1.484, p = 0.001), followed by diabetes (B = -1.744, p = 0.003) and obesity (B = -1.237, p = 0.018). We found a tendency towards SGLT2i usage to predict MGS (B = -0.979, p = 0.238). We thereby created a pretest calculator of inadequate MGS. AUC for pretest calculator is 0.857 and for BHB alone 0.802. ***Conclusion:*** BHB measured with a point-of-care device is useful in predicting MGS. Using information attainable before imaging, a pretest calculator may further increase patient-to-patient customization of preparation protocol to ensure proper diagnostics or exclusion of an inflammatory cardiac disease.

## EPS-128

### Diagnostic accuracy of global parameters obtained during dynamic PET/CT with 13N-Ammonia and vasodilator stress in patients with triple-vessel stenotic lesion of coronary arteries and stable form of CAD

***A. Shakhova****, E. Golukova, I. Aslanidis, I. Shurupova, N. Surkova, M. Rumyantseva, I. Ekaeva;*
*A.N. Bakulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION., Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Balanced ischemia with triple vessel (3v) coronary artery disease (CAD) is difficult to diagnose with semiquantitative myocardial perfusion imaging (MPI).The aim was to find out the features of 3v CAD by means of global parameters derived from dynamic PET combined with computer tomography (PET/CT) in patients with a stable form of CAD ***Materials and Methods:*** 135 patients with known CAD and angiographic narrowing >70% in at least of one (of the major) coronary artery were enrolled: 13 - with 3V CAD, 122 - one or two-vessel CAD; 54 had chronic total occlusions (CTO). PET/CT with 13N-ammonia at rest and after adenosine stress test was performed in dynamic mode. The global summed stress and difference score (SSS and SDS respectively) were calculated. Myocardial blood flow (MBF) at rest and stress, myocardial flow reserve (MFR) were quantified. ***Results:*** Patients with 3v CAD had significantly increased SRS, SSS, and SDS compared to patients without it: 4.0 (2.0; 6.0) versus 1.0 (0.0; 3.0), 22.0 (17.0; 27.0) versus 9.0 (4.3; 16.0) and 19.0 (15.0; 21.0) versus 7.0 (3.0;13.0),respectively (p<0.001). There was similar resting MBF between patients with and without 3v CAD: 0.92 (0.87; 0.98) versus 0.83 (0.79; 0.92) ml/g/min (p=0.198), but significantly lower stress MBF of 1.29 (1.19; 1.51) versus 1.89 (1.64; 2.31) ml/g/min, and simillary lower MFR of 1.6 (1.5; 2.1) versus 2.6 (2.1; 3.0), (p<0.001). The prevalence of CTOs was highter in 3v group: 77% (n=10) versus 35% (n=43), p=0,003. The discriminant function to expect 3-vessel CAD was: for SSS AUC 0,858 (p<0,001) with cutoff >13 (sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy (DA) of 92%, 60%, 20%, 99% и 63%, respectively; for SDS AUC = 0.834 (p<0.001) with cutoff >15 (77%, 83%, 32%, 97% и 82% respectively). For absolute values AUCs with optimal cutoff were: MBF < 1.51 ml/g/min and AUC 0.787 (p<0.001) (Se, Sp, PPV, NPV and DA were 77%, 86%, 37%, 97% and 85%, respectively); MFR < 1,8 and AUC 0,843 (p<0.001) (69%, 93%, 53%, 97% и 91% %, respectively). ***Conclusion:*** MFR showed the highest accuracy in identifying 3V CAD due to a high specificity of 93% and allowable sensitivity of 69%. The high sensitivity of the SSS in is associated with the widespread of CTOs which leads to a more pronounced "heterogeneity" of perfusion severity, practically excluding the presence of "balanced" ischemia.

## EPS-129

### Does global value of myocardial flow reserve using 13N-ammonia positron emission tomography independently predict identification of multivessel coronary artery disease

***A. Shakhova****, E. Golukhova, I. Aslanidis, I. Shurupova, N. Surkova, M. Rumyantseva, I. Ekaeva;*
*A.N. Bakulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Standard relative myocardial perfusion imaging (MPI) is widely used for the assessment of obstructive coronary artery disease (CAD), but when multivessel (MV) CAD is present,

total perfusion defect (PD) scoring can lead to underestimation of degree of obstructive atherosclerotic burden. The aim of this study was to assess whether assessment of global myocardial flow reserve (MFR) measured with 13N-ammonia PET is an independent predictor of severe MV CAD. ***Materials and Methods:*** In this study 135 consecutive patients with available 13N-ammonia PET within 3 months of invasive coronary angiography (ICA) and no cardiac events between them were included. 87 patients had significant single-vessel, 48 had two- or three-vessel lesion, (64.1 ± 10.3 years, 75% men), those with myocardial scar, history of coronary artery bypass graft (CABG), severe valvular disease and ejection fraction < 40% were exclude. PET/CT with 13N-ammonia at rest and after adenosine stress test was performed in dynamic mode. The global summed stress score (SSS) was derived, quantitative values of myocardial blood flow (MBF) at rest and stress, with subsequent calculation of myocardial flow reserve (MFR) was made. The presence or absence of transient ischemic dilatation (TID) on visual analysis was also noted. ECG was monitored continuously during adenosine stress for ST-depression. Crude odds ratio (COR) and adjusted odds ratio (AOR) were calculated from regression coefficients. ***Results:*** On univariable analysis MFR (COR: 0.15 (95% CI: 0.07-0.32, p<0.001) and SSS (COR: 1.12 (95% CI: 1.07-0.19, p<0.001), as well as ST-depression during stress test (COR: 5.46 (95% CI: 1.61-18.52, p=0.006) were associated with MV CAD, while TID was not (p=0,678). The multivariable analysis suggests that MFR and SSS independently predicts MV CAD after considering significant confounders mentioned above: AOR: 0.23 (95% CI: 0.10-0.54, p<0.001) and 1.09 (95% CI: 1.02-1.16, p=0.007) respectively. ***Conclusion:*** The global MFR is a strong predictor of MV CAD and further facilitates the identification detection of "hight risk" CAD. A 1.0 unit reduction in MFR, increases the likelihood MV CAD by 6.8 times. The traditional non-parametric predictors of MV CAD didn't demonstrate diagnostic capability in the presence of parametric PET/CT indices.

## EPS-130

### Defining a Significant Change with serial assessment of myocardial perfusion metrics, obtained during dynamic Positron Emission Tomography with 13 N-Ammonia in patients with CAD

***A. Shakhova****, E. Golukhova, I. Aslanidis, I. Shurupova, M. Rumyantseva, N. Surkova, I. Ekaeva;*
*A.N. Bakulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Serial perfusion assessment is attractive for clinical status evaluation in patients with stable coronary artery disease (CAD). The aim was to determine the direction and magnitude of change of global parameters obtained during dynamic positron emission tomography (PET/CT) in patients receiving optimal medical therapy (OMT) of CAD alone. ***Materials and Methods:*** In total 26 patients with known or suspected CAD were retrospectively enrolled (59.1 ± 12.8 years, 66% men) who did not underwent coronary revascularization between routine serial dynamic PET/CT scans. The median interval between baseline and follow-up PET scans was 18 (12.0; 36.8) months with no cardiac events between them. PET/CT with 13N-ammonia at rest and after adenosine stress test was performed in dynamic mode. The global summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS) were calculated. Based on the obtained global quantitative values of myocardial blood flow (MBF) at rest and stress, myocardial flow reserve (MFR) was quantified. The rate pressure product was calculated by multiplication of systolic pressure with heart rate. ***Results:*** There was not significant difference between serial PET MPI measurement: for SRS 2.0 (1.0; 4.0) at baseline versus (vs) 2.0 (0,0; 5.0) at follow-up (p=0.612), for SSS 7.0 (3.0; 12.3) at baseline vs 6.5 (3.0; 11.3) at follow-up (p=0.809) and for SDS 4.5 (0.0; 7.3) at baseline vs 4.0 (2.0; 6.5) at follow-up (p=0.617 ). Within absolute MBF values there was not significant difference for MBF at rest and stress: 0.81 (0.63; 1.04) vs 0.80 (0.63; 0.92) mg/l/min (p=0.328) and 2.08 (1.80; 2.38) vs 2.17 (1.95; 2.37) mg/l/min respectively. Significant improvement of global MFR, however, was observed in 19 (73%) cases, with increasing from 2.5 (2.2; 3.0) to 3.1 (2.4; 3.5) (p=0.017). The rate pressure product (RPP) at follow-up was lower than at the baseline: 9878 (8231; 11765) vs 11024 (7551; 14023). Mean difference in MFR was 0.27+/-0.67 (25%+/-17). ***Conclusion:*** Observed improvement of global MFR is probably due to individual variability in RPP and, as a consequence, MBF at rest between two PET/CT examinations, and is not suitable by oneself for the assessment in MBF changes in patients on OMT alone. We should be more careful when drawing the conclusion about the improvement of MBF based only on global MFR metrics with expected variability about 25%, if evaluation of serial studies is necessary.

## EPS-131

### Relationship between myocardial flow reserve measured by a dynamic cadmium-zinc-telluride camera and increase rate in myocardial uptake of radionuclide during exercise

***T. Niimi***[1]*, K. Hirayama*[1]*, S. Yoshida*[2]*;*
[1]*Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital, Nagoya, JAPAN,* [2]*Nagoya University, Nagoya, JAPAN.*

***Aim/Introduction:*** A cadmium-zinc-tellurium (CZT) camera can simultaneously evaluate myocardial flow reserve (MFR) and perform myocardial perfusion imaging. Therefore, unlike conventional single-photon emission computed tomography (SPECT) cameras, it can detect the presence of multi-vessel coronary artery disease (CAD) without underestimating it. However, obtaining MFR measurements by routine SPECT examination is difficult. To determine if the increase rate could be an alternative in the absence of MFR measurements, we examined the relationship between MFR measured simultaneously with a dynamic CZT camera and the increase rate in myocardial radionuclide uptake during exercise. ***Materials and Methods:*** We evaluated 40 patients with suspected or known CAD who underwent dynamic CZT SPECT after injection of 250 MBq and 820 MBq of 99mTc-sestamibi for rest and stress imaging, respectively. Radionuclide was injected at 1 $ml^3/s$ using an automatic injector and flushed with 30 ml of saline. Dynamic CZT SPECT imaging data for calculating MFR was net-retention analyzed using commercially available software. An increase of radionuclide uptake in myocardial during exercise was defined as an increase rate, and CAD detection was tested from myocardial perfusion imaging. An increase rate was calculated as an exercise image/rest image normalized by dose. ***Results:*** Comparing the global CAD diagnostic performance of MFR and increase rate, the area under the receiver operating characteristic curve was 77% for MFR and 58% for increase rate (p=0.114, cutoff value of MFR was 2.68 and increase rate was 1.31). However, in cases of three-vessel lesions (2 of 40 cases), which were difficult to evaluate with relative distribution images, both showed lower than the cutoff value (MFR: 1.23 ± 0.37, increase rate: 0.82 ± 0. 28) and assisted diagnosis. ***Conclusion:*** The relationship between MFR measured by a dynamic CZT camera and the increase rate

in myocardial uptake of radionuclide during exercise was verified. Although the global CAD diagnostic performance of the increase rate was lower than that of the MFR, the detection accuracy was similar to that of MFR in cases of three-vessel lesions that were difficult to assess on relative distribution images. The increased rate of myocardial uptake of radionuclide during exercise may provide additional information to myocardial perfusion imaging, such as the diagnosis of multi-vessel lesions, even when MFR measurements are not possible.

## EPS-132

### Stress-only versus rest-stress SPECT MPI in the detection and diagnosis of myocardial ischemia and infarction by machine learning

***F. Wang***[1], *H. Yuan*[1], *L. Jiang*[1,2];
[1]*PET Center, Department of Nuclear Medicine, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, CHINA,*
[2]*Guangdong Provincial Key Laboratory of Artificial Intelligence in Medical Image Analysis and Application, Guangzhou, CHINA.*

***Aim/Introduction:*** To investigate the performance of stress-only versus rest-stress SPECT myocardial perfusion imaging (MPI) in detecting and diagnosing myocardial ischemia and infarction by machine learning (ML). ***Materials and Methods:*** 276 patients with suspected coronary artery disease (CAD) were randomly divided into training (184 patients) and test (92 patients) cohorts. Variables extracted from clinical, physiological, and rest-stress SPECT MPI were screened. Stress-only and rest-stress MPI using ML were established and compared using the training cohort. Then the diagnostic performance of two models in diagnosing myocardial ischemia and infarction was evaluated in the test cohort. ***Results:*** Using 6 ML algorithms, stress-only MPI models were constructed entering summed stress score (SSS), summed wall thickness score of stress% (sSTS%), and end-diastolic volume of stress (sEDV). Stress-only MPI performed equally good as rest-stress MPI in detecting myocardial ischemia and infarction (area under the curve [AUC] using logistic regression [LR] model: 0.863 vs. 0.877, P=0.519). Furthermore, using ML models, stress-only MPI showed a reasonable prediction of reversible deficit as shown by rest-stress MPI (AUC using LR model: 0.861). Subsequently, predictive nomograms for myocardial ischemia and reversible perfusion deficit using the above-identified variables in the stress-only MPI were constructed, which showed good discrimination in the training and test cohorts. ***Conclusion:*** Stress-only MPI demonstrated similar diagnostic performance compared with rest-stress MPI using 6 ML algorithms. ML models based on stress-only MPI might replace rest-stress MPI to differentiate the reversibility of perfusion deficit, and hence ischemia from scar.

## EPS-133

### A Meta-Analysis of Bone Tracer Scintigraphy in the Diagnosis of Cardiac Amyloid ATTR and Al, Comparing HMDP with DPD and PYP Sensitivity and Specificity in Biopsy Proven Cases

***A. ALDEHLAUI***[1,2], *C. Fowler*[2];
[1]*King Abdullah Medical City, Makkah, SAUDI ARABIA,*
[2]*King's College London, London, UNITED KINGDOM.*

***Aim/Introduction:*** Cardiac amyloidosis (CA) is an underdiagnosed cause of heart failure with preserved ejection fraction. Two types of cardiac amyloidosis, transthyretin (ATTR) and light-chain (AL), are treated differently. Both $^{99m}$Tc-DPD and $^{99m}$Tc-PYP scintigraphy already have well-established roles in diagnosing ATTR and differentiating it from AL CA. $^{99m}$Tc-HMDP is another radiopharmaceutical that has been studied for the same purpose and acknowledged by the ASNC and EANM guidelines but has no clear established role in this clinical context yet. To the best of our knowledge, there is no published review comparing HMDP to DPD or PYP in the same cohort. The study aims to systematically assess and validate the diagnostic sensitivity and specificity of$^{99m}$Tc-HMDP whole-body planar scintigraphy in biopsy-proven ATTR CA studies of patients compared to DPD and PYP as a meta-analysis. ***Materials and Methods:*** AA comprehensive online literature search using PubMed, Embase, and Medline databases of studies on HMDP, DPD, and PYP imaging diagnostic values in cardiac amyloidosis was conducted in 2021 to identify high-quality studies on cardiac amyloidosis in single-photon imaging and diagnosis based on HMDP, DPD, and PYP radiopharmaceuticals. The relevant identified studies were filtered based on biopsy-proven patients who had undergone bone scintigraphy, including 20 subjects or more, patients' medical history must be free of other myocardiopathies, and tracer related specificities and sensitivities to distinguish ATTR CA from AL. Then the quality of the studies was assessed using NIH Quality Assessment Tool for Before-After (Pre-Post) Studies With No Control Group. Finally, the mean sensitivity and specificity of nuclear bone scintigraphy in the differentiation of ATTR from AL amyloidosis were calculated from the selected studies for the three tracers. ***Results:*** Eight selected studies were identified on HMDP, DPD, and PYP bone scintigraphy in cardiac amyloidosis, including 868 biopsy-proven patients that were included in the meta-analysis, provided the following ***results:*** the pooled and calculated sensitivity for ATTR of HMDP, DPD, and PYP is 98.3%, 99.6% and 97.4%; and specificity 98.6%, 87.6% and 93.8% respectively. The sensitivity of the tracers in diagnosing AL was 5.0%, 41.3%, and 35.0%, and specificity was 2.0%, 12.8%, and 8.3%, respectively. ***Conclusion:*** A meta-analysis of the literature shows HMDP has equivalent sensitivity and higher specificity in comparison with DPD and PYP for diagnosing ATTR cardiac amyloidosis.

## EPS-134

### CT-free attenuation correction for cardiac-dedicated CZT SPECT: preliminary results of the CASCTEC study

***M. Hesse***, *B. El Jari, F. Dupont, O. Gheysens, R. Lhommel, V. Roelants;*
*Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.*

***Aim/Introduction:*** It is known that attenuation-correction (AC) improves the diagnostic accuracy of myocardial perfusion scintigraphy (MPS) for detecting coronary artery diseases (CAD). However, most clinical cardiac-dedicated CZT cameras are not equipped with a CT to reduce costs and footprint. Therefore, the CASCTEC clinical study aims at developing an approach to generate AC images from emission scans only on a pinhole CZT camera, without the need for CT. ***Materials and Methods:*** CASCTEC is a single-center prospective study enrolling patients referred for MPS. Two-day stress/rest myocardial SPECT imaging was performed on a pinhole CZT camera. A standard of care (SOC) 5-10 minute acquisition was immediately followed by an additional 5-minute acquisition after retracting the detectors without moving the patient. Subsequently all patients underwent SPECT/CT imaging serving as reference. The acquisition with retracted detectors allowed to delineate the patient body contour, and together with the SOC acquisition, enabled the segmentation of soft and lung tissues to generate an attenuation map. Non-corrected (NC) and AC pinhole CZT images were compared among themselves and

against the SPECT/CT images using the AHA 17-segment model and visual evaluation of stress and rest summed scores. ***Results:*** 12 patients have been included until March 2023. CASCTEC-AC stress and rest perfusion images showed a more homogeneous tracer distribution, especially in the inferior wall, similar to the reference. All perfusion defects observed on the SPECT/CT-AC images were also visible on CASCTEC-AC images. The mean visual summed score for AC images was 17.7±3.8 for CASCTEC and 19.9±4.5 for SPECT/CT (p=0.002). The CASCTEC mean relative uptake increased by up to 30% in the inferior segments compared to the NC image. Changes by less than 10% were observed for all other segments, except for the apical segment that decreased by up to 30%. The differences of the changes in summed scores from NC to AC between CASCTEC and SPECT/CT images were -0.5±5.2 (p=0.37) and 0.5±3.6 (p=0.35), respectively for stress and rest scans. ***Conclusion:*** These preliminary results show that the CT-free patient-specific attenuation map enhances NC perfusion in the inferior wall similarly to CT-based AC images from a SPECT/CT acquisition. This method might enhance the diagnostic accuracy of current cardiac pinhole CZT systems for detecting obstructive CAD but further studies are warranted.

## EPS-135

### The effect of Ursodeoxycholic Acid on early hepatic clearance of 99mTc-sestamibi in patients undergoing myocardial perfusion scintigraphy

***E. Hosseinzadeh***, *M. Ghodsirad, H. Garavand;*
*Nuclear medicine department, shohadaye tajrish hospital, Shahidbeheshti university, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The aim of this study is to investigate the effect of Ursodeoxycholic Acid (UDCA) on hepatic clearance of 99mTc-sestamibi in patients undergoing myocardial perfusion scintigraphy (MPS). 99mTc-sestamibi is a commonly used radiopharmaceutical that is used in MPS to assess myocardial blood flow. However, the clearance of 99mTc-sestamibi from the liver is important for accurate diagnosis and reducing artifacts.UDCA has a choleretic effect and facilitates the excretion of bile acid from hepatocytes, and in addition it has cell protection, membrane stabilization, and immune modulator effects. ***Materials and Methods:*** This study involved 174 patients who underwent MPS and were divided into two groups: the UDCA group (n=90) and the control group (n=84). The UDCA group received a single dose of UDCA (300 mg) and underwent MPS after one and four hours, while the control group received a placebo. The hepatic clearance of 99mTc-sestamibi was measured in both groups using a gamma camera, and the results were compared. ***Results:*** The results showed that after four hours, the mean hepatic clearance of 99mTc-sestamibi was significantly higher in the UDCA group compared to the control group ($p<0.05$). Additionally, the mean hepatic uptake of 99mTc-sestamibi and hepatic to cardiac ratio were significantly lower in the UDCA group compared to the control group ($p<0.05$). However, there was no significant difference between the UDCA and control groups in after one-hour MPS. ***Conclusion:*** In conclusion, this study suggests that administering UDCA four hours prior to MPS can significantly improve hepatic clearance of 99mTc-sestamibi and reduce hepatic uptake in patients undergoing MPS. Therefore, UDCA may be considered as a potential treatment option to improve the accuracy of MPS in patients. However, further studies are needed to confirm these findings and determine the optimal dosage and duration of UDCA treatment.

## EPS-136

### The Role Of Myocardial Perfusion Scintigraphy In Asymptomatic Patients With 50-70% Coronary Artery Stenosis In Coronary Ct

***A. Doumas***[1], *D. Boundas*[2], *E. Giannoula*[1], *P. Exadaktylou*[1], *A. Tsangaridi*[1], *N. Papadopoulos*[1], *G. Gerasimou*[1], *E. Papanastasiou*[1], *I. Iakovou*[1];
[1]*Aristotle University, Thessaloniki, GREECE,* [2]*Private Nuclear Medicine Centre, Ippokratis, Thessaloniki, GREECE.*

***Aim/Introduction:*** Angiography of the coronary vessels using 64 or 128-slice CT (CTA) has become a widely used method for the exclusion of possible coronary artery disease, especially in young people with low probability of coronary artery stenosis as recommended by the new guidelines of the American Heart Association. The aim of the study was to define the role of myocardial perfusion scintigraphy in asymptomatic patients with 50-70% coronary artery stenosis in CTA. ***Materials and Methods:*** 136 subjects, 87 men and 49 women with an average age of 67 years (43-79 years) underwent heart scintigraphy after stress (94 subjects), or drug-related stress (42 subjects). All of them had abnormal CTA with stenoses in the range of 50-70%. A dual-head gamma camera (General Electric Millennium MG) was used for heart scintigraphy following an exercise-rest protocol after administration of 8 mCi SESTAMIBI at stress and 25 mCi at rest. The results were analyzed quantitatively (Emory Toolbox). If the image after stress was normal, the study was terminated (stress only), otherwise imaging was repeated at least two hours later. ***Results:*** The presence of ischemia was detected in only 11 subjects (8%), quantitative analysis showed that of these 11 subjects only 4 had ischemia exceeding 10% of the total myocardial mass. ***Conclusion:*** A very small percentage of the 50-70% of stenoses discovered on CTA are hemodynamically significant and of these, a very small percentage require revascularization surgery. It may be necessary for the cardiology community to reconsider the "critical" percentage of stenosis, as CTA tends to overestimate the extent of lesions compared to conventional coronary angiography.

## EPS-137

### Artefacts and False Positive Results of Myocardial Perfusion SPECT with CZT D-SPECT Camera

***M. Esnault***[1], *D. Legallois*[2], *D. Agostini*[2], *P. Richard*[3], *M. Alain*[2];
[1]*Caen University, Caen, FRANCE,* [2]*Caen University Hospital, Caen, FRANCE,* [3]*Hospital Privé Saint Martin, Caen, FRANCE.*

***Aim/Introduction:*** The artifacts occurring during myocardial perfusion SPECT acquisition with a CZT camera potentially reduce the specificity of the results and are poorly documented. The aim of our study was to analyze the relationship between these artefacts and the occurrence of false-positive myocardial SPECT examinations. ***Materials and Methods:*** Quality control of myocardial SPECT images from 60 consecutive patients with a True Positive (TP) (n=30) or False Positive (FP) (n=30) perfusion SPECT was retrospectively analyzed. All examinations were performed with a D-SPECT camera (Spectrum dynamics, Caesarea, Il), using a 99mTc-labeled radiopharmaceutical and a 1-day stress/rest protocol. All patients had coronary angiography within 3 months after myocardial perfusion SPECT. Artefacts were considered and classified as follows: (1) inadequate positioning of the heart within the cardio-focal area (0%, 30%, 60%, or 100% outside), (2) nonidentical patient positioning during stress and rest acquisition, (3) number of patient movements during stress and rest acquisition (graded as 0 [no movement], 1 [single movement], to 2 [more than 1 movement]), (4) quality of ECG-gating (good or poor), and (5) stress and rest myocardial count statistics (<500 kcts or ≥500 kcts). ***Results:*** Our study revealed that there was a majority

of men in both groups (n=21, 70% for TP and n=22, 73% for FP). In the FP group, the main indication for SPECT was diagnostic SPECT for suspected coronary artery disease (n=25, 83%), whereas in the TP group, the main indication was risk assessment in patients with documented coronary artery disease (n=16, 53%). Patients considered FP were younger (mean age = 64±11 vs. 69±10 y/o in VP, p< 0.05) with an increased BMI (32±8.6 vs. 27±5.3 kg/m$^2$ in VP, p=0.02). Among the quality control characteristics, the occurrence of a false-positive SPECT examination was significantly associated with the inadequate position of the heart in the cardio-focal area (p < 0.05), non-identical patient positioning during stress and rest imaging (p < 0.05), number of patient movements (p < 0.05), and low count statistics at rest (p < 0.05). The number of artefacts was strongly associated with the occurrence of false-positive examinations, with an 80% false-positive rate in patients with at least 2 artefacts (p = 0.0003). ***Conclusion:*** In this retrospective study, the false-positive rate dramatically increased with the number of artefacts, which shows the importance of having a robust quality control.

## EPS-138

### Impact of Initial Myocardial Perfusion Imaging versus Coronary Angiography on Costs and Outcomes in Patients with Coronary Artery Disease in China

***L. Yang***, *Y. Hu, S. Li;*
*First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** In patients with stable coronary artery disease (CAD), there are two main options for guiding treatment: initial coronary angiography (CAG) or selective CAG after the risk stratification of myocardial perfusion imaging (MPI). Debate continues regarding whether patients with suspected or stable coronary artery disease might benefit from initial myocardial perfusion imaging or coronary angiography. This study compares and analyses costs and clinical outcomes in our hospital regarding the two strategies. ***Materials and Methods:*** This study included 664 patients who presented to the hospital between January 2018 and end of December 2019 with suspected or known stable CAD, excluding patients with acute coronary syndrome, previous myocardial infarction (MI) or coronary revascularization. Patients were divided into two groups based on initial use of CAG or MPI, and each group was followed up to the end of 2022 for costs due to suspected or known stable CAD, and rates of myocardial revascularization, myocardial infarction and all-cause mortality. Univariate and multivariate COX proportional risk models were used to estimate the risk of events. ***Results:*** There were 332 patients in the MPI and CAG groups respectively, with a similar Charlson comorbidity index (CCI). In terms of cost, initial MPI strategy was on average 61% cheaper than CAG strategy (P<0.0001). In terms of clinical outcomes, the MPI group had a significantly and dramatically lower incidence of cardiac events (27 vs. 92, P<0.0001) than the CAG group. Further, the incidence of revascularization (19 vs. 60, P<0.0001), MI (6 vs. 27, P<0.001), and all-cause mortality (2 vs. 5, P>0.05) were also lower in the MPI group than in the CAG group. Multivariable analysis adjusting for age, gender, CCI, and comorbidities showed that in the MPI group fewer patients had revascularization (HR 0.20, 95% CI 0.11-0.34) and MI (HR 0.18, 95% CI 0.07-0.45) than CAG group, and the rate of all-cause mortality was lower (HR 0.80, 95% CI 0.12-5.58). ***Conclusion:*** In patients with suspected or stable CAD, this study showed that a diagnostic strategy guided by MPI could reduce costs and the incidence of cardiac events, resulting in savings in healthcare resources and health insurance funds.

## EPS-139

### The value of gated blood pool SPECT in assessment of stress-induced changes of the right ventricular contractile function.

***V. Shipulin***, *S. Andreev, V. M. Shipulin, S. Polikarpov, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** There is increasing attention for the investigation of the role of right ventricle (RV) contractile function in ischemic heart failure (IHF). However, the precise assessment of RV function, particularly its stress-induced changes, is a quite challenging task. The wide use of gamma cameras equipped with solid-state CZT detectors makes possible to reduce GBPS acquisition time up to 5 min and perform examinations on pharmacological stress tests, in particular, with dobutamine. The purpose of current study was to assess the feasibility of CZT GBPS in evaluation of stress-induced changes of RV contractile function. ***Materials and Methods:*** A total of 63 patients with IHF were included in this study. All patients underwent GBPS at rest and on the stepwise increased doses of dobutamine (10/15μg/kg/min) on CZT gamma camera (GE Discovery NM/CT 570c). The following parameters were estimated: end-diastolic and end-systolic (ESV) volumes, ejection fraction (EF), stroke volume (SV), peak ejection (PER) and filling (PFR) rates, as well as mechanical dyssynchrony (MD) indices (phase standard deviation, phase bandwidth (HBW) and phase entropy) of RV and interventricular dyssynchrony. ***Results:*** Significant changes in EF were observed at a dobutamine dose of 10 μg/kg/min (p<.001), while to detect stress-induced changes in SV (p<.001), ESV (p<.001), PER (p<.001) and PFR (p=.005) the dobutamine dose of 15 μg/kg/min was required. Neither interventricular nor intraventricular MD indices showed significant changes during stress test, despite a decreasing trend. Among all patients, 18 (29%) have shown drop of EF at the dobutamine dose of 15 μg/kg/min, which was accompanied by a significant increase of HBW (p<.001). ***Conclusion:*** CZT GBPS is feasible to assess RV volume and contractility on dobutamine stress test in patients with IHF. Dobutamine dose of 10 μg/kg/min is sufficient to achieve diagnostically significant stress-induced changes of RV EF, while to detect changes in SV, ESV, PER and PFR higher doses are required. Moreover, the association between RV EF drop on 15 μg/kg/min dobutamine dosage and increase of HBW was found.

## EPS-140

### Simultaneous PET/MRI myocardial perfusion measurements using Gd-DOTA CMR and 68Ga-DOTA-PET

***S. Kvernby***[1], *T. Kero*[1], *K. Azarbar*[1], *C. Rischpler*[2], *J. Sörensen*[1], *I. Velikyan*[1], *M. Lubberink*[1];
[1]*Uppsala University, Uppsala, SWEDEN,*
[2]*Klinikum Stuttgart, Stuttgart, GERMANY.*

***Aim/Introduction:*** Myocardial perfusion imaging using magnetic resonance imaging (MRI) often includes the use of a gadolinium-based contrast agent bound to the DOTA-molecule (DOTAREM). Quantification of myocardial blood flow (MBF) using MRI aims to measure the shortening of the T1 relaxation time that occurs in the myocardium when the Gd-DOTA molecules pass through the myocardium. For accurate MBF quantification, the MRI signal needs to be converted to Gd-concentration, which is challenging. The extraction rate of the DOTA-molecule is also

limited and has to be established when converting Gd-uptake rate to MBF. In contrast to MRI, the signal in a PET image is direct proportional to the radioactivity concentration in tissue. The aim of this study is to use a $^{68}$Ga PET-analog of DOTAREM to evaluate the kinetics of the DOTA-molecule and compare it with that of Gd-DOTA in a simultaneous PET/MRI scanner. ***Materials and Methods:*** Eight patients referred for assessment of ischemia underwent 10 min dynamic $^{68}$Ga-DOTA-PET scans during rest and during adenosine stress on a PET/MRI scanner. Simultaneously with the PET scan, an MRI-perfusion scan was performed by injection of Gd-DOTAREM (0.05 mmol Gd/kg body weight) using an ultrafast gradient echo sequence (FGRE) together with myocardial T1-mapping for individual estimation of the native T1-relaxation time. Both the $^{68}$Ga-DOTA-PET and the Gd-DOTA MRI scan were analyzed using single-tissue reversible compartment model. For the MRI perfusion data, a conversion was first made from signal-curve to T1-curve and then to Gd-concentration curve. The uptake rate constant $K_1$ was compared between the two DOTA-perfusion methods. ***Results:*** The myocardial uptake rate constant $K_1$ had a moderate correlation between $^{68}$Ga-DOTA-PET and the MRI Gd-DOTA (Pearson correlation coefficient, r=0.75 for whole myocardium and r=0.46 for the 16 segment model). Extraction was low for both methods with average whole myocardium $^{68}$Ga-DOTA $K_1$ ranging from 0.22-1.66 mL/cm$^3$/min and Gd-DOTA $K_1$ ranging from 0.37-1.82 mL/cm$^3$/min. Average $K_1$ was significantly higher for Gd-DOTA than for $^{68}$Ga-DOTA (paired t-test, p<0.05). ***Conclusion:*** Quantitative myocardial perfusion using $^{68}$Ga-DOTA-PET in a simultaneous PET/MRI demonstrated moderate correlation with the Gd-DOTA-MRI myocardial uptake rate constant $K_1$. Extraction rate was low for both methods but was significantly higher for Gd-DOTA compared with $^{68}$Ga-DOTA.

## EPS-141

### Detection of mental stress induced myocardial ischemia with myocardial perfusion imaging in patients with anxiety and/or depression after coronary revascularization

***W. Dong****, J. Jiao, N. Nan, T. Mou, H. Mi, X. Song;*
*Beijing Anzhen Hospital, Beijing, CHINA.*

***Aim/Introduction:*** The aim of this study was to detect mental stress induced myocardial ischemia (MSIMI) and long-term changes of MSIMI in CAD patients with anxiety and/or depression after coronary revascularization using baseline and follow-up myocardial perfusion imaging (MPI). ***Materials and Methods:*** Patients with anxiety and/or depression(GAD-7≥5 and/or PHQ-9≥5)who underwent coronary revascularization from Dec 2018 to Dec 2019 were prospectively recruited. Mental stress was induced by the Stroop Color and Word Test (SCWT). All participants underwent baseline mental stress/rest MPI at least 4 weeks after coronary revascularization, and were followed-up 12 months with mental stress/rest MPI. At baseline and during follow-up, all participants received secondary prevention of CAD, but did not receive intervention in psychotropic drugs. MSIMI was defined as the presence of at least one of four abnormal MPI phenomena: reversible perfusion defect (RPD), transient ischemic dilation (TID), reverse redistribution (RR), and stress ejection fraction (EF) decreased by ≥5%. Kendall's tau-b correlation coefficient was used to test the consistency of the two MPI results. ***Results:*** 93 patients with anxiety and/or depression after coronary revascularization completed the baseline MPI and follow-up MPI for 14.25 ±4.42 months. Among them, 51 patients (54.8%, 51/93) detected MSIMI at baseline and 42 patients (45.2%, 42/93) detected MSIMI at follow-up. The agreement rate was 58.1%, which was not statistically significant (Kendall's tau-b 0.172, P = 0.098). The incidence of abnormal components of MSIMI from high to low was RPD (25.8%, 24/93) >stress EF decreased by ≥5% (14.0%, 13/93) >TID (10.8%, 30/93) >RR (6.5%, 6/93) at baseline MPI and RPD (24.7%, 23/93) >RR (9.7%, 9/93) >stress EF decreased by ≥5% (7.5%, 7/93) =TID (7.5%, 7/93) at follow-up MPI. Among the four MSIMI abnormal components, RPD accounted for the highest proportion of MSIMI. Of the 24 patients with RPD at baseline, 17 patients (17/24, 70.8%) still had RPD at follow-up. Only the two MPI results of RPD were highly consistent (Kendall's tau-b 0.630, P < 0.001). ***Conclusion:*** MSIMI can be well identified by MPI in patients with anxiety and/or depression after coronary revascularization. In addition, RPD has always existed in patients at baseline and during long-term follow-up MPI. As for these high-risk patients with MSIMI, more attention should be paid to emotional control and early intervention.

## EPS-142

### Radionuclide Assessment of Myocardial Mitochondrial Dysfunction in Patients with Multivessel Coronary Artery Disease

***K. Zavadovsky****[1], A. Kalinovsky[2], M. Gulya[1], K. Kopyeva[1], N. Kamenshikov[1];*
*[1]Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution "Tomsk National Research Medical Center of the Russian Academy of Sciences", Tomsk, RUSSIAN FEDERATION, [2]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Myocardial perfusion single-photon emission computed tomography of the myocardium (SPECT) with $^{99m}$Tc-sestamibi (MIBI) is widely used in CAD patients for diagnostic and prognostic purposes. MIBI accumulates in cardiomyocytes by passive diffusion, predominantly (up to 90%) in mitochondria, thus allows to assess mitochondrial dysfunction. Although, there's data regarding diagnostic value of MIBI washout rate in severe heart failure patients, there is lack of knowledge about mitochondrial dysfunction in multivessel CAD (MVCAD) patients. MIBI washout rate could be potentially used as a marker for the detection of MVCAD, even when perfusion images show a mild or moderate decrease in myocardial perfusion. The aim of this study is to evaluate the MIBI washout rate in patients with MVCAD as compared to those without obstructive lesion. ***Materials and Methods:*** A total of 38 patients were enrolled in the study. Multivessel group (MVCAD) consists of 18 patients (male=12, age=65±7 years; CHF NYHA I-III). 10 (56%) patients have a history of acute myocardial infarction. Risk factors are diabetes mellitus (17%), smoking (39%). 20 patients (male=12, age=62.0±6 years; without obstructive CAD were recruited as a comparison group (NOCAD)). Risk factors are hypertension (75%), diabetes mellitus (8%), smoking (7%). All patients underwent stress/rest SPECT. As a part of a research protocol rest study was acquired twice - 1h and 4h after $^{99m}$Tc-MIBI injection. The washout rate (WR) was quantified using the percentage difference in $^{99m}$Tc-MIBI accumulation adjusted for the half-life of $^{99m}$Tc (6.04 h). For MVCAD group, the number of significant stenoses was estimated. Statistical processing was performed in Statistica 12.0. The differences were considered statistically significant at the level of p<0.05. ***Results:*** Obstructive multivessel coronary artery lesion was diagnosed in all MVCAD patients: LMA - 4 patients (22%), LAD - 13 (72%), LCX - 7 (39%), RCA - 7 (39%). A statistically significant increase in the WR was revealed in the MVCAD group 8,26 (IQR 6.88; 16.65) compared with the group without obstructive lesions (3.72 (IQR 1.03; 5.42))

(p<0.001). The median value of LVEF was comparable (p=0.8) in MVCAD and NOCAD patients: 65% (IQR 56; 69) and 64.25% (IQR 62.40; 65.60), respectively. ***Conclusion:*** An increase in the $^{99m}$Tc-MIBI WR in patients with MVCAD occurs despite the preserved ejection fraction what may be due to the presence of mitochondrial dysfunction resulting from chronic myocardial ischemia. Thus, the assessment of the $^{99m}$Tc-MIBI WR by serial SPECT is valuable for the assessment of chronic ischemia in MVCAD.

## EPS-143

### Multidisciplinary approach for the early detection of amyloid in patients who undergo carpal tunnel syndrome or lumbar stenosis surgery. Results of an ongoing study.

***N. Orta***[1,2], *T. Ripoll*[3,2,4], *S. Rubí*[1,2,4], *J. Pons*[1,2], *E. Fortuny*[1,2], *M. Bosch*[1,2,4], *C. Nadal*[1], *I. Torralba*[1], *G. Salvà*[1,4], *N. Mora*[1,4], *S. Lirola*[1], *R. Marí*[5], *J. Femenias*[1], *M. Llabrés*[1], *A. Álvarez*[1], *B. Barceló*[1,2,4], *V. Daza-Cajigal*[1,2], *A. Pérez*[1,2], *D. Heine*[1,2], *A. Sharma*[1], *A. Piñar*[1], *M. Villar*[1], *C. Peña*[1,2];
[1]*Hospital Universitari Son Espases, Palma, SPAIN,* [2]*IdISBa, Palma, SPAIN,* [3]*Hospital Universitari Son Llàtzer, Palma, SPAIN,* [4]*Department of Medicine, University of the Balearic Islands, Palma, SPAIN,* [5]*Hospital Sant Joan de Déu, Palma-Inca, SPAIN.*

***Aim/Introduction:*** Symptomatic carpal tunnel syndrome(CTS) and lumbar stenosis(LS) seem to precede the cardiac manifestations of cardiac amyloidosis(CA) due to transthyretin amyloidosis(ATTR), so they could represent early markers of CA. CTS is more commonly present in CA due to wild-type ATTR(ATTRwt), although it can also be present in its hereditary variant(ATTRv) and in primary amyloidosis caused by immunoglobulin light chain deposition(AL). Therefore,in this ongoing study, our aim is to evaluate the prevalence of amyloidosis in patients undergoing CTS or LS surgery, in an endemic area of the TTR mutation Val50Met(ATTRv). ***Materials and Methods:*** To date,234 operated patients have been included(180 CTS,54 LS) in whom an intraoperative biopsy was obtained(ligamentum flavum in LS; synovial tissue or flexor retinaculum in CTS) for histopathological analysis using Congo Red staining for amyloid detection and immunohistochemistry(IHC) or mass spectrometry(MS) for subtyping in amyloid A(AA), kappa,lambda and ATTR. Blood and urine test to rule out a monoclonal component and a cardiac scintigraphy(CS) with $^{99m}$Tc-DPD to detect myocardial uptake were performed, which analysis was visual by Perugini scale. A cardiac SPECT/CT was performed in cases with a positive planar imaging,according to the ASNC/EANM Cardiac Amyloidosis Practice Points. ***Results:*** Total of 192 biopsies were obtained(144 CTS,48 LS), 14 of them were amyloid positive(6 CTS,8 LS).All IHC were negative for AA, kappa and lambda. IHC for ATTR and MS analysis are still pending. 33 operated patients without biopsy(29 CTS,4 LS). Nine biopsies are pending for histopathological result. 194 laboratory tests and CS have been performed: 4/194 CS were positive(grade 3) and underwent CTS surgery with 3/4 positive biopsies for amyloid(1/4 without biopsy). 190/194 CS were negative(grade 0). In 14/194 laboratory tests, a monoclonal component was detected. 119/145 completed cases have completed the study (all tests negative). To date, positivity for amyloid has been obtained in 17/234 cases(7.3%): 13 positive biopsies (one of them with a positive blood test for monoclonal gammopathy of undetermined significance, 2 with positive CS and 10 with negative blood/urine test and CS), 2 positive biopsies with CS and blood/urine test still pending and 2 CS positive without biopsy and normal blood/urine test. In the follow-up(1.75 years) of patients with positivity, 23.5%(4/17) manifests cardiomyopathy, 3 of them with positive CS, and 88.2%(15/17) has previously other orthopedic manifestations. ***Conclusion:*** The estimated prevalence of amyloidosis in our series of surgically treated patients with CTS or LS is 7.3% to date. These are preliminary data from an ongoing study.

## EPS-144

### A 3-month of physical exercise reduces stress-related neurobiological activity in obese women: a prospective 18F-FDG PET/CT study

***K. Pahk***, *H. Kwon, S. Kim;*
*Korea University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Psychological stress is considered as a major risk factor for cardiovascular disease (CVD). Chronic exercise is known to reduce CVD risk partly through attenuating psychological stress. Obesity has been linked with increased levels of psychological stress. We aimed to prospectively evaluate whether physical exercise could alleviate stress-associated amygdala metabolic activity, assessed by $^{18}$F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) in women with obesity. ***Materials and Methods:*** A total of 43 participants were enrolled in this study. Twenty-three obese women were participated in a physical exercise program 5 days per week for 3 months. The exercise program consisted of aerobic exercise and resistance training. Serial $^{18}$F-FDG PET/CT was taken before the start of physical exercise program (baseline) and after finishing the program (post-exercise). A total of 20 participants who underwent $^{18}$F-FDG PET/CT for general health check-up were enrolled as non-obese control group. Brain amygdala activity (AmygA) was calculated as maximum standardized uptake value (SUVmax) of amygdala normalized to mean SUV of temporal lobe. ***Results:*** Chronic physical exercise significantly reduced AmygA and improved body adiposity and systemic inflammation. AmygA was highest in baseline, intermediate in post-exercise, and lowest in non-obese control group ($0.76 \pm 0.17$, $0.61 \pm 0.1$, $0.52 \pm 0.09$, $p < 0.001$). Furthermore, physical exercise also abrogated the association of AmygA with systemic inflammation. ***Conclusion:*** Chronic physical exercise reduced stress-associated amygdala metabolic activity and broke its association with systemic inflammation in obese women. This study could explain the putative mechanism underlying the health beneficial effect of exercise on CVD via attenuation of stress neurobiology.

## EPS-145

### Prognostic Value of 18F-FDG PET/CT Brain metabolism and Brain Network in Patients with Heart Failure

***Y. Bai***, *M. Yun, X. Zhang;*
*Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** To investigate the cerebral neurometabolic ventricular dyssynchrony interactome in patients with heart failure with reduced ejection fraction (HFrEF), and the association with prgnosis. ***Materials and Methods:*** Patients with HFrEF who underwent gated single-photon emission computed tomography/computed tomography (CT), myocardial perfusion imaging and the brain $^{18}$F-fluorodeoxyglucose positron emission tomography/CT were prospectively enrolled. Relationships between the regional brain metabolism and major arrhythmic events were assessed using Cox models and mediation analyses. ***Results:*** A total of 392 patients [age: 59.0 (51.0, 65.0) years, 88.5% male] were included in the current study, and 60 (15.3%) patients experienced MAEs during a median follow-up time of 3.9 years. Compared with patients without MAEs (n = 332), patients

with MAEs (n = 60) showed decreased glucose metabolism in some brain regions, mainly located in the insula, hippocampus, amygdala, cingulate gyrus, caudate nucleus and thalamus, which are related to the autonomic nervous system (all P value< 0.001). The decreased cerebral glucose metabolism activity in the autonomic nervous system related brain regions such as the insula, hippocampus, amygdala, cingulate gyrus, caudate nucleus and thalamus were independent predictors of MAEs in patients HF (all P value < 0.05). The glucose metabolism activity in the insula, hippocampus, amygdala, cingulate cortex, and caudate nucleus was correlated with the ventricular dyssynchrony (r = -0.10- 0.24, P value < 0.05). Mediation analysis showed that the metabolic activity of autonomic nervous system related brain regions such as the insula, hippocampus, amygdala, cingulate gyrus, and caudate nucleus was reduced, which affected ventricular mechanical dyssynchrony and electrical dyssynchrony, and mediated the occurrence of MAEs in patients with HF. In patients with HF, compared with non-MAEs patients, the central autonomic neural networks were damaged in patients with MAEs (P value < 0.05). Compared with the sympathetic neural network, the parasympathetic neural network was more severely disturbed, that is, the central autonomic neural network is imbalanced. ***Conclusion:*** The decreased glucose metabolism related to the autonomic nervous system is associated with MAEs in patients with HF. Neuronal metabolism affects ventricular mechanical dyssynchrony and ventricular electrical dyssynchrony, and mediates the occurrence of MAEs. In addition, central autonomic neural network imbalance can predict MAEs in patients with HF.

## EPS-146

### Characterization of brain structure and metabolism in heart failure patients with reduced or preserved ejection fraction: a simultaneous PET/MR study

***C. Zheng***[1], *Y. Cui*[1], *Q. Ge*[2], *Y. Yang*[3], *X. Li*[4], *J. Lu*[1];
[1]*Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA,* [2]*Central Research Institute, United Imaging Healthcare, Shanghai, CHINA,* [3]*Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA,* [4]*Division of Nuclear Medicine Department of Biomedical Imaging and Image-guided Therapy. Vienna General Hospital Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** It is controversial whether the cognitive impairment associated with heart failure (HF) is due to left ventricular ejection fraction (LVEF). The purpose of this study was to determine whether HF patients with reduced ejection fraction (HFrEF) or ejection fraction preserved heart failure (HFpEF) exhibits evidence of cognitive impairment and brain alterations compared to healthy controls (HC). ***Materials and Methods:*** A total of 78 subjects were included in this study, including 26 patients with HFrEF, 20 patients with HFpEF, and 32 age- and sex-matched individuals with HC. All HF patients suffer from left ventricular myocardial infarction. Basic clinical information and clinical cognitive scale assessments were collected, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). All subjects underwent an integrated 18F-fluorodeoxyglucose ($^{18}$F-FDG) PET/MR scan. High-resolution T1-weigthted imaging structural images and $^{18}$F-FDG PET images were acquired for all subjects. The normalized gray matter volume (GMV) images and normalized PET standardized uptake value ratio (SUVR) with pons as the reference region images were obtained using the CAT12 and SPM12 toolboxes. Voxel-wise analysis was used to evaluate abnormalities in brain metabolism and structure in the HF patients. Age and gender were used as covariates of no interest in PET image comparison, and age, gender, and total intracranial volume were used for GMV images. ***Results:*** There were no significant differences in education, hyperlipidemia, or other vascular risk factors among the three groups. Both HFrEF and HFpEF patients showed reduced MOCA and MMSE scores compared to HC subjects (all P<0.05). However, there was no significant difference in MMSE and MoCA scores between the two HF groups. Compared to HC, HFrEF patients showed hypometabolism in the bilateral inferior temporal gyrus, insula, and superior frontal gyrus, as well as the right inferior temporal gyrus and right hippocampal GMV loss. HFpEF patients showed hypometabolism in the bilateral thalamus, bilateral hippocampus, bilateral caudate nucleus, bilateral superior temporal gyrus, and GMV loss in the medial superior frontal gyrus, compared to HC. Nevertheless, no differences were found in glucose metabolism and GMV between the two groups of HF patients. ***Conclusion:*** Our findings demonstrate that patients with HF with reduced or preserved LVEF have impairments in brain metabolism and gray matter structures in cognitively relevant areas of the brain. These results may provide imaging evidence for clinical patient management.

### Description of an imaging protocol in patients with glioblastoma treated with [$^{177}$Lu]Lu-DOTA-TATE.

***E. Córdoba Cañete***[1], *M. Caballero Vivancos*[1], *N. González Corredera*[1], *E. Triviño Ibañez*[1], *R. Sánchez Sánchez*[2];
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,*
[2]*Hospital Universitario Virgen de las Nieves, Maracena, SPAIN.*

***Aim/Introduction:*** Glioblastoma is the most commonly occurring malignant central nervous system tumor accounting for 14.6% of all tumors. It is an aggressive primary brain tumor, with a high mortality rate despite extensive efforts to develop new treatments. "[177Lu]Lu-DOTA-TATE" is a targeted radioligand therapy binding with high-affinity to somatostatin receptors (SSTR), with highest affinity for subtype 2 receptors (SSTR2). Pathologic conditions, including brain tumors (i.e. GB) and chemical or physical stimuli such as surgery, RT, some chemotherapy agents, could increase the blood brain barrier (BBB) permeability disrupting its integrity. [68Ga]Ga-DOTA-TATE PET/CT (or PET/MRI) will be performed during screening to select patients presenting uptake in the tumoral region before the administration of the first dose of [177Lu]Lu-DOTA-TATE.The aim of our job is to present our imaging protocol in gliobalstoma patients treated with [177Lu]Lu-DOTA-TATE ***Materials and Methods:*** Whole body planar image will be acquired on the day of [177Lu]Lu-DOTA-TATE administration 1 to 3 hours after end of [177Lu]Lu-DOTA-TATE infusion. Matrix 256 x1024 Zoom 1. Both detectors. supine position. Exploration extension from 200 cm to 10 cm/min scanning speed. Automatic contours. Photopeak centered at 208 Kev with a window of +-15%. Two more attached windows are enabled both above and below the main 4% picking up the top and bottom dispersion. SPECT/CT scan will be acquired in 24 hours after the end of [177Lu]Lu-DOTA-TATE infusion. Matrix 128 x 128 60 images at 20sec/image on two beds including head-thorax-abdomen. 360 degrees of rotation. 180 degree detector configuration. Orbits not circular in advance and take. Energy window of 208 Kev. CT parameters Using the CareDose 4D method of dose modulation, a CT scan is performed with 3-slices. mm with window reconstructions of the abdomen (B31s medium homog) and bone (B70sdefined) and mediastinal window with expanded Fov for attenuation correction. ***Conclusion:*** The introduction of therapy with new radioligands makes it necessary to optimize the acquisition protocols for the correct evaluation of the images.

## TEPS-002

### [$^{18}$F]AlF-complexation of pamidronic acid, a NOTA-conjugated bisphosphonate, as a potential tracer for PET bone imaging

***H. Hassan***[1], *M. Othman*[2], *H. Abdul Razak*[3], *Z. Zakaria*[4], *F. Ahmad Saad*[1];
[1]*Universiti Putra Malaysia, Serdang, MALAYSIA,* [2]*Universiti Teknologi MARA, Bandar Puncak Alam, MALAYSIA,*
[3]*University of Exeter, Devon EX1 2LU, UNITED KINGDOM,*
[4]*Universiti Malaysia Sabah, Kota Kinabalu, MALAYSIA.*

***Aim/Introduction:*** The use of radiopharmaceuticals in nuclear imaging offers greater advantages than conventional diagnostic imaging. Although [$^{18}$F]sodium fluoride ([$^{18}$F]NaF) is recognised to be superior to [$^{99m}$Tc]-Tc-methyl diphosphate ([$^{99m}$Tc]Tc-MDP) and 2-deoxy-2-[$^{18}$F]fluoro-D-glucose (2-[$^{18}$F]FDG) in bone diagnostics, there is a concern that [$^{18}$F]NaF uptake is not cancer-specific, leading to a higher number of false-positive interpretations. Therefore, in this study, a bisphosphonate drug, pamidronic acid, was conjugated to a NOTA for [$^{18}$F]AlF complexation of pamidronic acid using the aluminium fluoride (Al-F) technique and evaluated for its in vitro uptake. ***Materials and Methods:*** The conjugation of NOTA-pamidronic acid was prepared using the N-hydroxysuccinimide (NHS) ester strategy and validated by liquid chromatography-mass spectrometry analysis (LC-MS) before being isolated in pure form. The conditions for the [$^{18}$F]AlF complexation of pamidronic acid were optimised to achieve an acceptable radiochemical yield (RCY) between 40 and 60% and radiochemical purity (RCP) above 90%. It was ensured that [$^{18}$F]AlF-NOTA-pamidronic acid met all quality control requirements for radiopharmaceuticals prior to in vitro bone binding assay with hydroxyapatite and in vitro cell uptake studies with normal human osteoblast cell lines (hFOB 1.19) and human osteosarcoma cell lines (Saos-2) were performed. ***Results:*** Conjugation of NOTA-pamidronic acid in a molar ratio of 5:1 of pamidronic acid to NOTA-NHS at room temperature for 4 hours with pH adjusted to 8 successfully yielded 24.13% of NOTA-pamidronic acid. The purity of the NOTA-pamidronic acid fractions was 92%, with no free NOTA impurities detected. [$^{18}$F]AlF-NOTA-pamidronic acid prepared in a 1:1 molar ratio of aluminium chloride ($AlCl_3$) to NOTA-pamidronic acid and heated at 100 °C for 15 minutes in the presence of 50% ethanol (v/v) proved to be optimal. [$^{18}$F]AlF-NOTA-pamidronic acid also successfully met all radiopharmaceutical quality control requirements and was also stable in the final formulation and in human plasma (n = 6). The in vitro bone-binding study showed that [$^{18}$F]AlF-NOTA-pamidronic acid was as sensitive as [$^{18}$F]NaF in binding hydroxyapatite. Although [$^{18}$F]NaF was more strongly taken up by both cell lines, the results nevertheless demonstrated that [$^{18}$F]AlF-NOTA-pamidronic acid was specific, as a higher cellular uptake of [$^{18}$F]AlF-NOTA-pamidronic acid was observed in the Saos-2 cell lines. ***Conclusion:*** The novel radioconjugate [$^{18}$F]AlF-NOTA-pamidronic acid prepared by the Al-F technique appears to be a potential PET tracer for bone imaging. The preliminary in vitro results indicate that further preclinical studies with [$^{18}$F]AlF-NOTA-pamidronic acid are needed before it can be translated to clinical research.

## TEPS-003

### Evaluation of Variation method to Improve the Sensitivity of Immunoradiometric Assay

***W. Kwon***, *J. Kim;*
*Seoul National University Bundang Hospital, Seongnam-si, Gyeonggi-do, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** The concentration of PSA (Prostate Specific Antigen) after radical prostatectomy in prostate cancer patients is a predictor of biochemical recurrence, and the AUA (American Urological Association) is defined as biochemical recurrence when the concentration of PSA is measured at 0.2 ng/ml or more, and when the concentration is measured at 0.2 ng/ml or more at the retest. This standard is also applied our hospital. In this laboratory, the PSA reagent using IRMA (Immunoradiometric Assay) is used, and the sensitivity at a very low value was not as good as the reagent used in the department of laboratory medicine. This study aims to increase the reliability of the results by improving the precision and sensitivity of very low values. ***Materials and Methods:*** As a reagent for the study, PSA reagent using IRMA was used. As a method to improve the precision and sensitivity of very low values, a variation method on the serum volume(25ul, 50ul, 100ul, 200ul) was studied, and variation usefulness evaluation was conducted. The evaluation items were compared the results of precision, analytical sensitivity, recovery rate, dilution test, high-dose hook test, parallel test and very low concentration values(n = 20). ***Results:*** The validation results were displayed in the order of 25ul, 50ul, 100ul, 200ul. As the serum volume increased, it was confirmed that CV (Coefficient of Variation)(%) improved. Analytical sensitivity(ng/ml) was 0.038, 0.041, 0.017, 0.015 and recovery rate(%) was 101±3, 101±3, 99±2, 97±4. very low concentration values(ng/ml) between each volume(n=20) were 0.135±0.068, 0.076±0.050, 0.048±0.034, 0.046±0.034. and high dose hook effect appeared as the serum volume increased. ***Conclusion:*** Through the variation usefulness evaluation, it was confirmed that as the serum volume increased, the precision and sensitivity improved at very low concentration values. However, it is necessary to pay special attention to the occurrence of high-dose hook effect as the serum volume increases. In the case of tests that requires very low concentration values, it is thought that the reliability of the result will be increased if the variation method is properly used after the variation usefulness evaluation.

## TEPS-004

### Comprehensive management of paediatrics in nuclear medicine: sharing the experience of technologists in a leading cancer center

***M. GOLVET***, *M. Luporsi, N. Jehanno, S. Lasalle, N. Sanchez Bertomeu;*
*Department of nuclear medicine, Institut Curie, Paris, FRANCE.*

***Aim/Introduction:*** In our nuclear medicine department, located in one of the leading cancer centers in Europe, we are used to taking care of patients of all ages. However, management of paediatrics is one of the most challenging part of our daily activities. Therefore we had to develop several technical and communication skills in order to perform the best image quality while offering the least invasive procedure as possible. In this poster, we would like to share our experience enriched by decades of daily practice. ***Materials and Methods:*** Paediatrics management is based on a collaborative approach between all members of imagery department, relying as much on secretaries, as the physicists, the radiopharmacist, the physician and finally the technologist. The versatility of the technologists on other modalities such as MRI and CT helps to ensure effective pediatric care. We mainly focus here on the involvement of the technologists for the well running of nuclear medicine imaging involving paediatric patients. ***Results:*** In 2022 we performed respectively 83 MIBG scan (range [1 months-17 yo], <6yo : 46/83) and 123 PET/CT (range [3months-17yo] ; < 6 yo : 17/123) on paediatrics, without requiring any general anesthesia and with only a very rare use of premedication for anxiolysis. Many soft strategies help us to welcome the child and his/her family in a pleasant and secure environment (attractive stickers on walls and equipements, toys in waiting rooms, colourful light diffusers, DVD and music players). Then a communication adapted to the child's language and his comprehension appeases everyone and helps to install a relionship of trust between the caregiver, the child and the parents, actively involving them into the procedure. Some of our technologists are also specifically trained in pain management (inhalation of nitrous oxide for injection, anaesthetic cream) and in conversational hypnosis to facilitate injection and/or installation. Optimal installation and immobilization with age-adapted devices is finally on of the key point of the procedure (cushions, paediatric cradle⋯) ***Conclusion:*** Thanks to a multidisciplinary approach and the development of technical and communication skills over the years, we take care of children and teenagers every day, for PET/CT and scintigraphies, trying to perform the best image quality while remaining as less invasive as possible.

## TEPS-005

### Ultra-fast Gallium-68 is it possible in the era of digital PET/CT imaging

***Z. Alqallaf***[1], *L. Ghadhanfer*[2], *A. Sadeq*[1], *H. Alfake*[1], *F. Marafi*[1];
[1]*Jaber Al Ahmed Center For Nuclear Medicine & Molecular Imaging, Sabah Medical area, KUWAIT,* [2]*Faculty of Allied Health Kuwait university, Jabriya, KUWAIT.*

***Aim/Introduction:*** Digital PET/CT scanners system has higher sensitivity when compared to analog PET/CT scanners. New digital PET/CT has enhanced specifications with higher count statistic, time-to-flight ratio, and camera resolution contributing to better sensitivity. Gallium68 is an isotope labeled with a wide range of radiotracers used in oncology and inflammatory diseases due to the availability of Germanium-68/Gallium-68 generator. However, it has less favorable properties that lower image quality mainly due to lower positron yield (89.14%) and higher positron energy (1,899 keV) with higher kinetic energy resulting in further distance between positron emission and annihilation. This reflect on the image resolution and contrast as it increases the scatter and therefore image noise. The aim of this study is to determine the possibility of ultra-fast imaging time with optimal OSEM and Q. Clear filter for better image resolution in digital PET/CT imaging. ***Materials and Methods:*** Flangeless PET phantom was used which has solid cylindrical shaped attached to the lid with diameter of 8, 12, 16mm, and three with diameter of 25mm. Gallium-68 was added to the phantom with ratio of 8:1 concentration of cylindrical shape to background, starting from 25 followed by 8, 12,16mm sequentially. The other 25mm cylindrical shape one filled with water and the other is filled with air for attenuation purposes. In the other end of the phantom there are cold rods diameters: 4.8, 6.4, 7.9, 9.5, 11.1 and 12.7 mm* Height of rods: 8.8 cm. The images were acquired by digital PET/CT camera at different time points per bed starting with 5min, 4min, 3min, 2:30min, 2min, 1:30min, 1min, and 0:30sec. The images were reconstructed using OSEM and Q.Clear filters, and it was analyzed by two nuclear medicine physicians. ***Results:*** In both the iterative reconstruction and Q.Clear all the hot lesions were identified clearly by the two

readers, up to 4mm at 30sec per bed. However, the cold lesions in 4.8 and 6.4mm were blurred in iterative reconstruction, while the resolution were enhanced and identified in the Q.Clear. ***Conclusion:*** In the era of the digital PET system, this preclinical study demonstrates the ability of obtaining high quality images with optimal contrast to background ratio and better image resolution. This study could establish a new opportunity for ultra-fast digital PET scanning providing potentials for clinical trials in which patients can be imaged in shorter time. Q.Clear filter showed superiority over iterative reconstruction especially with cold lesions of smaller diameter.

## TEPS-006

### The Effect of Using Radiopharmaceutical Multidose Injector for 18F FDG on the Received Effective Doses of Radiographers

***D. Sercic****, J. Peric, U. Cotar;*
*Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** To determine the possible impact of using radiopharmaceutical multidose injector for $^{18}$F Fluorodeoxyglucose (FDG) on the received effective dose of employed radiographers. ***Materials and Methods:*** The retrospective study included data on the received effective doses of 10 radiographers over a period of 12 months (a total of 120 received effective doses). During that period, radiographers were 6 months applicated $^{18}$F FDG manually and 6 months using radiopharmaceutical multidose injector. Thermoluminescent dosimeters (TLDs) were used to measure and calculate received effective doses monthly. Depending on the data normality, Mann-Whitney U test were used to determine potential impact of using radiopharmaceutical multidose injector for $^{18}$F FDG on the received effective dose. ***Results:*** Data analysis showed that the received effective dose of radiographers is significant different between manual application of $^{18}$F FDG and using radiopharmaceutical multidose injector for application $^{18}$F FDG (p=0.046). Mean ± STD of measured effective dose during manual application of radiopharmaceutical $^{18}$F FDG was 0.137 ± 0.143 mSv per month and effective dose measured during use radiopharmaceutical injector was 0.083 ± 0.044 mSv per month. ***Conclusion:*** The difference of effective dose between two methods of radiopharmaceuticals application was statistically significant. Results showed that mean of measured effective dose during manual application of $^{18}$F FDG was 39.4% higher in comparison with measured effective dose during use radiopharmaceutical multidose injector.

## TEPS-007

### Decontamination of Lu-177-PSMA and Tc-99m-Pertechnetate Spills from Laboratory Floor: Comparing Four Cleansing Agents

***S. Rajala***[1]*, I. Rantala*[1]*, L. Elg*[2]*, A. Honkanen*[2]*, J. Lehto*[2]*, E. Hippeläinen*[2]*, V. Ahtiainen*[1,3]*, M. Ladev*[1]*, M. Eskola*[1]*, S. Keskimäki*[4]*, K. Kiviluoto*[4]*, J. Tervonen*[4]*, M. Salomaa*[1]*, V. Reijonen*[1]*;*
*[1]HUS Comprehensive Cancer Center, Helsinki, FINLAND, [2]HUS Diagnostic Center, Helsinki, FINLAND, [3]University of Helsinki, Helsinki, FINLAND, [4]HUS Pharmacy, Helsinki, FINLAND.*

***Aim/Introduction:*** Accidental spills may occur when one works with unsealed radioactive sources. Nuclear medicine staff are trained to prevent, monitor and handle radioactive contamination that may result from the use of radiopharmaceuticals. The selection of diagnostic and therapeutical radiopharmaceuticals is versatile, and new agents are developed and coming to clinical use. The optimal choice of decontamination solvent for each radiopharmaceutical and surface material is different, which is why ready-made cleansing mixtures can be a practical solution for daily routine. ***Materials and Methods:*** Small pieces of plastic laboratory floor material (polyurethane-coated polyvinyl chloride) were contaminated with a low activity of either Lutetium-177-PSMA (prostate-specific membrane antigen, peptide) or Technetium-99m-pertechnetate: 10 µl droplet was pipetted and spread with glass rod on a 2 cm x 2 cm area. The contaminated pieces were left to dry in a laminar flow hood for 1 hour or 24 hours. The pieces were then decontaminated with wipes moistened with a cleansing agent: water, 80% ethanol, commercial solution 1, or commercial solution 2. In order to equalise the decontamination process, we constructed an apparatus: Two plastic tiles were covered with disposable tape, and the wipe was placed between these two. Each contaminated piece was then pushed through the gap between the plastic tiles, with a 966 g lead block placed above to apply constant pressure. The contaminated pieces were measured just before the decontamination (that is, after drying), and after decontamination. ***Results:*** For Lu-177-PSMA, the decontamination efficiency (reported as an average of two measurements for each cleansing agent) after 1 hour/24 hour drying time was 99%/99% with water, 95%/91% with ethanol, 99%/99% with commercial solution 1, and 99%/99% with commercial solution 2. For Tc-99m-pertechnetate, 72%/48%, 87%/36%, 87%/52%, and 81%/65%, respectively. For Lu-177-PSMA, all four decontaminating agents were efficient for both 1 and 24 hour spills. However, decontamination efficiency with ethanol was slightly lower than for the other agents. For Tc-99m-pertechnetate, the average decontamination efficiency was higher after 1 hour drying time compared to 24 hours drying time, indicating the longer the spill had time to dry, the harder it was to decontaminate. ***Conclusion:*** The differences in cleansing efficiency between all four tested decontamination solutions were minor. Decontamination of Tc-99m-pertechnetate was more difficult after 24 hours than 1 hour of drying time, whereas Lu-177-PSMA was easy to clean in both cases.

## TEPS-008

### Development of a specialized image reconstruction technique for dedicated breast positron emission tomography

***K. Hanaoka***[1]*, S. Watanabe*[1]*, D. Ishikawa-Morimoto*[1]*, Y. Yamakawa*[2]*, T. Kobayashi*[2]*, A. Ohtani*[2]*, S. Kumakawa*[2]*, T. Ito*[3]*, Y. Komoike*[3]*, H. Kaida*[1]*, K. Ishii*[1]*;*
*[1]Institute of Advanced Clinical Medicine, KINDAI University, Osaka-sayama, JAPAN, [2]Shimadzu Corporation, Kyoto, JAPAN, [3]Division of Breast and Endocrine Surgery, KINDAI University, Osaka-sayama, JAPAN.*

***Aim/Introduction:*** FDG dedicated breast PET (db-PET) has been employed for clinical presentation and diagnosis. However, the quality of images has been compromised at the periphery of the patient's field of view(FOV), i.e., near the chest wall, due to out-of-field scattered radiation from the brain and heart, as well as decreased sensitivity of detection at the edges during db-PET acquisition. To address this issue, the present study endeavors to develop a db-PET reconstruction technique and evaluate its effectiveness. ***Materials and Methods:*** In an effort to balance noise reduction and preservation of resolution, we have developed a novel reconstruction methodology that combines a 3x3x3 Median filter and a Non-Local Means filter(I:0.5, S:3, P:6). This method was evaluated using data acquired from the BresTome, manufactured by Shimadzu Corporation. The performance of this new method was contrasted against that of the conventional reconstruction

approach utilizing a 2.2 mm Gaussian filter, by utilizing both phantom and clinical data. This assessment began with a 5-minute acquisition of a 20 cm diameter cylindrical phantom containing 10 MBq, where the coefficient of variation(CV values) within the central homogeneous region in each slice after reconstruction was measured along the depth direction from the edge of the FOV and compared between the different reconstructions. Furthermore, the maximum standard uptake value(SUVmax) in 53 lesions and SUVavg on mammary grand and fat were compared between reconstructions in a cohort of 30 breast cancer cases. ***Results:*** The new method was found to be effective in reducing CV values by a mean of 27% when compared to the conventional method. This effect was observed to be independent of the depth from the periphery of the FOV. In clinical cases, the mean SUVmax of 53 lesions(mean size 11.6±7.9 mm) and mean SUVavg of normal mammary tissue were not significantly difference in new method compared to conventional method(9.11±5.83 vs 8.92±5.62, p=0.332 and 0.93±0.29 vs 0.90±0.30, p=0.984). On the other hand, the mean SUVavg on fat tissue tended to be lower in new method compared to conventional method(0.24±0.10 vs 0.31±0.14, p<0.001). The image quality was found to be improved in all cases with the use of the new technique. ***Conclusion:*** The reconstruction method developed, which incorporates a Non-Local Means filter, has the ability to effectively reduce background noise encountered in db-PET. ***References:*** 1) Ishii K, Hanaoka K, et al. J Nucl Med 2023;64, 2) Morimoto-Ishikawa D, Hanaoka K, et al. EJNMMI Phys. 2022;9:88.

## TEPS-009

### Impact of Image Space PSF Correction on Quantitative Values and SNR of Clinical PET Images in SiPM-based PET/CT with List-Mode Acquisition

***Y. Shirakawa****, K. Ebine, M. Kawada, J. Suyama;*
*Kyorin University Hospital, Tokyo, JAPAN.*

***Aim/Introduction:*** The Cartesion Prime (Canon) SiPM-based PET/CT scanner employs list-mode acquisition and reconstruction, along with image space PSF (iPSF) correction for spatial resolution improvement. This study aimed to evaluate the impact of iPSF on the quantitative values and signal-to-noise ratio (SNR) of clinical images in a high spatial resolution SiPM-based PET/CT scanner. ***Materials and Methods:*** Lung cancer cases (83 nodules) classified as T1a (≤ 1 cm), T1b (1 cm < ≤ 2 cm), or T1c (2 cm < ≤ 3 cm) in the Tumor-Node-Metastasis (TNM) classification (UICC 8th edition) were analyzed in 78 patients undergoing $^{18}$F-FDG PET/CT examination. All patients fasted for at least 4 hours before PET/CT and received an intravenous infusion of 215.7±40 MBq of $^{18}$F-FDG followed by a 60-minute resting period. The injection dose per body weight was 3.6±0.4 MBq/kg, and acquisition began 60 minutes after administration. Collection was performed at 3 minutes/bed. Image reconstruction was performed by 3D-OSEM with subset 12, iteration 3, time-of-flight (+), iPSF correction (-/+), Gaussian filter FWHM 4 mm. $SUV_{max}$ and liver SNR (n=78) of lung nodules were measured with and without iPSF, and cases of lung nodules were divided into sizes based on T1a-c classification, and statistical analysis was performed using Wilcoxon signed rank test. P values less than 0.05 were considered statistically significant in all analyses. ***Results:*** $SUV_{max}$ was 5.0±1.9 for nodule diameter ≤1 cm without iPSF, 8.2±2.7 for 1 cm < nodule diameter ≤2 cm, 12.0±2.9 for 2 cm < nodule diameter ≤3 cm, and 5.9±2.4, 9.5±3.3 and 13.4±3.5 with iPSF, respectively. The liver SNR was 10.5±1.6 without iPSF and 12.5±2.2 with iPSF. ***Conclusion:*** Although the application of iPSF resulted in a higher liver SNR, the effect was small, and the guideline recommendations were met without any problem without iPSF, thus limiting the effect of the iPSF. ***References:*** 1) Tong S, Alessio AM, Kinahan PE. ## TEPS-010

### Comparison between MIRD-based and Monte Carlo simulation-based patient-specific dosimetry in177Lu-DOTATATE

***N. Miyaji****[1], K. Miwa[1], K. Yamashita[2], T. Yamao[1], K. Hasegawa[1], N. Oriuchi[3], T. Terauchi[2];*
*[1]Fukushima Medical University, Fukushima, JAPAN, [2]Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, JAPAN, [3]Advanced Clinical Research Center, Fukushima Medical University, Fukushima, JAPAN.*

***Aim/Introduction:*** Patient-specific image-based dosimetry for PRRT is beneficial for assessing adequate lesion response while minimizing normal tissue toxicity. The present study aimed to compare the absorbed dose derived from voxel-level dosimetry using Medical Internal Radiation Dosimetry (MIRD) and Monte Carlo simulation (MC). ***Materials and Methods:*** We retrospectively investigated four patients treated with 7.4 GBq $^{177}$Lu-DOTATATE. Each patient underwent an abdominal SPECT/CT scan using the Symbia Intevo 16 (Siemens Healthcare) at 24 and 168 hours after injection. The SPECT images were acquired in a step-and-shoot mode with 60 views using a 128×128 matrix and low-medium energy general purpose collimators. The energy window was set to a photopeak of 113, 208 keV with a 15% width. Liver, spleen, kidneys and lesion absorbed dose distributions were calculated from the projection data using a MIRD-based and MC-based dosimetry software (Hermes Medical Solutions)[1)]. The absorbed dose with MC was calculated at single or two time-points of estimation (24, 168 and 24/168 hours). ***Results:*** The MC-based absorbed doses at each time point showed higher values in the order of 24-hour point, 24/168-hour point, 168-hour point. The MC-based mean absorbed doses at two time points were higher, ranging from 1.6 to 6.3 Gy, than the MIRD-based doses (with average relative differences ranging between 27.4% and 127.2%) in the kidneys. However, no patient had received greater than the accepted threshold for renal toxicity of 23 Gy. In the lesions, the MC-based mean absorbed doses at the 24-hour time point were lower, ranging from -0.4 to -7.3 Gy, than the doses at two time points. In contrast, the absorbed dose at the 168-hour time point was higher, ranging from 1.3 to 10.2 Gy, than the doses at two time points. ***Conclusion:*** The MC-based dosimetry at single time point of the early or late phase caused variation in the absorbed dose. Multipoint MC-based dosimetry can be expected to provide a reliable assessment compared with uncertain MIRD-based dosimetry. ***References:*** 1) Hippeläinen ET, Tenhunen MJ, Mäenpää HO, Heikkonen JJ, Sohlberg AO. Dosimetry software Hermes Internal Radiation Dosimetry: from quantitative image reconstruction to voxel-level absorbed dose distribution. Nucl Med Commun. 2017;38(5):357-365.

## TEPS-011

### [18F]fluorocholine PET is more resource-effective than conventional [99mTc]sestamibi scintigraphy in patients with primary hyperparathyroidism

***S. Rep***[1,2], *I. Slodnjak*[1], *K. Sirca*[3], *K. Zaletel*[1,4], *M. Hocevar*[3], *L. Lezaic*[1,4];
[1]*Department for Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [2]*University of Ljubljana, Faculty of Health Sciences, Medical Imaging and Radiotherapy Department, Ljubljana, SLOVENIA,* [3]*Department of Oncological Surgery, Institute of Oncology Ljubljana, Ljubljana, SLOVENIA,* [4]*University of Ljubljana, Faculty of Medicine, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** Minimally invasive parathyroidectomy is the treatment of choice in patients with primary hyperparathyroidism, but it needs a reliable preoperative localization method to detect hyperfunctioning parathyroid tissue. Higher sensitivity and lower radiation exposure were demonstrated for [18F]fluorocholine PET/CT (FCh-PET) in comparison to [99mTc]sestamibi (MIBI) scintigraphy. However, data of its cost-effectiveness is lacking. The aim of our study was to determine the cost-effectiveness of FCh-PET in comparison to conventional MIBI scintigraphy. ***Materials and Methods:*** A group of 234 patients who underwent surgery after MIBI scintigraphy was compared to a group of 163 patients who underwent surgery after FCh-PET.The whole working process from the implementation of imaging to the completion of surgical treatment was analysed. The economic costs were expressed in the time needed for the required procedures. ***Results:*** The time needed to perform imaging was reduced by 80 % after FCh-PET in comparison to MIBI scintigraphy. The time needed to perform surgery was reduced by 41 % when intraoperative parathyroid hormone monitoring was not used. There was no significant difference in the time of surgery between FCh-PET and MIBI scintigraphy. Postoperative complications occurred in 16.6 % of patients after SS and SPECT/CT and 6.1% of patients after FCh-PET (p= < 0.001). ***Conclusion:*** FCh-PET reduces the time of imaging and the time of surgery and potentially reduces the number of reoperations for persistent disease. ***References:*** 1. ## TEPS-012

### Does $^{18}$F-FDG-PET require withdrawal of Glucagon-like peptide 1 (GLP-1) analogs in diabetic patients?

***B. Olsson***[1], *U. Bitzén*[1], *S. Garpered*[1], *S. Leide-Svegborn*[2], *A. Stenvall*[2];
[1]*Clinical Physiology and Nuclear Medicine, Malmö/Lund, SWEDEN,* [2]*Radiation Physics, Malmö/Lund, SWEDEN.*

***Aim/Introduction:*** Many patients undergoing $^{18}$F-FDG-PET examinations have diabetes mellitus and their medication can potentially alter the physiological $^{18}$F-FDG distribution. Glucagon-like peptide 1 (GLP-1) analogues, a group of diabetes type 2 pharmaceuticals introduced some years ago, stimulate the release of insulin from pancreas. To date, no literature was found about possible effects of these pharmaceuticals in $^{18}$F-FDG-PET. The aim was to study if GLP-1 analogues affect the physiological $^{18}$F-FDG distribution. ***Materials and Methods:*** Twenty-two diabetic patients (46 $^{18}$F-FDG PET/CT scans) with BMI range 22-41 and medicated with GLP-1 analogues, either once daily with liraglutide (5 patients, 14 scans) or once weekly with semiglutide (17 patients, 32 scans) referred for 18F-FDG-PET were retrospectively included. As a control group 30 non-diabetic patients with BMI range 22-40 were included. They were all injected with 4 MBq/kg and scanned after 60 minutes on a PET/CT with SiPM detectors. In each scan three volumes-of-interest (VOIs) were drawn, one in each of the reference organs mediastinal blood pool, liver and thigh muscle. SUVmean were determined for each VOI. SUVmean were related to BMI and blood glucose level at time of $^{18}$F-FDG injection. ***Results:*** No obvious difference in SUVmean in any of the reference organs; mediastinal blood pool, liver or muscle was found for GLP-1 medicated diabetics compared to a control population. This result was regardless of BMI, blood glucose level or GLP-1 analogue regimen investigated. ***Conclusion:*** The physiological $^{18}$F-FDG distribution, reflected by SUVmean in reference organs, was similar in patients with GLP-1 analogues compared to the control group. Hence, $^{18}$F-FDG-PET does not require withdrawal of GLP-1 analogues in diabetic patients.

## TEPS-013

### $^{99m}$Tc-Colloid residuals dependency on the syringe and needles

***D. Teixeira Macarico***[1], *C. Laurins*[1], *L. Hogg*[2], *R. Williamson*[1], *J. Dennis*[1], *A. Nicol*[1];
[1]*Nuclear Medicine Department, Queen Elizabeth University Hospital, Department of Clinical Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM,* [2]*Medical Physics, Royal Alexandra Hospital, Department of Clinical Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** Lymphoscintigraphy is a common nuclear medicine procedure essential for the prognosis and treatment of breast cancer, allowing identification of sentinel lymph nodes during theatre using gamma probes and subsequent biopsy. The administration technique performed in our department was by subdermal injection of $^{99m}$Tc-Nanocoll (10MBq or 40MBq for same-day or following day surgery) with a 25G (0.5mm) needle and 1mL syringe, peri-areolar at the same quadrant as the tumour. Following feedback from the surgical team of some patients with lower counts, a review was performed including the syringe & needle and an audit of syringe residual activity. Peer review at other centres identified the use of a different needle gauge (insulin needle and syringe system 29G 0.33mm) and this was adopted. The aim of this study is to compare radiopharmaceutical retention (RR) with both needle gauges. ***Materials and Methods:*** Experiments were performed by dispensing 10MBq/40MBq of $^{99m}$Tc-Nanocoll and measuring RR, similar to a patient administration. A total of 16 experiments were performed by two operators using the 25G needle and 1mL syringe and 8 experiments using the 29G insulin syringe system. Additionally, retrospective analysis of administrations using the 25G needle (54 patients) and prospective analysis with the 29G needle (4 patients to date - data collation is ongoing) were performed to determine RR after administration. ***Results:*** The experiments showed a RR of 20% (SD=8.2%) for the 25G needles and RR of 7.9% (SD=2%) for 29G needles (t-test shows differences statistically significant for p<0.01). The analysis of the patient administrations with the 25G needle showed an average of RR of 21% (SD =

8%). For the 29G syringe the average of RR was 5% (SD = 2%). These differences were statistically significant (t-test, p<0.01). ***Conclusion:*** A significantly lower RR of the radiopharmaceutical was observed for the insulin syringe and needle (29G) system in both experiments and patients administrations, which can help explain some lower counts in the lymph nodes reported by the surgical team. Following these results, the standard operator protocols were changed and positive feedback is reported by the surgical team. Acknowledgements: thanks to Nuclear Medicine teams in all Glasgow sites.

## TEPS-014

### Usefulness of $^{99m}$Tc-MIBI Myocardial SPECT/CT Subtraction Protocol with CZT Gamma Camera

***K. Nam***, *H. Cho, J. Lee, W. Lee;*
*Seoul National University Bundang Hospital, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** This study introduces $^{99m}$Tc-MIBI gated myocardial SPECT/CT subtraction protocol with CZT gamma camera (NMCT 870 CZT) which can reduce examination time and provide a comfortable examination for patients. ***Materials and Methods:*** Medical staff performed a pharmacologically induced stress test on the patient. The heart rate and blood pressure were monitored during this phase. 296 MBq of $^{99m}$Tc-MIBI was injected in the middle of the test. After the test, the patient ingested fatty meals to reduce uptake of liver. After at least 30 min, myocardial SPECT stress scan was started with 6 degree angle, 30 projections and 40 sec of each acquisition. Also, helical CT scan was performed with 120 kVp, 20 mA and 18.75 mm/rot for attenuation correction. Immediately after the stress scan, 925 MBq of $^{99m}$Tc-MIBI has been injected and myocardial SPECT rest scan was started with 6 degree angle, 30 projections and 30 sec of each acquisition. Afterwards, technician subtracted myocardial stress images from rest images with arithmetic software installed as standard and reconstructed true rest images. ***Results:*** Pharmacologically induced stress test took 6 min. After 30 min, myocardial SPECT stress scan was performed for 10 min. CT scan was performed for 2 min. Myocardial SPECT rest scan took 8 min. Overall $^{99m}$Tc-MIBI myocardial perfusion SPECT/CT subtraction protocol was completed within 56 min. ***Conclusion:*** $^{99m}$Tc-MIBI myocardial perfusion SPECT/CT single isotope subtraction protocol with CZT gamma camera is expected to reduce overall examination time within an hour, which will increase the patient's satisfaction, be more useful for patients who have difficulty in examination for a long time, and improve the efficiency of equipment usage. ***References:*** Heiba Sherif I ,Hayat Nasser J ,Salman Hani S ,Higazy Ezzat,Sayed Mohammed E ,Saleh Zuhair,Khalaf Ali I ,Naeem Mohammed,Bourosly Suhair. ## TEPS-015

### Validation of Diagnostic Accuracy for Primary Aldosteronism with Quantitative Adrenal SPECT: Comparison with Adrenal Venous Sampling

***T. Sato***[1], *N. Matsutomo*[2], *T. Yamamoto*[2], *M. Fukami*[2], *T. Kono*[3];
[1]*Chiba Aoba Municipal Hospital, Chiba, JAPAN,* [2]*Kyorin University, Tokyo, JAPAN,* [3]*Chiba University, Chiba, JAPAN.*

***Aim/Introduction:*** The type of disease that cause primary aldosteronism (PA) is characterized by lateralization of adrenal hormone secretion. Adrenal venous sampling (AVS) is the gold standard test for differentiating them and determining the course of treatment, meanwhile it is invasive and can fail at times. This study aimed to evaluate the diagnostic accuracy for PA with the maximum and mean standardized uptake values (SUVmax and SUVmean) on $^{131}$I-6B-iodomethyl-19-norcholesterol (NP-59) single-photon emission computed tomography (SPECT) and compared with AVS in clinical study to verify whether it can be established alternatively. ***Materials and Methods:*** Adrenal NP-59 SPECT was acquired under the optimized image parameters determined by preliminary phantom experiment using Symbia Intevo in 14 patients with suspected PA. In addition, AVS was also performed in 7 of them. SPECT images using two-way reconstruction method were analyzed with region of interest to measure the adrenal lesion SUVmax and SUVmean and their ratios to the values on the contralateral side (SUVRmax and SUVRmean). ***Results:*** SUVmax and SUVmean on NP-59 SPECT images using the ordered-subset conjugate gradient minimization (OSCGM), a high-resolution reconstruction algorithm, were significantly higher for aldosterone-producing adenoma (APA) than for bilateral adrenal hyperplasia (BAH) or nonfunctioning adenoma (P=0.0475 and P=0.0447). The areas under the receiver-operating characteristic curve for SUVmax and SUVmean were the same 0.933 with OSCGM and 0.844 with the three-dimensional ordered-subset expectation maximization (3D-OSEM), while SUVRmax and SUVRmean were the same 0.725 with OSCGM and 0.750 with 3D-OSEM. Quantitative SPECT improved PA diagnostic accuracy over visual inspection. The lesion SUVmax and SUVmean were higher than on the contralateral side, and SUVRmax and SUVRmean were higher than 1.0 in 5 of the 6 cases (except one patient with bilateral APA) in which the aldosterone concentration on the lesion side or the lateralized ratio exceeded the cutoff value on AVS. Additionally, both SUV and aldosterone concentration of AVS on the side with the lesion were higher for APA than for BAH. ***Conclusion:*** SUV and SUVR of NP-59 SPECT with OSCGM algorithm appear to hold promise as indices for PA diagnosis. Furthermore, SUV and SUVR were associated with the diagnostic features on AVS and consistent with lateralization of adrenal hormone secretion by AVS in most patients. Quantitative adrenal SPECT can be an alternative to AVS. ***References:*** Yen RF, Wu VC, Liu KL, et al. 131I-6beta-iodomethyl-19-norcholesterol SPECT/CT for primary aldosteronism patients with inconclusive adrenal venous sampling and CT results. ## TEPS-016

### Image characteristics of $^{99m}$Tc myocardial perfusion SPECT/CT using a new multi-focal collimator: comparison with conventional SPECT with LEHR collimator

***K. Takami***[1], *M. Onoguchi*[1], *T. Shibutani*[1], *A. H. Vija*[2], *F. Massanes*[2], *T. Shimizu*[2], *H. Yoneyama*[3], *T. Konishi*[3], *K. Nakajima*[4];
[1]*Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa Japan, Kanazawa, JAPAN,* [2]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA,* [3]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa Japan, Kanazawa, JAPAN,* [4]*Department of Functional imaging and Artificial Intelligence, Kanazawa University, Kanazawa Japan, Kanazawa, JAPAN.*

***Aim/Introduction:*** A multi-focal collimator for SPECT imaging with a suitable high resolution and extended magnification volume (SZHRX) was used in cardiac, neurologic, and orthopedic applications. We evaluated the characteristics of myocardial perfusion imaging with the SZHRX collimator to compare with low-energy high-resolution (LEHR) collimator. ***Materials and Methods:*** A Symbia Intevo 16 (Siemens Healthineers) SPECT/CT system was used and equipped with LEHR and SZHRX collimators. An anthropomorphic phantom was filled with 99mTc. The radioactive concentration ratio between myocardium, liver and background was set to 14:8:1. Normal myocardium and inferior defect myocardium were used as myocardial models. Traditional SPECT data with LEHR collimator was acquired with 64×64 matrixes, 1.45 zoom, 6.6mm pixel size, with a circular body centered orbit radius of 24cm, and angular step of 6 deg. Subsequently. SPECT data with SZHRX collimator was acquired with 256×256 matrixes, 2.4mm pixel size, with a circular body centered orbit radius of 26 and 28cm, and continuous mode. Image reconstruction of the SPECT data with LEHR collimator was used Flash3D and SZHRX collimator was used a prototype quantitative xSPECT using the ordered subset conjugate gradient minimizer (OSCGM) including attenuation, scatter, and resolution corrections. A Gaussian filter with a full width at half-maximum of 10 mm was used as a post filter. For physical analysis, %CV and %uptake used 17 segments of polar map, and contrast was calculated for normal myocardium. The %uptake for defect myocardium used circumferential profile curve. ***Results:*** The %CV for LEHR and SZHRX collimator with the radius of 26 cm and 28 cm was 5.6%, 8.7% and 8.8% respectively. The %CV for xSPECT with SZHRX collimator was equivalent to traditional SPECT with LEHR collimator. The contrast for LEHR and SZHRX collimator with the radius of 26 cm and 28 cm was 53.2%, 78.1% and 77.5%. The contrast for SZHRX collimator was higher values than that of the LEHR collimator. The defect %uptake for LEHR and SZHRX collimator in the radius of 26 cm and 28 cm was 39.1%, 26.8%, and 32.3% respectively. ***Conclusion:*** The %CV for SPECT image using the new multi-focal SZHRX collimator was equivalented to the traditional LEHR collimator, and the contrast for SZHRX collimator was higher than that for LEHR. Then, the defect detectability for the SZHRX collimator was superior to that for LEHR.

## TEPS-017

### The effect of data-driven respiratory gating on myocardial SPECT

***T. Shibutani***[1], *M. Onoguchi*[1], *A. H. Vija*[2], *F. Massanes*[2], *T. Shimizu*[2], *H. Yoneyama*[3], *T. Konishi*[3], *K. Nakajima*[4];
[1]*Department of Quantum Medical Technology, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Ishikawa, JAPAN,* [2]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA,* [3]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa, Ishikawa, JAPAN,* [4]*Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa, Ishikawa, JAPAN.*

***Aim/Introduction:*** A cardiac study often exhibits motion, which affects the image quality and quantitation of myocardial single-photon emission computed tomography (SPECT). While data-driven respiratory gating (DDG) correction is clinically established in positron emission tomography, data-driven methods for SPECT scans have not yet been clinically adopted. We demonstrated the effect of DDG on myocardial SPECT. ***Materials and Methods:*** A SPECT/CT scanner (Symbia Intevo 16, Siemens Healthneers) with a low-energy high-resolution collimator was used. Two myocardial models of normal myocardium and anterior wall infarction were created using an anthropomorphic myocardial phantom. The myocardial, liver, and background areas were filled with $^{99m}$Tc solutions of 93, 53 and 6.6 kBq/mL. The SPECT data was acquired with 256 matrices, 2.4 mm pixel size, with non-circular orbit and 3 deg sampling angular step using list-mode. The anthropomorphic myocardial phantom was moved in a cycle at a steady speed to simulate respiratory motion, with a respiratory rate of 18 breaths/min and movement distances of ±0.5, ±1, and ±1.5 cm, respectively. A stationary myocardial phantom was acquired as a reference. The projection data was reconstructed by the ordered subset conjugate gradient method with attenuation and scatter corrections using a prototype reconstruction engine. Subset and iteration were set at 1 and 48, and a Gaussian filter of the full width at half maximum (FWHM) was applied as a post-filter. We created two images with and without DDG correction. Cavity contrast, percent coefficients of variance (%CV), %uptake and wall thickness with FWHM of normal myocardial model and the %uptake of anterior wall defect model were used to compare with and without DDG correction. ***Results:*** The %uptake of normal myocardium was decreased by 4-8% in the anterior wall and 10~20% in the inferior wall more than ± 1 cm compared with the reference. Cavity contrast and %CV of movement distance ±1.5 cm was approximately 40% decreasing and 5% increasing compared with the reference. The %uptake, cavity contrast and %CV were improved by DDG correction. The FWHM of anterior and inferior walls was higher with increasing movement distances without DDG correction. While the FWHM of DDG correction showed constant values independent of movement distance. ***Conclusion:*** The influence of respiratory motion on myocardial SPECT was particularly severe for motion exceeding ±1 cm, which improved the image quality and physical indices by DDG correction.

## TEPS-018

### High dose adenosine overcomes the effect of caffeine intake in Rubidium PET perfusion

***B. Ribeiro***, *S. Townrow, C. Pacheco, C. Lopez Martinez, E. Reyes, L. Menezes;*
*Barts Health NHS Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** Caffeine reduces the vasodilatation effect of adenosine stress in myocardial perfusion imaging (MPI). Almost 10% of patients may be under-stressed (Manisty et al. Radiology 2015). High dose adenosine overcomes caffeine antagonism (Reyes et al. JACC 2008). This study sought to confirm its effectiveness in practice in Rubidium PET perfusion. ***Materials and Methods:*** A retrospective review of the department database to identify patients who received 210 mcg/kg/min adenosine, over 4 years, due to recent caffeine ingestion. Tolerability, conduction abnormalities, the haemodynamic effects, any reduction of splenic counts during stress, normalcy rates, and global myocardial flow reserve, were recorded. ***Results:*** 142 out of 4972 patients were identified on the 210 mcg/kg/min adenosine protocol. 111 were male, 31 female, with mean age 66.3 ± 11.7. Only one patient was

unable to tolerate the 6 minute of adenosine infusion due to side effects, while minor and well tolerated side effects were reported in all the other patients. There were no sustained episodes of AV block. Heart rate increased by 19.2 ± 14.8 bpm. Systolic BP decreased by 9.0 ± 21.5 mmHg and diastolic BP decreased by 4.9 ± 16.6 mmHg. The spleen was included in the FoV in 100% of patients. There was a reduction in splenic uptake in 96.5% of studies. The global myocardial flow reserve was 2.22 ± 0.86, 59.9% patients had a global MFR of >2. ***Conclusion:*** High dose adenosine is safe and well tolerated and overcomes the antagonist effects of caffeine as evidenced by a reduction in splenic uptake, and an average global MFR>2. The haemodynamic effects are modest. It can be reliably used in PET MPI and by extension in SPECT MPI, rather than cancelling or rebooking a patient who has ingested caffeine.

## TEPS-019

### Dose reduction for nuclear medicine technicians through implementation of automated dispensing and infusion devices: a retrospective study

***E. Hendrikse***, *W. Huisman, J. Medema, P. H. Elsinga, A. T. M. Willemsen;*
*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Over the last years the number of Positron Emission Tomography (PET) procedures in the department of Nuclear Medicine and Molecular Imaging (NGMB) of the University Medical Center Groningen (UMCG) has risen. The dose report of Mirion Dosimetry Services reported an increasing whole-body and extremity dose of personnel as a possible result of the increasing number of procedures. Shielded automated dispensing and infusion devices have recently been introduced. Unlike manual preparation and injection, these automatic devices offer the technicians more protection against radiation exposure and allow them to keep more distance during the procedures. The aim of the study was to evaluate the effect of an automatic syringe dispensing and injection system on the whole-body and extremity dose of technicians compared to manual dispensing and injection. ***Materials and Methods:*** The whole-body and extremity dose per four weeks (one period) for all personnel working at the PET were measured with ring and badge dosimeters and compared between four periods of manual (12-08-2019 to 08-12-2019) and four periods of automatic (16-08-2021 to 5-12-2021) dispensing and injection. ***Results:*** The mean whole-body dose rate was not significant different between the periods of automatic and manual dispensing and injection (p=0,236). However the extremity dose rate reduced from 35,72 ± 39,84 µSv/h to 9,97 ± 8,97 µSv/h (p<0,001). ***Conclusion:*** The use of an automatic syringe dispensing and injection system resulted in a 72,1 ± 40,8% reduction of the extremity dose. At the same time the whole-body dose did not change. Additional investments are needed to further reduce the whole-body dose for technicians.

## TEPS-020

### A comparative study regarding deep inhalation breath-hold and free-breathing total-body PET/CT with half-dose [18F]-FDG

***J. Jia***, *K. Yuan, M. Liu, Y. Cui, S. Tang, C. Zhou, W. Zhang;*
*Sun Yat-Sen University Cancer Center, Department of Nuclear Medicine, Guangzhou, Guangdong, China., Guangzhou, CHINA.*

***Aim/Introduction:*** To compare the image quality and diagnostic efficacy between 30-seconds deep inspiration breath-hold (DIBH) PET/CT 8 min and free-breathing (FB) using a total-body PET-CT (uEXPLORER) with half-dose [18]F-FDG. ***Materials and Methods:*** From July 2022 to February 2023, 19 patients with suspected or confirmed upper abdominal malignancies who underwent half-dose (0.05mCi/kg) [18]F-FDG PET/CT in Sun Yat-sen University Cancer Center were enrolled. They underwent a 30-seconds DIBH PET/CT quick scan after a FB 8 min total-body PET-CT scanning. PET images of FB-8min, FB-30s, and DIBH-30s were reconstructed, and the SUVmax of the liver, spleen, bone marrow, mediastinal blood pool, upper lung, and lower lung were measured as background reference. Distances of the hepatic dome of PET and CT were used as quantitative measurements for image registration of FB-8min, FB-30s, and DIBH-30s, respectively. We measured the lesion center offset, SUVmax, SUVmean, SUVpeak, MTV, and TBR in a free-breathing scan and DIBH quick scan. ***Results:*** DIBH scanning was successfully performed in 16 of 19 cases, a total of 43 lesions were detected in 19 patients. 37 (86%) lesions' PET and CT were well aligned. There was no significant difference in SUVmax of the liver, spleen, bone marrow, and mediastinal blood pool of PET between the FB-30s group and DIBH-30s group, and both were higher than that of FB-8min. For upper abdominal lesions: the focal center deviation (mm) of DIBH-30s vs. FB-30s vs. FB-8min was 1.67±2.35 vs. 4.66±3.43 vs. 4.43±3.27. DIBH-30s showed a significantly lower focal center deviation compared with the other groups (p<0.001). The SUVmax of DIBH-30s vs. FB-30s vs. FB-8min was 11.05±3.36vs. 8.99±3.14vs. 8.39±2.93, DIBH-30s was significantly higher than other groups (p<0.001). The MTV value of DIBH-30s vs. FB-30s vs. FB-8min was 0.69±0.90 vs. 0.80±0.99 vs. 0.84±1.05, where the DIBH-30s was significantly lower than other groups (p<0.05). The TBR of DIBH-30s vs. FB-30s vs. FB-8min was 4.15±1.26 vs. 3.40±1.20 vs. 3.47±1.28, DIBH-30s was significantly higher than other groups (p<0.001). ***Conclusion:*** Compared to routine free-breathing PET-CT, DIBH PET/CT can effectively improve PET-CT registration of the lesion, and improve the semi-quantitative measurements. Half-dose 18F-FDG breath-hold PET/CT is feasible in clinical practice and may increase diagnostic confidence for abdominal lesions.

## TEPS-021

### Developments in Radiochemical Processing of Solid Targets for Radiopharmaceuticals Production

*G. Sciacca[1], P. Martini[2], S. Cisternino[1], L. Mou[1], G. Balajan[1], J. Amico[3], J. Esposito[1], G. Gorgoni[3],* ***E. Cazzola[3];***
*[1]INFN-LNL, Legnaro, ITALY, [2]University of Ferrara, Ferrara, ITALY, [3]Sacro Cuore Don Calabria Hospital, Negrar di Valpolicella, ITALY.*

***Aim/Introduction:*** Accelerator-produced radiometals are growing in importance in nuclear medicine applications. In this regard, for their efficient production solid precursor materials are usually preferred. However, this implies the need to properly manage the target dissolution process for radioisotope recovery. For this purpose, various systems based on a patent by INFN (Italian National Institute for Nuclear Physics) have been developed by our research group to perform this operation with automated synthesis modules. This was done in the framework of a collaboration between the LARAMED (LAboratory of RAdionuclides for MEDicine) project of INFN, the radiopharmacy department of the Sacro Cuore Don Calabria Hospital (Negrar, VR), and the radiochemistry laboratories of the Ferrara University. ***Materials and Methods:*** The developed reactors consist of an open-bottom vial, installed on one of the module's motors for syringe plungers via a frame connection system, and a target holder designed to be plugged into the module's reactor heater. For target processing, once the irradiated target is placed on

its holder, the vial is pressed over it by the module's motor to confine the chemical attack by means of an interposed O-ring. To guarantee adequate sealing, the connecting system is engineered to automatically correct any misalignment between the vial and the target. ***Results:*** This reactor configuration allows to remotely perform all the synthesis operations in a single hot cell and to selectively dissolve only the precursor material if a composite target with an inert interlayer is used. It has been successfully tested with various modules by different brands in radioisotope recovery and radiopharmaceutical synthesis operations. The simplicity of this system has paved the way for the ongoing STarDiS (Solid Target Dissolution System) project, funded by the INFN National Committee for Technology Transfer (CNTT) to develop a prototype for production routine in good manufacturing practice environments. ***Conclusion:*** A new concept of solid target dissolution reactor is here proposed. It allows the use of automatic modules for rapid, cheap, and easy integration in radiopharmaceutical facilities already equipped for radioisotope recovery from solid targets. ***References:*** 1) G.Sciacca et al., Molecules. 2021 26. 6255. 2) V.Palmieri et al., WO/2019/053570, 7 September 2018. 3) J.Esposito et al., Molecules. 2018 Dec 21; 24(1):20.

**Feasibility of $^{177}$Lu-PSMA-617 radioligand therapy in a patient with recurrent high-grade glioma**

***A. Holzgreve***[1], *A. Delker*[1], *V. Wenter*[1], *M. J. Zacherl*[1], *N. Thon*[2], *P. Harter*[3], *M. Brendel*[1], *L. M. Unterrainer*[1], *M. Niyazi*[4], *P. Bartenstein*[1], *L. von Baumgarten*[2], *N. L. Albert*[1];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Center for Neuropathology and Prion Research, LMU Munich, Munich, GERMANY,* [4]*Department of Radiation Oncology, University Hospital, LMU Munich, Munich, GERMANY.*

***Aim/Introduction:*** $^{177}$Lu-based radioligand therapy (RLT) targeting the prostate-specific membrane antigen (PSMA) is a well-established treatment for advanced prostate cancer (PCa) and has been approved in 2022 by both the FDA and EMA. Although other tumour entities also overexpress PSMA and an application of PSMA-RLT has been continuously propagated for those entities, it has scarcely been performed beyond PCa. Here, we present preliminary data on PSMA-RLT in a glioma patient. ***Materials and Methods:*** A 31-year old patient with anaplastic oligodendroglioma, IDH-mutant, 1p/19q-codeleted, CNS WHO grade 3 presented for a re-recurrence. The initial diagnosis had been made 13 years earlier, and the patient had undergone multiple prior treatments including repeated resections, chemoradiotherapy with concomitant temozolomide, interstitial brachytherapy, a combination of lomustine and olaparib, and others. In view of the repeated recurrences and a lack of established further therapy lines, the interdisciplinary tumour conference made a decision to evaluate and perform PSMA-RLT under compassionate use in compliance with §13.2b of the German Medicinal Products Act (AMG). Pre-therapeutic PET imaging showed increased tumoral PSMA-radioligand uptake. There were no contraindications including sufficient kidney function and bone marrow reserve. ***Results:*** 7912 MBq of $^{177}$Lu-PSMA-617 were intravenously injected. The patient received concomitant prophylactic dexamethasone. There were no immediate adverse events of PSMA-RLT, the treatment was well tolerated. Post-therapeutic 2-bed position SPECT and low-dose CT scans of the head, neck, thorax, and upper abdomen were performed at 3h, 24h, 48h, 5d, and 7d p.i., and used for dosimetry analyses, values were not recovery-corrected. The tumor volume was 1.9 ml, mean tumor dose was 1.34 Gy. A focally increased tumoral uptake was found until 7 days p.i. Mean dose in the kidneys was 1.87 Gy, in the parotid glands 0.85 Gy and in the submandibular glands 0.80 Gy. Continuous follow-up over 5 weeks showed no adverse events, a second cycle was planned. ***Conclusion:*** As shown by this preliminary data, the dose of $^{177}$Lu-PSMA-617 in organs-at-risk in a patient with high-grade glioma was not superior to those known for patients with advanced PCa, despite the significantly lower total tumour volume compared to advanced PCa. $^{177}$Lu-PSMA-617 showed a prolonged retention in the tumor. The tumor dose was low compared to PCa and a previously reported glioblastoma case, however the association between dose and efficacy in glioma deserves further consideration, and may encompass immunological mechanisms of action. More data are warranted to evaluate safety and efficacy of $^{177}$Lu-PSMA-RLT in glioma.

### OP-468

**First-In-Human CXCR4 & FAP Instillation Theranostics in Muscle invasive bladder cancer patients predicted not to respond to Neoadjuvant chemotherapy within the Bladder BRIDGister.**

***Aim/Introduction:*** Patients with muscle invasive urothelial carcinoma (MIBC) achieving pathological complete response (pCR) upon neoadjuvant chemotherapy (NACT) have improved prognosis. CXCR4 and FAP is found in chemoresistant, stroma-associated MIBC. This study aimed to prospectively validate the predictive value of molecular target typing and to assess CXCR4 & FAP radioligand instillation imaging and therapy in selected patients of the „Bladder BRIDGister". ***Materials and Methods:*** Formalin fixed paraffin embedded (FFPE) tissues from transurethral resections (TUR) before chemotherapy and cystectomy samples after NACT of 36 patients were retrospectively

collected and 650 TURB samples were prospectively collected as part of the Bladder BRIDGister. RNA from FFPE tissues were extracted by commercial kits, relative gene expression of subtyping markers (KRT5, KRT20, FGFR1) and radioligand target genes (CXCR4, FAP) were analyzed by standardized RT-qPCR systems (STRATIFYER Molecular Pathology GmbH, Cologne). PET/CT Imaging by $^{68}$Ga-CXCR4 instillation was performed after completion of cisplatinum based NACT. $^{177}$Lu-FAP treatment was performed subsequently by instillation +/- systemic application. ***Results:*** The retrospective NACT cohort consisted of 36 patient (median age: 69, male: 83%). Hierarchical clustering revealed that CXCR4 and FAP are elevated in stromal rich, KRT5 & KRT20 negative tumors not responding to NACT. Elevated FAP above mdian mRNA expression was significantly associated with resistance to NACT (chi$^2$ 4.314 p=0,0378). Combining elevated FAP and CXCR4 mRNA expression did identify 28% of the patients to be at high risk of NACT resistance (90%). TUR biopsies from MIBC patients undergoing NACT were molecularly analyzed for subtype and radioligand expression. Exemplarily one pT2 G3 MIBC patient was selected for PET/CT imaging after two cycles that was predicted to be unresponsive to NACT. As CXCR4 radioligand imaging is associated with hematologic toxicity we instilled $^{68}$Ga CXCR4 and did see tumor specific uptake into the chemotherapy-resistant MIBC invading the adjacent soft tissue. Subsequent instillation and systemic therapy cycles with $^{177}$Lu-FAP also revealed strong uptake into the invading MIBC and a newly developed cancer site within the bladder. ***Conclusion:*** We show that the mRNA expression of the radioligand targets CXCR4 and FAP in TURB tissue of MIBC patients is associated with aggressive, stromal-like tumors not responding to neoadjuvant chemotherapy. This could be validated by selecting patients for FAP & CXCR4 PET/CT and imaging of resistant tumor residues invading surrounding soft tissue. Instillation of radioligands into the bladder revealed to be safe and effective for imaging and therapy of patients being unresponsive to standard therapies.

## OP-469

### Dual-tracer PET/CT imaging in response assessment to peptide receptor radionuclide therapy - a case report

***I. Próspero***, *G. Ferreira, J. C. Ferro, D. Barbosa, D. G. Silva, S. Fontão de Castro, J. P. Teixeira, H. Duarte, I. Lucena Sampaio; Instituto Português de Oncologia do Porto, Porto, PORTUGAL.*

***Aim/Introduction:*** Dual-tracer positron emission tomography/computed tomography (PET/CT) using 2-[$^{18}$F]FDG PET/CT combined with somatostatin receptor (SSTR) PET/CT identifies tumor heterogeneity in neuroendocrine neoplasms (NENs), providing prognostic information and allowing optimal therapeutic decision. Nevertheless, standardized criteria for its selective use in NENs assessment before and after peptide receptor radionuclide therapy (PRRT) are not yet established. ***Materials and Methods:*** We report a case of a 63-year-old man with an asymptomatic Grade 2 (G2) Pancreatic Neuroendocrine Tumour (Pan-NET) with hepatic metastasis, diagnosed in 2011. He underwent a distal pancreatectomy and splenectomy in 2012, three procedures of embolization with polyvinyl alcohol (PVA) between 2011 and 2014, three cycles of PRRT with [$^{177}$Lu]Lu-DOTATATE in 2016, and has been under long-acting somatostatin analogue therapy since 2013. The disease was considered stable for almost 4 years after PRRT. Due to new hepatic lesions detected in [$^{68}$Ga]Ga-DOTANOC PET/CT in 2020 and 2021, the patient was referred for a PRRT retreatment (consisting of 2 cycles of 7400 MBq each), which he completed in December 2021. ***Results:*** The evaluation of treatment response in a [$^{68}$Ga]Ga-DOTANOC PET/CT performed two months later showed a decrease in the number of hepatic lesions expressing SSTR relatively to the imaging acquired before PRRT retreatment. A 2-[$^{18}$F]FDG PET/CT carried out two weeks afterwards demonstrated two lesions DOTANOC-negative/FDG-positive and one lesion DOTANOC-positive/FDG-positive, with the remaining hepatic metastasis classified as DOTANOC-positive/FDG-negative. An abdominal MRI (Magnetic Resonance Imaging) acquired nine months after the last PRRT cycle confirmed disease progression. The patient remained asymptomatic. It was then decided to treat the liver metastasis with transarterial embolization, which was performed in January 2023. ***Conclusion:*** The results suggest that functional imaging response assessment to PRRT by SSTR PET/CT alone may not be sufficient in some metastatic NENs. Furthermore, disease characterization before PRRT retreatment could have been performed with 2-[$^{18}$F]FDG PET/CT, additionally to SSTR PET/CT, since histological grade may have evolved over time from the first biopsy, developing a more aggressive disease pattern, which could eventually change treatment choice. Therefore, this case highlights the role of dual-tracer PET/CT imaging in NENs, particularly in the context of PRRT retreatment, with the potential for a better optimization of treatment decision and response evaluation.

## OP-470

### Bone-Marrow dosimetry with 177Lu-DOTATATE treatment in a hemodialysis patient.

***S. CHAIB***[1,2], *P. Tylski*[1], *C. Lachachi*[1], *T. Keniza*[1], *E. Levigoureux*[1,2]; [1]*Hospices Civils de Lyon, Lyon, FRANCE,* [2]*Claude Bernard Lyon 1 University, Lyon Neuroscience Research Center, CNRS, INSERM, Lyon, FRANCE.*

***Aim/Introduction:*** The main excretion for the 177Lu-DOTATATE targeted therapy is renal. Consequently doses to organs at risk for hemodialysis patients may be higher, but there is no recommendation to adapt the prescribed activity. In absence of nephrotoxicity, the bone marrow is the primary organ at risk. This case study details a hemodialysis-dependant patient with a metastatic neuroendocrine tumor treated with 177Lu-DOTATATE. ***Materials and Methods:*** A 63-year-old female patient with stage V chronic renal failure was hospitalized for 3 days to receive an injection of 3700 MBq of 177Lu-DOTATATE. Two hemodialysis sessions were performed at day +1 and day +3 post-injection. Seven whole blood samples were collected during the stay and counted in duplicate. During this period, five whole-body images were acquired and a SPECT/CT scan was acquired 3 hours after the start of injection. The 177Lu-DOTATATE elimination and the dose to the bone marrow were estimated using two methods, one based on blood counts and another based on planar imaging (1) , distinguishing between low- and high-uptake compartments. Additionally, measurements for radiation protection were taken for medical staff and the environment. ***Results:*** During the first dialysis, 177Lu removed was 76% and 41% in blood for the 2nd dialysis session. The estimated number of disintegrations in the bone marrow compartment was 0.71 MBq.h/MBq using the image-based method and 0.97 MBq.h/MBq using the blood based method. The corresponding absorbed dose to the bone marrow was 0.66 Gy and 0.74 Gy using the two methods respectively, corresponding to doses per injected activity of 185 and 207 mGy/MBq. The dose rate measurements taken from the patient during the period between injection and discharge ranged from 400 to 266 µSv/h at contact and 14.1 to 6.5 µSv/h at 1 meter away. The operational dosimeters worn by the dialysis

nurses recorded doses of 19 µSv and 16 µSv during the first and second hemodialysis sessions, respectively. ***Conclusion:*** The mean doses estimated are below the toxicity threshold of 2 Gy for the bone marrow suggesting a safe administration for hemodialysis patients although the estimated doses are higher than those typically reported for patients without renal failure (between 2 and 150 mGy/MBq). ***References:*** 1. Svensson, J. et al. A novel planar image-based method for bone marrow dosimetry in 177Lu-DOTATATE treatment correlates with haematological toxicity. EJNMMI physics 3, 1-12 (2016).

## OP-471

### Evaluation of the potential use of [$^{18}$F]F-Al-NOTA-Octreotide as a theranostic probe for PRRT with [$^{177}$Lu]Lu-DOTA-TATE compared to [$^{111}$In]In-DTPA-Pentetreotide

***B. A. M. Lima****, R. C. M. Felix, D. A. Bulzico, P. B. Pujatti;*
*Brazilian National Cancer Institute, Rio de Janeiro, BRAZIL.*

***Aim/Introduction:*** To evaluate uptake sites in [$^{18}$F]F-Al-NOTA-Octreotide PET/CT and [$^{111}$In]In-DTPA-Octreotide SPECT/CT of a 49 years old female patient submitted to [$^{177}$Lu]Lu-DOTA-TATE. Initially submitted to enterectomy after intestinal obstruction in 2017 with intraoperative mesenteric mass and liver nodules. Pathology study revealed a G2 neuroendocrine tumour (Ki67 of 10%). Liver disease progression was observed in conventional imaging methods two years later and the patient was submitted to liver metastasectomy and retroperitoneal lymphadenectomy. After this second surgery [$^{111}$In]In-DTPA-Octreotide scan showed one focal liver uptake (Krenning 3). Asymptomatic, she lost follow-up, returning in July 2022 referring flushing and dhiarrhoea. New [$^{111}$In]In-DTPA-Octreotide scan abnormal focal uptakes were noticed in the liver and in a supraclavicular lymph node (Krenning 3) and long acting somatostatin analogue therapy was introduced. Imaging control exams were performed in December 2022 including a new [$^{111}$In]In-DTPA-Octreotide that revealed two new mesenteric foci. After tumour board discussion, the patient was referred to peptide receptor radionuclide therapy (PRRT) with [$^{177}$Lu]Lu-DOTA-TATE. ***Materials and Methods:*** As our Institution is conducting a clinical trial comparing [$^{18}$F]F-Al-NOTA-Octreotide PET-CT with [$^{111}$In]In-DTPA-Octreotide SPECT-CT in the context of cost-effectiveness of somatostatin-receptor imaging in a Public Health System of a developing country, she was invited to participate, conceived formal consent and prior to PRRT was submitted to PET-CT scan 90 minutes after i.v. injection of 4.4 MBq/kg of [$^{18}$F]F-Al-NOTA-Octreotide. ***Results:*** PET/CT showed uptake in three hepatic lesions (SUVmax 25,1), the supraclavicular lymph node (SUVmax 17,2) and others lymph nodes in paraesophageal, retroperitoneal, paraortic and mesenteric regions (SUVmax of 8,4, 7,2 and 4,4, respectively), and two pancreatic foci (SUVmax 14,4). So far, she has been submitted to two cycles of 7.4 GBq of [$^{177}$Lu]Lu-DOTA-TATE and the post-PRRT scans shows uptake in one hepatic lesion, the supraclavicular and two mesenteric lymph nodes and one discrete uptake in the mid paraesophageal lymph node observed in PET-CT. ***Conclusion:*** This case report shows that not only the same lesions with somatostatin receptor expression in [$^{111}$In]In-DTPA-Octreotide SPECT/CT were observed in the post-PRRT scans but also in [$^{18}$F]F-Al-NOTA-Octreotide PET-CT, a new probe with suitable pharmacokinetics and high somatostatin receptor affinity[1] suggested to be able to outperform current gold standard [$^{68}$Ga]Ga-DOTA-TATE[2], indicating its adequate use for theranostics purpose. ***References:*** 1.Laverman P, et al. A novel facile method of labeling octreotide with (18)F-fluorine. ## OP-472

### Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTA-TATE in the treatment of malignant insulinoma: a case report of remarkable clinical and imaging response

***D. Barbosa****, H. Duarte, A. Paula Santos, J. Ferro, I. Próspero, D. Silva, S. Gil-Santos, R. Calheiros, S. Fontão de Castro, G. Ferreira, J. P. Teixeira, I. Lucena Sampaio;*
*Portuguese Institute of Oncology, Oporto, PORTUGAL.*

***Aim/Introduction:*** Malignant insulinomas are a rare type of functional pancreatic neuroendocrine tumors (panNETs), often associated with high morbidity and mortality, mainly due to life-threatening hypoglycemic episodes. Since studies on its therapeutic algorithm are scarce, we present the case of a patient with malignant insulinoma treated with PRRT just 4 months after diagnosis. ***Materials and Methods:*** A 78 year-old woman with apparently non-functional metastatic panNET G2 performed a [68Ga]68Ga-DOTA-Somatostatin Analog Positron Emission Tomography/Computed-Tomography ([68Ga]68Ga-DOTA-SSA-PET/CT) revealing high somatostatin receptors (SSTRs) expression in pancreatic body/tail, in a celiac lymph node and in several hepatic lesions. 2-[18F]fluoro-2-desoxi-D-glucose PET/CT (2-[18F]FDG-PET/CT) was also performed and didn´t reveal discordant lesions (FDG+;SSTR-). Careful review of symptoms at our Institute revealed episodes of nocturnal sweating and dizziness. Symptomatic hypoglycemia and endogenous hyperinsulinism due to malignant insulinoma was confirmed (elevated insulinemia, proinsulin and C-peptide). Therapy with sub-cutaneous 100mcg octreotide was introduced. Due to worsening of hypoglycemic episodes, lanreotide was added every 28 days and octreotide frequency was increased. Given the high expression of SSTRs in most lesions and the rapid onset of symptoms, the patient underwent 4 cycles of PRRT with [177Lu]Lu-DOTA-TATE with an interval of 8-10 weeks (cumulative activity: 29,6GBq). ***Results:*** Just 10 days after the first cycle of PRRT, the patient showed significant clinical improvement with only 2 episodes of hypoglycemia; in 1 month, octreotide was discontinued and C-peptide and insulin values reverted to normal. After the second cycle, the patient normalized the number of daily meals (4-5) and revealed a great improvement in symptoms. Ten weeks after fourth PRRT cycle, the patient remained without hypoglycemic crises with grade 1 hematological toxicity. Abdominal reassessment CT (3 months after fourth PRRT cycle) revealed a decrease in number and lesion size. [68Ga]68Ga-DOTA-SSA-PET/CT performed 6 months after the end of treatment (13 months after the first cycle and 17 months after diagnosis) revealed a decrease in the extent of radiopharmaceutical uptake in the pancreas and the disappearance of uptake in most liver lesions and in the celiac lymph node. Currently, 20 months after diagnosis, the patient remains under follow-up, asymptomatic, with a clear improvement in her quality of life and a persistent tumor burden reduction in imaging studies. ***Conclusion:*** The optimal time to initiate PRRT in malignant insulinomas is still up for debate. This case supports that PRRT is safe and can be considered as a second-line treatment for progressive malignant insulinomas. More studies, with larger samples, are required.

## OP-473

### Peptide receptor radionuclide therapy as neoadjuvant treatment in pancreatic neuroendocrine tumours

***I. Próspero***, *G. Ferreira, J. C. Ferro, D. Barbosa, D. G. Silva, S. Fontão de Castro, J. P. Teixeira, H. Duarte, I. Lucena Sampaio; Instituto Português de Oncologia do Porto, Porto, PORTUGAL.*

***Aim/Introduction:*** In pancreatic neuroendocrine tumours (Pan-NETs), peptide receptor radionuclide therapy (PRRT) is traditionally recommended in unresectable or metastatic, progressive disease, after failure of other systemic therapies. Therefore, its role as a neoadjuvant treatment is not yet established in current treatment guidelines. ***Materials and Methods:*** A 52-year-old man, presenting with weight loss, was diagnosed in 2017 with a Grade 2 (G2) Pan-NET through radiological studies and a biopsy. The lesion, measuring 60 x 58 mm in the axial plane, was located in the pancreatic head, causing dilation of the main pancreatic duct, and had extensive contact with the superior mesenteric vein and the inferior vena cava; hence, invasion of these structures could not be excluded. Staging through [$^{68}$Ga] Ga-DOTANOC PET/CT and 2-[$^{18}$F]FDG PET/CT revealed intense uptake of [$^{68}$Ga]Ga-DOTANOC [maximum standardized uptake value (SUVmax)= 76,9] and moderate glycolytic metabolism (SUVmax= 4,0), with no evidence of metastasis. The tumour was considered potentially unresectable, and the patient was referred for PRRT, with the objective of reducing the tumour volume and subsequent reevaluation of the feasibility of a surgical approach. ***Results:*** The patient underwent three cycles of PRRT with [$^{177}$Lu] Lu-DOTATATE (7400 MBq per cycle; 12 weeks between cycles) from March to September 2018, with no clinically significant toxicity. He started long-acting somatostatin analogue therapy in the following month. Restaging through morphologic imaging (three months after completing PRRT) revealed a reduction in the tumour size to 48 x 44 mm (-20% in the longest axial diameter), and absence of invasion of the (aforementioned) vascular structures. The patient was submitted to a pancreaticoduodenectomy with curative intent in February 2019. Subsequent treatment assessments through morphologic and functional imaging have revealed no signs of residual disease or recurrence to date, for a follow-up period of approximately 49 months. ***Conclusion:*** PRRT exhibits potential as an effective neoadjuvant therapy in unresectable localized Pan-NETs, contributing to tumour downsizing and subsequent resectability, namely in the context of suspected vascular invasion and large tumour size, with promising disease free survival results. ***References:*** 1. ## OP-474

### Safety and Efficacy in a Recurrent Squamous Cell Carcinoma of the Foot treated with Sequential Applications of 188Re-resin

***L. Vetrone***[1], *P. Castellucci*[2], *C. Baraldi*[3], *S. Vichi*[4], *F. Zagni*[5], *B. Piraccini*[3], *L. Strigari*[5], *S. Fanti*[1,6];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, BOLOGNA, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [3]*Dermatology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [4]*Clinical Engineering Department, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [5]*Medical Physics Department, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY,* [6]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** Brachytherapy using $^{188}$Re-resin is an emerging and promising technique to treat Non-Melanoma Skin Cancers. However, most of the (scarse) literature is based on single treatments since the response rate ranges between 90-95%. Aim of this report is to assess feasibility, efficacy and safety of multiple sequential treatments using $^{188}$Re-resin in a 69 years old female with recurrent squamous cell carcinoma (SCC). ***Materials and Methods:*** The patient was enrolled according to the following inclusion criteria: histologically proven SCC; lesion's thickness lower than 3 mm; difficult to treat with surgery, evaluation with biopsy and dermoscopy after 6 months. Toxicity was evaluated according to Common Terminology Criteria for Adverse Events (CTCAE-5.0) scale, while cosmetic results were assessed according to the Radiation Therapy Oncology Group (RTOG) scale. The patient had a biopsy proven SCC on the left foot with a surface area of 14.5cm$^2$ and 1mm of neoplastic invasion. We treated the lesion using 400MBq $^{188}$Re-resin for 61minutes of application time; absorbed dose at 0.5 mm depth was 27Gy, absorbed dose at 1mm was 15Gy, superficial absorbed dose was 78Gy. Seven months after therapy, the patient showed an 8cm$^2$ recurrence of SCC 1mm thick. Two months later a retreatment was performed using 126 MBq $^{188}$Re-resin for 146 minutes; absorbed dose at 0.5mm was 32Gy, absorbed dose at 1mm was 20Gy and superficial dose was 106Gy. Eight months later a second smaller recurrence has been observed showing a surface area of 2cm$^2$ and 1.5mm neoplastic invasion. A third $^{188}$Re-resin treatment was performed using 150MBq for 50minutes; absorbed doses were: 40Gy at 0.5mm, 25Gy at 1.5mm and 130Gy at the surface. ***Results:*** Five weeks after each treatment toxicity was G1 according to the CTCAE scale; the first two treatments showed excellent cosmetic results according to the RTOG scale. Not significant adverse events nor pain during and after treatments were reported, however we cannot report the efficacy of the third treatment since the patient is still under follow up. ***Conclusion:*** In this case the early recurrences were probably due to an underestimation of the real thickness of the lesion since, especially in large lesions, it is possible that neoplastic invasion is deeper than the one assessed by biopsy. For this reason, it should be always recommended to perform multiple biopsies before 188Re-resin therapy. Finally, re-treatment with $^{188}$Re-resin in case of recurrence is safe even after several applications in the same area.

**Functionalized rigidified pentadentate chelators useful for the [Al$^{18}$f]$^{2+}$labeling of biomolecules**
***L. Tei***[1], *J. Martinelli*[1], *L. Russelli*[2], *G. Multhoff*[3], *C. D'Alessandria*[2]; [1]*Department of Science and Technological Innovation, University of Piemonte Orientale, Alessandria, ITALY,* [2]*Department of Nuclear Medicine, Technical University Munich, Munich, GERMANY,* [3]*Department of Radiation Oncology, TranslaTUM, Technical University Munich, Munich, GERMANY.*

***Aim/Introduction:*** Al(III) complexes have been recently investigated for their use in PET imaging by formation of ternary complexes with the radioisotope fluorine-18 ($^{18}$F). The gold standard chelator for such methodology is NOTA (1,4,7-triazacyclononane-1,4,7-triacetic acid), although it requires high temperature to obtain reasonable radiochemical yields.[1,2] Thus, non-macrocyclic, semi-rigid pentadentate chelators having two N- and three O-donor atoms such as RESCA1 and AMPDA-HB have been recently proposed with the aim to allow room temperature [Al$^{18}$F]$^{2+}$ labelling of temperature sensitive biomolecules.[3,4] ***Materials and Methods:*** The 2-aminomethylpiperidine (AMP)-based chelators 2-AMPTA, 2-AMPDA-HB and NHB-2-AMPDA were synthesized and labelled with [Al$^{18}$F]$^{2+}$ at different temperatures (25-90°C) and in the pH range 4-6.5.[3] Once found the most effective chelator for [Al$^{18}$F]$^{2+}$ labelling, bifunctional derivatives bearing NHS-activated ester (2-AMPDA-HB-NHS) and maleimide (2-AMPDA-HB-mal) groups were synthesized and conjugated to an antibody fragment anti-Galectin-3 (antiGal3-F(ab')) and to a tumor cell-penetration peptide probe (TPP), recognizing the tumor-specific membrane heat shock protein 70 (Hsp70) expression. After purification, the purity of the tracers was confirmed via radio-HPLC and radio-TLC, whereas their stabilities were measured in vitro (up to 4h in PBS, Serum and EDTA) and in vivo in a syngeneic subcutaneous breast cancer (4T1) mouse model. ***Results:*** The chelator AMPDA-HB showed the best [Al$^{18}$F]$^{2+}$ labelling performance at 37°C and pH 5.5-6 (70-80%). In vivo experiments in in tumor-free mice highlighted high rapid hepatobiliary and renal excretion of the labelled complex and low accumulation in the bones. The labelling with AlF-18 of the bioconjugates 2-AMPDA-HB-antiGal3-F(ab') and 2-AMPDA-HB-mal-TPP resulted in a radiochemical yield respectively of 28 and 22% (radio-TLC), and a radiochemical purity of >94% after purification. Once the in vitro stability was confirmed in human serum, the AlF-18 labelled 2-AMPDA-HB-mal-TPP was injected i.v. in 7 mice with subcutaneous breast cancer (4T1). PET scans were acquired 1h after injection of the tracer for 15 min after which the tracer accumulated in the tumor as determined in biodistribution assays. The in vivo study on 2-AMPDA-HB-antiGal3-F(ab') is ongoing. ***Conclusion:*** The development of the

AMP-based pentadentate chelators and their conjugation to selected biomolecules brings important innovation in the field of AlF-18 radiolabelling providing a new tool for the application of Al-F18 approach to oncological or ImmunoPET imaging. ***References:*** [1] Schmitt, S.; Moreau, E. ### Development of a kit formulation of Technetium-99m labeled holmium microspheres as scout dose for radioembolization treatment planning.

***M. Boswinkel***[1], *P. Laverman*[1], *T. Weisheit*[2], *R. Drescher*[2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Clinic of Nuclear Medicine, University Hospital Jena, Jena, GERMANY.*

***Aim/Introduction:*** Treatment planning of radioembolization with holmium-166 microspheres ($^{166}$Ho-MS) is currently performed using technetium-99m macroaggregated albumin particles ($^{99m}$Tc-MAA) or a scout dose of $^{166}$Ho-MS. While the distribution $^{166}$Ho-MS better corresponds to the therapeutic dose of $^{166}$Ho-MS, it must be pre-ordered, $^{99m}$Tc-MAA provides better imaging quality. Therefore we developed a kit formulation to label non-radioactive Holmium-165 microspheres (Ho-MS) with Tc-99m, to obtain a product with reliable distribution, optimal availability, and good imaging quality. ***Materials and Methods:*** Sterilized GMP-grade Ho-MS (60 mg) were labeled with 300 MBq [$^{99m}$Tc]pertechnetate in the presence of various amounts of stannous chloride, and incubated for various temperatures and durations. Parameters investigated included stannous chloride concentration, incubation temperature and duration, and the use of a glass vial or an Eppendorf tube. Quality control was performed using ITLC and centrifugation (supernatant and radiolabeled microspheres were separated, and radioactivity measured in each sample). Radiochemical purity (RCP) and maximal specific activity were determined. Stability tests were performed in 0.1% pluronic at room temperature (RT), and in plasma at 37 °C for 2 h. Microsphere integrity was investigated using multisizer analysis, microscopy, and free acetylacetonate (AcAc) concentration. ***Results:*** Optimization of the $^{99m}$Tc labeling was performed in several steps. A stannous chloride concentration of 100 µg was found optimal, and a temperature of 37 °C more efficient than RT. Using a glass vial the RCP increased from 72% to 94%. In addition, the incubation time could be decreased from 2 h to 15 min. Specific activity was increased from 2.5 MBq/mg to 5 MBq/mg Ho-MS, by using a higher starting activity, resulting in a final product containing of 300 MBq/60 mg Ho-MS (single patient dose). Preliminary tests showed that the integrity of the microspheres was not affected by $^{99m}$Tc labeling. Microscopy images showed intact structure of the microspheres, multisizer analysis showed that the microspheres had a mean diameter of 27 µm (range 15-60 µm), and free AcAc concentration was less than 0.4 wt%, indicating good integrity. Radiolabeled product was stable in 0.1% pluronic and plasma, with a RCP of 95% and 83%, respectively, after 2 h. ***Conclusion:*** $^{99m}$Tc-labeled Ho-MS can be labeled in 15 min and are a therefore promising for scout dosing of radioembolization patients. Using these $^{99m}$Tc-Ho-MS as a scout dose may lead to optimized and flexible treatment planning with high similarity to the therapeutic $^{166}$Ho-MS dose and with better imaging quality.

## OP-489

### Large-scale, GMP-compliant production and quality control of Al[$^{18}$F]F-NOTA-Octreotide

***V. Kramer***[1,2], *A. Bispo*[3], *C. Gomez*[3], *D. Zouain*[3], *L. Cantuarias*[1], *C. Soza-Ried*[1,2], *N. Emmanuel*[4], *G. Decoux*[4], *C. Goncalves Gameiro*[4];
[1]*Positronpharma, Santiago de Chile, CHILE,* [2]*Nuclear Medicine & PET/CT Center Positronmed, Santiago de Chile, CHILE,* [3]*R2IBF, Rio de Janeiro, BRAZIL,* [4]*Ion Beam Applications, Louvain-la-Neuve, BELGIUM.*

***Aim/Introduction:*** [$^{68}$Ga]Ga-DOTATATE is well established for PET/CT imaging of neuroendocrine tumors (NET). Al[$^{18}$F]F-NOTA-Octreotide is an emerging radiotracer for the same indication, allowing for large-scale, centralized production improving patient access to precision imaging for the same indication[1]. In this work, our objective was to evaluate the production capacity and the influence of starting activities on critical parameters such as radiochemical yields (RCY), purity (RCP), reliability and stability. ***Materials and Methods:*** A GMP-compliant production process for Al[$^{18}$F]F-NOTA-Octreotide was developed, optimized, and validated at two independent radiopharmacies. Briefly, [$^{18}$F]fluoride was trapped on a QMA cartridge, rinsed with water, and eluted with EtOH/NaCl 0.9%. Subsequently, the precursor solution was added and heated to 100 **°C** for 10 minutes before standard workup and reformulation. Quality control was performed including appearance, pH, radionuclidic, radiochemical, and chemical purity, residual solvents, endotoxins, and sterility, compliant with the European pharmacopeia. We collected and analyzed 60 production records from executed between August 2022 and March 2023, applying the same methods for production and quality control. ***Results:*** From starting activities of 157,8 ± 47,5 GBq we obtained an overall average of 51,0 ± 23,5 GBq (31,8 ± 9,8 % RCY n.d.c., n=57) Al[$^{18}$F]F-NOTA-Octreotide with 96,5 ± 2,9 % RCP. The implemented process can provide up to 100 GBq of Al[$^{18}$F]F-NOTA-Octreotide with high RCPs and stability was confirmed of up to 10h EOS. Of a total of n=61 analyzed production batches, n=3 (5%) were out of specification, n=1 (1.6%) resulted in no product and from n=57 batches, 550 doses have been supplied to >10 PET imaging sites with excellent clinical results as previously published[3] ***Conclusion:*** Al[$^{18}$F]F-NOTA-Octreotide can be obtained in large amounts, with excellent and reliable radiochemical yields and purity, and improves patient access to precision diagnostic imaging of NETs. ***References:*** 1. ## OP-490

### Fully Automated Radiosynthesis of [$^{89}$Zr]Zr-Crefmirlimab Berdoxam for Clinical Multi-Centre PET Imaging of CD8$^+$ T-Cell Trafficking

***C. Wichmann***[1], *Z. Cao*[1], *A. McDonald*[1], *N. Guo*[1], *S. Poniger*[2], *F. Scott*[1], *F. Jia*[3], *K. Brady*[3], *W. Le*[3], *A. Scott*[1];
[1]*Olivia Newton John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*iPhase Technologies Pty Ltd, Rowville, AUSTRALIA,* [3]*ImaginAb Inc., Inglewood, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Presence of CD8$^+$ tumour infiltrating lymphocytes in the tumour microenvironment is critical for the immune-oncology therapy response in solid tumours and lymphoma. [$^{89}$Zr]Zr-crefmirlimab berdoxam (formerly [$^{89}$Zr]Zr-Df-IAB22M2C) is a promising novel radiotracer that can reveal whole body CD8$^+$ T-cell distribution using positron emission tomography [1]. [$^{89}$Zr]Zr-crefmirlimab berdoxam is currently being investigated in clinical trials (e.g. iPREDICT study, NCT05013099). In order to support Australian trials, we have developed a fully automated protocol for the clinical radiosynthesis of [$^{89}$Zr]Zr-crefmirlimab berdoxam. ***Materials and Methods:*** Based on our prior work, automated radiolabelling of Df-Crefmirlimab with $^{89}$Zr, formulation, and sterile filtration was established using a disposable cassette-based synthesis module. Starting activity and protein amount were optimized to satisfy patient dose requirements avoiding further manual intervention. Quality control was performed on the formulated product to satisfy clinical release and stability criteria over 6 days. ***Results:*** Df-Crefmirlimab with an approximate chelator-to-minibody ratio of 2 was used for radiolabelling experiments. Radiolabelling reactions were performed in sodium succinate pH 6 with 0.02% Tween 80 which gave >95% conversion after 15 minutes at ambient temperature. Overall process yield of formulated sterile [$^{89}$Zr]Zr-crefmirlimab berdoxam was 76% ± 7% (n=15) at end-of-synthesis (EOS) with a process time of 45 minutes. Product was formulated in a volume of 10.2 mL ± 0.6 mL (n=15) with maximum total and apparent specific activities at EOS of 205 MBq and 105 MBq/mg, respectively. Calibrated patient dose activity was 40.5 MBq ± 2.9 MBq (n=15) and patient protein dose was 1.53 mg ± 0.17 mg (n=15). Radiochemical purity and immunoreactive fraction at EOS were 99.4% ± 0.5% (n=15) and 95.6% ± 1.8% (n=15), respectively, and dropped to 98.6% ± 0.6% (n=4) and 88.4% ± 1.7% (n=4), respectively, after storage at 4-8°C for 6 days. Size-exclusion HPLC analysis of formulated [$^{89}$Zr]Zr-crefmirlimab berdoxam demonstrated antibody integrity of 92.7% ± 2.1% (n=15) with 5.5% ± 2.1% (n=15) aggregation. pH of formulated [$^{89}$Zr]Zr-crefmirlimab berdoxam was 6.47 ± 0.05 (n=15) and sterility and endotoxin levels passed clinical release criteria. ***Conclusion:*** Fully automated production of [$^{89}$Zr]Zr-crefmirlimab berdoxam for clinical use was achieved with minimal exposure to the operator and excellent stability over 6 days allowing for centralised production. This demonstrates feasibility of automated production of $^{89}$Zr-radiopharmaceuticals in a clinical setting. ***References:*** [1] Pandit-Taskar N, Postow MA, et al. First-in-Humans Imaging with $^{89}$Zr-Df-IAB22M2C Anti-CD8 Minibody in Patients with Solid Malignancies: Preliminary Pharmacokinetics, Biodistribution, and Lesion Targeting. ## OP-491

### Radiopharmaceutical production of [$^{61}$Cu]Cu-NODAGA-LM3 injection solution

***M. Alejandre Lafont***[1], *T. Basaco Bernabeu*[1], *M. Blagoev*[2], *A. Johayem*[2], *F. De Rose*[3], *C. Porcelli*[3], *L. Jaafar-Thiel*[3], *M. Fani*[1];
[1]*Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND,* [2]*Department of Nuclear Medicine, University Hospital of Zürich, Zürich, SWITZERLAND,* [3]*Nuclidium AG, Basel, SWITZERLAND.*

***Aim/Introduction:*** Copper based radiotracers are promising compounds in Nuclear Medicine with a broad application field in diagnosis and therapy.[1] Based on pre-clinical results in our group, we present the radiopharmaceutical production of [$^{61}$Cu]Cu-NODAGA-LM3 (where NODAGA is 1,4,7-triazacyclononane,1-glutaric acid, 4,7-acetic acid and LM3 is p-Cl-Phe-cyclo(D-Cys-Tyr-D-Aph(Cbm)-Lys-Thr-Cys)D-Tyr-$NH_2$)), including an automatic labeling process and a full set of quality control procedures. This work serves as a preparation for a phase I clinical study on [$^{61}$Cu]Cu-NODAGA-LM3, which will be launched at University Hospital Basel. Additionally, we present a new and efficient validation procedure for radio-HPLC. ***Materials and Methods:*** [$^{61}$Cu]$CuCl_2$ was produced using a Nickel solid target irradiated at 40 µA for 2 h at the University Hospital Zurich cyclotron followed by cassette-based automated separation. NODAGA-LM3 was labeled on a clinical scale with [$^{61}$Cu]$CuCl_2$ in sodium acetate solution with our own labeling procedure, using a modified commercially available cassette mounted on a Modular-Lab PharmTracer synthesizer (EZAG). Chemical and radiochemical purity were determined by radio-HPLC and by radio-iTLC. Sterile filter integrity was proven with a self-designed semi-automatic device and other tests such as ethanol content, pH, ascorbate content and endotoxin testing were performed. ***Results:*** [$^{61}$Cu]$CuCl_2$ purified solution was obtained in 0.05 M HCl at activity levels of 1.5-2.0 GBq. We successfully developed a fast and reliable automated labeling method to produce [$^{61}$Cu]Cu-NODAGA-LM3 injection solution with radiochemical yield of around 95 % within 12 min. The achieved radiochemical purity and radio labelling yield were > 90 %. The new radio-HPLC method was successfully validated with proven linearity for chemical ($R^2$ = 0,9996) and for radiochemical ($R^2$ = 0.9994) purity, specificity, precision, recovery rate, trueness and sensitivity. The ethanol, and ascorbate content as well as the pH values were all within narrow ranges and met the required specifications. The process was validated for activity amounts on clinical scale. ***Conclusion:*** A production process of high-quality [$^{61}$Cu]$CuCl_2$ as an active pharmaceutical ingredient (API) was established on a routine basis. Following this, a new [$^{61}$Cu]Cu-NODAGA-LM3 production process was successfully established and can be carried out completely using a commercially available reagent kit and labeling cassette. It is supported by a new and validated radio-HPLC method and established additional QC-methods with suitable product specifications. A clinical phase I study based on these processes is pending. ***References:*** [1] M. Fani et al., J Nucl Med 2011; 52:1110-1118.

## OP-492

### Development of an ACE2-Targeting Radiotracer for PET Imaging of the SARS-CoV-2 Entry Receptor

***C. Müller***[1], *D. Beyer*[1], *J. Wang*[2], *C. Vaccarin*[1], *Y. He*[2], *L. Mu*[2], *J. W. Bode*[2], *R. Schibli*[1];
[1]*Paul Scherrer Institute, Villigen-PSI, SWITZERLAND,*
[2]*ETH Zurich, Zurich, SWITZERLAND.*

***Aim/Introduction:*** The expression level and dynamics of the angiotensin-converting enzyme-2 (ACE2) may be decisive for the susceptibility for SARS-CoV-2 infection and COVID-19 progression and outcome. In previous studies, we and others reported on the development of DX600-based radiopeptides for non-invasive imaging of ACE2, potentially enabling the identification of patients at risk for severe disease progression [1-3]. The aim of this study was to develop an $^{18}$F-based PET radiotracer based on the ACE2-binding inhibitor MLN-4760 [4]. ***Materials and Methods:*** ($SnMe_3$)-MLN4760 was synthesized as a precursor for the preparation of [$^{18}$F]F-MLN-4760, while F-MLN-4760 was synthesized as the reference compound [$^{18}$F]F-MLN-4760 was obtained in high yields (>1GBq). The radiotracer was investigated on ACE2- and ACE-expressing HEK cells to determine ACE2-specific uptake. The ACE2-binding affinity was determined in displacement experiments using F-MLN-4760 and [$^{3}$H]MLN-4760. Biodistribution and PET/CT imaging studies were performed at 15 min, 1 h and 3 h after injection of [$^{18}$F]F-MLN-4760 in nude mice bearing HEK-ACE2 and HEK-ACE xenografts. ***Results:*** ACE2-binding affinity of F-MLN-4760 ($IC_{50}$: 21.5 ± 2.3 nM) was similar to the original compound MLN-4760 ($IC_{50}$: 13.5 ± 2.5 nM). [$^{18}$F]F-MLN-4760 showed specific uptake in HEK-ACE2 cells (45 ± 4% and 63 ± 3% after 1 h and 3 h, respectively), whereas the co-incubation with excess MLN-4760 to block ACE2 prevented it (<1.5%). Binding of [$^{18}$F]F-MLN-4760 to HEK-ACE cells was negligible (<0.3%). The tissue distribution of [$^{18}$F]F-MLN-4760 (5 MBq/mouse) showed specific accumulation in HEK-ACE2 xenografts (13 ± 2% IA/g, 1 h p.i.), which declined over time (5.8 ± 0.9% IA/g at 3 h p.i.). No activity accumulation was observed in the HEK-ACE xenograft (<0.3% IA/g). Renal clearance of [$^{18}$F]F-MLN-4760 was relatively fast (5.1 ± 1.5% IA/g; 1 h p.i.), while substantial activity retention in the intestines was observed (28.2 ± 4.6% IA/g and 5.0 ± 4.8% IA/g after 1 h and 3 h, respectively). No radiodefluorination was observed. ***Conclusion:*** The study data confirmed ACE2-specific binding of [$^{18}$F]F-MLN-4760 in vitro and in vivo. Structural optimization of the radiotracer will be necessary to improve retention at the target and reduce hepatobiliary excretion. This will be particularly important to enable the imaging of (patho)physiological expression levels of ACE2 in COVID-19 patients. ***References:*** [1] Parker et al. Nucl Med 2021 62:1631. [2] Zhu et al. Adv. Sci. 2021, 8: 2100965. [3] Beyer & Vaccarin et al. EJNMMI Research 2023, 13:32. [4] Towler et al. J Biol Chem 2004, 279, 17996.

### One-pot combinatorial 18F fluorination: Innovative high-throughput radiolabelling for acceleration of tracer development

***S. Xiao***[1], *M. Kominia*[1], *A. Domling*[2], *B. Cornelissen*[1], *P. Elsinga*[1];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Palacky University, Department of Innovative Chemistry, Olomouc-Holice, CZECH REPUBLIC.*

***Aim/Introduction:*** Positron emission tomography (PET) heavily relies on the employment of radiolabeled molecules. These obtained radiopharmaceuticals are rationally designed or screened from a library of radiolabelled compounds. Selection of suitable lead candidates can be a drawn-out process which is often slow as a construction of the library of radiolabelled compounds is required with high affinity and high specificity. Thus, high-throughput screening and structure-activity relationship studies would be very helpful to accelerate the development of tracers. Currently, molecules can already be synthesized in high-throughput by the multicomponent reaction (MCR). Therefore, rapid, simple and high-throughput radiolabelling methods would be highly advantageous. We investigated whether high-throughput radiolabelling methods were feasible and chose tetrazole compounds as the test system. Some derivatives of tetrazoles could be used to treat neurodegenerative disorders such as Alzheimer's and Parkinson's disease. Several tetrazoles with different lipophilicities were designed for investigating brain penetration. Fluorine-18 has extensive clinical and research applications in PET due to its compatible half-life and chemistry, matching a wide variety of radiolabelled small molecules. This work aims to achieve fast and multiplexed fluorine-18 radiolabelling of a panel of tetrazoles for screening tracer uptake in brain. ***Materials and Methods:*** A panel of tetrazoles containing aryl boronic pinacol esters (Bpins) and the corresponding fluorine-19 versions are synthesized using MCR. Then, the multiple Bpins are converted to radioactive $^{18}$F-fluoro compounds in one pot using $Cu(OTf)_2(Py)_4$ as a catalyst. The conditions of the labeling experiment are optimized to improve radiochemical conversion (RCC) with respect to base, solvent, the amounts of reagent and catalyst. ***Results:*** Several Bpins with different lipophilicities and their fluorine-19 versions were synthesized. Five different Bpins were simultaneously and successfully converted into fluorine-18 compounds at small-scale in a one-pot reaction. Relatively high RCC was obtained with potassium oxalate, dimethylacetamide, 25 µmol of precursors and 7.5 µmol of catalysts. Under optimized conditions, the cumulative RCC for all $^{18}$F-compounds was 66% ±10% (n=3). ***Conclusion:*** A fast and multiplexed fluorine-18 radiolabelling method was constructed. Next, we will expand the types and quantities of precursors and explore the interaction between precursors. In short, MCR and bulk radiolabelling may offer a fast and simple method to compile and screen larger numbers of radiolabelled compounds for PET.

## OP-494

### To Have and To Hold: The exceptional attraction of $^{225}$Ac and Macropa

***A. Amor Coarasa***[1,2], *M. Friebe*[1], *S. Ponnala*[1], *P. K. Singh*[1], *S. DiMagno*[1], *J. W. Babich*[1];
[1]*Ratio Therapeutics Inc, Boston, MA, UNITED STATES OF AMERICA,* [2]*Albert Einstein College of Medicine, Bronx, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Actinium-225 radiopharmaceutical development displays significant tumor cell-killing effect in vivo, but is fraught with challenges. To date, there are two macrocyclic chelators proven to form stable complexes with $^{225}$Ac: DOTA and Macropa. DOTA is a versatile chelator, but not selective for $^{225}$Ac. Moreover, labeling requires elevated temperatures, a condition not compatible with labile targeting ligands. This work characterizes the radiolabeling and stability of [$^{225}$Ac]Macropa and [$^{225}$Ac]DOTA constructs. ***Materials and Methods:*** We evaluated four different Macropa containing PSMA targeting ligands, a bifunctional version of Macropa ($M\text{-}NH_2$), and an equivalent DOTA containing PSMA targeting ligand for comparison. Labeling was performed in 1 M $NH_4OAc$ to produce a clinically-relevant radioconcentration [25-35 µCi/ml injectable solution] of $^{225}$Ac-labeled formulated

drug product. We evaluated labeling conditions, impact of metal impurities, and long-term stability in the absence of anti-oxidants or radical scavengers using various QC methods. ***Results:*** [$^{225}$Ac]Macropa labeling experiments uniformly showed ≥99% yields (25ºC, 30 minutes). A 7-day stability study showed no change in RCP (>99%) of the $^{225}$Ac-Macropa complexes. This study also showed that while $^{221}$Fr is released from the chelator, its longer half-life daughter ($^{213}$Bi) is readily complexed by Macropa (92.5±1.2%), thereby ensuring high drug product purity at any given time prior to injection. Macropa demonstrated remarkable selectivity; deliberate contamination (50 ppm) with common metal ions (Zn, Al, Cu, Co, Ni, Mn, Cr, and Fe) did not interfere with the formation of the [$^{225}$Ac]Macropa at 25ºC (RCP>99%). In comparison, DOTA chelation at 95ºC did not produce pure (54.4%<RCP<78.7%) drug products in the presence of such metal ion contaminants, even when challenged at a significantly lower concentration (5 ppm). In addition, Macropa complexes (confirmed by MS) of isotopically stable Ce, Bi, Sm, and Lu ions underwent quantitative displacement by $^{225}$Ac (25ºC, 30 minutes). Finally, a sequential dilution experiment showed that Macropa will quantitatively label actinium in concentrations as low as 1-10 µM, or a molar ratio of approximately 50:1. ***Conclusion:*** Macropa possesses remarkable advantages as an actinium chelator: it labels quantitatively at room temperature, even in the presence of high levels of metal ion impurities, the 225Ac complex remains stable for at least 7 days, and it complexes 213Bi released via alpha decay from 221Fr at dose levels present in the formulated drug product solution kept at room temperature. The rapid labeling kinetics, solution stability, ease of use, and daughter recapture supports Macropa as the actinium chelator of choice for medicinal products.

## Cutting Edge Science Track - TROP Session: Current Issues of Radiation Protection

### OP-495

**Radiation Protection of Undertakers (Transport/ Embalming of the Body) and Crematorium Staff in Case of a Patient Death Shortly After Radionuclide Therapy**

***C. Michel****, H. Caplin, D. Célier, E. Blanchardon, A. Mathieu, A. Isambert;*
*Institute for Radiation Protection and Nuclear Safety (IRSN), Fontenay-aux-Roses, FRANCE.*

***Aim/Introduction:*** A patient death shortly after a radionuclide therapy is rare. Nevertheless, this situation can be complicated to manage by healthcare professionals, undertakers, and crematorium staff as there are few radiation protection guidelines, and especially for the new therapeutic radionuclides. That is why, at the request of the French nuclear safety authority (ASN), the French Institute for radiation protection and nuclear safety (IRSN) performed a study (1) about occupational radiation protection issues in the case where a patient dies shortly after radionuclide therapy with new radiopharmaceuticals. The objectives of this piece of work were to perform a synthesis of the recommendations about death and cremation of nuclear medicine patients, and to assess the doses which could be received by undertakers (performing transport and embalming of the body) and crematorium staff. ***Materials and Methods:*** IRSN reviewed European recommendations about death and cremation. These European data were completed with some recommendations from countries outside Europe (USA, Canada) and data from international organisations (i.e. International Commission on Radiological Protection, and International Atomic Energy Agency). For 4 most promising new therapeutic radionuclides identified in a previous IRSN study (2) - Lutetium-177, Radium-223, Holmium-166, and Actinium-225 - the doses which could be received by undertakers and crematorium staff were assessed using realistic scenarios and conservative hypotheses. For instance, for transport and embalming, the times of presence near the body, namely at 50 cm, were 1 and 2 hours, respectively. ***Results:*** For Radium-223 and Actinium-225, the immediate transport and embalming of the body is possible as the assessed doses for undertakers are negligible. For Lutetium-177 and Holmium-166, a few days period after the death is necessary before the transport and the embalming to comply with regulatory dose constraints, without exceeding the French legal time frame for funeral operations.For cremation, the assessed doses are usually under 0.3 mSv per cremation (excepted for Actinium-225). ***Conclusion:*** Considering the assessed occupational doses, practical radiation protection proposals were established in case of a patient death shortly after radionuclide therapy, which may be useful for radiation protection authorities, undertakers, and crematorium staff. ***References:*** (1) French Institute for Radiation Protection and Nuclear Safety (IRSN), Avis 2023-00004, January 2023, https://www.irsn.fr/sites/default/files/2023-02/Avis-IRSN-2023-00004.pdf (2) French Institute for Radiation Protection and Nuclear Safety (IRSN), Nouveaux radionucléides en médecine nucléaire - Première partie : étude bibliographique des nouveaux radionucléides et perspectives d'utilisation clinique en France - Rapport IRSN 2021-00083, February 2021, https://www.irsn.fr/FR/expertise/rapports_expertise/Documents/radioprotection/IRSN_Rapport-2021-00083-nouveaux-radionucleides-medecine.pdf

### OP-496

**Justification of the radiation dose to a pregnant carer and comforter**

***E. Morris****[1,2], F. Sansum[2], M. Easty[2], L. Biassoni[2], M. Burniston[1];*
*[1]Barts Health NHS Trust, London, UNITED KINGDOM, [2]Great Ormond Street Hospital for Children, London, UNITED KINGDOM.*

***Aim/Introduction:*** Generally, individuals who are pregnant would not be accepted as a carer and comforter within Nuclear Medicine. However, in a busy children's hospital, preventing a pregnant individual from supporting their child may prohibit that child from having a medically necessary scan. In UK legislation, the Ionising Radiation Regulations 2017 states the annual radiation dose limit for a member of the public (including foetuses) to be 1 mSv [1] and the Ionising Radiation (Medical Exposures) Regulations 2017 specifies no dose limit for carers and comforters, requiring locally set dose constraints and justifiaction of the exposure by a practitioner [2]. The aim of this project is to provide evidence to allow the Nuclear Medicine Practitioner to justify the exposure to a pregnant carer and comforter whilst having confidence that the radiation dose received by the foetus will remain under 1 mSv. Additionally, to give pregnant individuals appropriate information to allow them to knowingly and willingly agree to act as a carer and comforter. ***Materials and Methods:*** Non-pregnant individuals attending with their child wore a calibrated electronic personal dosemeter on their waistband which recorded total radiation dose received by the abdomen for the duration of their time in the

department. The radiation dose received after the individual had left the department was estimated from a dose rate measured at the end of the exam and calculated assuming normal close contact patterns. These results were summed to estimate of the total radiation dose received by the abdomen due to that appointment. Activity remaining in the patient at the end of the appointment which could be excreted or vomited was calculated to allow estimations of the potential risk to the carer and comforter from contamination. ***Results:*** Abdominal radiation doses received by studied carers and comforters were routinely low for most investigations, with little risk of breaching the 1mSv dose limit. ***Conclusion:*** In situations where the carer and comforter is pregnant, the additional information acquired in this study provides greater confidence for the practitioner justifying the exposure and has contributed to the development of improved information leaflets for pregnant carers and comforters. If a child were to undergo multiple studies within the pregnancy, a personalised dose estimate for the carer and comforter should be completed. ***References:*** [1] The Ionising Radiations Regulations. 2017. ## OP-497

### Investigating the contamination risk during $^{177}$Lu-PSMA and $^{225}$Ac-PSMA therapies of advanced prostate cancer patients

***J. Brosch-Lenz****, S. Nekolla, L. Tischendorf, J. Allmann, W. Weber, M. Eiber;*
*Klinikum rechts der Isar, der Technischen Universität München, Munich, GERMANY.*

***Aim/Introduction:*** $^{177}$Lu-PSMA radiopharmaceutical therapy (RPT) is an approved treatment option for metastatic castration-resistant prostate cancer (mCRPC) using beta-radiation. In cases of beta-resistance, alpha-emitting $^{225}$Ac-PSMA RPT has also shown promising results. mCRPC patients typically present with many comorbidities including urinary incontinence. The aim of this work was to investigate the contamination risk in patient rooms during $^{177}$Lu- and $^{225}$Ac-PSMA RPT to avoid unintended dispersion of radioactivity. ***Materials and Methods:*** Wipe samples were collected to detect a possible contamination of high-touch areas (door handles, faucet, toilet seat, chairs) in patient rooms at 24h and 48h after RPT. After patient discharge, floors were screened with a hand-held contamination monitor and further wipe samples were collected when local contaminations were detected. All samples were measured in a gamma counter that was calibrated for $^{177}$Lu and $^{225}$Ac and the activities were decay corrected to the time point of sample collection. ***Results:*** Samples were taken from a total of 19 $^{177}$Lu- and 5 $^{225}$Ac-PSMA RPT patients with median injected activities of 7.39 GBq and 7.84 MBq, respectively. A total of 251 samples was measured and maximum detected activities were 46.70 kBq and 5.62 kBq, respectively. The surfaces with highest contaminations were the toilet seats followed by faucets and door handles. Mean activities were 0.56 kBq and 0.01 kBq (faucet), 6.64 kBq and 1.13 kBq (toilet seats), 0.28 kBq and 0.03 kBq (door handles), and 0.18 kBq and 0.05 kBq (chairs) for $^{177}$Lu and $^{225}$Ac, respectively. Floor contaminations were found in 88 % (21 out of 24) of therapies with a maximum of 5163.60 kBq/m$^2$ and 4.70 kBq/m$^2$, respectively. These floor contaminations were detected in patients' bathrooms and decontamination measures were taken. ***Conclusion:*** Our investigation indicates an increased contamination risk in patient bathrooms and on door handles. As a first step, cautious instructions to avoid any contamination during bathroom cleaning and when sharing bathrooms should be introduced. This especially applies when using alpha emitters which are more harmful in case of incorporation. In addition, our results may yield further specifications for radiation protection actions in hospital and patient households for out-patient treatment.

## OP-498

### Assessment of Occupational Radiation Exposure During Administration of [$^{177}$Lu]Lu-DOTA-TATE Using Active and Passive Dosimetry

***M. Riveira-Martin***[1]*, L. Struelens*[2]*, J. Muñoz Iglesias*[3]*, W. Schoonjans*[2]*, J. M. Nogueiras Alonso*[4]*, O. Tabuenca*[3]*, F. J. Salvador Gomez*[5]*, A. Lopez Medina*[5]*;*
*[1]Galicia Sur Health Research Institute, Vigo, SPAIN, [2]Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM, [3]Meixoeiro Hospital, University Hospital of Vigo, Nuclear Medicine Department (SERGAS), Vigo, SPAIN, [4]Meixoeiro Hospital, University Hospital of Vigo, Nuclear Medicine Department (GALARIA), Vigo, SPAIN, [5]Meixoeiro Hospital, University Hospital of Vigo, Medical Physics and RP Department (GALARIA), Vigo, SPAIN.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-DOTA-TATE has become popular for treating neuroendocrine tumours, but its high demand, novelty, and inconsistencies in procedures, can increase exposure of the staff. However, there is a shortage of data on the resulting occupational radiation exposure. This study aims to investigate radiation doses received by the staff during the administration of [$^{177}$Lu]Lu-DOTA-TATE. ***Materials and Methods:*** At our institution, [$^{177}$Lu]Lu-DOTA-TATE is administered by a physician and a nurse (7.4 GBq/session). Four nurses and two physicians were monitored throughout 32 sessions. Five thermoluminescent dosimeters (TLDs) in different positions on both dominant (D) and non-dominant (ND) hand provided doses in terms of Hp(0.07). Eye lens dosimeters measured Hp(3) values. Effective doses in terms of Hp(10) were obtained with Optically Stimulated Luminescence (OSL) dosimeters placed at chest level, under the lead apron. These detectors were provided and analysed by the Belgian Nuclear Research Centre (SCK CEN). Additionally, dose rates and effective dose in terms of Hp(10) were recorded with personal electronic dosimeters (PEDs). Staff wore lead aprons (0.5 mm lead equivalent), although three sessions were performed without aprons to evaluate the effect on Hp(10) using the PEDs. Dose values were normalized to the total administered activity (A). A P-value<0.05 was considered significant. ***Results:*** Lead aprons reduced dose rates/effective doses by 71%/69% for the physician, and by 56%/68% for the nurse. On average, Hp(10)/A showed lower values with electronic (0.65 ± 0.18 μSv/GBq) than with OSL (11.6 ± 2.9 μSv/GBq) dosimeters, so further measurements are needed. Median [range] of maximum Hp(0.07)/A values for all workers involved were (μSv/GBq): 41.5[33.8 - 49.2] for ND and 28.8[20 - 37.6] for D hand for physicians; 15.4[8.5 - 33.1] for ND and 13.9[9.5 - 14.8] for D hand for nurses. Doses are significantly higher for physicians as they manipulate the vial closer, but not significantly different between D and ND hands. The thumb and index fingertip receive the highest doses more frequently. Physicians should correct their middle/ring finger doses by at least a factor of 5/6 to account for maximum doses (on ND hand) and nurses by 3/4 (irrespective of the hand). Maximum Hp(3)/A ranged from (μSv/GBq) 1.4 - 2.2 (physicians) and 0.5 - 1.3 (nurses).

***Conclusion:*** Under appropriate safety measures, administration of [$^{177}$Lu]Lu-DOTA-TATE is a safe procedure. However, regular monitoring is recommended to ensure that the annual dose limits are not exceeded. Acknowledgments: Funded by Euratom 2019 - 2020 under GA 945196 (SINFONIA)

## OP-499

### Tracer validation for non [$^{18}$F]FDG PET pharmaceuticals in automatic injector

***M. Hammar***[1], *R. Solem*[2], *F. Mörnsjö Centofanti*[2], *E. Evetovic*[2], *A. Akbari*[1], *K. Benner*[2], *B. Olsson*[1], *E. Höljer*[2], *J. Oddstig*[2];
[1]*Skane University Hospital, Malmö, SWEDEN,*
[2]*Skane University Hospital, Lund, SWEDEN.*

***Aim/Introduction:*** Automatic injectors have been shown to reduce personal dose, especially to fingers, compared to manual administration for PET radiopharmaceuticals [1]. As our clinic's use of $^{18}$F-PET tracers increases we wanted to validate our Iris automatic injectors for other tracers, namely $^{18}$F-labelled PSMA, Roche, FET and Flutemetamol. ***Materials and Methods:*** For each radiopharmaceutical the following injector characteristics were validated 1. The trueness, as average percentage deviation, of the injector administered activity compared to a stand-alone dose calibrator (geometry calibrated against secondary standard Fidelis dose calibrator) for three injections. 2. An appropriate rinsing volume with respect to residual activity in the patient line. 3. Radiopharmaceutical quality control of the third injection and, if radiopharmaceutical was diluted by injector, on the radiopharmaceutical vial after finished run. This quality control is identical to the one routinely performed post-production. Data points for rinsing volumes were collected by performing two consecutive 4 ml rinsing's into separate vials after an administration (which include a variable initial rinsing). The activity in the vials was measured in a dose calibrator and the initial rinsing was set to 10, 15 and 20 ml for the three test injections. Quality control measuring presence of solvent (ethanol/acetonitrile) and radiochemical purity (TLC/HPLC) was performed on third injection. For [$^{18}$F]FET and [$^{18}$F]PSMA-1007 QC was also performed on radiopharmaceutical vial after the run. ***Conclusion:*** All four radiopharmaceuticals were successfully validated. Injections of [$^{18}$F]PSMA-1007 and [$^{18}$F]FET have since been performed using automatic injection in clinical routine. However, for [$^{18}$F]Flutemetamol and [$^{18}$F]Roche, errors in estimated vial activity concentration ("Measure bulk") was observed and the errors lead to the injector not being able to withdraw and inject the prescribed activity unless being repeatedly recalibrated. Lipophile substances, like Roche and Flutemetamol, are known to adsorb on surfaces. Individual tubing parts were measured separately in a dose calibrator post injection and a significant amount of activity was adsorbed in the initial tube connecting the radiopharmaceutical vial to the 4 way manifold for both radiopharmaceuticals. The same measurement for [$^{18}$F]PSMA shows little residual activity in tubing. Therefore, [$^{18}$F]Flutemetamol and [$^{18}$F]Roche has not been implemented despite being validated. ***References:*** [1] Cunha L, Dabin J, Leide-Svegborn S, Zorz A, Kollaard R, Covens P. ## OP-500

### Implementation of CT tin filter in PET-CT: dose savings and image quality evaluation for tissues and dose levels relevant to PET-CT

***P. Holdgaard***[1], *N. A. Bebbington*[2], *K. B. Christensen*[1], *L. L. Østergård*[1];
[1]*Lillebælt University Hospital, Vejle, DENMARK,*
[2]*Siemens Healthcare A/S, Aarhus, DENMARK.*

***Aim/Introduction:*** CT dose optimisation is particularly important in PET-CT since most examinations cover the whole-body. The tin filter has demonstrated dramatic dose savings for a range of clinical indications in standalone (diagnostic-level) CT. The aim was to evaluate tin filter dose and image quality in high- and in low contrast tissues at dose-levels relevant to PET-CT. ***Materials and Methods:*** The Kyoto-Kagaku adult CT-body-phantom underwent 39 whole-body (WB, vertex-to-knee) scans in standard and obese patient configurations, with standard CT settings used in clinical practice for localisation/characterisation of FDG (120kV/40mAs-eff-ref) and NaF (120kV/20mAs-eff-ref) examinations, and with a range of tin filter settings utilising Sn100kV and Sn140kV spectra with 25-500mAs-ref. Dose length product (DLP) was recorded, and effective dose (ED) calculated from DLP. Two expert observers scored image quality (IQ) in three low-contrast areas (aqueduct in pons cerebri, liver veins, renal pelvis) and two high-contrast areas (bronchial branching, bone/facet joint). Scores were made on a 5-point scale: 1=not detectable, 2=barely visible (AC only), 3=acceptable (localisation), 4=good (characterisation), 5=excellent (diagnostic). Exposure settings and doses with tin filter used to provide a given level of IQ in the respective tissue was determined, and dose savings for comparable IQ to non-tin CT were calculated. ***Results:*** Reference scan: The 120kV/40mAs-eff-ref clinical FDG scan settings gave a WB-ED of 1.21mSv in the standard phantom configuration. Observer 1 gave IQ scores of 3 to the aqueduct, liver and renal pelvis, and scores of 4 to the bronchi and bone/facets. IQ was matched using the tin filter with relative dose reductions of 39% (aqueduct), 57% (liver), 48% (kidney pelvis), 89% (bronchi) and 57% (bone). Observer 2 gave IQ scores of 3 to the aqueduct and renal pelvis, 4 to the liver, and 5 to the bronchi and bone/facets. IQ was matched using the tin filter with relative dose reductions of 39% (aqueduct), 39% (liver), 57% (bronchi) and 48% (bone). Sn100kV provided greater dose reduction than Sn140kV in all tissues. Both observers deemed WB-ED as low as 0.14mSv (89% lower than FDG clinical reference) sufficient for localisation in bone/facets and characterisation in bronchi. Although absolute doses were greater with the obese phantom configuration, similar dose-savings for comparable IQ to the obese reference scan were observed. ***Conclusion:*** The tin filter allows localisation and characterisation CT IQ for PET-CT at ultra-low WB doses, providing large dose reductions compared with standard (non-tin) settings, with the greatest benefits noted in high-contrast structures.

## OP-501

### Ultra-low Dose CT With and Without Tin Filter for PET Attenuation Correction: Dose Savings and Quantification

***N. Bebbington***[1], *K. B. Christensen*[2], *L. L. Østergård*[2], *P. C. Holdgaard*[2];
[1]*Siemens Healthcare A/S, Aarhus, DENMARK,* [2]*Department of Nuclear Medicine, Lillebælt University Hospital, Vejle, DENMARK.*

***Aim/Introduction:*** A tin (Sn) filter can be used to reduce CT radiation dose to patients by filtering out a greater proportion of lower energy x-rays from the beam, compared with standard aluminium filtration. The aim was to determine by how much

dose can be reduced with ultra-low-dose (ULD) Sn- and non-Sn CT protocols, without significantly impacting PET quantification. ***Materials and Methods:*** The NEMA image quality phantom was imaged under three conditions: (1) water-filled (0HU representing soft tissue) with $^{18}$F-FDG; (2) cylindrical insert containing homogenous mix of sand, flour, water (SFW, approximately 400HU representing trabecular bone) and $^{18}$F-FDG, with water background; (3) cylindrical insert containing sand (approximately 1200HU representing cortical bone) and $^{18}$F-FDG, with water background. Each phantom condition underwent a 1 bed position PET-CT scan (26.3cm axial field-of-view) comprising 1 PET and 13 CT acquisitions. CT acquisitions used tube current modulation and were performed at 120kV/50mAs-ref (reference standard), 100kV/7mAs-ref (current ULDCT for attenuation correction (AC) standard), Sn140kV (mAs range 7-50-ref) and Sn100kV (mAs range 12-400-ref). PET data were reconstructed with μ-maps provided by each CT dataset, and volumes of interest assigned to measure PET activity concentration. Differences in CT dose length product (DLP) and PET quantification were determined relative to the 120kV/50mAs-ref reference standard. ***Results:*** At all tube voltages, differences in PET quantification were greater with increasing material density and reducing mAs. Compared with reference standard CT, differences in PET quantification for the 100kV/7mAs scans for the three phantom conditions were ≤1.7%, and DLP was reduced by 85.0% (DLP in water phantom =7.0 mGy.cm). For Sn100kV scans, differences in PET quantification were negligible (≤1.2%) for all three phantom conditions down to 50mAs-ref (DLP in water phantom=2.8mGy.cm, effective dose=0.04mSv), giving 94.2% DLP reduction compared with the reference, and 60% DLP reduction compared with the non-Sn ULDCT protocol. Below this level, differences in PET quantification were >2% for at least one of the three phantom conditions (2.3% at 25mAs-ref in SFW and 6.4% at 12mAs-ref in sand). At Sn140kV, quantification differences were ≤0.6% for all scans in the water phantom, increasing to 1.7-2.1% in SFW, and 2.9-3.7% in sand. DLP reductions at Sn140kV ranged from 65.2% (50mAs-ref) to 92.7% (7mAs-ref). ***Conclusion:*** CT protocols for PET AC with and without Sn filter (Sn100kV/50mAs-ref and 100kV/7mAs-ref) provide ultra-low doses with negligible impact on PET quantification. This Sn protocol provides 60% lower dose than the non-Sn ULDCT protocol for PET AC.

## OP-502

### How Low Can You Go With Ultra-low-dose Tin Filter CT in PET-CT? Evaluation of Dose and Artifacts in a Whole-body Patient Phantom

***N. Bebbington***[1], *K. B. Christensen*[2], *P. C. Holdgaard*[2], *L. L. Østergård*[2];
[1]*Siemens Healthcare A/S, Aarhus, DENMARK,* [2]*Department of Nuclear Medicine, Lillebælt University Hospital, Vejle, DENMARK.*

***Aim/Introduction:*** A CT tin filter can be used to reduce patient dose, and previous work demonstrated accurate PET quantification in the NEMA PET image quality phantom at such ultra-low dose CT (ULDCT). However, in patient CT scans, artifacts can sometimes be seen in images between structures providing very high attenuation, such as the shoulders and femoral heads, and could in turn affect PET attenuation correction (AC). The aims were to measure artifacts in standard low-dose (SLD) scans and ULD tin filter scans, to help determine appropriate exposure settings for ULDCT for AC in whole-body PET imaging, and to measure whole-body CT effective dose (ED). ***Materials and Methods:*** An adult whole-body CT phantom underwent repeated CT scans in standard and obese configurations, with tube current modulation at 120kV/20mAs-ref (SLD reference for PET bone imaging with localisation/characterisation CT), 100kV/7mAs-ref (non-tin ULDCT for AC protocol), Sn140kV (mAs range 7-50-ref) and Sn100kV (mAs range 12-400-ref). A semi-quantitative artifact score was calculated for each dataset, by identifying the most severe artifact in each group of 20 axial slices, and measuring the difference in HU (through placement of ROIs) for the most affected area and a corresponding unaffected area. Differences of 0-20HU, 20-30-HU, 30-50HU, 50-70HU and >70HU gave artifact scores of 0-4, respectively, for each group of slices. Whole-body artifact scores were calculated as the sum of all slice groups. Dose-length-product (DLP) was converted to whole-body (vertex-to-knee) ED for each scan using a DLP to ED whole-body conversion factor. ***Results:*** With SLD settings, whole-body artifact scores were 17 and 31, and EDs 1.4mSv and 2.3mSv, for standard and obese phantoms, respectively. At Sn100kV/50mAs-ref, artifact scores were considered matched to those with SLD settings, at 15 and 28, for standard and obese phantoms, with EDs at 0.2mSv and 0.4mSv. At Sn100kV/25mAs-ref, artifact scores increased to 37 and 98, albeit at lower doses of 0.1mSv and 0.2mSv. At Sn140kV, its highest artifact scores of 7 and 18 were provided at 7mAs-ref, with EDs of 0.2mSv and 0.3mSv, for standard and obese phantoms. At 100kV/7mAs-ref, artifact scores were 45 and 75, with EDs at 0.6mSv. ***Conclusion:*** ULDCT scans for PET AC with tin filter give a whole-body ED of 0.2mSv in a standard patient, whilst providing comparable or lower artifact scores to the SLD CT scan, with 85% lower dose. Artifact scores and EDs are also considerably lower than those for the current non-tin ULDCT protocol.

## OP-503

### Ultra-low-dose CT for Long Axial Field of View PET/CT: A Phantom Study

***S. Mostafapour***[1], *M. Greuter*[2], *P. van Snick*[1], *J. van Sluis*[1], *A. A. Lammertsma*[1], *C. Tsoumpas*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Department of Radiology, University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Attenuation correction (AC) CT contributes to the overall radiation exposure associated with (repetitive) whole-body PET/CT scans. Several approaches have been investigated to reduce CT radiation dose in whole-body PET/CT examinations (1). In some new CT scanners, a tin (Sn) filter can potentially reduce radiation dose without degrading PET image quality. The purpose of this phantom study was to evaluate ultra-low dose attenuation correction CT using various dose reduction options, such as a tin (Sn) filter, reducing the tube current, increasing the pitch factor, and applying tube current modulation. ***Materials and Methods:*** The ultra-low dose CT protocol was evaluated using five phantoms that mimic a wide range of tissue densities: 1) Tissue Characterization Phantom, 2) NEMA IQ phantom, 3) CT Whole Body Phantom, 4) Head Phantom, and 5) Anthropomorphic Torso Phantom. All phantoms were scanned on a LAFOV PET/CT scanner, applying the various CT dose reduction parameters. Two metrics (CT dose index volume available from the scanner and dose length product) were used to determine the dose resulting from the CT scans in the whole body. Several volumes of interest (VOIs) and voxel-based evaluations were performed to assess the effects of CT protocol changes. These assessments were performed by analysing the ultra-low dose CT images in some phantoms or the PET-AC scans in other phantoms against corresponding scans acquired and

reconstructed using a reference CT. CT images of the Whole-Body Phantom were compared in terms of contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) as well. ***Results:*** Using the tin filter and applying other dose reduction parameters resulted in a reduction of the effective radiation dose by almost 97%. At the same time, the reduction in SNR and CNR within the CT images was less than 65%. VOI and voxel-based comparisons of PET images showed a relative difference of less than 5% for all parts of the Torso phantom. ***Conclusion:*** Using a tin filter during CT scanning substantially reduces the overall radiation dose of whole-body PET/CT without a large impact on image quality. Nevertheless, future studies are needed to assess the effect of this method of dose reduction on PET quantification in human PET/CT studies therefore, the patient part of this study is scheduled. ***References:*** 1. Prieto, E., et al., 2021. Ultra-low dose whole-body CT for attenuation correction in a dual tracer PET/CT protocol for multiple myeloma. Phys Med, 84, 1-9.

## Clinical Oncology Track - TROP Session: Prostate Cancer Biochemical Recurrence

### OP-504

**Final Analysis of a Prospective, Single-center, Phase II/III Imaging Trial of $^{68}$Ga-RM2 PET/MRI in Patients with Biochemical Recurrence of Prostate Cancer**

***H. Duan***, *F. Moradi, G. A. Davidzon, T. Liang, H. Song, A. Loening, S. Vasanawala, S. Srinivas, J. D. Brooks, S. L. Hancock, A. Iagaru; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The recent NCCN guideline has included prostate-specific membrane antigen (PSMA)-targeted PET for the detection of biochemical recurrent (BCR) prostate cancer (PC). However, up to 10% of PC do not express PSMA, and given the high intratumor heterogeneity, targeting a single tumor characteristic might not be sufficient to reflect full extent of disease. Gastrin releasing peptide receptors (GRPR) have shown to be overexpressed in PC and can be targeted with $^{68}$Ga-RM2. In this study, we evaluated the diagnostic performance of $^{68}$Ga-RM2 PET/MRI in BCR PC. ***Materials and Methods:*** This prospective, single-center, open-label, single-arm, phase II/III trial was performed at Stanford University. Patients ≥18 years with Karnofsky performance ≥50, rising PSA ≥0.2 ng/mL after prostatectomy, or ≥2 ng/mL above nadir after radiotherapy, and non-contributory conventional imaging (negative CT and/or bone scan) were eligible. The primary outcome was to assess diagnostic performance of $^{68}$Ga-RM2 PET/MRI vs MRI alone. Each PET scan was interpreted by three independent masked readers using a standardized evaluation criteria. This study is registered with ClinicalTrials.gov NCT02624518 and is complete. ***Results:*** Between December 12, 2015 and July 27, 2021, 209 patients were screened for eligibility, of whom 100 were included. The primary endpoint was met; $^{68}$Ga-RM2 PET/MRI showed significantly higher detection rates than MRI alone (143 vs 96 lesions, respectively; P<0.001) and sensitivity (85.2%; 95% CI 75.6, 92.1 vs 49.4%; 95% CI 38.1, 60.7, respectively; P<0.001) while specificity was comparably high (100.0%; 95% CI 82.4, 100.0 vs 94.7%; 95% CI 74.0, 99.9, respectively; P=0.303). ***Conclusion:*** $^{68}$Ga-RM2 PET/MRI showed better diagnostic performance than MRI alone in BCR PC with significantly higher detection rates, sensitivity, and accuracy. Therefore, $^{68}$Ga-RM2 PET should be considered in BCR PC patients in aiding disease detection and management decision. Further prospective comparative studies with PSMA-targeted PET are needed to gain a better understanding of GRPR and PSMA expression patterns in BCR PC.

### OP-505

**Prospective Single-Centre Phase II Clinical Trial On The Diagnostic Accuracy of Fully Hybrid [68Ga]Ga-PSMA-11 PET/MRI and [68Ga]Ga-RM2 PET/MRI in Patients with Biochemically Recurrent Prostate Cancer**

***S. Ghezzo***[1,2], *P. Mapelli*[1,2], *A. Samanes Gajate*[2], *A. Palmisano*[3], *V. Cucchiara*[4,5], *G. Brembilla*[1,3], *C. Bezzi*[1,2], *N. Suardi*[6], *P. Scifo*[2], *A. Briganti*[1,4,5], *F. De Cobelli*[1,3], *A. Chiti*[1,2], *A. Esposito*[1,3], *M. Picchio*[1,2]; [1]*Vita-Salute San Raffaele University, Milan, ITALY,* [2]*Department of Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [3]*Department of Radiology, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [4]*Department of Urology, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [5]*Division of Experimental Oncology, URI, Urological Research Institute, Milan, ITALY,* [6]*IRCCS Ospedale San Martino, Genova, ITALY.*

***Aim/Introduction:*** This study aims to evaluate the diagnostic accuracy of [68Ga]Ga-PSMA-11 PET/MRI and [68Ga]Ga-RM2 PET/MRI in patients with biochemically recurrent prostate cancer (PCa). The secondary aim is to compare the patient and region-based detection rates of these imaging modalities. Furthermore, the association between imaging findings and clinical data is explored. ***Materials and Methods:*** Forty-four patients with biochemically recurrent PCa underwent [68Ga]Ga-PSMA-11 PET/MRI and [68Ga]Ga-RM2PET/MRI within 16 days (median:2,range:2-16 days). Two Radiologists interpreted MRI and two Nuclear Medicine physicians analysed PET images. Images were then re-examined to produce an integrated PET/MRI report for both [68Ga]Ga-PSMA-11 and [68Ga]Ga-RM2. In the integrated report, imaging was considered positive for malignancy if at least one imaging modality was clearly positive for PCa recurrence or if both modalities were concordant in the suspect of recurrence. Clinical and instrumental follow-up (median follow-up:22.8,range:6-31.5 months) was used to validate imaging findings at the patient-level. Diagnostic performance was assessed with accuracy, sensitivity, specificity, positive and negative predictive value. McNemar's test was used to compare sensitivity and specificity on a per-patient base and detection rate on a per-region base. Prostate bed, locoregional lymph nodes, non-skeletal distant metastases, and bone metastases were considered. Univariable logistic regression was used to identify the role of age, ISUP grade, time to biochemical recurrence, PSA at time of scans, initial PSA, PSA doubling time and PSA velocity for the prediction of positive imaging. P-value significance was defined below the 0.05 level after correction for multiple testing. ***Results:*** Patients' median age was 69.8 years (IQR=61.8-75.1) and median PSA level at time of imaging was 0.53 ng/mL (IQR=0.33-2.04). Evidence of PCa recurrence was observed in 31/44 patients at follow-up. [68Ga]Ga-RM2 PET showed lower sensitivity compared to [68Ga]Ga-PSMA-11 PET and MRI (0.613 vs 0.839 and 0.871,p=0.046 and 0.043, respectively), while specificity was comparable among the imaging modalities (1 vs 0.846 and 0.692,p=0.479 and 0.134; respectively). Combining MRI with[68Ga]Ga-PSMA-11 PET and [68Ga]Ga-RM2 PET resulted in sensitivity =1 and 0.935 and specificity of 0.692 and 0.692; respectively. The integrated assessment of PET (both with [68Ga]Ga-PSMA-11 and [68Ga]Ga-RM2) and MRI improved the detection rate of locally

recurrent PCa. No significant associations were found between the investigated clinical data and imaging findings. ***Conclusion:*** PET/MRI is useful to characterize patients with biochemically recurrent PCa. Furthermore, it was reported high sensitivity for [68Ga]Ga-PSMA-11 PET and MRI, while the utility of [68Ga]Ga-RM2 PET in absence of a simultaneous whole-body/multiparametric MRI remains to be determined.

## OP-506

### Higher Preoperative Maximum Standardised Uptake Values ($SUV_{max}$) are Associated with Higher Biochemical Recurrence Rates After Robot-Assisted Radical Prostatectomy for $^{68}$Ga-PSMA-11 and $^{18}$F-DCFPyL PET/CT

***K. De Bie***[1], *H. Veerman*[1], *Y. J. L. Bodar*[1], *D. Meijer*[1], *P. J. van Leeuwen*[2], *H. G. van der Poel*[2], *M. Donswijk*[2], *A. N. Vis*[1]; [1]*Amderdam UMC, Amsterdam, NETHERLANDS,* [2]*Nederlands Kanker Instituut, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** In patients with primary prostate cancer (PCa), the visual and semi-quantitative measuring of PSMA tracer uptake in the prostate lesions by the maximum standardized uptake value ($SUV_{max}$) are essential. We evaluated whether in patients with primary PCa, the $SUV_{max}$ on preoperative PSMA PET/CT was associated with the development of biochemical recurrence (BCR) after robot-assisted radical prostatectomy (RARP). ***Materials and Methods:*** We retrospectively analysed 446 PCa patients who underwent a $^{68}$Ga-PSMA or $^{18}$F-DCFPyL PSMA PET/CT scan prior to RARP. PET/CT scan images were visually and semi-quantitatively analysed by measuring $SUV_{max}$ in the clinically suspicious prostate cancer lesions. BCR was defined as two consecutive PSA values ≥0.2 ng/mL after RARP. The predictive value of $SUV_{max}$ for BCR was evaluated using uni- and multivariable Cox regression analyses, adjusting for preoperative variables: radiologic tumor stage (mT), biopsy International Society of Urological Pathology grade group (bISUP), and positive lymph nodes on PSMA PET/CT (miN1), or postoperative variables: pathologic ISUP group (pISUP), pathologic T-stage (pT), and positive surgical margins (R1). Based on the $SUV_{max}$ distribution among the patients, $SUV_{max}$ was classified into two groups (high: $SUV_{max}$ >10 and low: $SUV_{max}$ ≤10). ***Results:*** $SUV_{max}$ >10 was a significant predictor for BCR (p<0.001). This was also true for the subgroups bISUP3-5, mT3, and EAU classification: high risk for BCR (p<0.001, p=0.002, and p=0.004, respectively). Negative lymph node status (miN0) was associated with developing BCR (p=0.01), as opposed to miN1 (p=0.11). In multivariable analysis, adjusting for mT, bISUP, and miN1, $SUV_{max}$ was an independent preoperative predictor for the development of BCR (p=0.03). ***Conclusion:*** PSMA tracer expression of the dominant prostate cancer lesion on PSMA PET/CT, defined as $SUV_{max}$, was an independent predictor for BCR after RARP in patients with primary PCa. $SUV_{max}$ >10 might be used as a prognostic factor for an unfavourable outcome after RARP.

## OP-507

### Staging with [68Ga]Ga-PSMA-11 PET/CT in patients with intermediate and high-risk prostate cancer prior surgery. Is there any association between semiquantitative parameters and biochemical recurrence?

***J. Rosales***[1], *J. Bastidas*[1], *A. Bronte*[1], *V. Betech-Antar*[1], *F. Minguez*[1], *M. Romera*[1], *F. Pareja*[1], *E. Guillen*[2], *S. Menendez-Sanchez*[1], *C. Beorlegui*[3], *J. Arbizu*[1], *J. Peréz Gracia*[4], *M. Rodriguez-Fraile*[1]; [1]*Nuclear Medicine Department, University Clinic Of Navarra, Pamplona, SPAIN,* [2]*Nuclear Medicine Department, University Clinic Of Navarra, Madrid, SPAIN,* [3]*Planning Evaluation and Knowledge Management Health Department, Government of Navarra, Pamplona, SPAIN,* [4]*Oncology Department, University Clinic Of Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** We aimed to describe semiquantitative parameters of PSMA-PET in intermediate and high-risk prostate cancer (PCa) patients prior to surgery and their prognostic value for biochemical recurrence (BR). ***Materials and Methods:*** Fifty PCa patients referred for PSMA-PET/CT for initial staging and scheduled for radical prostatectomy (RP) were included. PET-parameters including tumor SUVmax, Prostate Molecular Tumor Volume (pMTV), Prostate Volume (pV), Prostate Total Lesion Activity (pTLA) and Prostate Disease Burden % (pDB) were recorded. pV was obtained by automated segmentation of prostate gland on CT images using work in progress syngo.via MI General Anatomy Segmentation software (Siemens Healthineers, Knoxville, TN). pDB was calculated using the formula (pMTV x 100 / pV). Moreover, other clinical and tumor-specific characteristics were also analyzed. Receiver-operating-characteristic (ROC) curve analysis was used to determine optimal cut-off values for the PET parameters to identify BR. Univariate and multivariate logistic regression analysis were used to determine the association between clinicopathologic variables, PET-parameters before RP and the occurrence of BR. ***Results:*** Twenty-two intermediate-risk (IR) and twenty-eight high-risk (HR) PCa patients were included. The median SUVmax was 10.85 (9.96-12.90) in the IR group and 13.49 (7.08-17.76) in the HR group. The median pMTV and pTLA in the HR group were 3.85 cm3 (2.43-7.97) and 28.10 (14.99-60.19) respectively and 2.86 cm3 (1.87-5.65) and 19.05 (11.44-25.57) in the IR group. After a median follow-up of 24 months (± 8.8), 42% of patients experienced BR within 2 years of RP. pMTV, pTLA, pDB were statistically higher in patients with BR than in patients who remained with undetectable PSA levels (p<0.05 each, Table 1). The ROC curves showed that a pDB cut-off value of 8.10% had a sensitivity of 77% and a specificity of 75% (AUC=0.716 [95%CI: 0.55-0.87; p=0.014]), for discriminating those patients who experienced BR during follow-up. On multivariate regression analysis, both Gleason Score ≥8 (OR=5.5 [95%CI: 1.2-25.8, p=0.030]) and pDB >8.10% (OR=6.8 [95%CI:1.6-29, p=0.010)], significantly predicted BR at the last follow-up, whereas other clinical, tumor-specific and semiquantitative parameters did not. ***Conclusion:*** Preoperative PSMA-PET semiquantitative parameters (pMTV, pTLA and pDB) were significantly higher in patients with BR than in patients who remained with undetectable PSA levels. Both Gleason Score ≥8 and pDB >8.10% were significant predictors for the risk of postoperative BR. Further studies with a larger number of patients and longer follow-up periods are necessary.

## OP-508

### From CHAARTED low- and high-volume disease to PSMA PET imaging volume in mHSPC patients: an international multicenter retrospective study

***L. Unterrainer***[1,2], *T. A. Hope*[3], *H. Ndlovu*[4], *F. Barbato*[5], *W. P. Fendler*[5,6], *K. Herrmann*[5,6], *M. Sathekge*[4], *J. Czernin*[1], *J. Calais*[1]; [1]*UCLA, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*LMU Munich, Munich, GERMANY,* [3]*UCSF, San Francisco, CA, UNITED STATES OF AMERICA,* [4]*University of Pretoria, Pretoria, SOUTH AFRICA,* [5]*University Hospital Essen, Essen, GERMANY,* [6]*German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY.*

***Aim/Introduction:*** In patients with mHSPC, the volume of disease (high-volume disease (HVD) / low-volume disease (LVD)) as defined by the CHAARTED criteria based on conventional imaging (CT + bone scan (BS)), is associated with overall survival and used for treatment decisions. PSMA-PET has a higher sensitivity and specificity than conventional imaging. It remains unknown how the definition of HVD and LVD can be

transferred to PSMA-PET-based criteria. ***Materials and Methods:*** In this retrospective study, mHSPC patients who underwent a $^{68}$Ga-PSMA-11 PET/CT or PET/MRI and a BS (CI) (within a maximum time interval of 100 days) at 4 international sites were included. Patients with treatment in between both scans were excluded. HVD and LVD was retrospectively determined on the BS and the CT/MRI component acquired with PET. Additionally, CHAARTED stratification into HVD and LVD was applied to PSMA-PET. HVD was defined by the presence of visceral metastases and / or ≥ 4 bone metastases (with ≥ 1 beyond spine and pelvis). EXINIbone™ 3.4 (EXINI Diagnostics) was used to obtain the number / localization of bone metastases on BS and the quantitative bone scan index. The whole-body (WB) PSMA-PET positive tumor volume (PSMA-TV) was obtained using a semi-automatic thresholding method on Affinity 3.0.2 (Hermes Medical Solutions). ***Results:*** 40 mHSPC patients with paired PSMA-PET+BS were included. Median PSA was 42.2 (0.2 - 5675.0) ng/ml. 12/40 patients had disease detected in the prostate fossa, 23/40 in lymph nodes, 25/40 in bones and 2/40 in visceral organs by CI and 24/40, 24/40, 20/40 and 2/40 by PSMA-PET, respectively. 12/40 patients had $CI_{HVD}$ (30%) and 28/40 $CI_{LVD}$ (70%) based on CI, and 16/40 patients had PSMA-$PET_{HVD}$ (40%) and 18/40 PSMA-$PET_{LVD}$ (45%) by PSMA-PET. 6/40 (15%) patients had no PSMA-positive lesion or only in the prostate fossa while CI was at least $CI_{LVD}$. Overall, mean WB-PSMA-TV was 394.9 ml (0 - 3734.0 ml). In $CI_{HVD}$, mean WB PSMA-TV was 961.1 (0.3 - 3734.0) ml, in $CI_{LVD}$, 111.9 (0-1201.0) ml and in PSMA-$PET_{HVD}$ 870.8 (0 - 1427.0) ml and in PSMA-$PET_{LVD}$ 59.7 (0 - 117.0) ml, respectively. Upstaging (LVD to HVD) from CI to PSMA-PET occurred in 5/40 patients (12.5%), and downstaging in 6/40 patients (15.0%). ***Conclusion:*** Stage migration between LVD/HVD from conventional imaging to PSMA-PET occurs both by upstaging and downstaging. Correlation with outcome of the new definitions of HVD/LVD based on PSMA-PET/CT is warranted.

## OP-509

### Head-to-head comparison of $^{68}$Ga-PSMA-11 PET with $^{99}$mTc-MDP bone scan for detection of bone disease in prostate cancer patients with biochemical progression during ADT: a single center prospective study

***A. Gafita****, R. Alano, M. Rettig, J. Shen, W. Armstrong, T. R. Grogan, S. Liu, M. R. Benz, J. Czernin, J. Calais;*
*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** $^{68}$Ga-PSMA-11 PET/CT (PSMA-PET) was approved in patients with prostate cancer (PCa) at primary staging or biochemical recurrence. However, it is unclear if bone scan (BS) remains indicated in men with PCa and with biochemical progression under ADT. This study aimed to compare the detection rate of bone disease for PSMA-PET vs BS in men with PCa and with biochemical progression during ADT. ***Materials and Methods:*** This was a prospective single-center, open-label, single-arm, head-to-head comparison, prospective phase 2 study (NCT04928820). Men with i) biopsy-proved PCa, ii) who had rising PSA levels on 2 successive occasions ≥1 week apart, iii) were receiving treatment with hormonal therapy, iii) and had an absolute PSA value ≥1 ng/ml were eligible. Men who were enrolled received PSMA-PET and bone scan within 30 days. The primary endpoint was detection rate of bone disease for PSMA-PET vs BS. Secondary endpoint was the number of bone lesions detected by PSMA-PET vs BS. Number of lesions was categorized into: 0 vs 1 vs 2 vs 3 vs 4 vs 5 vs >5. A p <0.05 was considered statistically significant. ***Results:*** 22 men were enrolled between July 8, 2021 and June 9, 2022. The median patients age was 71 years (range: 56-94). The median time between scans was 12 days (range: 1-29). The median PSA value was 9.5 ng/ml (range: 1.2 - 1717). 11/22 (11%) patients had hormone-sensitive PCa, while 11/22 (50%) had castration-resistant PCa prior to receiving the scans. The positivity rate for bone disease was equal for PSMA-PET and BS in all cases: 7/22 (32%) patients had negative scans on both imaging modalities and 15 (68%) had ≥1 bone lesion detected on both imaging modalities (p=1.00). In 15/22 (68%) men, both imaging modalities showed equal number of bone lesions: 0 lesions in 7/22 (32%) men and >5 lesions in 8/22 (36%) men. In 3/22 (14%) men BS showed higher number of lesions, while in 4/22 (18%) men PSMA-PET showed higher number of lesions (Table 1). No statistical difference was noticed between PSMA-PET and BS in number of bone lesions detected (p>0.05). PSMA PET scan detected non-bony disease in 13/22 (59%) men: TrN0M0 in 10/22 (45%), TxN1-M1a in 7/22 (32%), and TxNxM1c in 4/22 (18%) men. ***Conclusion:*** In this prospective study of patients with prostate cancer with rising PSA levels under hormonal therapy, $^{68}$Ga-PSMA-11 PET and $^{99}$mTc-MDP bone scan had similar detection rate for bone disease.

## OP-510

### Factors Affecting Diagnostic Performance of Ga-68 PSMA PET/MRI in Biochemical Recurrent Prostate Cancer and Nomogram Model

***S. Küçükali****, U. Aydos, E. Balcı, Ü. Akdemir, L. Atay;*
*Gazi University, Faculty of medicine, Ankara, TÜRKIYE.*

***Aim/Introduction:*** This study aimed to evaluate the diagnostic performance of imaging and to examine the factors affecting the detection rate in prostate cancer (PC) patients who underwent Ga-68 PSMA PET/MR imaging for biochemical recurrence (BCR) after radical prostatectomy (RP). ***Materials and Methods:*** This study included 104 PC patients who underwent PET/MRI between 2016 and 2022 due to post-RP BCR. In the visual evaluation, the presence, localization and number of pathological lesions were assessed. Total PSA(ng/ml), ISUP Gleason grades(GG), presence of androgen deprivation therapy (ADT), and PSA doubling time (PSAdt) were recorded. Logistic regression analysis was performed to determine the factors predicting PET/MRI positivity. Additionally, a nomogram was created to determine the probability of PET/MRI positivity in the early BCR group (PSA<1.0 ng/ml) by using the lrm() and nom() functions in the R software rms package. ***Results:*** In 73 (70.2%) patients, positive findings consistent with recurrence were detected on imaging. Of the patients, 11 had local recurrence, 50 had pelvic lymph node involvement, 17 had distant lymph node metastasis, 13 had bone metastasis, and 8 had visceral organ metastasis. In multivariate logistic regression analysis, total PSA and PSAdt were found as independent predictive factors for imaging positivity (Table 1). According to total PSA values, imaging positivity rates were 38% in patients with a PSA level of <0.2, 41.2% in patients with a PSA level between 0.2-<0.5, 75% in patients with a PSA level between 0.5-<1.0, 94.1% in patients with a PSA level between 1.0-<2.0, and 100% in patients with a PSA level of ≥2.0. The imaging positivity rate was 97.6% in the patient group with total PSA value of ≥1.0 ng/ml. In patients with early BCR (n=62), the detection rate was 80% in patients with a PSAdt ≤3 months, 68.2% in patients with a PSAdt between 3 months and 6 months, and 20% in patients with a PSAdt >6 months. Figure 1 shows the nomogram that predicted imaging positivity in patients with PSA<1.0 ng/ml. In the nomogram, the variables are scored on a 0-100 scale, and the probability of PSMA PET/MR positivity can be calculated

according to the total score. ***Conclusion:*** If PSA level is ≥1.0 ng/ml in PC patients with BCR after RP, Ga-68 PSMA PET/MRI has a very high lesion detection rates. In patients with PSA<1.0 ng/ml, the PSAdt is very effective in the diagnostic performance of the imaging method and should be considered in patient selection.

## OP-511

### The diagnostic performance of $^{68}$Ga-PSMA-11 PET/CT versus multiparametric MRI for detecting intra-prostatic radiorecurrent prostate cancer

***A. Light***[1], *S. Lazic*[2], *M. Bayne*[3], *M. J. Connor*[1], *H. Tam*[2], *H. U. Ahmed*[1], *T. T. Shah*[1], *T. D. Barwick*[2];
[1]*Imperial Prostate, Imperial College London, London, UNITED KINGDOM,* [2]*Department of Radiology, Charing Cross Hospital, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM,* [3]*Imperial Urology, Charing Cross Hospital, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** For patients with biochemical recurrence after radiotherapy for prostate cancer, PSMA PET/CT is increasingly used to detect extra-prostatic disease. However, its ability to localise intra-prostatic lesions is unclear, with previous studies omitting histological verification of imaging findings. This is important for planning any local salvage treatment. Using a histopathological reference standard, we evaluated the diagnostic accuracy of $^{68}$Ga-PSMA-11 PET/CT for this purpose and compared this to mpMRI. ***Materials and Methods:*** In this single-centre retrospective series (2017-2022), men with a rising PSA post-radiotherapy underwent mpMRI, $^{68}$Ga-PSMA-11 PET/CT and systematic and/or targeted biopsy. PET/CT was performed with both standard knees-to-vertex acquisitions (mean 61 minutes post-injection) and delayed post-micturition pelvic acquisitions (mean 91 minutes post-injection). Each PET/CT was reported in sextants by a single expert blinded to previous imaging and clinical data. Suspicion of intra-prostatic radiorecurrence was denoted by a 5-point Likert score, with scores 3-5 indicating a suspicious scan. Diagnostic accuracy metrics were calculated comparing PET/CT versus MRI, and comparing PET/CT with MRI used together versus MRI alone. Analyses were performed at the hemi-gland level using cluster bootstrapping with 1,000 resamples. ***Results:*** 35 men (70 hemi-glands) were included. 45/70 (64%) hemi-glands had a suspicious PET/CT, and 41/70 (59%) had a suspicious MRI. When using both modalities in conjunction, 55/70 (79%) hemi-glands were deemed suspicious. 43/70 hemi-glands (61%) had cancer on biopsy. PET/CT missed 6/43 (14%; 95%CI 6-28%). MRI missed 12/43 cancers (28%; 95%CI 17-43%), with 10/12 of these cancers detected by PET/CT. PET/CT sensitivity and specificity were 0.86 (95%CI 0.76-0.95) and 0.71 (95%CI 0.54-0.87), respectively, which were not significantly different to MRI sensitivity and specificity (sensitivity: 0.72, 95%CI 0.61-0.83, p=0.2; specificity: 0.64, 95%CI 0.44-0.83, p=0.8). PET/CT PPV was 0.83 (95%CI 0.70-0.93), and NPV was 0.76 (95%CI 0.58-0.92), both also not significantly different to MRI (PPV: 0.76, 95%CI 0.62-0.90, p=0.3; NPV: 0.59, 95%CI 0.41-0.75, p=0.09). When both PET/CT and MRI were used together, sensitivity was 0.95 (95%CI 0.89-1.00), significantly higher than MRI alone (p=0.004). NPV was 0.88 (95%CI 0.67-1.00), also significantly higher than MRI alone (p=0.004). Specificity was 0.50 (95%CI 0.30-0.68), and PPV 0.75 (95%CI 0.62-0.87), both not significantly different versus MRI alone (p=0.1 and 0.8, respectively). ***Conclusion:*** $^{68}$Ga-PSMA-11 PET/CT has high sensitivity, though the use of both $^{68}$Ga-PSMA-11 PET/CT and mpMRI together, provides a significantly greater sensitivity and NPV than mpMRI alone. Negative imaging with both modalities could therefore be a useful rule-out tool in this population.

## OP-512

### The imaging characteristics of theranostic $^{99m}$Tc/$^{188}$Re-PSMA-GCK01 is equivalent to dedicated diagnostic $^{99m}$Tc-HYNIC-iPSMA in prostate cancer

***E. Mamlins***[1], *J. Cardinale*[1,2], *M. Krotov*[1], *E. Winter*[2], *H. Rathke*[2,3], *U. Haberkorn*[2], *C. Kratochwil*[2], *F. Giesel*[1];
[1]*Department of Nuclear Medicine, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY,* [3]*Department of Nuclear Medicine, Inselspital Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Radiolabelled PSMA-ligands play a major role in today's nuclear medicine. Since approval of $^{177}$Lu-PSMA-617 for therapy of metastatic prostate cancer, both the capacity of PSMA-PET and the availability of $^{177}$Lu became bottleneck of supply due to the high demand. Recently a theranostic PSMA-ligand, PSMA-GCK01, was developed which can be labelled either diagnostically or therapeutically based on de-centralized available $^{99}$Mo/$^{99m}$Tc and $^{188}$W/$^{188}$Re generator nuclides. This novel tracer might solve supply limitations. In this investigation, the diagnostic imaging characteristics of $^{99m}$Tc-PSMA-GCK01 were compared with the purely diagnostic reference compound $^{99m}$Tc-HYNIC-iPSMA in patients with advanced stage prostate cancer. ***Materials and Methods:*** Between 01/2021 and 02/2022 two cohorts (n=21 vs. n=22) of patients with metastatic castration-resistant prostate cancer matched for age, tumor stage and total Gleason score underwent a planar gamma camera imaging with $^{99m}$Tc-HYNIC-iPSMA and $^{99m}$Tc-PSMA-GCK01 prior to PSMA-ligand therapy for PSMA-phenotyping. The imaging data were retrospective analysed for salivary gland, kidney, liver, soft-tissue and tumor-uptake on a semi-automated ROI-analysis using Hermes Medical Solution (HMS, Sweden). ***Results:*** Out of the cohort of $^{99m}$Tc-HYNIC-iPSMA, two patients has been excluded due to incomplete records. All other data set were semi-automated quantified on a ROI-based analysis. The tumor-to-background presented equal results of $^{99m}$Tc-PSMA-GCK01 compared to $^{99m}$Tc-HYNIC-iPSMA. The physiological PSMA-positive organs like salivary gland presented also equal uptake in counts/MBq (salivary gland median 9,48 $^{99m}$Tc-PSMA-GCK01 vs. median 9,11 $^{99m}$Tc-HYNIC-iPSMA), while liver-to-kidney ratio presented a slide shift to the liver parenchyma using $^{99m}$Tc-PSMA-GCK01 (0,83) compared to $^{99m}$Tc-HYNIC-iPSMA (0,55) with no statistical significance. ***Conclusion:*** The novel theranostic tracer $^{99m}$Tc/$^{188}$Re-PSMA-GCK01 demonstrates comparable diagnostic imaging characteristic compared with diagnostic reference compound $^{99m}$Tc-HYNIC-iPSMA. These results pave the way for the PSMA-targeting imaging and theranostic agents for a broader, rather low-cost, generator applied radio-ligand therapy utilisation.

### 99mTc-white blood cell scintigraphy performance in thoracic aortic vascular graft infection: be careful in early post-operative period

***B. Mahida***[1,2], *M. Para*[2,3], *C. Regis*[1,4], *L. Deconinck*[5], *K. Ben Ali*[1,2], *X. Duval*[3,6], *B. IUNG*[3,7], *F. Rouzet*[1,2];
[1]*Nuclear medicine department, Bichat Hospital, AP-HP, Paris, FRANCE,* [2]*Université Paris Cité, Paris, FRANCE,* [3]*Department of Cardiovascular Surgery and Transplantation, Bichat Hospital, AP-HP, Paris, FRANCE,* [4]*Department of Medical Imaging, Institut de cardiologie de Montréal, Université de Montréal, Montréal, QC, CANADA,* [5]*Infectious Disease Department, Bichat Hospital, AP-HP, Paris, FRANCE,* [6]*Clinical Investigation Center, Bichat Hospital, AP-HP, Paris, FRANCE,* [7]*Cardiology Department, Bichat Hospital, AP-HP, Paris, FRANCE.*

***Aim/Introduction:*** Thoracic aortic vascular graft infection (TAVGI) is rare, yet it is associated with a high morbidity and mortality. TAVGI diagnosis in early postoperative stages is challenging particularly with conventional anatomic imaging tools. The aim of this study was to assess the value and performance of 99mTc-hexamethypropylene amine oxime labeled autologous white blood cell (WBC scintigraphy) in the diagnosis of TAVGI during early postoperative period following TAVG surgery. ***Materials and Methods:*** From January 2011 to February 2022, 46 patients with suspected TAVGI who underwent WBC scintigraphy were retrospectively included. The final diagnosis was established by local multidisciplinary team considering clinical, bacteriological and imaging findings after a >6-month follow-up. Since 2 patients were lost to follow-up, the final analysis was performed on 44 patients. The median age was 63 years (range 22-85). A majority of patients underwent Bentall procedure (72%). Twenty-seven patients were finally diagnosed with TAVGI. They were all treated with antibiotics alone (n=22) or in combination with redo surgery (n=5). The rest of the study population underwent medical observation. The mean delay between initial vascular graft surgery and WBC scintigraphy was 734±1226 days. ***Results:*** In the overall study population, the diagnostic sensitivity, specificity, positive predictive value, and negative predictive value were 81.5%, 64.7%, 78.6%, and 68.8% respectively. Out of 29 patients with positive WBC scintigraphy, 6 were false positive because no relapse occurred during the follow-up without antibiotic treatment. The delay between vascular graft procedure and WBC scintigraphy was <35 days in 4 of them. One of the 2 other false positive patients underwent iterative embolization procedures, 2 months prior to scintigraphy and showed intense uptake on the vascular plugs sites, while the other patient had progressing pseudoaneurysm at the site of positive scintigraphy. When WBC scintigraphy was performed in the early postoperative period (<35 days), all scans were positive (n=13) with 100% sensitivity and 4 false positive conversely to the 33 scans performed ≥ 35 days after surgery with a 72% sensitivity and a 84.6% specificity. ***Conclusion:*** WBC scintigraphy is reliable to rule out thoracic aortic vascular graft infection. However its specificity decreases in the early post-operative period following surgery (<35 days).

## OP-514

### Fast-Track Pathway for Early Diagnosis and Management of Giant Cell Arteritis At University College London Hospital: Positive Impact of FDG PET-CT for Detection of Active Vasculitis

***A. Alduraibi***[1,2], *D. Ludwiga*[3], *S. Vöö*[4], *V. Morrisa*[3];
[1]*Department of Radiology, College of Medicine, Qassim University, qassim, SAUDI ARABIA,* [2]*University College London Hospitals Nhs Foundation Trust, London, UNITED KINGDOM,* [3]*Department of Rheumatology, University College London Hospital, University College London Hospitals NHS Foundation Trust (UCLH) and bInstitute of Nuclear Medicine, UCLH, London, UNITED KINGDOM,* [4]*Institute of Nuclear Medicine, University College London Hospital, London, UNITED KINGDOM.*

***Aim/Introduction:*** Giant cell arteritis (GCA) is the most common type of vasculitis characterized by systemic inflammation, arteritis, and critical ischemia. Immediate, accurate diagnosis and access to appropriate treatment are key factors in preventing morbidity associated with this disease. Recent developments in vascular imaging prompted a review of our management of GCA patients. Here, we present the newly implemented Fast-track pathway (FTP) in GCA at the University College London Hospital, using combined temporal artery ultrasound (TAUS) and [18F]-fluorodeoxyglucose PET- computed tomography (FDG PET-CT). ***Materials and Methods:*** All patients with clinical suspicion of GCA were prospectively included in the study and evaluated following the existent GCA FTP. Patient underwent temporal artery ultrasound (TAUS) and temporal artery biopsy (TAB) within 24 h of presentation and FDG PET-CT within 72 h. Imaging protocol and interpretation were based on current clinical guidelines. FDG PET-CT images were considered positive if FDG uptake in vascular regions (thoracic aorta, abdominal aorta, subclavian arteries, axillary, carotid, vertebral, iliac, and femoral arteries) was higher or equal to the background FDG uptake in the liver. Imaging results were correlated with TAB outcomes and gold-standard clinical follow up. ***Results:*** Of 21 patients assessed by FTP (from June to December 2019), 13 patients (61.9%) had a positive diagnosis of GCA. TAB was positive in less than half of the GCA-positive cases (5/13). Of the TAB-positive cases, there was a strong correlation observed between TAB and imaging (TAUS + FDG PET-CT) findings. Most GCA-positive cases on TAB demonstrated GCA-positive features on imaging (4/5), indicating an excellent positive predictive value for our FTP in GCA. Eight patients (8/13) were negative on TAB, with high clinical suspicion of GCA demonstrated and typical GCA features on imaging (TAUS and FDG PET-CT). Two of these positive patients (2/13) had positive PET-CT, whereas both TAB and TAUS were negative for temporal artery involvement. Two GCA-mimics were detected on FDG PET-CT (2/21): one case of malignancy and one skull base infection. ***Conclusion:*** The use of FDG PET-CT increases the diagnostic yield of FTP for early detection of GCA. The combination of TAUS and FDG PET-CT shows a higher diagnostic accuracy compared to TAB. In addition, FDG PET-CT is valuable in identifying GCA-mimics, preventing inappropriate steroid therapy, and prompts for further secondary referrals in GCA-mimic cases.

## OP-515

### [18F]FDG-PET/CT as a Prognostic Inflammatory Imaging Marker in Giant Cell Arteritis

***P. Nienhuis***, *Y. Van Sleen, E. Brouwer, R. H. J. A. Slart;*
*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Giant cell arteritis (GCA) is a large vessel vasculitis affecting the aorta, its major branches, and the arteries of the head and neck. Predicting its disease course is difficult because clinical presentation and inflammatory biomarkers are not disease specific. Hence, adequate management of the disease may be challenging. [18F]-fluoro-deoxyglucose (FDG) positron emission tomography-computed tomography (PET/CT) is an established diagnostic tool in GCA, but its prognostic value remains unclear. This study aimed to investigate [18F]FDG-PET/CT as a prognostic tool for GCA. ***Materials and Methods:*** This study involved patients with newly diagnosed GCA enrolled a prospective cohort study who underwent [18F]FDG-PET/CT prior to glucocorticoid therapy. The aorta, its major branches, and the cranial arteries were visually scored on a scale of 0-3, after which the scores were summed for a total vascular score (TVS). The same arteries were also manually segmented for volumetric semiquantitative analysis using total lesion glycolysis (TLG), which is a multiplication of the mean standardized uptake value and the volume of inflamed arterial wall. The relationship between [18F]FDG-PET/CT data and clinical outcomes was examined, with treatment-free remission as the primary endpoint. ***Results:*** In total, 29 patients were included in the study. The a median follow-up time was 4.4 years (range 1.0-9.8 years). Using receiver operating characteristics (ROC) analysis, TLG was able to distinguish patients who achieved treatment-free remission at 3 years (AUC 0.82, p=0.0076). Those having high TLG scores were more likely to have achieved treatment-free remission. Using the optimal ROC-based cut-off, Kaplan-Meier analysis showed that patients with high TLG achieved treatment-free remission faster (p=0.0442). No significant differences were observed when using TVS. ***Conclusion:*** High TLG was linked to a better response to treatment in GCA patients, while TVS did not show any association with disease course. These findings contrast with previous studies that reported a high TVS to be associated with a more complicated disease course or to have no relationship with disease course [1,2]. TLG provides a more comprehensive measure of the degree of inflammation in the vessel wall compared to visual scoring, which may explain the contrasting findings of this study. Moreover, high volumetric FDG uptake reflects heightened metabolic and inflammatory activity and therefore may indicate a greater responsiveness to anti-inflammatory medication. ***References:*** [1] Grayson et al. Arthritis Rheumatol 70.3 (2018): 439. doi: 10.1002/art.404032 [2] Sammel et al. Int J Rheum Dis 23.4 (2020): 582-588. doi: 10.1111/1756-185X.13724

## OP-516

### 18F-FDG-PET/CT imaging on the LAFOV-PET/CT in patients with suspected large vessel vasculitis: reference values and diagnostic performance.

***L. Knappe***, *C. Bregenzer, N. Gözlügöl, C. Mingels, A. Rominger, F. Caobelli;*
*Department of Nuclear Medicine, Inselspital Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** 18F-FDG PET/CT is an important diagnostic tool in suspected large vessel vasculitis (LVV). However, reference values and diagnostic performances are still unknown for PET-scanner with long-axial field-of-view (LAFOV). ***Materials and Methods:*** Images of 110 patients with suspected LVV were retrospectively evaluated. All underwent 18F-FDG PET/CT on a LAFOV-PET/CT-Scanner 60 minutes after injection of 3.0 MBq/Kg FDG. Semiquantitative parameters were calculated for supra-aortal vessels (temporal, carotid and subclavian arteries) and aortic/infra-aortal vessels (thoracic and abdominal aorta, external iliac and femoral arteries). To liver and bloodpool (BP) normalized values were also calculated in all vessels. The final diagnosis was obtained by consensus in a multidisciplinary meeting. ***Results:*** 50 of 110 patients (45.5%) had a final diagnosis of LVV. Both for supra-aortic and infra-aortic vessels, all semi-quantitative parameters were significantly different between patients with and without LVV ($p<0.01$ for all). At ROC-Curves analysis the following parameters yielded highest diagnostic accuracy for supra-aortal LVV: to-liver-$SUV_{max}$ (AUC 0.90, threshold 0.65 with sensitivity 86% and specificity 77%), to-BP-$SUV_{max}$ (AUC 0.92, threshold 1.00 with sensitivity 90% and specificity 79%), to-liver-$SUV_{peak}$ (AUC 0.87, threshold 0.61 with sensitivity 80% and specificity 72%), to-BP-$SUV_{peak}$ (AUC 0.90, threshold 0.94 with sensitivity 88% and specificity 80%) and for infra-aortal LVV: to-liver-$SUV_{max}$ (AUC 0.98, threshold 0.83 with sensitivity 96% and specificity 90%), to-BP-$SUV_{max}$ (AUC 0.97, threshold 1.27 with sensitivity 92% and specificity 92%), to-liver-$SUV_{peak}$ (AUC 0.96, threshold 0.76 with sensitivity 94% and specificity 87%), to-BP-$SUV_{peak}$ (AUC 0.95, threshold 0.94 with sensitivity 90% and specificity 95%). ***Conclusion:*** Our results confirm the usefulness of 18F-FDG-PET/CT in the diagnostic workup of LVV. In this regard LAVOF-PET/CT may yield increased diagnostic accuracy thanks to improved spatial and temporal resolution. Similarly, to what already reported normalized semi-quantitative values appear to be more robust in the diagnostic workup. However, thresholds for LAFOV-PET/CT may differ from those reported in literature for different scanners. Hence, prospective studies are warranted to implement new reference values in clinical practice when using high sensitivity scanners.

## OP-517

### C-X-C Motif Chemokine Receptor 4-directed PET/CT in Newly Diagnosed Giant Cell Arteritis - Initial Results from a Phase II Trial

***M. Fröhlich***[1], *S. E. Serfling*[2], *K. V. Guggenberger*[3], *T. Higuchi*[2], *M. Gernert*[1], *S. Samnick*[2], *M. Schmalzing*[1], *A. K. Buck*[2], *T. A. Bley*[3], *R. A. Werner*[2];
[1]*Medical Department II, Rheumatology, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, Germany, Würzburg, GERMANY,* [3]*Institute of Diagnostic and Interventional Radiology, University Hospital Würzburg, Würzburg, GERMANY.*

***Aim/Introduction:*** We aimed to report on initial results of inflammatory-targeting, C-X-C motif chemokine receptor 4 (CXCR4)-directed imaging in newly diagnosed patients with giant cell arteritis (GCA). ***Materials and Methods:*** In a phase II trial NCT05604482, seven treatment-naïve patients with confirmed GCA received dual-tracer imaging without therapy between PET/CT using [18F]FDG (FDG) and [68Ga]PentixaFor (PEN). A total of 13 arterial segments were analyzed per patient. In addition, eight joints were analyzed for concurrent polymyalgia rheumatica. We compared both scans on a visual (using PETVAS) and quantitative level (by calculating target-to-background ratios (TBR) with blood pool serving as reference). CXCR4 is expressed by lymphocytes; therefore, quantitative PET results were also correlated with peripheral blood white blood cell counts (WBC) at the time of imaging. ***Results:*** On a visual level, PETVAS on FDG ($24.29 \pm 5.5$) was higher relative to PEN ($20.14 \pm 3.18$, P=0.19). TBR from FDG ($2.38 \pm 1.11$) was not significantly different when compared to PEN

(1.55 ± 0.44, P=0.78). Of note, interquartile ranges (IQR) were lower for PEN (IQR, 0.46) when compared to FDG (IQR, 1.81), indicative for less scatter and higher accuracy on CXCR4-directed PET-based quantification. This phenomenon was also observed for joints (PEN: IQR, 0.25; FDG: IQR, 0.49). We observed higher correlative indices between TBR and WBC in patients imaged with PEN (PEN, R=0.45, P=0.45) when compared to FDG (R=0.27, P=0.65). ***Conclusion:*** In newly diagnosed patients with GCA, quantitative assessment of PEN was not inferior to FDG for vessel wall and joint read-outs. The quantified PEN signal may emerge as an image biomarker for active inflammation, provide guidance towards novel anti-inflammatory treatment or be useful in the context of artificial intelligence applications.

## OP-518

### [$^{68}$Ga]Ga-FAPI-46 PET/CT in patients with Large Vessel Vasculitis and comparison with age gender-matched controls.

***J. Rosales***[1], *J. Hoppner*[2], *U. Haberkorn*[2], *W. Merkt*[2], *P. Kvacskay*[2], *M. Röhrich*[2];
[1]*University Clinic Of Navarra, Pamplona, SPAIN,* [2]*University Hospital of Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** Giant Cell Arteritis and Takayasu Arteritis are the main forms of Large Vessel Vasculitis (LVV). Evaluation of disease activity is often difficult and different imaging modalities have been used in the assesment of structural and inflammatory changes. Fibroblast Activation Protein-PET (FAPI-PET) has shown promising results as a new imaging method not only in cancer patients but also in nonmalignant-inflammatory diseases. We aim to describe FAPI-PET semiquantitative parameters in patients with active and clinically inactive LVV and compare them with control subjects. ***Materials and Methods:*** We present a retrospective analysis of [$^{68}$Ga]Ga-FAPI-46 PET/CT semiquantitative parameters in eight patients with LVV performed at University Hospital Heidelberg. Three males with active disease (median-age: 58) and five females with clinically inactive disease (median-age: 59) were included. Eight age-gender-matched patients with no previous history of vascular inflammation served as controls [median-age: 58]. SUVmax, SUVmean and TBR were obtained placing a small ROI over the highest uptake in seven vascular segments: subclavian artery, ascending aorta, aortic arch, thoracic descending aorta, abdominal aorta, iliac and femoral arteries in all three groups. Patient-based and segment-based analysis were performed and compared with clinical data and MRI findings as a standard of reference. ***Results:*** On a patient-based analysis, SUVmax was significantly higher in patients with active disease than in clinically inactive cases and age-gender-matched controls (active, median-value, 3.35, inactive: 2.71 and controls: 1.76; $p<0.005$ each). SUVmean and TBR were also higher in active cases than inactive and control cases ($p<0.05$). On a segment-based analysis, average SUVmax and average SUVmean were significantly higher in the active group when compared with age-gender-matched controls in four vascular segments: ascending aorta, aortic arch, thoracic descending aorta and abdominal aorta ($p<0.05$ each). TBR was also significantly higher in active LVV group but only in the ascending aorta, descending aorta and abdominal aorta ($p<0.05$ each). Interestingly, average SUVmax and average SUVmean in the ascending aorta, aortic arch, thoracic descending aorta and abdominal aorta were significantly higher in the inactive group than in controls ($p<0.05$ each). Active and inactive cases did not differ significantly in terms of either SUVmax, SUVmean or TBR in patient-based or segment-based analysis. ***Conclusion:*** [$^{68}$Ga]Ga-FAPI-46 PET/CT is a promising new imaging modality and could potentially play a role in the evaluation of patients with LVV, not only to determine the extension of the disease in newly diagnosed cases, but also for the assesment and follow-up of clinically inactive cases.

## OP-519

### Improved [$^{18}$F] FDG PET/CT diagnostic accuracy for infective endocarditis: cardiac motion correction using different gating strategies

***D. ten Hove***[1,2], *B. Sinha*[1,2], *P. J. H. Van Snick*[1,2], *R. H. J. A. Slart*[1,2], *A. W. J. M. Glaudemans*[1,2];
[1]*Rijksuniversiteit Groningen, Groningen, NETHERLANDS,* [2]*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Infective endocarditis is a serious and diagnostically challenging condition. The most recently published European Society of Cardiology's guidelines includes [18F] FDG-PET/CT as a major diagnostic criterion for the diagnosis due to its high sensitivity and specificity, particularly in patients with prosthetic heart valves. However, [18F]FDG-PET/CT is susceptible to motion related artefacts, which are not routinely corrected for in clinical practice. This study investigated the potential benefits of incorporating cardiac motion correction into [18F]FDG-PET/CT to enhance its diagnostic accuracy and clinical interpretability. ***Materials and Methods:*** In this prospective case series, patients receiving [18F] FDG-PET/CT for suspected IE underwent one or two additional motion corrected sequences using a conventional and/or a novel, list-mode data derived cardiac gating sequence. PET/CT scan preparation, acquisition and evaluation were performed in accordance with EANM recommendations. Scans were assessed for signs of IE by two experienced nuclear medicine physicians who were blinded to patients' clinical context. Clinical diagnosis of IE was established based on surgical findings or multidisciplinary consensus after a minimum of 4 months follow-up. ***Results:*** A total of 7 patients participated in the study, undergoing both an ungated [18F] FDG-PET/CT and a scan with cardiac gating. Cardiac gating improved interpretability of suspected intracardiac infection in 3 out of 4 patients with valvular lesions, regardless of the method of motion correction used. Importantly, in one of these 3 patients IE was confirmed, while the diagnosis was missed on ungated PET/CT. In another of the 3 patients, motion corrected PET demonstrated fluttering of a vegetation at the aortic valve. ***Conclusion:*** Motion correction of [18F] FDG PET/CT improved the diagnostic interpretability of [18F]FDG PET/CT. This is may improve the sensitivity of PET/CT while patient burden is negligible beside limited extra time in the scanner. Further larger comparative studies are necessary to confirm the additive value of the motion correction methods. ***References:*** Habib G et al. EHJ. 2015. Baddour LM et al. Circulation. 2015. ## OP-520

### Impact and diagnostic performance of dedicated cardiac [$^{18}$F]-FDG digital PET/CT in infective endocarditis

***S. Notohamiprodjo***[1], *K. Scheidhauer*[1], *M. Eiber*[1], *I. Yakushev*[1], *S. Kleiner*[1], *J. Kraus-Deuringer*[1], *H. W. A. Krebs-Fleischmann*[1], *A. G. Villagran Asiares*[1], *S. G. Nekolla*[1], *R. Eggerstedt*[2], *B. Eglseder*[3], *W. A. Weber*[1];
[1]*Technical University of Munich, Munich, GERMANY,* [2]*German Heart Centre Munich, Munich, GERMANY,* [3]*Krankenhaus GmbH Landkreis Weilheim-Schongau, Weilheim, GERMANY.*

***Aim/Introduction:*** For modified Duke criteria (mDC) for the diagnosis and management of patients with suspected infective endocarditis (IE), FDG-PET/CT was recently introduced as a new criterion, but not routinely recommended due to low sensitivity and lack of clinical impact. But recently a new generation of digital PET/CT-systems are commercially available with improved spatial resolution and equipped with integrated ECG

and respiratory-gating. As data regarding such a sophisticated acquisition approach in diagnosis of endocarditis are currently lacking, this study aimed to assess the impact and diagnostic performance of a dedicated cardiac protocol for [18F]-FDG-PET/CT, that includes state-of-the-art digital PET and a dual-ECG-respiratory-gating technique (dedicated-cardiac-PET), compared to conventional whole-body-PET in diagnosis of IE determined by the consultant and nuclear medicine physician in training (trainee). ***Materials and Methods:*** 44 patients suspected for IE underwent conventional whole-body- and dedicated-cardiac-PET on a digital PET/CT-system after overnight fasting. Visual and semiquantitative analyses were performed and the diagnostic performances were determined. The readers were instructed to describe findings and to confirm/reject the diagnosis of IE, blinded to the protocols used for the examination and other criteria for mDC. Consensus of multidisciplinary IE task force served as gold standard. ***Results:*** The median of maximum-Standardized-Uptake-Value (SUVmax) for confirmed IE was 5.2, respectively, for rejected IE 2.5. In ROC-analysis a cutoff value of SUVmax > 3.8 identified positive cases with sensitivity and specificity of 92% and 77%. High resolution dedicated-cardiac-PET revealed higher interobserver reliability of valvular uptake characteristics for IE-focus detectability than conventional-PET, indicating higher diagnostic confidence. Consultant-group determined pooled sensitivity, specificity and accuracy of >91% in dedicated-cardiac-PET and of >77% in conventional-PET. Trainee-group established values of >69% in dedicated-cardiac-PET and >48% in conventional-PET. Compared to conventional-PET, substantial improvement of the diagnostic performance in diagnosis of native valve endocarditis using dedicated-cardiac-PET in consultant and trainee group was evident. Substantial improvement in diagnosis prosthetic valve endocarditis was found in trainee-group, but only minimal in consultant-group at initial high performance in conventional-PET. In consultant-group, dedicated-cardiac-PET revealed remarkable higher interobserver reliability in scoring of FDG-uptake characteristic and of confidence of scoring than in conventional-PET, indicating higher diagnostic confidence. The interobserver reliability in trainee-group was poor. The high intraobserver reliability in consultant and trainee-group demonstrated robust reproducibility. ***Conclusion:*** Dedicated-cardiac-PET has the potential as an adequate adjunctive diagnostic modality in challenging possible IE-cases and may have a significant impact on IE-related morbidity, mortality and patient's management, provided the investigators have the desired expertise.

## OP-521

### New semiquantitative parameters to improve diagnostic accuracy of FDG-PET/CT in suspected endocarditis

***C. Bregenzer***, *L. Knappe, C. Mingels, N. Gözlügöl, A. Rominger, F. Caobelli;*
*Department of Nuclear Medicine, Inselspital, University Hospital Bern, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Infective endocarditis (IE) is an infection of the endocardium involving native and prosthetic valves. In the diagnostic workup, FDG-PET is now recommended in uncertain cases. However, the image-derived diagnosis relies mostly on a visual interpretation and is often challenging, especially in patients with prosthetic valves. We aimed to evaluate semiquantitative parameters able to yield an accurate diagnosis of IE. ***Materials and Methods:*** In our center, patients with suspected IE in native and prosthetic valves who underwent a [18F]FDG-PET/CT scan after 72-hours of low-carb diet were included. If a focal increased uptake was present, it was evaluated semiquantitatively. Standardized uptake value (SUV) max/mean/peak and normalized values (to-liver, to-mediastinum, to-surrounding uptake) were calculated with a volume of interest (VOI) and a 40% isocontour around detectable hypermetabolic foci. Sorrounding activity was defined as the presence of homogeneous and circumferential uptake at the valve/prosthesis level. Final diagnosis of confirmed or rejected IE was obtained by consensus in a multidisciplinary board, by evaluating clinical, laboratory and imaging data. ***Results:*** Fifty patients (44 males), aged 57.99 ± 18.86y were evaluated. Forty-five (90%) had a prosthetic valve, in the remaining IE was suspected on native valves. IE was confirmed in 25/50 patients and rejected in 25. Visually detectable hypermetabolic foci (n=44) were seen in 28 patients (56%). Of these, 20 were finally diagnosed with IE. Several semiquantitative measures on the foci of increased uptake as well as normalized values differed between patients with and without IE (values expressed as median [IQR]): $SUV_{peak}$ (5.45 [2.32] vs. 3.37 [2.04], p=0.02), to-liver $SUV_{max}$ (2.31 [1.34] vs. 2.13 [2.1], p=0.001), to-liver $SUV_{mean}$ (1.31 [0.39] vs. 1.2 [1.2], p=0.001), to-liver $SUV_{peak}$ (1.97 [1.18] vs. 1.49 [1.23], p<0.001), to-mediastinum $SUV_{max}$ (3.13 [1.14] vs. 2.64 [3.53], p =0.001), to-mediastinum $SUV_{mean}$ (1.66 [0.62] vs. 1.44 [1.47], p=0.001), to-mediastinum $SUV_{peak}$ (2.37 [1.3] vs.1.66 [1.53], p<0.001), to-surrounding-activity $SUV_{max}$ (1.75 [0.8] vs. 1.25 [1.62], p<0.001), to-surrounding-activity $SUV_{mean}$ (1.29 [0.38] vs. 1.15 [0.45], p<0.001) and to-surrounding-activity $SUV_{peak}$ (1.6 [0.92] vs. 1.04 [0.97], p<0.001). Highest accuracy was yielded by ROC-Curves analysis for $SUV_{peak}$ (AUC 0.79, p=0.02, threshold 3.93 with sensitivity 85% and specificity 75%), and to-surrounding activity $SUV_{peak}$ (AUC 0.79, p=0.02, threshold 1.23 with sensitivity 85% and specificity 75%). ***Conclusion:*** Semiquantitative parameters in our cohort proved to be accurate and should be recommended in clinical practice to assist in the interpretation of [18F]FDG-PET/CT in patients with suspected IE.

## Thyroid Committee - TROP Session: Iodine-131 Therapy in Differentiated Thyroid Cancer: Present and Future Perspective

## OP-522

### Efficacy of $^{131}$I therapy and its influencing factors in children and adolescents with differentiated thyroid cancer lung metastases: comparative analysis with youth using propensity score matching

***X. Zhang***[1], *H. Feng*[2];
[1]*Department of Nuclear Medicine, Zhujiang Hospital Southern Medical University, Guangzhou,Guangdong Province, CHINA,* [2]*Department of Nuclear Medicine, Zhujiang Hospital Southern Medical University, 广州市, CHINA.*

***Aim/Introduction:*** The aim of this study was to analyse the factors influencing lung metastases in pediatric patients with differentiated thyroid cancer(DTC) and to evaluate the efficacy of $^{131}$I therapy. To compare its efficacy with that of young differentiated thyroid cancer patients by propensity score matching. ***Materials and Methods:*** We performed a retrospective analysis of DTC pediatric patients who were hospitalized in our institution between 2010 and 2018. All patients had undergone

total thyroidectomy and $^{131}$I treatment. According to the cut-off point of age 14 years old, The group was divided into children (≤14 years old) and adolescents (15-21 years old). Efficacy evaluation was divided into PD and non-PD (non-PD, including CR, PR, SD). Factors affecting lung metastasis were identified and evaluated for $^{131}$I treatment efficacy by univariate and multifactorial COX regression analysis. In order to compare the prognosis of pediatric patients with lung metastases with youth patients, Patients with DTC in pediatric patients from 2014 to 2018 were matched in a ratio of 1:6 through propensity score matching. ***Results:*** A total of 1095 patients were included in our study, including 168 paediatric patients and 927 youth patients. The median follow-up time of was 70.2 months, and the incidence of lung metastases was 25.9%. Age, gender, underlying disease (i.e. no underlying disease versus Hashimoto's thyroiditis-containing disease), number of lesions, involvement of glands, and lateral cervical lymph nodes metastasis were found to be significant predictors of the presence of lung metastases in pediatric patients in a univariate analysis ($p > 0.05$); In Cox regression analysis of pediatric patients, no statistically significant difference was found between the treatment outcome of $^{131}$I in patients with lung metastases and that of patients with non-lung metastases. After propensity score matching, no statistically significant difference in $^{131}$I treatment outcome was obtained between pediatric patients with lung metastases and youth patients. ***Conclusion:*** The incidence of lung metastases was higher in pediatric patients with DTC. The treatment effect of $^{131}$I in children with lung metastases was the same as that in children without lung metastases. The treatment effect of $^{131}$I in patients with pediatric patients lung metastases was similar to that in youth patients with lung metastases, and both had good treatment effect.

## OP-523

### Prognostic factors in children with differentiated thyroid cancer

***S. Zakavi***[1], *F. Nesari Javan*[1], *E. Askari*[1], *S. Shafiee*[1], *V. Roshanravan*[1], *A. Aghaei*[1], *N. Ayati*[2];
[1]*Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** Prognostic factors of follicular cell derived differentiated thyroid carcinoma (DTC) are not studied extensively. In this study, we analyzed prognostic factors in children with DTC who have been treated in a single center in the last 27 years. ***Materials and Methods:*** We studied 126 children with an age range of 5 to 18 years. The patients have been treated by near-total thyroidectomy followed by radio-iodine therapy and thyroid hormone administration for the purpose of TSH suppression. Follow-up of the patients was done more frequently in the first year after treatment (2, 6, and 12 months) and then by yearly evaluation. Response to treatment was defined according to the American Thyroid Association (ATA) guideline ***Results:*** Majority of the patients (93.7%) had papillary thyroid cancer and 52.4% had lymph node metastasis at presentation, which was extensive (>5) in 30% of the patients. All patients with extranodal extension had extensive lymph node invasion. Distant metastasis was seen in 8.8%, and the majority of them (90.9%) were in the lung. The mean initial dose of I-131 was 3.7±1.9 GBq in total or 74±42.2 MBq/kg of body weight. The median follow-up was 82 months and the median time to achieve an excellent response was 29 months. One year after therapy, 18% of the patient achieved excellent response, and the figure increased to 46.4% in the last follow up. The pre-ablation stimulated thyroglobulin (psTg) level was 153.0±245.7 ng/ml in patients with incomplete response compared to 11.2±17.5 ng/ml in others (P<0.001). Furthermore, using logistic regression, the psTg level was the only significant predictor of distant metastasis. Additionally, distant metastasis was more common in boys (14.7%) than girls (6.5%), and it took longer time for boys to achieve an excellent response. Younger children tended to have more advanced diseases. ***Conclusion:*** The pre-ablation sTg level was the only significant predictor of incomplete response and distant metastases in children with DTC. Boys had more advanced diseases and worse prognosis than girls.

## OP-524

### Impact of micro-extrathyroidal extension and bilateral topography of malignancy on clinical initial stating and early outcome of differentiated thyroid cancer (<4cm) patients.

***A. Campenni'***[1], *R. Ruggeri*[1], *M. Siracusa*[1], *D. Cardile*[1], *S. Russo*[1], *A. Nicocia*[1], *A. Rappazzo*[1], *V. Davi*[1], *A. Alibrandi*[1], *S. Baldari*[1], *L. Giovanella*[2];
[1]*Ospedale Gaetano Martino, Messina, ITALY,* [2]*Ente Ospedaliero Cantonale, 6500 Bellinzona, SWITZERLAND.*

***Aim/Introduction:*** The latest 2017 American Joint Committee on Cancer downstaged the impact of micro-extrathyroidal extension (mETE) on both clinical tumor staging and outcome of differentiated thyroid cancer (DTC) (<4 cm) patients. However, literature data showed conflicting evidence. This study was aimed to assess mETE impact on initial tumor staging and outcome of DTC patients in a real clinical scenario. ***Materials and Methods:*** We reviewed the records of 360 (F=295, M=82) low or intermediate-risk DTC patients [pT1-T3,Nx(0,1),Mx(0)]. Papillary thyroid cancer was carried out in 324/360 (90%) patients while 24 (6.6%) had a follicular thyroid carcinoma and 12 (3.4%) had a Hurthle cell carcinoma. In 75, 109, 122 and 54 DTC patients, malignant lesion(s) was localized in bilateral, left, right and multi-focal-unilateral lobes, respectively. mETE was diagnosed in 73/360 (20.3%) DTC patients.All patients had undergone (near)-total thyroidectomy followed by iodine-131 therapy (RIT) with ablative or adjuvant purpose. A post-therapy whole body scintigraphy coupled with SPECT-CT (pT-imaging) was obtained 2-5 days after RIT. The response to initial treatments was evaluated 8-12 months after RIT and patients were classified according to 2015 American Thyroid Association guidelines (2015 ATA). ***Results:*** At initial diagnosis/treatments, metastatic disease was noted in 36/73 (49.3%) and 75/287 (26.1%) patients with or without mETE, respectively (p= <0.001). In DTC patients with or without mETE, an excellent response (ER) or less than excellent response to initial treatments (i.e. bio-chemical or structural persistent disease) was noted in 62/73 (84.9%), 269/287 (93.7%), 11/73 (15.1%) and 18/287 (6.3%) cases, respectively (p=0.014). mETE emerged as an independent risk factor for having both metastatic disease at initial diagnosis/treatments and persistent disease at early follow-up (p=0.01).Interestingly, DTC had a bilateral topography in 6/11 (54.5%) patients with mETE and less than ER (p= 0.005). In such patients, the risk of having metastatic disease at initial diagnosis/treatments or persistent disease at early follow-up was higher than other patients (Odds Ratio=1.869 and 3.007, respectively; p=0.008 and p=0.005, respectively).Noteworthy, the association between mETE and bilaterality emerged at multivariate analysis as an independent risk factor for having persistent disease at early follow-up (p=0.008). ***Conclusion:*** The prevalence of metastatic disease at initial diagnosis/treatment

such as persistent disease at early follow-up is significantly higher in DTC patient with mETE than others. The association between mETE and bilateral DTC topography is an independent risk factor for significantly increasing the risk of metastatic disease at initial diagnosis/treatment and persistent disease at early follow-up.

### Postoperative Thyroglobulin as a Yard-stick for Radioiodine Therapy: Decision Tree Analysis in a European Multicenter Series of 1317 Patients with Differentiated Thyroid Cancer

***L. Giovanella***[1], *L. Milan*[1], *W. Roll*[2], *M. Weber*[3], *S. Schenke*[4], *M. Kreissl*[4], *A. Vrachimis*[5], *K. Pabst*[6], *T. Murat*[7], *P. Petranović Ovčariček*[8], *B. Riemann*[9], *L. Ceriani*[1], *A. Campenni'*[10], *R. Goerges*[6];
[1]*Imaging Institute of Southern Switzerland, Bellinzona, SWITZERLAND,* [2]*University Hospital Muenster, Muenster, GERMANY,* [3]*University Hospital of Essen, Essen, GERMANY,* [4]*University Hospital Magdeburg, Magdeburg, GERMANY,* [5]*German Oncology Center, Limassol, CYPRUS,* [6]*University Hospital Essen, Essen, GERMANY,* [7]*Hacettepe University, Ankara, TÜRKIYE,* [8]*University Hospital Center "Sestre milosrdnice", Zagreb, CROATIA,* [9]*University Hospital Münster, Münster, GERMANY,* [10]*Ospedale Universitario di Messina, Messina, ITALY.*

***Aim/Introduction:*** An accurate postoperative assessment is pivotal to inform postoperative $^{131}$I treatment in patients with differentiated thyroid cancer (DTC). Our study developed a predictive model for post treatment-whole body scintigraphy (PT-WBS) results (as a proxy for persistent disease) by adopting a decision tree model. ***Materials and Methods:*** Age, sex, histology, T stage, N stage, risk classes, remnant estimation, TSH, and Tg were identified as potential predictors and were put into regression algorithm (conditional inference tree, ctree) to develop a risk stratification model for predicting the presence of metastasis in PT-WBS. ***Results:*** The lymph node (N) stage identified a partition of the population into two subgroups (N positive vs negative). In N positive patients a Tg value >23.3 ng/mL conferred a 83% probability to have metastatic disease compared to those with lower Tg values. Additionally, N negative patients were substratified in three subgroups with different risk rates according to their Tg values. The model remained stable and reproducible in the iterative process of cross validation. ***Conclusion:*** We developed a simple and robust decision tree model able to provide reliable informations on the probability of persistent/metastatic DTC after surgery. Provided informations may guide post-surgery $^{131}$I administration by selecting patients requiring curative rather than adjuvant $^{131}$I therapy schedules.

## OP-526

### Diffuse Sclerosing Variant of Papillary Thyroid Carcinoma is Related to A Poor Outcome: A Comparison Study Using Propensity Score Matching

***L. Yang***, *M. Zhao, L. Xiao, L. Li, P. Dong;*
*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Clinical outcome of diffuse sclerosing variant of papillary thyroid carcinoma (DSV-PTC) remains still controversial. We aimed to determine whether DSV-PTC is associated with increased risk of persistent/recurrent disease. ***Materials and Methods:*** We performed a retrospective cohort study of DSV-PTC and classic variant of papillary thyroid carcinoma (CV-PTC) after post-surgical radioactive iodine therapy. We used the propensity score matching (1:3 matching ratio) to account for differences between recipients of DSV-PTC vs CV-PTC. Univariable and multivariable analysis were performed to assess the independent factors for persistent/recurrent disease. Kaplan-Meier curve analyses were used to compare disease-free survival (DFS). ***Results:*** In total, 35 (12.7%) patients with DSV-PTC and 240 (87.3%) patients with CV-PTC were included. After propensity score matching, 35 pairs of patients were selected (DSV-PTC, n = 35; CV-PTC, n = 105). In the matched analysis, higher proportions of DSV-PTC experienced persistent/recurrent disease compared with CV-PTC (25.7% vs 5.7%; p = 0.003). In multivariate analyses of clinical and tumor characteristics, only the histologic type of DSV-PTC (odds ratio, 6.288; 95% confidence interval, 1.900-20.811; p = 0.003) was associated with increased risk of persistent/recurrent disease. The five-year DFS rates for the DSV-PTC and CV-PTC groups were 69.2% and 93.6%, respectively. The Kaplan-Meier analysis indicated that the DSV-PTC group (p = 0.001) had shorter DFS. ***Conclusion:*** This propensity-matched analysis found that the histologic type of DSV-PTC may increase the risk of persistent/recurrent disease.

## OP-527

### Radiomics approaches for predicting non-iodine-avid status of lung metastases in patients with differentiated thyroid cancer based on CT: a prospective observational study

***X. Gao***;
*Department of Radiology, Zhejiang Cancer Hospital, Hangzhou, CHINA.*

***Aim/Introduction:*** Identifying non-iodine-avid status of lung metastases (LMs) in time is crucial to avoid radioactive $I^{131}$ for patients with differentiated thyroid cancer (DTC) who will not benefit from it. In this study, we speculated that vivid radiomics features and deep learning features of routine chest CT scans may reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. To evaluate this hypothesis, different radiomics models were built with machine learning, deep learning and novel integration of radiomics features and deep learning features to discriminate non-iodine-avid LMs from iodine-avid LMs in patients with DTC. ***Materials and Methods:*** Models were built in 1445 pretreated LMs of 270 consecutive DTC patients with pretreated initially diagnosed LMs who underwent both chest CT and radioiodine whole-body scanning between January 2010 and December 2019 in Zhejiang Cancer Hospital. Integration models based on machine learning were built with selected radiomics features and deep learning features and compared with classic machine learning models (Random Forest, K-Nearest Neighbor, Logistic Regression, and Support Vector Machine), or deep learning models to predict non-iodine-avid status of lung metastases**.** To validate these radiomics approaches prospectively, we recruited 244 consecutive patients with 876 LMs between January 2020 to October 2022. ***Results:*** Among all the machine learning models, the Support Vector Machine showed the best discrimination, with a 0.815 area under the curve (AUC), a 0.754 sensitivity and a 0.730 specificity. The deep learning model reached a 0.869 AUC, a 0.794 sensitivity and a 0.798 specificity. All the integration models were significantly better than classic machine learning or deep learning alone, with the best AUC of 0.904, sensitivity of 0.812, specificity of 0.823. ***Conclusion:*** Radiomics features and deep learning features of routine chest CT scans can reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. Our study highlights a possible role of radiomics approaches from routine chest CT as a noninvasive, less radioactive and cost-effective way to evaluate iodine-avid status of LMs in DTC.

## OP-528

### Could Coprococcus catus be used as a biomarker for the treatment response of I-131 in thyroid cancer patients?

***A. Fernandes***[1], *R. Soares*[2], *P. Barata Coelho*[3];
[1]*Centro Hospitalar e Universitário São João, Porto, PORTUGAL,* [2]*Faculdade de Medicina da Universidade do Porto, Porto, PORTUGAL,* [3]*Universidade Fernando Pessoa, Porto, PORTUGAL.*

***Aim/Introduction:*** Given the growing evidence that highlights the connection between the gut microbiota and response to certain therapeutics and that the gut microbiota may act as a regulator of immunity and, therefore, may indirectly play a role in tumorigenesis, we conducted a prospective observational study to assess whether there were microbial signatures that correlated with therapeutic response to RAIT. To do this, we profiled baseline samples of responders and non-responders of differentiated thyroid cancer patients to find potential biomarkers for predicting response after RAIT. ***Materials and Methods:*** Faecal samples of 37 thyroid cancer patients with the indication for RAIT were collected 2 to 3 days before therapeutics. After DNA extraction, the overall composition of the gut microbiota was studied by shotgun metagenomics. Patients were separated into responders if they had negative TgAb and Thyroglobulin (suppressed Tg<0.2ng/mL or stimulated Tg<1 ng/mL) and non-responders if they did not achieve these parameters. Those without follow-up or with an indeterminate response were excluded (n=11). Finally, 13 patients were considered responders and 13 non-responders. To explore key phylotypes that may contribute to the observed differences in microbial communities between cohorts, linear discriminant analysis (LDA) effect size (LEfSe) was performed to estimate differentially abundant features with biological consistency and statistical significance, with an LDA threshold value of > 3.0. $\rho < 0.05$ values were considered statistically significant. ***Results:*** LEfSe analysis showed that the specie Coprococcus catus was enriched in patients with thyroid cancer that responded to therapeutics, with an LDA score of 3.069, p=0.01. ***Conclusion:*** Our results suggest that the pre-existing changes in the gut microbial ecology may serve as a potential predictive marker to identify patients more likely to respond to treatment. Coprococcus catus is a short-chain fatty acid (SCFA) producer bacteria. SCFAs improve gut health through several local effects, including maintaining and improving intestinal barrier integrity, increased absorption of some nutrients and mineral elements, mucus production, and protection against inflammation. In addition, SCFAs can inhibit histone deacetylase and activate NIS re-expression in thyroid cancer cells, thereby inducing re-differentiation and iodine uptake. The relationship between thyroid cancer and SCFA-producing bacteria has also been investigated, and investigations have deduced that the loss of these bacteria might promote the development of thyroid cancer. This study provides a conceptual basis for further investigations that may increase our comprehension of response to therapeutics. ***References:*** doi: 10.1016/j.jare.2021.04.001; 10.3389/fendo.2022.943408.

## OP-529

### Determination of whole-body effective half-life of I-131 on differentiated thyroid cancer patients with a cloud-based remote dose meter

***L. Kääriä***[1,2], *M. Lapela*[3,2], *M. Seppänen*[4,2], *J. Ruohola*[3,2], *A. Ålgars*[5,2], *T. Noponen*[6,2];
[1]*Department of Nuclear Medicine, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND,* [2]*University of Turku, Turku, FINLAND,* [3]*Department of Oncology, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND,* [4]*Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND,* [5]*Deparment of Oncology, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND,* [6]*Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing services county of Southwest Finland, Turku, FINLAND.*

***Aim/Introduction:*** We analysed continuously monitored external dose rate signals from remote dose rate meters to determine the effective half-life of I-131 in differentiated thyroid cancer (DTC) patients. The aim is to gain novel understanding of the retention of radioiodine in DTC patients and to demonstrate that remote cloud-based dose rate meter solutions can be reliably used in the real-time monitoring of external dose rate and discharging radionuclide therapy patients. ***Materials and Methods:*** 135 DTC patients who received postoperative radioiodine therapy between September 2018 and February 2022 in Turku University Hospital were studied retrospectively. The activity administered in 29 low-risk patients ranged from 1.055 to 1.223 GBq and in 106 higher-risk patients from 3.149 to 4.048 GBq. The external dose rates of the patients were continuously monitored during their hospitalization with a remote dose rate meter fixed on the ceiling of the radiation isolation room. Patients' normal movements in the isolation room affect to the measured dose rate signals. Therefore, location correction factors were determined from the calibration measurements of the meter using a radioiodine capsule in the isolation room. The dose rate signals were adjusted by using the location correction factors that transferred the location of the patient moving around the room into a standardized location on the hospital bed. The dose rate signal of each patient was location corrected and resampled whereafter monoexponential function was fitted in the signal. Finally, the effective half-life was calculated from the fitted equation. The group differences of effective half-lives were statistically analysed with Mann-Whitney U test. A possibility to use the remote dose-rate measurements to discharge the radioactive therapy patients was also evaluated. ***Results:*** The mean effective half-life was 13.47 ± 5.43 h for all patients. For low-risk patients the mean effective half-life was 13.78 ± 5.51 h and for higher-risk patients 13.38 ± 5.43 h. There were no statistically significant difference (p=0.718) in half-lives observed between the groups administered the activities of 1.1 and 3.7 GBq. The remotely measured dose rate signals could reliably be used to discharge the patients. ***Conclusion:*** The administered activity has no effect on whole-body effective half-life of the patient. With the continuously measured dose rate signals, it may be possible to obtain more accurate information on the removal of radioiodine than before. This information can be used to optimize the length of radiation isolation period, discharge instructions and be utilized for dosimetry purposes.

## OP-530

### Preliminary results from a clinical trial combining $^{131}$I and external beam radiotherapy for treatment of metastatic radioiodine-refractory thyroid cancer

***R. Hobbs***, *I. Marsh, H. Quon, P. Santhanam, P. Ladenson, B. He, D. Kaplin, K. Lowe, H. Wang, G. Sgouros;*
*Johns Hopkins, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Treatment of well differentiated thyroid cancer with radioiodine ($^{131}$I) has a long and successful history. However, tumor uptake of $^{131}$I can be diminished in patients with recurrent metastatic disease resulting in sub-therapeutic absorbed doses (AD) to the tumors. Here we present results from an ongoing clinical trial combining $^{131}$I with stereotactic radiotherapy (SRT), using personalized dosimetry. ***Materials and Methods:*** Four

patients have been enrolled in the trial to date. Patients are simulated for the external beam portion of the therapy and then administered a tracer amount of $^{131}$I, with multiple time point whole body probe and blood activity measurements. These measurements are used in a two source compartment S value dosimetry model to determine the patient-specific maximum tolerated therapeutic activity based on bone marrow constraints. Following administration of the therapeutic $^{131}$I, three SPECT/CT images are acquired using the patient-specific fixation device(s) from the SRT simulation, which improves the registration of images across time and reduces the uncertainty in the $^{131}$I AD calculations. The images are reconstructed, registered, and the target lesion(s) delineated. S value dosimetry is used to determine mean lesion AD, which is then converted to EQDX, where the X is the dose per fraction of the SRT treatment, determined as the amount needed to deliver a combined total of 80 Gy of EQD2 to the target lesion(s). ***Results:*** In the case of the first patient, two lesions were identified and treated, the $^{131}$I portion was calculated to have delivered ADs of 16.6 and 12.5 Gy (14.7 and 11.0 Gy EQDX), respectively, to lesion PTVs. The lesions were then treated with 5 fractions of SRT of 9.0 Gy and 9.5 Gy (66.0 Gy and 71.3 Gy EQD2), respectively. Following treatment, the patient experienced tumor volume reduction and pain relief. Thyroglobulin levels fell from 89,000 to 55,000 ng/ml three months post-treatment and TSH increased to 9.0 mU/L, indicating reduction in overactive thyroid tissue. The other patients have received similar treatments with follow-up data to come. ***Conclusion:*** Personalized dosimetry-based combination radiopharmaceutical therapy (RPT)-SRT is feasible and allows for AD delivery to target lesions that would not be achievable by either single modality alone and may benefit from reduced toxicity. The low level of AD from $^{131}$I seen here may indicate a need for a more quantitative triage approach and a wider application of this methodology. This work sets the groundwork for more generalized routine clinical RPT-external beam combinations.

### Improving the quantification of tau pathology in Alzheimer's Disease: A data-driven analysis using 18F-PI2620 PET.

***G. Bischof***[1,2], *M. Kanekiyo*[3], *M. Irrizari*[3], *A. Stephens*[4], *T. van Eimeren*[1], *A. Drzezga*[1,2,5];
[1]*University Hospital Cologne, Cologne, GERMANY,* [2]*Molecular Organization of the Brain, Institute for Neuroscience and Medicine (INM2), Juelich, GERMANY,* [3]*Eisai Inc., Nutley, NJ, UNITED STATES OF AMERICA,* [4]*Life Molecular Imaging, Berlin, GERMANY,* [5]*German Center for Dementia Research (DZNE), Bonn, GERMANY.*

***Aim/Introduction:*** The second-generation tau tracer 18F-PI2620 has been developed with high on-target affinity to tau pathology in Alzheimer's Disease (AD), paralleled by reduced off-target binding. However, due to the lack of autopsy studies, optimal reference regions to quantify standard uptake value ratios (SUVRs) are missing. The identification of suitable reference regions is however imperative to optimize quantification of on-target binding patterns of tau deposition for disease staging. ***Materials and Methods:*** We analyzed static images of 18F-PI2620 PET of AD patients (N=88) and healthy controls (HC; N=9) to assess regions as candidates for reference regions. In the discovery sample we evaluated differences in off-target binding between HC vs. AD patients (N=28) using a data-driven non-parametric statistical mapping technique. Results were applied to the testing sample (N=60) and SUVRs were computed for a global measure and for a temporal meta- region of interest (ROI). Two-sample t-tests and effect sizes (Hedges g') were computed for each potential region that could serve as a suitable reference region. ***Results:*** We identified several sub-regions of the cerebellum as reference regions Computed SUVRs showed significant differences between AD vs. HC for most of the examined regions and effect sizes were in the range of 0.8-1.7. AAL2- cerebellum 6 and a data-driven cerebellar cluster yielded the highest effect sizes. ***Conclusion:*** Here we improve the quantification of in vivo tau PET imaging in a non-parametric data-driven fashion. This novel reference region can lead to improved SUVR estimates and allows better staging of disease severity.

## EPS-148

### Single Tracer ATN Assessment With Dynamic 18F-PI-2620 Recordings

***J. Gnörich***[1], *M. Zaganjori*[1], *M. Groß*[1], *M. Scheifele*[1], *A. Bronte*[2], *R. Perneczky*[3], *K. Bürger*[4], *J. Levin*[5], *O. Sabri*[6], *P. Bartenstein*[1], *H. Barthel*[6], *N. Franzmeier*[4], *M. Brendel*[1];
[1]*LMU Munich, Department of Nuclear Medicine, Munich, GERMANY,* [2]*Universidad de Navarra, Pamplona, SPAIN,* [3]*LMU Munich, Department of Psychiatry and Psychotherapy, Munich, GERMANY,* [4]*Institute for Stroke and Dementia Research, LMU Munich, Munich, GERMANY,* [5]*LMU Munich, Department of Neurology, Munich, GERMANY,* [6]*Department of Nuclear Medicine, Leipzig, GERMANY.*

***Aim/Introduction:*** Patients with neurodegenerative diseases are now molecular categorized by the A/T/N classification system, which can use characteristic features derived from amyloid-PET (A), tau-PET (T), and FDG-PET (N). Recent studies showed that the early perfusion phase of tau-PET recordings can serve as a surrogate of neuronal injury comparable to FDG-PET (i.e. "N"). We evaluated if dynamic tau-PET with [$^{18}$F]PI-2620 can also serve to predict the amyloid status (i.e. "A") via tissue clearance (k2) in tau-positive regions, with the goal of testing PET based assessment of A/T/N in individual patients during a single imaging session. ***Materials and Methods:*** We obtained dynamic PET recordings with [$^{18}$F] PI-2620 from 19 participants with a clinical diagnosis of probable AD (3/4-repeat(R)-tauopathy; amyloid-PET positive) and from 30 suspected amyloid-negative controls with corticobasal syndrome (CBS) and progressive supranuclear palsy (PSP) (4R-tauopathies). [$^{18}$F]PI-2620-PET scans were acquired 0-60 min p.i. and z-scores, the delivery (R1), efflux (k2) and distribution volume ratio (DVR) were calculated via simplified reference tissue modeling 2 (SRTM2), all values being compared between 3/4R- and 4R-tauopathies. [$^{18}$F] PI-2620-positive cortical regions were defined as a DVR z-score ≥ 2 and patients exceeding 5 tau-positive regions of interest (ROIs) extracted from the Brainnatome atlas were considered tau-positive. Neurodegeneration was examined by assessment of cortical R1, whereas patients exceeding R1 z-score < -1,5 in more than 5 regions were assigned as neuronal impaired. ***Results:*** [$^{18}$F] PI-2620 indicated significant elevation of cortical tracer binding in 11/19 patients of the AD cohort and 10/30 patients of the 4RT cohort. After exclusion of tau-negative participants, multiple logistic regression considering k2 as a surrogate for amyloid status revealed a negative predictive value of 90% and positive predictive value of 91%. Receiver operating characteristic showed

an area under the curve of 0.98 for prediction of amyloid-PET by k2 (p=0.0003). 8/19 AD patients showed impaired [$^{18}$F]PI-2620 delivery compared to 9/30 patients in the 4R-tauopathy cohort confirming previous findings for R1 as a surrogate marker of neuronal injury. ***Conclusion:*** [$^{18}$F]PI-2620 imaging may facilitates assessment of PET based A/T/N in a single dynamic PET session.

## EPS-149

### Early-phase [18F]FBB PET vs [18F]FDG PET in atypical dementia: preliminary data from a multicentric study (AMY-ITA).

***D. Cecchin***[1], *A. Chincarini*[2], *S. Mozzetta*[3], *C. Gagliani*[3], *A. Osele*[3], *S. Morbelli*[4], *S. Sestini*[5], *F. Dore*[6], *M. Dottorini*[7], *L. Ruffini*[8], *G. Trifirò*[9], *M. Farsad*[10], *L. Turk*[3], *A. Cagnin*[3];
[1]*Nuclear Medicine University Hospital Padova, Padova, ITALY,* [2]*Istituto Nazionale di Fisica Nucleare (INFN), Genova, ITALY,* [3]*University of Padova, Padova, ITALY,* [4]*University of Genoa, Genoa, ITALY,* [5]*Hospital of Prato, Prato, ITALY,* [6]*Azienda sanitaria universitaria Giuliano Isontina, Trieste, ITALY,* [7]*Azienda Ospedaliera di Perugia, Perugia, ITALY,* [8]*Azienda Ospedaliero Universitaria di Parma, Parma, ITALY,* [9]*ICS Maugeri, Pavia, ITALY,* [10]*Ospedale di Bolzano, Bolzano, ITALY.*

***Aim/Introduction:*** Amyloid PET and [18F]FDG PET scans are commonly used in patients with uncertain diagnosis of AD. Different studies showed that early frames of amyloid PET correlate well with FDG PET images, providing perfusion-like information, thus being a potential surrogate for FDG PET. However, there is still limited evidence in certain classes of patients. We investigated whether the early frames of the FBB PET scan are comparable to the FDG PET images in terms of regional uptake deficits, in patients with a clinical suspicion of an atypical form of Alzheimer's disease. ***Materials and Methods:*** AMY-ITA is a still ongoing prospective multicenter study conducted in 9 Italian centres. Until now, 81 patients have been enrolled, collecting data from brain magnetic resonance imaging, FBB and FDG PET scan. Each patient underwent dual time-point FBB PET, acquiring images 0 - 15 min and 90 - 110 min after injection of the tracer. The brain was divided into 8 different regions in both FDG and early-frames FBB PET scans. Then each region for each tracer was visually and blindly analysed, defining the tracer uptake abnormality, using a scale of 0 to 3. A statistical analysis was then performed using Spearman and Wilcoxon tests. ***Results:*** Visual analysis of the brain was performed on available data and revealed similar patterns between early-frame FBB PET and FDG PET images in atypical forms of Alzheimer's disease; however, the scores of abnormal uptake were globally higher in FDG PET. The Spearman test showed a statistically significant correlation in all brain regions ($\rho$ from 0.798 to 0.927, $P < 0.0001$), however Wilcoxon's test, showed a statistically significant difference in the temporal and parietal regions (from 0.001 to 0.041, $P < 0.05$). ***Conclusion:*** Early-phase FBB PET acquisitions correlated well with FDG PET scans in atypical forms of dementia, showinga metabolic-like image, suggesting the use of the amyloid tracer as a surrogate marker of synaptic dysfunction. A consequence of this would be the possibility to eliminate the FDG PET scan, reducing patient radiation exposure and health costs.

## EPS-150

### Clinical outcomes up to 9 years after [$^{18}$F]flutemetamol amyloid-PET in a symptomatic memory clinic population

***L. Collij***[1,2], *G. Farrar*[3], *M. Zwan*[1], *E. M. van de Giessen*[1], *R. Ossenkoppele*[1,2], *F. Barkhof*[1,4], *A. Rozemuller*[1], *Y. Pijnenburg*[1], *W. M. Van der Flier*[1], *F. Bouwman*[1];
[1]*Amsterdam UMC, location VUmc, Amsterdam, NETHERLANDS,* [2]*Lund University, Lund, SWEDEN,* [3]*GE Healthcare, Amersham, UNITED KINGDOM,* [4]*University College London, London, UNITED KINGDOM.*

***Aim/Introduction:*** Previous studies demonstrated increases in diagnostic confidence and change in patient management after amyloid-PET. However, studies investigating longitudinal outcomes over an extended period of time are limited. We therefore aimed to investigate clinical outcomes up to 9 years after amyloid-PET to support the clinical validity of the imaging technique. ***Materials and Methods:*** We analyzed longitudinal data from 200 patients ($M_{age}$=61.8, 45.5% female, $M_{MMSE}$=23.3) suspected of early-onset dementia that underwent [$^{18}$F]flutemetamol-PET. Baseline amyloid status was determined through visual read (VR). Information on mortality was available with a mean follow-up of 6.7 years (range=1.1-9.3). In a subset of 108 patients, longitudinal cognitive scores and clinical etiological diagnosis (eDx) at least 1 year after amyloid-PET acquisition was available (M=3.06 years, range=1.00-7.02). VR- and VR+ patients were compared on mortality rates with Cox Hazard's model, prevalence of stable eDx using chi-square test, and longitudinal cognition with linear mixed models. Neuropathological data was available for 4 patients (mean delay=3.59±1.82 years, range = 1.2-6.3). ***Results:*** At baseline, 184 (92.0%) patients were considered to have dementia. Majority of VR+ patients had an etiological diagnosis of AD (122/128, 95.3%), while the VR- group consisted mostly of non-AD etiologies, mainly frontotemporal lobar degeneration (29/72, 39.7%). Overall mortality rate was 48.5% and did not differ between VR- and VR+ patients. eDx at follow-up was consistent with baseline diagnosis for 92/108 (85.2%) patients, with most changes observed in VR- cases (VR-=14/35, 40% vs VR+=2/73, 2.7%, $\chi^2$=26.03, $p<0.001$), who at no time received an AD diagnosis. Within the VR- group, 7/35 still had a primary etiological diagnosis of AD at baseline after disclosure of the amyloid-PET status. Etiological diagnosis changed at follow-up for 5/7 of these cases, with 2 cases receiving a 'dementia other' diagnosis, 1 primary psychiatric disorder, 1 FTLD, and 1 primary vascular etiology. VR+ patients declined faster than VR- patients based on MMSE ($\beta$=-1.17, p=0.004), episodic memory ($\beta$=-0.78, p=0.003), fluency ($\beta$=-1.44, $p<0.001$), and attention scores ($\beta$=16.76, p=0.03). Amyloid-PET assessment was in line with post-mortem confirmation in all cases; two cases were VR+ and showed widespread AD pathology, while the other two cases were VR- and showed limited amyloid pathology. ***Conclusion:*** In a symptomatic population, we observed that amyloid-status did not impact mortality rates, but is predictive of cognitive functioning over time across several domains. Also, we show particular validity for a negative amyloid-PET assessment, as these patients did not receive an AD diagnosis at follow-up.

## EPS-151

### Gender influences the expression of metabotropic glutamate receptor 5 in the brain of cognitively impaired individuals: a PET/MR study

***W. Jie***[1], *Y. Guan*[2], *F. Xie*[2];
[1]*Fudan University, shanghai, CHINA,* [2]*Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** To investigate the differences in the expression of metabotropic glutamate receptor 5 (mGluR5) as seen on PET imaging between normal controls and cognitively impaired individuals, as well as the impact of gender on its expression. ***Materials and Methods:*** The study included 31 individuals with cognitive impairment and 25 normal controls who underwent [18F]Florbetapir PET/CT and [18F]PSS232 PET/MR scans, as well as neuropsychological testing. Based on the region of interest analysis, we compared the expression of mGluR5 between the two groups using a two-sample t-test and explored the impact of gender using a one-way variance.To investigate the differences in the expression of metabotropic glutamate receptor 5 (mGluR5) as seen on PET imaging between normal controls and cognitively impaired individuals, as well as the impact of gender on its expression. ***Results:*** In the whole cohort, individuals with cognitive impairment had decreased mGluR5 expression compared to normal controls in the medial temporal lobe (P = 0.046). Males had more mGluR5 expression than females in the occipital cortex (P = 0.044), precuneus (P = 0.022), frontal lobe (P = 0.042), medial temporal lobe (P = 0.014), and posterior cingulate cortex (P = 0.007). In stratified analyses, there was no significant difference in mGluR5 expression between male and female individuals with cognitive impairment, while in the normal controls, males had more mGluR5 expression than females in the lateral parietal lobe (P = 0.040), precuneus (P = 0.013), frontal lobe (P = 0.042), and posterior cingulate gyrus (P = 0.024). In the female subgroup, individuals with cognitive impairment had decreased mGluR5 expression compared to normal controls in the lateral parietal lobe (P = 0.017), precuneus (P = 0.011), frontal lobe (P = 0.035), and medial temporal lobe (P = 0.036). No such differences were observed in the male subgroup. ***Conclusion:*** Our findings indicate reduced mGluR5 expression in the brains of individuals with cognitive impairment compared to normal controls on 18F-PSS232 PET/CT imaging, This expression was influenced by gender and was more pronounced in the female group.

## EPS-152

### Prevalence of Limbic-predominant Age-related TDP-43 Encephalopathy (LATE) in Tertiary Care Cognitive Disorder Clinics

***E. Park****, C. J. Cliatt-Brown, Y. Anzai, S. Minoshima;*
*University of Utah, Salt Lake City, UT, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The prevalence of a recently recognized form of neurodegenerative dementia, limbic-predominant age-related TDP-43 encephalopathy (LATE), was investigated among patients referred for imaging evaluation by cognitive disorder clinics. ***Materials and Methods:*** This retrospective study involved 404 consecutive patients who were referred for imaging evaluation of dementia by cognitive disorder clinics at a tertiary healthcare center. Each patient underwent standard clinical assessments, brain FDG PET, and MRI with or without regional volumetric analysis. PET images were analyzed voxel-by-voxel compared to those of age-similar healthy subjects. Since there is currently no specific biomarker for TDP-43, the diagnosis of probable LATE was established by identifying unique patterns of reported imaging findings: 1) accentuated glucose hypometabolism (Z-score > 3) involving medial temporal lobes and orbitofrontal cortices and 2) accentuated atrophy in the medial temporal lobe. In addition, the concomitant presence of the established pattern of Alzheimer's disease (AD) was independently assessed on PET within the probable LATE group. ***Results:*** Fifty-four of 404 patients (13%) were diagnosed as probable LATE based on the findings of FDG PET and MRI. Additional 35 patients (9%) showed the findings consistent with probable LATE and concomitant AD, totaling 22% of LATE among the dementia patients referred for imaging evaluation. Age of patients with probable LATE only was significantly older than that of non-LATE group (77.1±5.6 years, mean±SD, vs. 69.0±8.6 years, respectively, p<0.00001). Age of patients with probable LATE with or without concomitant AD was also significantly older (74.5±7.8 years, p<0.00001). The gender distribution was similar between the probable LATE (Men:Women = 59%:41%) and non-LATE (54%:46%) groups. ***Conclusion:*** A notable fraction of the patients who are referred for imaging evaluation by the cognitive disorder clinics at a tertiary healthcare center demonstrates imaging findings consistent with probable LATE with or without a concomitant AD pattern. These patients are significantly older than the patients with non-LATE dementia. The recognition of the LATE patterns on the brain FDG PET and MRI is critical in the evaluation of dementia patients. ***References:*** Nelson PT, Dickson DW, Trojanowski JQ, et al. ## EPS-153

### Application of principal component analysis on amyloid-PET and clinical data to predict conversion from mild cognitive impairment to Alzheimer's disease

***E. Perrone***[1,2], *F. Cocciolillo*[2], *S. Taralli*[2], *D. Quaranta*[3], *D. Santoni*[4], *M. Mazzei*[4], *C. Marra*[5], *M. L. Calcagni*[1,2];
[1]*Nuclear Medicine Institute, University Department of Radiological and Hematological Sciences, Università Cattolica del Sacro Cuore, Rome, ITALY,* [2]*Nuclear Medicine Unit, Diagnostic Imaging, Radiation Oncology and Hematology Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [3]*Neurology Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [4]*Institute for System Analysis and Computer Science "Antonio Ruberti", National Research Council of Italy, Rome, ITALY,* [5]*Memory Clinic, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY.*

***Aim/Introduction:*** Principal component analysis (PCA) is a multivariate analysis used to manage large multidimensional dataset eliminating redundant features, looking for relevant uncorrelated variables. Amyloid-PET is used for non-invasive assessment of cortical amyloid burden in patients with mild cognitive impairment (MCI). This study aimed to evaluate whether PCA, applied to clinical-neuropsychological data and semi-quantitative PET parameters, can predict conversion from MCI to Alzheimer's disease (AD). ***Materials and Methods:*** Clinical-neuropsychological assessment and amyloid-PET were performed in 61 patients: 37 with amnestic-MCI single-domain

(aMCI-sd), 14 with amnestic-MCI multi-domain (aMCI-md), 10 with subjective cognitive impairment (SCI). 18F-Flutemetamol (180.9±7.9 MBq) PET/CT was acquired in dynamic list-mode (20min). Images were considered positive when amyloid uptake in grey matter was equal or higher than that in white matter. SUVr was calculated in ten cortical VOIs and in whole grey matter, considering the cerebellum as reference. PCA was applied to clinical (age, education, neurological scores) and SUVr data. PCA was carried out through ad-hoc designed software and the statistical pipeline was implemented through R Package R version 4.1.3. The principal components (PCs) were listed in decreasing order of importance in terms of variance. ***Results:*** After mean follow-up of 3.4 years, 36/61 (59%) patients converted to AD (22 aMCI-sd, 10 aMCI-md; 4 SCI). Among converters, 31/36 were amyloid-PET positive with mean time to conversion of 2.1 years (vs. 2.4 years in 5/36 amyloid-PET negative patients). Among 25 non-converters patients, 14/25 were amyloid-PET positive, 11/25 were amyloid-PET negative. PCA resulted in two main components explaining the 63% of the total variance: PC1 was represented by SUVr data, accounting for 45%; PC2 included two cognitive scores, semantic verbal fluency and delayed recall, accounting for 18%. PCA did not extract any differences in amyloid uptake among cortical regions. ***Conclusion:*** Global amyloid cortical burden is the strongest component able to predict conversion from MCI to AD, independently of neurological data, regional or lateralised amyloid uptake, followed by episodic memory and executive function impairment. Non-converters AD patients with amyloid-positive PET could represent a subpopulation in which amyloid does not exert pathologic action for some factors, including individual cognitive reserve and resilience. Longer follow-up should be considered also. Converters-AD patients with amyloid-negative PET could represent a subpopulation of different AD phenotypes including primary age related tauopathy, or TDP-43 pathology, characterized by the absence of amyloid plaques.

## EPS-154

### Clinical utility of Amyloid Brain PET in patients with Mild Cognitive Impairment

***M. Pudis***[1], *L. Rodríguez-Bel*[1], *M. Suarez-Piñera*[1], *C. Martínez-Ramos*[1], *J. Gascón-Bayarri*[2], *J. Campdelacreu-Fumado*[2], *S. Bondia-Bescós*[1], *B. Hervás-Sanz*[1], *J. Diaz-Moreno*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [2]*Neurology Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** Several studies have demonstrated that a negative Amyloid Brain PET scan is associated with a low risk of progression to Alzheimer's disease (AD) in patients with mild cognitive impairment (MCI). The aim of this study was to assess, through statistical parameters, the diagnostic accuracy of amyloid brain PET in patients with MCI. ***Materials and Methods:*** A retrospective study of 153 patients with clinical criteria for MCI who underwent an Amyloid Brain PET was performed between the years 2014 and the end of 2021. The patients were subclassified, according to the PET result, into two subgroups: positive (+) and negative (-). In both subgroups, PET results were correlated with follow-up for a mean of 5 years [15-101 months] and possible conversion to AD by clinical criteria. We calculated the sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of this diagnostic technique. ***Results:*** Out of 85 patients with (+) amyloid PET, 70 patients during the follow-up were diagnosed with AD with a mean conversion time of 26 months [5-68 months] and 15p did not show AD conversion during a mean follow-up time of 4,5 years [19-101 months]. Of the 68p with amyloid PET (-), 6 patients were diagnosed with AD with a mean conversion time of 24.33 months [8-50]. The calculated sensitivity was 92%, specificity 81%, PPV 82% and NPV 91%. ***Conclusion:*** Amyloid brain PET in the workup of patients with MCI has a high diagnostic value beyond what can be obtained through a comprehensive clinical evaluation. The negative result helped to rule out conversion to AD with a high negative predictive value. The positive result helped to confirm the presence of amyloid plaques with high sensitivity, confirming the conversion to AD with a mean time of 2 years.

## EPS-155

### Unilateral Nasal Septal Deviation Mediates Contralateral Loss of Striatal Dopamine Transporter Uptake in Patients with Parkinson's Disease

***J. Wang***[1,2], *J. Ge*[1], *F. Liu*[3], *M. Tian*[2], *J. Wang*[3], *C. Zuo*[1];
[1]*Department of Nuclear Medicine/PET center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Human Phenome Institute, Fudan University, Shanghai, CHINA,* [3]*Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** Laterality is a key feature of Parkinson's disease (PD), usually manifesting in the early stages, but the underlying mechanism remains unclear. In our previous study, we found that injecting lipopolysaccharide (PM2.5 component) unilaterally into the nasal cavity of mice resulted in reduced striatal dopamine transporter (DaT) uptake and α-synuclein aggregation in the substantia nigra, causing apparent asymmetric motor features[1]. Since the nasal cavity is a gateway for environmental neurotoxins to enter the brain, our study aimed to investigate the correlation between asymmetric loss in striatal subregions and unilateral nasal septal deviation (NSD). ***Materials and Methods:*** We retrospectively reviewed 453 PD patients who underwent $^{11}$C-CFT or $^{18}$F-FP DTBZ PET/CT at Huashan Hospital between March 2011 and February 2020, all of whom met the diagnostic criteria of the United Kingdom Parkinson Disease Society (UKPDS). Quantitative analyses were calculated based on six volume-of-interest templates of bilateral striatal subregions, including the caudate, anterior putamen (AP), and posterior putamen (PP). These measures included the ratio of specific to nonspecific binding, the intersubregional gradient from PP to AP (PP/AP), and the caudate to putamen (C/P) ratio. We also defined the NSD index (NSDI) as the degree of NSD and the asymmetry index (AI) as the degree of DaT laterality between the two hemispheres. ***Results:*** 82.1% of PD patients with left-NSD had greater deficit on the right side of the putamen, while 73.3% of patients with right-NSD had greater deficit on the left side ($\chi^2$=17.9, P<0.001). The Cohen's kappa test demonstrated a significant negative agreement between the direction of NSD and the side with more affected DaT (kappa=-0.6, P<0.001). Patients with right-NSD had a significantly higher AI than those with left-NSD (P<0.001 for AP, PP, and caudate). The PP/AP was significantly higher in patients with right-NSD than in those with left-NSD (P<0.01), while the C/P was significantly lower in patients with right-NSD compared to those with left-NSD (P<0.05). For early PD, the Spearman test showed a significant negative correlation between NSDI and PP AI (r=-0.51, P<0.001). ***Conclusion:*** Our findings suggest that PD patients with unilateral NSD exhibit contralateral DaT loss. Moreover, the degree of NSD deviation is positively correlated with the extent of contralateral dopamine loss. These results provide a basis for further investigation of the underlying mechanisms of PD laterality.

## EPS-156

### Dopamine $D_1$ receptor availability in Gilles de la Tourette syndrome measured by [11C]SCH23390 PET

***M. Rullmann***[1], *D. Gkotsoulias*[2], *S. Schmitt*[3], *C. Fremer*[3], *C. Klages*[3], *K. Hartung*[3], *A. Bujanow*[2], *F. Zientek*[1], *K. Messerschmidt*[1], *M. Patt*[1], *O. Sabri*[1], *K. Müller-Vahl*[3], *H. Möller*[2], *H. Barthel*[1];
[1]*Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY,* [2]*Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY,* [3]*Clinic of Psychiatry, Social Psychiatry and Psychotherapy, Hannover Medical School, Hannover, GERMANY.*

***Aim/Introduction:*** Clinically, Gilles de la Tourette syndrome (GTS) is characterized mainly by motor and vocal tics. Current treatment strategies are often unsatisfactory. Therefore, it is necessary to further elucidate the underlying pathophysiology. The literature suggests a dysregulated dopaminergic system, with the selective dopamine $D_1$ receptor ($D_1R$) antagonist ecopipam showing promising treatment results in children and adults. To date, $D_1Rs$ have not been studied in vivo in GTS. We hypothesize that patients with GTS have reduced $D_1R$ availability that correlates with clinical disease severity. ***Materials and Methods:*** We performed a $D_1R$ PET scan with [11C]SCH23390 on a Siemens hybrid PET/3T-MRI system in patients with GTS and age- and sex-matched healthy control participants (HCs). After a 90 bolus injection of 474 ± 30 MBq, participants underwent a 90-minute dynamic PET scan. Dynamic data were motion corrected and coregistered with individual T1-MP2RAGE MRI data. We performed kinetic modeling to generate parametric maps of binding potential ($BP_{ND}$) and relative delivery ($R_1$) using MRTM2 with cerebellar cortex as the reference region. Parametric data were analyzed voxel-wise in SPM12 ($p < 0.001$ unc., $k > 10$ voxels). Clinical severity was assessed using the Yale Global Tic Severity Scale (YGTSS). ***Results:*** Our preliminary analysis of 20 GTS patients and 20 HCs suggests reduced $BP_{ND}s$ in patients with GTS in caudate, insula and putamen. $R_1$ levels were reduced in patients with GTS in occipital cortex. $BP_{ND}s$ were negatively correlated with YGTSS scores and subscores in precentral, striatal and parietal areas. ***Conclusion:*** These preliminary results suggest an altered D1R system in patients with GTS in relation to clinical severity. The analysis of additional data is still ongoing. As such, our first results will help to provide a more comprehensive picture of neurochemical abnormalities in GTS, especially when combined with MRI measures such as 1H-MRS and quantitative susceptibility mapping.

## EPS-157

### Multiparametric $^{11}$C-MET PET/MR for predicting survival of postsurgical glioma patients

***Y. Xu***, *C. Li, F. Liu, F. Hu, W. Ruan, X. Lan;*
*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

***Aim/Introduction:*** The study is aimed to evaluate the value of multiparametric $^{11}$C-MET PET/MRI for predicting survival for glioma patients after surgery. ***Materials and Methods:*** Newly diagnosed glioma patients with histologically confirmation were consecutively enrolled and evaluated by postsurgical $^{11}$C-MET PET/MR. A 10-min PET scan was started 20 minutes after injection, together with anatomical MR sequences, diffusion-weighted imaging (DWI), 3D Arterial Spin Labeling (3D ASL) perfusion imaging and magnetic resonance spectroscopy (MRS). Images were analyzed with visual evaluation and quantitative parameters such as $SUV_{max}$, $SUV_{mean}$, $TBR_{max}$ and $TBR_{mean}$ (lesion/contralateral normal frontal lobe), ADC, ADC ratio (lesion/normal thalamus), CBF, CBF ratio (lesion/contralateral brain), Cho/Cr and Cho/NAA for residual tumor lesions. Residual tumor lesions were then segmented with the thresholds of TBR above 1.3, 1.6 and 40%$SUV_{max}$ to get the metabolic tumor volume (MTV) and total lesion methionine metabolism (TLMM), avoiding physiological uptake or postsurgical alterations. Patient went through standard radiochemotherapy. Overall survival (OS) and progression-free survival (PFS) were determined by long-term follow-up. Log-rank test and COX regression model were used to analyze the association between image parameters, clinical features, and patient survival. Least absolute shrinkage and selection operator (LASSO) regression model was used to screen the parameters to establish a nomogram prediction model for internal validation. ***Results:*** Seventy-three patients were enrolled. During follow-up, 35 patients developed disease progression, 38 patients did not develop disease progression, 8 patients developed disease progression but still survive, and 28 patients died (including a patient who died before disease progression). Multivariate COX regression analysis showed that $SUV_{max}$, $SUV_{mean}$, $TBR_{max}$, $TBR_{mean}$, MTV (1.3TBR), MTV (1.6TBR), TLMM (1.3TBR), TLMM (1.6TBR), Cho/Cr and Cho/NAA were significantly associated with PFS. Only MTV (1.3TBR) was significantly associated with OS. A nomogram prediction model for overall survival was established including patient age, WHO grade, IDH mutation status and MTV(1.3TBR), whose concordance index could reach 0.900. ***Conclusion:*** Postsurgical $^{11}$C-MET PET/MR imaging had prognostic value for glioma patients. $SUV_{max}$, $SUV_{mean}$, $TBR_{max}$, $TBR_{mean}$, MTV, TLMM, Cho/Cr, and Cho/NAA were significantly associated with PFS. Only MTV with the threshold of TBR above 1.3 was significantly associated with OS.

## EPS-158

### A Feasibility Study of Ga68-PSMA PET/CT in Differentiating Brain Metastases from Radiation Necrosis

***F. Lattuada***[1], *S. Wagemaker*[2], *L. de Wit-van der Veen*[2], *D. Brandsma*[2], *M. Stokkel*[2];
[1]*Post Graduate School of Nuclear Medicine, University of Milano-Bicocca, Milano, ITALY,* [2]*NKI-AVL, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Prostatic-specific membrane antigen (PSMA) targeted radionuclide imaging has shown excellent results for the assessment and management of prostate cancer. Nevertheless, heterogeneous degrees of PSMA expression have been proven in other malignancies, including primary non-small cell lung cancer (NSCLC) and its metastases. Using conventional imaging methods, recurrent disease and treatment-related changes, including radiation necrosis (RN), in the brain are often indistinguishable on MRI. As RN represents a primary complication of stereotactic radiation therapy (SRT), this study aims to assess the diagnostic role of 68Ga-PSMA PET/CT in differentiating NSCLC brain metastasis and radiation necrosis in irradiated NSCLC brain metastasis. ***Materials and Methods:*** Two different cohorts of patients were selected: the first group (n=11) comprises patients with newly diagnosed NSCLC brain metastases, and the second group (n=13) patients with defined RN after irradiation of NSCLC brain metastases. All patients received 100 MBq of 68Ga-PSMA intravenously followed by a PET/CT scan 45 minutes post-injection. We selected 37 lesions with a diameter ≥ 1.0 cm based on

contrast-enhanced MRI in order to obtain a reliable quantification. All the lesions has been evaluated using semi-quantitative (SUVmax and SUVpeak) and visual assessment. ***Results:*** Of 37 lesions, 15 were brain metastases and 22 were RN. Mean SUVmax values for the brain metastasis group and the RN group were 7.62 (95% CI 5.10 - 10.15) and 4.05 (95% CI 2.98 - 5.12), respectively (p= 0.013). Mean SUVpeak values for the brain metastasis group and the RN group were 3.71 (95% CI 2.40 - 5.01) and 2.09 (95% CI 1.57 - 2.61), respectively (p=0.013). We also calculated semi-quantitative values normalized to background uptake identified as ΔSUVmax and ΔSUVpeak. Mean ΔSUVmax values for the brain metastasis group and the RN group were 7.38 (95% CI 4.86 - 9.89) and 3.72 (95% CI 2.65 - 4.78), respectively (p=0.009). Mean ΔSUVpeak values for the brain metastasis group and the RN group were 3.62 (95% CI 2.32 - 4.92) and 1.96 (95% CI 1.43 - 4.92), respectively (p=0.010). Visual assessment did not reveal additional value. ***Conclusion:*** This feasibility study showed a significant difference between brain metastases and RN uptake values on 68Ga-PSMA PET/CT imaging. A subsequent study will be initiated including a larger cohort of patients to be able to find a cut-off value that enables differentiation of the two entities in clinical practice.

## EPS-159

### Feasibility and initial experience of chemokine receptor-4 receptor-4 (CXCR4) expression using 68Ga-Pentixafor and O-2-18F-fluoroethyl-l-tyrosine (18F-FET) PET-MR image fusion in low- and high-grade gliomas

***Aim/Introduction:*** Amino acid agents and CXCR4 have been reported to be overexpressed in glioma cells, particularly in glioblastoma multiform. The current study aimed to evaluate the feasibility of MRI, 18F-FET, and 68Ga-Pentixafor PET to increase diagnostic accuracy and to improve the discrimination of treatment-emergent changes in low- and high-grade gliomas. ***Materials and Methods:*** We analyzed two separate databases; in the first subgroup, 29 patients with recurrent glioblastoma underwent 68Ga-Pentixafor PET/CT to examine CXCR4 expression before/after tumor mass resection. The second subgroup included 11 patients with histopathologically proven brain tumor suspected of having recurrent changes 3-4 months after surgery who were referred for an 18F-FET PET/CT scan. In addition, PET/MR image fusion for both 68Ga-Pentixafor and 18F-FET was performed. For both PET probes, visual and semi-quantitative calculation of image-derived metrics, SUVmax and tumor-to-background ratios (TBR), were performed. ***Results:*** Among eleven patients (age: 27-73 years; mean age of 47 ± 13 years) referred to 18F-FET PET/CT/MR imaging, nine cases (82%) had a positive MRI, six cases (55%) had a positive PET/CT and PET/MRI, and tumor recurrence was observed in 6 patients (55%). Sample follow-up indicated that accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were 64%, 85%, 25%, 67%, 50% for MRI alone and 91%, 85%, 100%, 100% and 80% for PET/CT/MRI, respectively. The results of 29 patients who underwent 68Ga-Pentixafor PET/CT were also evaluated visually and semi-quantitatively. Visual assessment of 68Ga-Pentixafor PET revealed that 27/29 cases were positive with a mean SUVmax of 3.92 (13 patients were female (13/29) and 16 patients were male (16/29); the mean age of the patients was 57.36 years). 17.24% (5/29) of patients had WHO grade III pathologies (anaplastic oligodendroglioma/anaplastic astrocytoma). 3 out of 29 participants had a stereotactic biopsy. The interval time between biopsy and imaging was 14-38 days (mean 21.71 days). The mean SUVmax of WHO grade IV lesions was significantly higher than grade III (3.131 ± 3.01 vs. 1.99 ± 0.45) and the mean SUVmax of blood pool activity was reported as 1.277 at the superior sagittal sinus area. While the mean target-to-background ratio of grade IV patients was 29.45, all grade III gliomas showed lower lesion uptake than background activity considered at the contralateral cortex. ***Conclusion:*** This study concluded that 68Ga-Pentixafor had a higher TBR (lower background in the cortex) than 18F-FET PET, with the ability to bond with 177Lu-Pentixather. 68Ga-Pentixafor imaging could improve recurrence detection.

## EPS-160

### Histopathological validation of 18F-FACBC uptake in high- and low-grade glioma

***B. Vindstad***[1], *L. K. Pedersen*[2], *E. M. Berntsen*[1,3], *O. Solheim*[3,1], *I. Reinertsen*[4,1], *H. Johansen*[3], *A. J. Skjulsvik*[1,3], *L. Eikenes*[1], *A. Karlberg*[1,3];
[1]*Norwegian University of Science and Technology, Trondheim, NORWAY,* [2]*University Hospital of North Norway, Tromsø, NORWAY,* [3]*St. Olavs Hospital, Trondheim, NORWAY,* [4]*SINTEF Digital, Trondheim, NORWAY.*

***Aim/Introduction:*** Accurate diagnosis, grading and tumor delineation of gliomas is essential for treatment planning and prognosis estimation. PET can provide quantitative information of cellular activity and metabolism, and amino acid PET is recommended as a complement to MRI for patients with suspected glioma. 18F-FACBC is an amino acid tracer with a very low uptake in normal brain parenchyma compared to the currently recommended tracers for glioma imaging, which could be beneficial in diagnostic applications for patients with gliomas.The aim of the study was to investigate the relationship between 18F-FACBC uptake and histopathology in patients with gliomas. The tracer was evaluated as a predictor for high-grade

and low-grade glioma, as well as individual molecular parameters associated with glioma. ***Materials and Methods:*** Patients with suspicion of primary or recurrent gliomas (n=27) were scanned with hybrid PET/MRI systems (Siemens Biograph mMR) prior to surgery. PET and MR images were used in the neuronavigation during sampling of a total of 61 image localized biopsies from eligible patients (n = 18, up to 4 biopsies per patient). 44 biopsies were analysed for increased cell density and IDH1 and ATRX mutation status, and an estimation of glioma grade in each biopsy (HGG, LGG or normal tissue) was made based on the histopathological results. Tumor-to-background ratio (TBR) of 18F-FACBC uptake was calculated for each biopsy location. The TBR value was evaluated as predictor for both the individual molecular parameters (cell density, IDH1 and ATRX) and the estimated diagnosis using ROC analysis. ***Results:*** 18F-FACBC uptake predicted classification of increased cell density, IDH1 and ATRX mutation status (high cell density: threshold = 3.69, AUC = 0.9; moderate or high cell density: threshold = 1.77, AUC = 0.73; IDH1 mutation: threshold = 2.44, AUC = 0.8; ATRX mutation: threshold = 2.44, AUC = 0.86). Preliminary results based on the estimates of diagnosis suggest that 18F-FACBC may predict HGG vs LGG/normal tissues (threshold = 3.41, AUC = 0.88), but has lower sensitivity for HGG/LGG vs normal tissues prediction (threshold = 1.68, AUC = 0.53). ***Conclusion:*** 18F-FACBC TBR is a good predictor of various molecular parameters associated with glioma. Increased cell density as well as IDH1 and ATRX mutation was predicted with high sensitivity. Preliminary results also suggest 18F-FACBC as a good predictor for HGG, but less so for LGG.

## EPS-161

### Prognostic Role of Preoperative [$^{11}$C]Methionine PET in IDH-Wildtype Astrocytomas

***G. Ninatti***[1], *M. Sollini*[2,3], *B. Bono*[2], *L. Antunovic*[4], *F. Gelardi*[2], *C. Landoni*[1,5], *F. Pessina*[2,3], *M. Rodari*[3], *A. Chiti*[6,4];
*[1]University of Milano Bicocca, Monza, ITALY, [2]Humanitas University, Pieve Emanuele, ITALY, [3]IRCCS Humanitas Research Hospital, Rozzano, ITALY, [4]IRCCS San Raffaele Scientific Institute, Milan, ITALY, [5]IRCCS-San Gerardo, Monza, ITALY, [6]Vita-Salute San Raffaele University, Milan, ITALY.*

***Aim/Introduction:*** IDH-wildtype astrocytomas are the most common and aggressive type of primary brain tumors. [$^{11}$C]Methionine (MET) positron emission tomography (PET) is commonly used for the preoperative evaluation of patients with glial neoplasms. This study aimed to investigate the prognostic role of [$^{11}$C]MET PET in newly-diagnosed IDH-wildtype astrocytic gliomas who underwent surgical treatment. ***Materials and Methods:*** Patients with a histomolecular diagnosis of IDH-wildtype astrocytoma who underwent surgery and preoperative (<100 days) [$^{11}$C]MET PET/CT were retrospectively included. Qualitative and semi-quantitative analyses of [$^{11}$C]MET PET images were performed. For qualitative analysis, lesions were classified as positive in case of increased radiopharmaceutical uptake compared to the normal brain and negative in all other cases. The mean and maximum tumor-to-background ratio (TBR), calculated as ratios between $SUV_{max}$ and $SUV_{mean}$ of the metabolic tumor volume, respectively, and uptake values of contralateral normal brain, were used for the semi-quantitative analysis. Progression-free survival (PFS) rates were analyzed by Kaplan-Meier curves and compared using the log-rank test. Cox proportional-hazards regression was used to test the association of imaging and clinical data to PFS. A p-value < 0.05 was considered statistically significant. ***Results:*** A total of 48 patients (M/F: 25/23; median age 55) were included in the study. At visual analysis 39 lesions (81%) were defined as positive at [$^{11}$C]MET PET, while 9 (19%) as negative. All IDH-wildtype astrocytomas with a known TERT promoter mutation were positive at [$^{11}$C]MET PET (9/9, 100%). Patients with positive [$^{11}$C]MET PET at diagnosis had a shorter median PFS compared to patients with a negative scan (15.9 months vs. undefined, p = 0.0427). Considering only the 29 patients (60%) who underwent complete surgical resection of the lesion, positive preoperative [$^{11}$C]MET PET scan was still significantly associated with shorter median PFS (16.8 vs. undefined, p = 0.0304). Extent of surgical resection (EOR), lesion contrast enhancement on MRI, $TBR_{max}$ and $TBR_{mean}$ at [$^{11}$C]MET PET were significantly associated with PFS on univariate analysis. EOR was an independent predictor of PFS on multivariate analysis. ***Conclusion:*** Preoperative [$^{11}$C]MET PET is able to identify the most aggressive IDH-wildtype glial neoplasms and to predict patient prognosis. [$^{11}$C]MET PET results may reflect the presence of genetic parameters typical of IDH-wildtype astrocytomas with a negative prognostic impact. Our findings highlight the usefulness of [$^{11}$C]MET PET for the preoperative assessment of this glioma type.

## EPS-162

### $^{99m}$Tc-ECD SPECT Predicts Neurological Recovery in Cardiac Arrest Survivors

***P. Chuang***[1], *Y. Chen*[2], *Y. Huang*[2], *C. Wang*[3], *W. Chang*[4], *Y. Wu*[5], *M. Cheng*[2];
*[1]Department of Nuclear Medicine, National Taiwan University Hospital Yunlin Branch, Douliu City, TAIWAN, [2]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei City, TAIWAN, [3]Department of Emergency Medicine, National Taiwan University Hospital Yunlin Branch, Douliu City, TAIWAN, [4]Department of Emergency Medicine and Cardiology, National Taiwan University Hospital, Taipei City, TAIWAN, [5]Department of Nuclear Medicine and Cardiology, Far Eastern Memorial Hospital, New Taipei City, TAIWAN.*

***Aim/Introduction:*** Neuroprognostication plays a pivotal role in managing patients who have been successfully resuscitated from cardiac arrest, particularly when facing the decision to withdraw or continue life-sustaining treatment. We aim to investigate whether $^{99m}$Tc-ECD SPECT helps to predict neurological outcome among cardiac arrest survivors. ***Materials and Methods:*** We conducted a retrospective analysis of a prospectively established cohort from January 2010 to February 2022 in a tertiary referral centre in Northern Taiwan. Patients successfully resuscitated from cardiac arrest were consecutively enrolled. Brain $^{99m}$Tc-ECD SPECT was performed 5 to 10 days after the index event. Individuals with traumatic cardiac arrest causes or major intracranial insults revealed by non-enhanced CT were excluded. The standard of reference was the neurological outcome assessed using the cerebral performance category (CPC) score at hospital discharge or 30 days after the index event, with scores of 3 to 5 denoting poor outcomes. $^{99m}$Tc-ECD SPECT/CT images were analysed by two experienced nuclear medicine specialists independently. Each image was segmented into 8 cortical brain areas (including bilateral frontal, parietal, occipital, and temporal lobes) and 5 areas of the ascending reticular activating system (including upper brainstem, bilateral thalami, and basal ganglia). Hypoperfusion severity in each brain area was graded on a scale of 0 (preserved perfusion) to 4 (no perfusion). A brain area graded >2 was considered hypoperfused. Semi-quantitative analysis was computed using PMOD software, with uptake ratios representing the mean count activity of each segmented brain area normalized to that of the bilateral temporalis muscles. The Youden's method

was used to determined cut-off values for uptake ratios, and a brain area with an uptake ratio below its cut-off value was also considered hypoperfused. Logistic regression analysis was used to identify predictors for poor neurological outcomes. ***Results:*** We analyzed 224 patients (138 men, 86 women; mean age, 66.8 ± 16.2 years), of which 176 patients (78.6%) had poor neurological outcome. The whole brain area showed no evidence of perfusion in $^{99m}$Tc-ECD SPECT significantly associated with poor outcome (OR, 18.99, 95% CI, 1.13-318.60; p=0.006). The number of hypoperfused brain areas in the ascending reticular activating system independently predicted neurological outcome with adjusted OR of 1.70 (95% CI, 1.10-2.63; p=0.017) using visual assessment, and 1.84 (95% CI, 1.32-2.56; p<0.001) using uptake ratios. ***Conclusion:*** Brain hypoperfusion evaluated with $^{99m}$Tc-ECD SPECT is helpful in predicting neurological recovery in cardiac arrest survivors, which might assist in informed decision-making for post-resuscitation care.

## EPS-163

### Cerebral perfusion imaging with [$^{15}$O]$H_2O$ and an image derived input function from an additional scan of the heart

***L. Marner***[1], *M. E. Larsen*[1,2], *A. O. Kellberg*[1], *A. C. Henriksen*[1], *S. Fuglsang*[1], *M. N. Lonsdale*[1], *L. Marner*[3];
[1]*Copenhagen University Hospital Bispebjerg, Department of Clinical Physiology and Nuclear Medicine, Copenhagen NV, DENMARK,* [2]*Copenhagen University Hospital Rigshospitalet, Department of Anestesiology, Copenhagen, DENMARK,* [3]*Copenhagen University Hospital Bispebjerg, Department of Clinical Physiology and Nuclear Medicine, Copenhagen, DENMARK.*

***Aim/Introduction:*** Quantitative cerebral perfusion imaging with [$^{15}$O]$H_2O$ PET is used for assessment of high risk stroke patients but has been limited by the need for invasive arterial cannulation. We aimed to validate a new method with an additional scan of the heart to achieve a non-invasive image derived input function (IDIF) compared to the reference standard with an arterial input function (AIF). ***Materials and Methods:*** Six patients suspected for cerebral hemodynamic insufficiency undergoing cerebral perfusion imaging with [$^{15}$O]$H_2O$ PET during clinical routine and two healthy elderly subjects were included. Participants had a total of four [$^{15}$O]$H_2O$ PET scans: a heart and a brain scan at rest followed by infusion of approx. 1 g of acetazolamide to induce vasodilation. After 20 min, the heart and brain scans were repeated. During all four scans, continuous arterial sampling was performed to achieve an AIF. The IDIF was extracted from a manual delineated volume-of-interest (VOI) in the left ventricle of the heart. After correction for injected dose and time-shifting, the IDIF's and AIF's were compared by means of area under curve (AUC) and sums-of-squares (SOS) from an averaged AIF. Using an univariate general linear model, two subsequent AIF's were compared, IDIF's were compared to AIF's, and the regional cerebral perfusion (rCBF) estimated from the AIF and IDIF, respectively, were compared. ***Results:*** Of the 32 scans, 26 had successful arterial sampling. Two subsequent injections of [$^{15}$O]$H_2O$ resulted in AIF's that were significantly dependent only on subject (p<0.001), and AUC and SOS were highly correlated between measurements (p<0.001 and p<0.000001, n=11 repeated measurements in 6 subjects). Further, AIF and IDIF were highly correlated and dependent on subjects (p<0.007 and p<0.001) but AUC were also significantly lower for IDIF (p<0.02). The lower AUC resulted in higher rCBF (p<0.001) for IDIF compared to AIF. rCBF were still highly dependent on subject (p<0.001, n=15 in 8 subjects). Bland Altman plot showed a positive bias of 3% [-7%, + 14%] using IDIF compared to AIF. ***Conclusion:*** Replacing the invasive arterial cannulation by an additional scan of the heart to achieve an IDIF results in an acceptable bias of 3% higher rCBF estimations. The method is applicable to all scanner systems and is independent of advanced partial volume correction methods.

## EPS-164

### Hypermetabolism in the Cerebellum is Related to M1 Microglial Activation in Temporal Lobe Epilepsy

***Y. Tang****, L. Xiao, J. Yang, J. Hou, B. Chen, S. Hu;*
*Xiangya Hospital Central South University, Changsha, CHINA.*

***Aim/Introduction:*** The cerebellum is a crucial subcortical structure involved in epileptic networks. Our previous study found hypermetabolism in the bilateral cerebellum among patients with temporal lobe epilepsy (TLE). However, the underlying pathophysiological mechanism remains unclear. This study aimed to explore the potential mechanism of abnormal cerebellar metabolism in TLE, providing deeper insights into the pathophysiology and furthering the search for new drug targets for better management of TLE. ***Materials and Methods:*** Twenty-one patients with TLE and 21 sex- and age-matched healthy controls who underwent [$^{18}$F]F-FDG PET/CT were enrolled in our study. Regional cerebral metabolic patterns were analyzed using statistical parametric mapping. Then, a rat model of TLE induced by lithium chloride-pilocarpine was subjected to [$^{18}$F]F-FDG micro-PET/CT imaging and dynamic metabolism changes in the cerebellum were analyzed. [$^{18}$F]F-DPA-714 micro-PET/CT imaging was implemented to confirm cerebellar neuroinflammation. Immunohistochemistry and western blotting were conducted to investigate the quantities of neurons, Purkinje cells, glial cells and glucose transporters. Flow cytometry and a Luminex assay were applied to verify cerebellar microglial activation and an immune inflammatory reaction. ***Results:*** Compared to healthy controls, patients with TLE showed hypermetabolism in the bilateral cerebellum in addition to hypometabolism in the temporal lobe. In the rat model of TLE, increased [$^{18}$F]F-FDG and [$^{18}$F]F-DPA-714 uptake in the cerebellum was confirmed in the chronic phase. We observed the loss of Purkinje cell without a significant decrease of Neun-expressing neurons, and the expression of glucose transporter-1 (Expressed in microglia) increased while there was no change of the glucose transporter-3 (Expressed in neurons) in the cerebellum, indicating that hypermetabolism in the cerebellum is not associated with increased glucose uptake of neurons. Compare to control animals, the immunofluorescence and Western blotting results showed that not only the number of microglia increased, but also the cell body of microglia increased and dendrites decreased in morphology in the chronic stage, there was no significant changes for astrocytes in cerebellum. Furthermore, we found an increase in M1-phenotype microglia, a decrease in M2-phenotype microglia, and an increase in inflammatory factors in the cerebellum. ***Conclusion:*** Patients with TLE exhibited hypermetabolism in the cerebellum, which was confirmed in the chronic phase in TLE rat model. Hypermetabolism of cerebellum may be associated with activation of M1 microglia and immune-driven neuroinflammation, which supports the network theory of epilepsy pathogenesis and may aid the selection of appropriate drug and network regulation targets for TLE interventions designed to address cerebellar inflammation.

## EPS-165

### Brain Networks Involved in Cancer Treatment Response:Insights from 18F-FDG PET Scans

***M. Namías***[1], *M. Perovnik*[2], *D. T. Huff*[3], *C. Tinetti*[1,4], *M. Azar*[4], *R. Jeraj*[5,6];
[1]*Fundación Centro Diagnóstico Nuclear, Buenos Aires, ARGENTINA,* [2]*University Medical Center Ljubljana, Ljubljana, SLOVENIA,* [3]*University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,* [4]*Instituto de Oncología "Ángel H. Roffo", Buenos Aires, ARGENTINA,* [5]*University of Wisconsin School of Medicine and Public Health, Madison, WI, UNITED STATES OF AMERICA,* [6]*Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** Neuroimmunology studies of the interaction between the nervous and immune systems. This field has shed light on how the brain coordinates behavior, metabolism, and immune response, and how psychological and physiological factors can affect the functioning of the immune system, including its ability to fight cancer. In this study, we aimed to investigate whether pre-treatment brain 18F-FDG PET metabolic patterns could predict treatment outcomes in oncology. Our research questions were: 1) Can we identify an 18F-FDG metabolic pattern of the brain that correlates with treatment outcome in oncology? 2) Is this pattern stable across cancer types and treatment modalities? We also sought to explore the cognitive implications of the identified patterns by evaluating differences in the expression of different brain networks. ***Materials and Methods:*** We retrospectively analyzed two 18F-FDG PET datasets from different cancer types and treatment modalities, including advanced metastatic melanoma patients treated with anti-PD1 immunotherapies and stage III breast cancer patients undergoing neoadjuvant chemotherapy. We extracted the brain region from whole-body PET scans and developed uptake patterns as group-level differences between patients who responded to treatment vs. non-responders. Individual pattern expression scores were obtained by multiplying brain scans with the t-score pattern. Scores between groups were compared by performing the Mann-Whitney U test and receiver operating characteristic curves. Classification performance was evaluated by performing both intra- and across-group crossvalidation. We also evaluated the expression of 10 brain networks obtained from the analysis of the BrainMap activation database. ***Results:*** The metabolic pattern was distributed across different brain regions, with regions of relative hypermetabolism in non-responders including the precuneus, Brodmann areas 7, 31 and 40, the cingulate gyrus, left angular gyrus and the middle temporal gyrus, and the cerebellum being the main region with relative hypometabolism. The metabolic pattern was stable across these two cancer types and treatment modalities, and can classify responders vs. non-responders to cancer treatment with areas under the curve of 0.68 and 0.86 for melanoma and breast cancer respectively. Finally, significant differences were found in the expression of the default mode and cognition-language networks between groups. ***Conclusion:*** Our results demonstrate that metabolic patterns of the brain correlate with treatment outcome in cancer patients. We anticipate our work to contribute to the understanding of the interrelation of the central nervous system and treatment response in the context of cancer therapies.

## EPS-166

### Correlation between neovascularization and macrophage inflammation in carotid atherosclerotic plaques evaluated by hybrid $^{18}$F-FDG PET/MR:a fused image-based histological validation study

***Y. Zhang***[1,2], *B. Cui*[1,2], *H. Yang*[1,2], *Y. Ma*[3], *J. Lu*[1,2];
[1]*Department of Radiology and Nuclear Medicine, Xuanwu Hospital Capital Medical University, Beijing, CHINA,* [2]*Beijing Key Laboratory of Magnetic Resonance Imaging and Brain Informatics, Beijing, CHINA,* [3]*Department of Neurosurgery, Xuanwu Hospital Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** Rupture of carotid atherosclerotic plaque is the primary cause of cerebral infarction. Inflammation may cause the occurrence, development and rupture of atherosclerotic plaque, but its physiological mechanism and relationship with the outcome of atherosclerotic plaque are unclear. Neovascularization and macrophage inflammation are the important components of inflammation and their interaction leads to plaque progression. MRI and PET are the non-invasive imaging technology and increasingly used to evaluate atherosclerotic plaque. As dynamic enhanced MRI is used for imaging neovascularization with high spatial resolution, $^{18}$F-FDG-PET can be used for quantitative imaging macrophages metabolism of response to inflammation with high sensitivity and specificity. This study determines to investigate the correlation between neovascularization and macrophage inflammation in atherosclerotic carotid plaques with hybrid $^{18}$F-FDG PET/MR, further to verify accuracy by histological examination, and to evaluate the clinical potential of hybrid $^{18}$F-FDG PET/MR. ***Materials and Methods:*** Twenty-five patients with transient ischemic attack or minor stroke in carotid territory and ipsilateral carotid artery stenosis of 50% to 90% were included. All patients underwent hybrid PET/MR a median of 130 min after injection of $^{18}$F-FDG. $^{18}$F-FDG standard uptake values with target-to-background ratio (TBR) were determined on corresponding PET sections. Neovascularization was quantified by transfer constant ($K^{trans}$) on corresponding DCE-MRI sections. A cohort of symptomatic patients (n=12) with carotid stenosis scheduled for carotid endarterectomy (CEA) was separately imaged with hybrid $^{18}$F-FDG PET/MR and findings were correlated with histochemical assessment of intact carotid plaques. Spearman rank correlation coefficients between TBR and $K^{trans}$ were calculated. ***Results:*** The correlation between TBR and $K^{trans}$ was only marginal in the whole study sample (r=0.25, p=0.043). The two variables correlated with each other in the symptomatic plaques (r=0.71, p=0.013), but were independent in the asymptomatic plaques (r=0.03, p=0.473). Neither TBR nor $K^{trans}$ was significantly higher in the symptomatic plaques, but both showed inverse relationships with time since last cerebrovascular ischemic event (r=-0.92 and -0.74 for TBR and $K^{trans}$, respectively). Histological findings from CEA confirmed that inflammation and neovascularization expression was localized within carotid vulnerable plaques. Co-localization of cellular CD31 and CD68 expression in the plaque was observed by immunofluorescence staining. ***Conclusion:*** The correlation between neovascularization and macrophage inflammation in carotid atherosclerotic plaques with hybrid $^{18}$F-FDG PET/MR varied with clinical conditions, pointing to a complex interplay between macrophages and neovessels under different pathophysiological conditions. Hybrid $^{18}$F-FDG PET/MR systems might help to evaluate the correlation between neovascularization and macrophage inflammation in carotid atherosclerotic plaques.

## EPS-167

**Brain-dedicated PET system shows non-inferiority compared to conventional PET-CT**

***P. Nespral***[1], *P. Bascuñana*[1], *G. Cuesta Domingo*[1], *A. Canora*[1], *A. Delgado-Cano*[1], *J. Matías-Guiu*[2], *J. Carreras-Delgado*[1], *M. Cabrera-Martín*[1];
[1]*Department of Nuclear Medicine, Instituto de Investigación Sanitaria San Carlos (IdISSC). Hospital Clínico San Carlos, Universidad Complutense, Madrid, SPAIN,*
[2]*Department of Neurology. Instituto de Investigación Sanitaria San Carlos (IdISSC). Hospital Clínico San Carlos, Universidad Complutense, Madrid, SPAIN.*

***Aim/Introduction:*** Conventional PET-CT equipment is often saturated due to the high demand for preferential oncological studies. The development of a dedicated brain PET would allow greater accessibility for PET studies in patients with neurodegenerative disease. This would allow for a broadening of clinical indications in addition to enabling improvements in sensitivity and spatial and temporal resolution, better quantification of small areas and nuclei, and the performance of dynamic studies, among other advantages. ***Materials and Methods:*** A total of 422 studies were performed in 211 patients (mean age 70.78±9.57(27-89)), 57.3% of whom were women. They were referred from the Neurology Department of the Hospital Clínico San Carlos for 18F-FDG PET-CT. The patients underwent a brain imaging study in the conventional PET-CT scanner and subsequently in the dedicated PET scanner after signing the informed consent form. Two nuclear physicians with more than 15 years of experience in neuroimaging evaluated the images without clinical information from the patients, establishing the degree of hypometabolism of the main brain regions and an image-based diagnose. The percentage of agreement between the PET diagnosis and the clinical diagnosis was estimated for both scans. The percentage of agreement and Cohen's Kappa between both scans were also evaluated. ***Results:*** The diagnostic ability of PET vs. clinical diagnosis (degenerative vs. non-degenerative cause) was 82.35% in the dedicated PET and 75.55% using the conventional PET-CT. Similarly, the agreement with the broad diagnosis of neurodegenerative diseases was 80.3% for the dedicated PET vs 75.23% for the conventional PET-CT. The inter-evaluator concordance percentage for degenerative vs. non-neurodegenerative was 83.8% in dedicated PET and 76.7% in conventional PET-CT. ***Conclusion:*** We found good concordance of the dedicated tomograph with conventional PET-CT equipment, having even slightly superior diagnostic capacity. These findings validate the clinical use of this new dedicated brain PET for the diagnosis of neurodegenerative diseases. .

***Aim/Introduction:*** This is a case report of a patient diagnosed with symptomatic multiple myeloma (MM) who was staged with [18F]F-FDG PET/CT (FDG-PET/CT), [68Ga]Ga-PSMA PET/CT (PSMA-PET/CT) and Whole-Body Magnetic Resonance with Diffusion Weighted Imaging (DWI-WB-MRI). ***Materials and Methods:*** A 56-year-old woman with recent diagnosis of MM underwent double-tracer PET/CT with [18F]F-FDG and [68Ga]Ga-PSMA in December 2022 (within a clinical protocol approved by local IRB, n° 538/2021/Oss/AOUBo) and DWI-WB-MRI in January 2023, 4 weeks apart from the first to the last imaging procedure. All the scans were carried out with standard procedure and before therapy onset. Upon imaging completion, the patient started pre-transplantation induction therapy, still ongoing. ***Results:*** FDG-PET/CT showed a low focal uptake corresponding to osteorarefaction and bulge of the tenth costovertebral joint and the lateral part of the eighth left rib ("cold" lesions, DS3). On the contrary, PSMA-PET/CT showed multiple areas of focal uptake in the skull (three lytic lesions with a SUVmax=5.3 in the left frontoparietal region), ribs (lytic lesion of the eighth left rib, with para-medullary extension, SUVmax=5.1; paravertebral part of the tenth rib, SUVmax=5.2) and the right sacral wing (SUVmax=4.8) with no corresponding morphological abnormalities. The subsequent DWI-WB-MRI, reported according to the MY-RADS criteria, showed signal alterations corresponding exactly to PSMA-PET/CT findings.

No bone marrow involvement nor extramedullary sites of myeloma were found by any of the imaging procedures. ***Conclusion:*** In this particular case, PSMA-PET/CT result was superimposable to DWI-WB-MRI and both of them turned out to detect more focal findings as compared to FDG-PET/CT at staging. However, no prognostic impact of PSMA-DWI positive / FDG negative lesions has ever been investigated so far. Despite that, this case suggests a possible role of PSMA-PET/CT to estimate the disease extension in newly diagnosed MM in the light of a subsequent theranostic approach. A larger patient population is needed to finally assess the potential of theranostics in this field.

## OP-535

### Anthracosis: a potential pitfall in 18F-FCH PET/CT and 18F-PSMA-1007 PET/CT interpretation

***A. Cimini***[1], *M. Ricci*[2], *A. Marzullo*[1], *M. Menichini*[1], *F. Di Stasio*[1], *M. Di Pietro*[1], *H. Arabi*[3], *H. Dadgar*[4], *G. L. Gravina*[5]; *[1]Nuclear Medicine Unit, St. Salvatore Hospital, L'Aquila, ITALY, [2]Nuclear Medicine Unit, Cardarelli Hospital, Campobasso, ITALY, [3]Division of Nuclear Medicine and Molecular Imaging, Department of Medical Imaging, Geneva University Hospital, Geneva, SWITZERLAND, [4]Cancer Research Center, RAZAVI Hospital, Imam Reza International University, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [5]Department of Applied Clinical Sciences and Biotechnologies Division of Radiotherapy, University of L'Aquila, L'Aquila, ITALY.*

***Aim/Introduction:*** 18F-Fluorocholine (18F-FCH) and 18F-Prostate Specific Membrane Antigen (18F-PSMA)-1007 are two PET radiopharmaceuticals commonly used in the evaluation of prostate cancer: nonetheless, other conditions such as inflammations may present high uptake of these two radiopharmaceuticals. In this case report, we describe the findings of both 18F-FCH PET/CT and 18F-PSMA-1007 PET/CT in a patient with anthracosis, a type of pneumoconiosis caused by repeated inhalation of coal dust. ***Materials and Methods:*** A 66-year-old man with history of prostate cancer (previously treated with radical prostatectomy) underwent 18F-FCH PET/CT scan due to biochemical recurrence (PSA 1.34 ng/ml): images showed significant uptake of the radiopharmaceutical in lymph nodes of the mediastinum and right pulmonary hilar region, and no uptake of 18F-FCH in subdiaphragmatic lymph nodes. Due to the rarity of spread to supradiaphragmatic lymph nodes, a subsequent 18F-PSMA-1007 PET/CT scan was performed, revealing high uptake of the radiopharmaceutical in lymph-nodes of the mediastinal and right pulmonary hilar region; subdiaphragmatic lymph nodes did not show significant uptake of the radiopharmaceutical also in this case. Therefore, a biopsy of mediastinal and hilar lymph nodes was performed. ***Results:*** 18F-FCH PET/CT scan showed uptake of the radiopharmaceutical in one lymph node located in the mediastinum (SUVmax 2.7) and in one lymph node of the right pulmonary hilum (SUVmax 4.9). Interestingly, 18F-PSMA-1007 PET/CT scan revealed high uptake of the radiotracer in two mediastinal lymph nodes (respectively with SUVmax 23.4 and SUVmax 8.3) and in two lymph nodes of the right pulmonary hilar region (respectively with SUVmax 6.3 and SUVmax 5.9). The biopsy revealed anthracosis and no malignant cells. Subsequently, the patient communicated previous exposures to coal dust due to his job. ***Conclusion:*** To our knowledge, this is the first report describing a patient with anthracosis evaluated both with 18F-FCH PET/CT and 18F-PSMA-1007 PET/CT: nuclear medicine physicians should be aware of potential pitfalls due to inflammatory conditions. Interestingly, 18F-PSMA-1007 PET/CT scan revealed a greater number of inflammatory lymph nodes, suggesting a possible higher sensitivity of this radiotracer for the detection of anthracosis.

## OP-536

### Epididymal metastasis of prostate adenocarcinoma in [$^{68}$Ga]Ga-PSMA-11

***B. Martins****, T. Timóteo, C. Loewenthal; Hospital da Luz, Lisboa, PORTUGAL.*

***Aim/Introduction:*** Reporting the clinical case of a 76-year-old man, with a personal history of dyslipidemia and high blood pressure, diagnosed with high-risk prostate adenocarcinoma in January 2015 - PSAi 48.34 ng/mL, Gleason score 9 (4+5 ), without perineural invasion, staged as cT3bN0M0. He was treated with neoadjuvant hormone therapy, followed by 70Gy (28 fractions) of external radiotherapy with fields on the prostate, seminal vesicles and lymphatic chains until October 2015, having been medicated with adjuvant hormone therapy from May 2015 until June 2018 (nadir PSA of 0,04ng/mL). The patient was clinical reassessed with the usual periodicity, maintaining excellent general condition (ECOG 0) and monitored with PSA, referred for PET-CT with [$^{68}$Ga]Ga-PSMA-11 with PSA of 1.82ng/mL in July 2022. ***Materials and Methods:*** A dynamic study of the pelvis was carried out immediately after intravenous administration of [$^{68}$Ga]Ga-PSMA-11 and a whole body image approximately one hour later, complemented with delayed images of the pelvis. Low-dose CT was obtained for attenuation correction and anatomical referencing. ***Results:*** Normal biodistribution of the radiopharmaceutical was observed, with no evidence of disease recurrence in the prostate gland. However, two foci of increased radiopharmaceutical uptake were observed - one on the left testicle (about 1x1.3cm - ApxLL) with SUVmax of 25.72 (which rose to 37.34 in the late images) and a second in a left paraaortic lymph node, with approximately 7x5mm and SUVmax of 6.18. No adenopathies were documented in the remaining lymphatic territories, nor images suggestive of visceral or bone involvement. In the subsequent clinical evaluation, the testicular nodule was palpated on physical examination and a scrotal ultrasound was performed, the result of which favored an inflammatory process of the left epididymis. ***Conclusion:*** The patient was subsequently submitted to bilateral orchidectomy. The pathological result confirmed prostatic metastasis in the left epididymis. The left para-aortic adenopathy was irradiated with SBRT. In subsequent evaluations, a progressive reduction in PSA was documented, which stabilized at 0.02ng/mL in January 2023. In general, the secondary involvement of prostate adenocarcinoma in the epididymis is rare and may result from direct invasion by the vas deferens or by venous or lymphatic retrograde dissemination[1]. In this case [$^{68}$Ga]Ga-PSMA-11 identified a true positive (image-histology match) uncommon site of prostate cancer secondary involvement, in a context in which the ultrasound suggested an inflammatory etiology. ***References:*** Zhang J. et al: Prostatic adenocarcinoma presenting with metastases to the testis and epididymis: A case report. Oncol Lett 11: 792-794, 2016

### PET/CT with $^{18}$F-FDG and $^{68}$Ga-DOTATOC: a case of negative findings in a Solitary Fibrous Tumor.

***L. Jonghi-Lavarini***[1], *F. Bono*[2], *A. Tuoro*[3], *C. Crivellaro*[4], *L. Guerra*[4,1], *C. Landoni*[4,5,6]; *[1]University Milano-Bicocca, Milan, ITALY, [2]Department of Pathology, IRCCS San Gerardo dei Tintori Hospital, Monza, ITALY, [3]Thoracic Surgery Department, IRCCS San Gerardo dei Tintori Hospital, Monza, ITALY, [4]Department of Nuclear Medicine, IRCCS San Gerardo dei Tintori Hospital, Monza, ITALY, [5]University of Milano–Bicocca, Milan, ITALY, [6]Tecnomed Foundation, Monza, ITALY.*

***Aim/Introduction:*** A 63-year-old woman affected by IBD and asthma during an Rx chest found a nodule in the right lung. A CT chest study confirmed a parenchymal pedicled nodule connected to the visceral pleura in the right upper lobe, with contrast enhancement uptake suggestive of a neuroendocrine tumour. ***Materials and Methods:*** The patient underwent PET imaging with [18F]-FDG and [68Ga]-DOTATOC radiotracers at the Nuclear Medicine Department of San Gerardo Hospital on a GE Discovery MI scanner with 3D acquisition mode according to the EANM guidelines. PET acquisition was performed after at least 6 hours of fasting, with glycemia < 160 mg/dL. About 250 MBq of [18F]-FDG and 150 MBq of [68Ga]-DOTATOC were administered and both acquisitions were performed 60 min after radiotracer injection. ***Results:*** The [18F]-FDG PET/CT study was performed the nodule showed a mild tracer uptake (SUVmax 1.37) consistent with low metabolic activity. Since such behaviour could be compatible with carcinoid, hamartoma, or bronchogenic carcinoma, a [68Ga]-DOTATOC PET/CT was performed without significant uptake at the lesion (SUVmax 1.46); no other uptake abnormalities of radiolabelled somatostatin analogues have been detected in the rest of the body. The bronchoscopic cytologic smear (without the chance to perform any special stain) of the lesion supported the suspicion of a carcinoid tumour due to uniform plasmacytoid bland nuclei and a scant amount of cytoplasm; thus, she underwent surgical resection of the involved lung lobe and some mediastinal lymph nodes. The final diagnosis was Solitary Fibrous Tumour (SFT), and immunostains confirm it through STAT6+, CKpool-, synaptophysin-, TTF1-, p63-, smooth muscle actin-. Ki67 index was 1-2% and mitotic count was low. ***Conclusion:*** SFT is a rare mesenchymal tissue-originating spindle cell tumour that can develop in all parts of the body, most frequently the pleura, with an annual incidence of 0.2/100,000 per year. In this case the location of the growth was the lung parenchyma, with its characteristic "adenofibromatous appearance". Due to its slow rate of growth, [18F]-FDG PET uptake is usually similar to the mediastinal blood pool. Some authors showed that SFTs may overexpress somatostatin receptors (SSTR), mimicking neuroendocrine tumours at [68Ga]-DOTATOC PET scan; on the other hand, in our case, SFT showed no significant uptake on either FDG or DOTA-peptide scan, and this is the first case, to the best of our knowledge. This is additional information for the characterization of lung lesions by using a combination of FDG and DOTA-PET scans.

## OP-538

### Flip-flop phenomenon on dual SSTR PET and amino acid PET in a case of pre-treated atypical meningioma CNS WHO grade 2

***A. Holzgreve***[1], *S. Quach*[2], *P. Harter*[3], *R. Forbrig*[4], *C. Schichor*[2], *J. Tonn*[2], *M. Niyazi*[5], *P. Bartenstein*[1], *L. von Baumgarten*[2], *N. L. Albert*[1]; [1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Center for Neuropathology and Prion Research, LMU Munich, Munich, GERMANY,* [4]*Institute of Neuroradiology, University Hospital, LMU Munich, Munich, GERMANY,* [5]*Department of Radiation Oncology, University Hospital, LMU Munich, Munich, GERMANY.*

***Aim/Introduction:*** Meningiomas overexpress somatostatin receptors (SSTRs) and, therefore, are susceptible to SSTR-targeted PET imaging. Amino acid PET, e.g. using the tyrosine analogue fluoroethyl-l-tyrosine (FET), is recommended for the imaging of glioma but has no established role in meningioma imaging. We here illustrate the potential value of dual SSTR and amino acid PET in a challenging case of pre-treated meningioma with heterogeneous imaging findings. ***Materials and Methods:*** A 65-year old patient in continuous clinical follow-up presented with a new unclear lesion on MRI near the left sphenoid bone, 5 years after stereotactic radiotherapy with 54 Gy and 1 year after craniotomy and tumor resection for a left temporal atypical meningioma CNS WHO grade 2. The patient received ongoing treatment with everolimus and octreotid for dural tumor remnants. At the current presentation, MRI showed new-onset edema and an increasing contrast-enhancing lesion in the left brainstem extending into the left cerebellar peduncle in direct vicinity to and/or continuation of the previously known meningioma remnant. MRI findings were rather suggestive of reactive changes but could not exclude vital tumor tissue. A decision was made to perform PET imaging. ***Results:*** SSTR-targeted PET/CT with 187 MBq [$^{18}$F]SiTATE showed a marked increase in SSTR-expression at the known meningioma residue, whereas the adjacent new lesion only showed low tracer uptake. SSTR PET therefore substantiated the suspicion of a radiation necrosis. Due to the uncommon late-onset 5 years after radiotherapy, however, additional amino acid PET imaging with 173 MBq [$^{18}$F]FET was performed. In contrast to SSTR PET, FET PET displayed only a minor uptake in the previously known meningioma residue, whereas the new lesion showed a markedly increased uptake typical for malignant tumor tissue. Taken together, the findings were suggestive for meningioma recurrence with signs of dedifferentiation or a radiation-induced secondary tumor. Subsequently, a stereotactic biopsy was performed and revealed malignant tumor tissue (classification of the tumor type currently ongoing); a radiation necrosis on the contrary could not be confirmed. Based on the imaging and consecutive biopsy results, the patient was scheduled for a surgical tumor resection ***Conclusion:*** Additional amino acid PET imaging in meningioma may be helpful in case of equivocal MRI and SSTR PET findings. Here, in a case of pre-treated atypical meningioma CNS WHO grade 2, a "flip-flop" constellation on dual SSTR and amino acid PET enabled to detect malignant tumor tissue, which might have been missed using MRI and SSTR PET alone.

## OP-539

### "Not always a zebra" - Clear Cell Renal Cell Carcinoma Metastasis detected in [$^{68}$Ga]Ga-DOTA-NOC PET/CT

***J. C. Ferro****, J. P. Teixeira, I. Próspero, D. Barbosa, D. G. Silva, S. Fontão de Castro, G. Ferreira, L. Violante, F. Lopes, H. Duarte, I. Lucena e Sampaio;*
*Instituto Português de Oncologia do Porto Francisco Gentil, Oporto, PORTUGAL.*

***Aim/Introduction:*** Renal cell carcinoma (RCC) constitutes approximately 3% of all malignant neoplasms diagnosed in adults, with clear cell RCC (ccRCC) being the most common histological type. Up to 30% of patients experience recurrence after surgery with curative intent, with distant metastases commonly occurring in the lung, bone, liver, and occasionally in the pancreas. The high recurrence rate underscores the importance of diligent follow-up, with computed tomography (CT) being considered the standard imaging modality for detecting disease recurrence after surgery. Positron emission tomography (PET) and CT with 2-[$^{18}$F]FDG (FDG-PET/CT) for restaging is not recommended due to limited sensitivity. However, the usefulness of $^{68}$Ga-labelled somatostatin analogues (DOTA-SST-PET/CT) for restaging RCC patients remains uncertain, despite high expression of somatostatin receptors in ccRCC, particularly subtype SST receptor 2. ***Materials and Methods:*** A 64-year-old female patient with a clinical picture of

abdominal pain, anorexia, and weight loss, underwent abdominal CT that revealed a mass in the body of the pancreas, suspicious for primary malignant pancreatic neoplasm. Relevant medical history includes ccRCC in remission, for which she underwent left radical nephrectomy 13 years ago. ***Results:*** In the context of staging, FDG-PET/CT was performed, which revealed a mass in the body of the pancreas and two lung nodules with mild 2-[$^{18}$F]FDG uptake. In contrast, DOTA-NOC-PET/CT showed intense and moderate uptake, respectively; incidentally, an expansive brain lesion centred in the right lateral ventricle was identified. Carcinoembryonic antigen (1.14ng/mL) and carbohydrate antigen 19-9 (11.2U/mL) were normal, and chromogranin A was high (1342.05ng/mL). Percutaneous biopsy of the pancreatic mass and one of the lung nodules was performed, and the histology was consistent with metastases from ccRCC, suggestive of metachronous metastasis. Later, the lesion in the right ventricle was characterized as meningioma. The patient initiated a tyrosine kinase inhibitor (pazopanib), resulting in stable disease on serial CT scans and normalization of chromogranin A levels. ***Conclusion:*** This clinical case serves as a reminder that [$^{68}$Ga]Ga-DOTA-SST uptake is not pathognomonic for neuroendocrine tumours and the possibility of ccRCC metastases should be considered in the differential diagnosis in an appropriate clinical scenario. Accurate restaging of RCC patients can impact therapeutic decisions and influence disease outcomes. Although FDG-PET/CT can effectively be used for restaging of RCC, the overall sensitivity for detecting distant metastases is limited, suggesting that DOTA-SST-PET/CT may be a useful imaging tool for detecting ccRCC metastases.

## OP-540

### Brain [$^{18}$F]FET PET/CT in acute myeloid leukemia

***G. Crosta***[1], *A. Castello*[2], *S. Pacella*[2], *V. Longari*[2], *L. Florimonte*[2], *M. Castellani*[2];
[1]*University of Milan, Milan, ITALY,* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY.*

***Aim/Introduction:*** Involvement of central nervous system (CNS) in patients with acute leukemia is relatively rare, accounting for 4-7% of patients with acute lymphoblastic leukemia and for 1-3% with Acute Myeloid Leukemia (AML) [1,2]. However, the presence of CNS lesions at diagnosis or relapse is associated with a worse prognosis. MRI is the first imaging technique used for the diagnosis of either primary or secondary brain tumours, although it is not free from drawbacks [3]. Morevoer, due to high uptake of healthy brain parenchima, [$^{18}$F]FDG PET/CT shows limited accuracy for characterization of brain lesions. ***Materials and Methods:*** [$^{18}$F]FET, analogue of the L-tyrosine, is an artificial amino acidic radiotracer that presents no uptake in normal cerebral cortex, with a higher tumor-to-background signal and low uptake in inflammatory cells. Therefore, it is used to characterize brain lesions, to differentiate between tumor progression and treatment related changes, for planning biopsy and radiotherapy, as well as for monitoring treatment. ***Results:*** A 58-year-old woman, with a history of AML in complete response, was referred to the Emergency department of our hospital for loss of consciousness. A brain MRI showed an intracranial mass suggestive for either primary brain tumor or brain metastasis. [$^{18}$F]FET PET/CT, performed for guiding stereotactic biopsy, revealed increased uptake of the lesion localized at the genu of the corpus callosum. Metastasis from AML was diagnosed after brain biopsy. To complete staging before starting chemotherapy, patient underwent [$^{18}$F]FDG PET/CT, including brain acquisition, that showed an uptake slightly below the adjacent healthy brain and physiological distribution of glucose without sites of abnormal extra-cranial accumulation. ***Conclusion:*** according RANO guidelines, brain [$^{18}$F]FET PET/CT is recommended for both glial tumors and suspected secondary localizations. Our case confirms the higher sensitivity of $^{18}$F-FET than $^{18}$F-FDG in the assessment of this rare case of brain metastasis from AML. ***References:*** 1 Ganzel C, Lee JW, Fernandez HF, et al. ## OP-541

### Two Cases of Diffuse Mild-Moderate 18F-Fluoroestradiol Lung Uptake in Women with Metastatic Estrogen Receptor Positive Breast Cancer

***E. Phillips****, P. Karak;*
*Hartford Hospital, Hartford, CT, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** 18F-Fluoroestradiol (FES) is a radiotracer that binds to estrogen receptors (ER) and is utilized for suspected disease recurrence or metastatic disease in patients with ER positive breast cancer. However, FES will also bind to wherever estrogen receptors are located within the body. Although estrogen receptors are located within the lungs, FES does not routinely demonstrate uptake within them. To date, FES has only been shown to demonstrate uptake within a focal region of the lung status post radiation therapy, but no cases have demonstrated diffuse uptake within the lungs which we do here. ***Materials and Methods:*** We reviewed the images from all patients at our institution, Hartford Hospital, who had 18F-Fluoroestradiol PET/CT scans performed. Data analysis and extensive literature search were performed. We present two patients with stage IV ER positive breast cancer who underwent FES PET/CT imaging to evaluate for metastatic disease. Both of the scans demonstrated mild-moderate diffuse uptake within the bilateral lungs. ***Results:*** We found that 2 of the 11 total patients who had 18F-Fluoroestradiol PET/CT scans done demonstrated diffuse mild-moderate bilateral lung uptake for a total of 0.18%. The first patient had a severe lung injury, acute respiratory distress syndrome and acute interstitial pneumonia, which was improving but still present at the time of her imaging. The second patient had a remote history of right breast radiation therapy for a prior breast cancer as well as emphysema. ***Conclusion:*** As breast cancer is the most commonly diagnosed cancer in women, FES PET/CT imaging will likely become more commonly performed. Therefore, it's important to understand where the radiotracer might demonstrate uptake and why. To date, only focal FES uptake has been demonstrated within the lungs which was secondary to fibrotic changes from prior radiation therapy. As diffuse bilateral mild-moderate lung uptake has not yet been reported we highlighted two unique cases that demonstrated such findings to provide further information about FES. Overall, we conclude that diffuse bilateral mild-moderate FES uptake within the lungs is likely secondary to inflammation, interstitial disease, or a combination thereof.

## OP-542

**The ultimate indication for surgical probe use: a case of an ectopic intraesophageal parathyroid adenoma.**

***A. Doumas***[1], *I. Pliakos*[2], *T. Papavramidis*[2], *P. Exadaktylou*[1], *D. Boundas*[3], *E. Giannoula*[1], *A. Tsangaridi*[1], *G. Gerasimou*[1], *E. Papanastasiou*[1], *N. Papadopoulos*[1], *I. Iakovou*[1];
[1]*Aristotle University, Thessaloniki, GREECE,* [2]*1st Surgery Clinic of Aristotle University of Thessaloniki, University Hospital AXEPA, Thessaloniki, GREECE,* [3]*Private Nuclear Medicine Centre, Ippokratis, Thessaloniki, GREECE.*

***Aim/Introduction:*** The scintigraphic demonstration of parathyroid adenomas in patients with known hyperparathyroidism is currently the main preoperative strategy. The combination of ultrasound and scintigraphic study by experienced imaging specialists increases the probability of accurate detection of adenoma to about 90%. In addition, the intraoperative use of the surgical probe after administration of a small amount of isonitrile (SESTAMIBI) contributes to the successful excision of the adenoma, reduces the operating time, and increases the surgeon's confidence. Our target is to present the validity of the intraoperative use of probe in patients with particularly challenging surgical localization of parathyroid adenoma. ***Materials and Methods:*** We present the case of a 53-year-old woman, with a clear suspicion of overactive parathyroid tissue evidenced by a history of nephrolithiasis for several years, very high PTH values and serum Ca consistently above 10 mg/dl for the past three years. In 2022, the patient underwent parathyroid scintigraphy, which revealed a parathyroid adenoma located at the lower left lobe of the thyroid and towards the midline. The imaging suggested that the adenoma was mobile, providing further evidence of its presence. Thyroid ultrasound also detected the adenoma. The patient was operated on by an experienced endocrine gland surgeon; however, despite a thorough exploration of the neck, the adenoma could not be located. Parathyroid hormone levels remained high both perioperatively and in the following months. Finally, 4 months later, the scintigraphy was repeated, with the same picture as an outcome. A few months after the last scintigraphy, the patient was administered 6mCi SESTAMIBI, and two hours later, using the surgical probe, the parathyroid gland was located intraesophageally and successfully excised. The intraoperative finding of successful adenoma excision by means of the probe was positive in the excised adenoma compared to the surrounding tissues. Furthermore, the intraoperative PTH value dropped by 70% in the next hour ***Conclusion:*** The intraoperative use of a surgical probe is the most reliable, fast, cheap, and absolutely necessary solution for the endocrine gland surgeon for the successful removal of parathyroid adenomas, especially when there is a suspicion of their ectopic location.

***Aim/Introduction:*** PARP1 is a key enzyme in DNA damage repair implicated in the pathophysiology of cancer and neurodegenerative disorders. We herein report the discovery and development of a blood-brain barrier (BBB) penetrant, subtype-selective high affinity PARP1 inhibitor, [$^{11}$C]AZ3391, as a novel PET radioligand for PARP1. ***Materials and Methods:*** The preclinical evaluation of [$^{11}$C]AZ3391 was conducted using in vitro autoradiography and PET in non-human primates (NHPs) (n=7, 23 PET in total). After giving informed consent, nine healthy volunteers and one patient were enrolled in the human study, which included 19 PET measurements. Total binding was estimated using semiquantitative (standardized uptake value, SUV) and quantitative (volume of distribution, $V_T$) analyses, the latter obtained using a two-tissue compartment model. ***Results:*** AZ3391 was labelled using $^{11}$C-methylation at high molar activity (162 GBq/μmol) and high radiochemical purity (>99%). In vitro autoradiography demonstrated dense binding of [$^{11}$C]AZ3391 to A549 tumour xenograft tissue as well as rat, mouse, NHP and human cerebellum. The binding could be obliterated (>99% inhibition) by co-incubation with two structurally distinct PARP inhibitors, namely olaparib (that targets PARP1 and other members of the PARP family) and AZD5305 (PARP1-selective), thus confirming specific binding to PARP1 in vitro**.** NHP PET demonstrated binding of [$^{11}$C]AZ3391 to PARP1 in bone marrow, pituitary, spleen and brain with highest regional binding in cerebellum. The binding was blocked in a dose-dependent manner after pre-treatment with two structurally distinct PARP-inhibitors (up to 99% inhibition), namely AZD9574 (PARP1-selective) and pamiparib (that targets PARP1 and other members of the PARP family), thus confirming specific [$^{11}$C]AZ3391 binding to PARP1 in vivo. PET measurements in healthy volunteers confirmed that [$^{11}$C]AZ3391 crossed the human BBB. Consistent with that observed in NHP PET, high binding was observed in the pituitary, bone marrow and cerebellum. Absolute test-retest variability (TRV) of the regional SUV estimates ranged from 5% to 10%. The TRV for $V_T$ ranged from 10% to 22%. A case study in a patient with glioblastoma multiforme (GBM) demonstrated several-fold higher total [$^{11}$C] AZ3391 binding in the tumor region compared to normal brain tissue. Interestingly, there was considerable heterogeneity in radioligand binding across the tumor. ***Conclusion:*** [$^{11}$C]AZ3391 is the first BBB penetrant and subtype-selective PET radioligand for PARP1. Its development opens up new opportunities for clinical research in cancer and neurodegenerative disorders as well as for dose-setting in clinical drug development.

## OP-557

**Development of a PET imaging agent for the detection of amyotrophic lateral sclerosis**

***B. Guérin***[1], *S. Ait-Mohand*[1], *V. Dumulon-Perreault*[2], *J. Rousseau*[1], *O. Sarrhini*[2], *S. Tremblay*[1], *M. Maier*[3], *M. Salzmann*[3];
[1]*Universite de Sherbrooke, Sherbrooke, QC, CANADA,* [2]*CRCHUS/CIUSSSE CHUS, Sherbrooke, QC, CANADA,* [3]*Neurimmune AD, Zurich, SWITZERLAND.*

***Aim/Introduction:*** Amyotrophic lateral sclerosis (ALS) is a rare neurodegenerative disease resulting from the loss of motor neurons in the motor cortex, brainstem, and spinal cord. It currently affects 2.1 to 3.8 per 100 000 person-years in Europe. Of all ALS cases ~10% are inherited (FALS) and the rest arise sporadically (SALS). Mutations in the superoxide dismutase 1 (SOD1) gene, leading to the misfolding of its protein product, are the second most common genetic cause of ALS. SALS patients had increased levels of misfolded SOD1 (mSOD1).[1] Currently, there is no approved diagnostic tool for ALS. We developed a recombinant human monoclonal antibody (AP-101) conjugated to $^{89}$Zr-desferoxamine ($^{89}$Zr-DFO), which selectively targets mSOD1. The purpose of this study was to validate $^{89}$Zr-DFO-AP-101 radiotracer for PET imaging of mSOD1. ***Materials and Methods:*** DFO-AP-101 was prepared

by conjugating AP-101 antibody with p-SCN-Bn-DFO and labelled with $^{89}$Zr ($t_{½}$=78.41h). A longitudinal imaging study was performed to identify the optimal mice age and time post administration of $^{89}$Zr-DFO-AP-101 (20-30 MBq) for the detection mSOD1 aggregation in transgenic (Tg, [B6.Cg-Tg(SOD1*G93A)1Gur/J)]) mice expressing mSOD1 and in wild type (Wt) mice. As control, a subset of mice were co-injected with AP-101 (100 mg/kg) to assess target specificity. PET/CT data were expressed as percent injected dose per gram of tissue (%ID/g). ***Results:*** $^{89}$Zr-DFO-AP-101 was able to engage mSOD1 aggregates in the spinal cord of Tg mice and imaging was optimal in 126-day-old Tg mice and at day 10 post administration. The number of detected aggregates was more important at day 10 (18) as compared to day-7 (6). All the spots found between the T11 and L2 vertebra. The concentration of $^{89}$Zr-DFO-AP-101 in the spinal cord and vertebra of the Tg mice significantly exceeded that of the Wt mice ($p = 0.01$). Co-injection with AP-101 considerably reduced the amount of mSOD1 aggregates detected from 67% (6/9) to 15% (2/13). The intensity of the aggregates was also decreased from 8.05 ± 1.30 %ID/g to 5.73 ± 0.28 with $^{89}$Zr-DFO-AP-101 alone or in presence of AP-101 in excess. Blocking with AP-101, significantly reduced the spinal cord ($p < 0.001$) and vertebra ($p < 0.0001$) uptake of $^{89}$Zr-DFO-AP-101. ***Conclusion:*** Our lead $^{89}$Zr-DFO-AP-101 can exhibited unprecedented detection of mSOD1 aggregate in transgenic mice. Such a PET tracer would find application in the early diagnostic of ALS and in the monitoring of therapeutic interventions. ***References:*** 1. Maier M, et al. Sci Transl Med. 2018;10(470).

## OP-558

### In vivo performance of different $^{18}$F-labelled cannabinoid receptor 2 radioligands

***D. Guendel***[1], *W. Deuther-Conrad*[1], *L. Ueberham*[2], *R. Teodoro*[1,3], *G. Bormans*[4], *M. Toussaint*[1], *E. Hey-Hawkins*[2], *K. Kopka*[5,6], *P. Brust*[1,7], *R. Moldovan*[1];

***Aim/Introduction:*** Cannabinoid receptor 2 (CB2) expression in healthy brain is very low and the upregulation is associated with inflammation, traumatic brain injury, neurodegeneration and cancer[1]. In view of the increasing interest in CB2-targeted therapies, PET offers an attractive strategy to quantify the availability of CB2 in the diseased brain. To achieve this goal, we developed a number of $^{18}$F-labelled CB2 ligands and biologically evaluated them in rodents. Here we present a comparative overview of the obtained results. ***Materials and Methods:*** Structure-activity-relationships-driven target compound identification, organic synthesis and radiofluorination was performed for compounds of the thiazole ([$^{18}$F]JHU94620[2] and [$^{18}$F]LUZ5[3]), naphthyridin-2-one ([$^{18}$F]LU14[4] and [$^{18}$F]LU13[5]) and indole ([$^{18}$F]RM365) families. The new radioligands were assessed in vitro by binding experiments using CHO(hCB2) cell membranes and rat spleen homogenates and by autoradiography on cryosections of rodent spleen. Furthermore, the radioligands were examined for their metabolic stability and biodistribution by PET. Furthermore, for selected radioligands the binding to highly expressed hCB2 in a rat model overexpressing hCB2(D80N) in the right striatum (AAV-hCB2)[6] was investigated. ***Results:*** The low- to subnanomolar hCB2 affinities of the presented radioligands were demonstrated in vitro by $K_d$ values ranging from 0.4 to 2.9 nM with a hCB2 selectivity against hCB1 of >1000-fold. The highest metabolic stability was observed for [$^{18}$F]RM365 with 55% and 90% and the lowest for [$^{18}$F]JHU94620 with 7% and 36% of the initial fraction in plasma and brain 30 min p.i., respectively. The in vivo experiments confirmed the in vitro autoradiographic results, and showed high uptake for [$^{18}$F]JHU94620, but low or non-displaceable uptake for [$^{18}$F]LU14, [$^{18}$F]LUZ5 and [$^{18}$F]RM365 in spleen. Contrary to the low uptake of [$^{18}$F]LUZ5 in the brain of naïve Wistar rats, target-specific and displaceable uptake for [$^{18}$F]LU14 and [$^{18}$F]RM365 was demonstrated in the AAV-hCB2 rat model, with the highest signal-to-noise ratio determined for [$^{18}$F]RM365 expressed as SUVR of 20 and lowest for [$^{18}$F]LU14 expressed as SUVR of 6. ***Conclusion:*** A novel series of CB2 receptor radioligands has been developed and preliminarily evaluated in rodents. Binding affinity to the CB2 varies between species, however PET scans with an AAV-hCB2 rat model revealed a high brain uptake and target specificity for hCB2 with excellent signal-to-noise ratios and displaceable binding. ***References:*** [1]Stasiulewicz et al. ## OP-559

### $^{18}$F-FDS PET imaging as a quantitative marker to investigate the magnitude and dynamics of enhanced of blood-brain barrier permeability induced by regadenoson

***B. Hosten****, S. Goutal, S. Leterrier, A. Winkeler, L. Breuil, M. Goislard, C. Truillet, N. Tournier;*
*Université Paris-Saclay, INSERM, CNRS, CEA, Biomaps, Orsay, FRANCE.*

***Aim/Introduction:*** The development of strategies to overcome the blood brain barrier (BBB) and enable drug delivery to the brain is tightly linked to the availability of translational biomarkers of BBB permeability to evaluate their efficacy in the living brain. Among translational imaging techniques, PET imaging benefits from absolute quantitative performances, which enables kinetic modeling. $^{18}$F-2-deoxy-2-fluoro-D-sorbitol ($^{18}$F-FDS, MW: 183 Da) is a non-metabolized hydrophilic small molecule repurposed as a PET marker of BBB permeability. $^{18}$F-FDS PET was optimized to capture the dynamics of transient BBB disruption induced by regadenoson a selective adenosine A2 receptor ($A_2R$) agonist. ***Materials and Methods:*** $^{18}$F-FDS was easily obtained by chemical reduction of commercial $^{18}$F-FDG. In anesthetized rats, regadenoson (0.05 mg/kg) or saline (control) was administered i.v., immediately before $^{18}$F-FDS microPET injection (bolus, 34 ± 5 MBq) followed by dynamic microPET acquisition. Six rats underwent arterial canulation for the determination of the arterial input function (AIF) of $^{18}$F-FDS during PET acquisition in both the control and regadenoson (n=3) to validate an image derived input function (IDIF). Other rats (6 control, 5 regadenoson) underwent bolus $^{18}$F-FDS PET without AIF. Kinetic modeling was performed from time-activity curves obtained in the brain and the left ventricle (IDIF) to estimate the total volume of distribution ($V_T$, Logan plot analysis) of $^{18}$F-FDS in brain regions. Then dynamic

$^{18}$F-FDS PET acquisition (90 min) using a bolus-infusion strategy (48 MBq bolus followed by 26 MBq/90 min infusion, i.v.) was tested to capture the dynamics of BBB disruption induced by regadenoson, injected 20 min after the start of infusion. ***Results:*** A significant correlation was observed between the AIF and IDIF (R = 0.88, p<0.001). In the whole-brain, regadenoson increased brain $V_T$ of $^{18}$F-FDS (+93.9+/-6.2% p <0.001). The effect was significantly different across brain regions (p<0.001) and was maximal in the striatum (+176.0+/-26.3% p<0.001) and minimal in the cerebellum (+76.0+/-5.9% p<0.001), consistent with the regional expression of $A_2R$. In the bolus-infusion experiments, an increase in $^{18}$F-FDS brain uptake relative to control rats was observed immediately after regadenoson injection and stopped after 24 min. ***Conclusion:*** The readily available $^{18}$F-FDS PET provides a convenient, quantitative and translational imaging techniques to evaluate and compare strategies of BBB permeabilization in vivo. Regadenoson offers a simple and efficient way for transient BBB permeabilization with perspectives for drug delivery to the brain.

## OP-560

### The 5-HT1A receptor modulates motor/exploratory activity, object recognition and DAT binding in the dorsal and ventral striatum of the rat

***S. Nikolaus***[1], *M. Beu*[1], *J. Henke*[1], *C. Antke*[1], *B. Fazari*[2], *E. Mamlins*[1], *F. L. Giesel*[1];
[1]*University Hospital Düsseldorf, Düsseldorf, GERMANY,*
[2]*Heinrich-Heine University, Düsseldorf, GERMANY.*

***Aim/Introduction:*** Both dopamine (DA) and serotonin (5-HT) are relevant for motor control as well as learning. In the present study, we assessed the effect of the 5-HT1A receptor (R) agonist 8-OH-DPAT on motor/exploratory behavior, memory for object and place and dopamine (DAT) and serotonin transporter binding (SERT) in the rat brain. ***Materials and Methods:*** Rats (n=41) underwent a 5-min exploration trial in an open field with two identical objects. A 5-min test trial with one of the objects replaced by a novel one and the other object transferred to a novel place was conducted 30 min after intraperitoneal injection of either 8-OH-DPAT (0.1 and 3 mg/kg) or vehicle (0.9% NaCl). Subsequently, 123I-FP-CIT; 11±4 MBq was injected into the tail vene. Specific binding of 123I-FP-CIT to DAT and SERT was determined by subtracting unspecific binding in the cerebellar reference region from radioligand concentrations obtained in the individual regions of interest (DAT: cingulate, caudateputamen, nucleus accumbens; SERT: thalamus, dorsal and ventral hippocampus, brainstem). Duration and frequency of object exploration, ambulation, sitting, rearing, head-shoulder-motility and grooming were evaluated with Ethovision XT. ***Results:*** 8-OH-DPAT (3 mg/kg) increased DAT binding in the caudateputamen relative to both vehicle (p=0.001) and 0.1 mg/kg 8-OH-DPAT (p=0.015). In the nucleus accumbens, DAT binding was decreased after 3 mg/kg 8-OH-DPAT relative to vehicle (p=0.006). In the test trial, 8-OH-DPAT dose-dependently increased ambulation and exploratory head-shoulder motility, whereas rearing was dose-dependently decreased ($0.001 \leq p \leq 0.05$). 3 mg/kg 8-OH-DPAT induced a memory deficiency for object relative to vehicle (p<0.05). Moreover, memory for place was impaired relative to both 0.1 mg/kg 8-OH-DPAT (p=0.003) and vehicle (p<0.001). ***Conclusion:*** Findings indicate that the 5-HT1AR modulates motor/exploratory behaviors, memory for object and place and regional DA function in the rat. It may be hypothesized that 8-OH-DPAT initially augmented neostriatal DA (possibly via a disinhibition of GABAergic microcircuits), resulting in the compensatory downregulation reflected by the increase of radioligand binding to the DAT. Conversely, in the NAC, 8-OH-DPAT may have reduced excitatory input from neocortex and hippocampus, resulting in the increase of available DA reflected by the decrease of radioligand binding to the DAT.

## OP-561

### Brain mitochondrial function and cerebral glucose utilization in non-human primate of Parkinson disease model with α-synuclein propagation via the olfactory system: a$^{18}$F-BCPP-EF and$^{18}$F-FDG PET imaging study

***H. Onoe***[1], *M. Sawamura*[2], *T. Hirato*[2], *H. Tsukada*[3], *T. Nakako*[4], *T. Nakayama*[4], *K. Ikeda*[4], *C. Chen*[5], *K. Isa*[5], *M. Nakamura*[5], *T. Isa*[5], *R. Takahashi*[2];
[1]*Human Brain Research Center, Kyoto University Graduate School of Medicine, Kyoto, JAPAN,* [2]*Department of Neurology, Kyoto University Graduate School of Medicine, Kyoto, JAPAN,* [3]*Central Research Laboratory, Hamamatsu Photonics K.K., Hamakita, JAPAN,* [4]*Sumitomo Pharma Co., Ltd., Osaka, JAPAN,* [5]*Department of Physiology and Neurobiology, Kyoto University Graduate School of Medicine, Kyoto, JAPAN.*

***Aim/Introduction:*** Parkinson's disease (PD) is a neurodegenerative disorder characterized by degeneration of dopaminergic neurons in the substantia nigra and the formation of alpha-synuclein (α-Syn) inclusion called Lewy bodies in neurons. PD is thought to progress through the amplification and propagation of α-Syn aggregates in the brain in a prion-like manner. Patients with Lewy body diseases exhibit variable degrees of cortical and subcortical hypometabolism. However, the underlying causes behind this progressive hypometabolism remain unresolved. Mitochondrial dysfunction, especially the impairment of complex I (MC-I), has been implicated in PD. Previously, we have developed a marmoset PD model with inoculation of α-Syn fibrils into the olfactory bulb, which induced α-Syn propagation through the olfactory system, and subsequent decreases in regional cerebral glucose utilization (rCGU) measured by $^{18}$F-FDG-PET. The aim of this study was to investigate whether mitochondrial dysfunction is proportionally linked to the magnitude of hypometabolism and α-Syn pathology by performing $^{18}$F-BCPP-EF-PET, which can measure MC-I activity, as well as $^{18}$F-FDG-PET using this model. ***Materials and Methods:*** We inoculated 3.2 μg α-Syn fibrils into the two sites of the bilateral olfactory bulbs. $^{18}$F-BCPP-EF-PET and $^{18}$F-FDG-PET were performed on four adult marmosets 1, 3, 6, 9 and 12 months after as well as before α-Syn inoculation. Immunohistochemical analysis for phosphorylated α-Syn has been performed after the last imaging, and a regression analysis of PET images has been performed for temporal changes from pre-inoculation to 12 months post-inoculation. Correlation between α-Syn pathology and result of PET at 12 months (Spearman's rank correlation coefficient analysis) was performed using region of interests (ROIs) in the marmoset standard brain MRI atlas. ***Results:*** We observed phosphorylated α-Syn aggregates, mainly in the olfactory pathway in accordance with our previous study. PET image analysis showed that MC-I activity decreased in the olfactory bulb, prefrontal area, piriform cortex, and amygdala while rCGU decreased particularly in the occipital lobe. Statistical analysis revealed that α-Syn pathology was significantly negatively correlated with MC-I activity ($r_s$=-0.33, p=0.0001) but had no correlation with rCGU, indicating that α-Syn aggregation was associated with mitochondrial dysfunction. ***Conclusion:*** Mitochondrial dysfunction is proportionally linked to the magnitude of α-Syn pathology but not directly associated with hypometabolism in non-human primate PD model. $^{18}$F-BCPP-EF-PET is expected as a biomarker of prodromal

synucleinopathies for PD, especially disease-associated α-Syn aggregates. ***References:*** Sawamura M. et al, Lewy body disease primate model with α-synuclein propagation from the olfactory bulb, Mov Disord, 37(10):2033-2044, 2022.

## OP-562

### Discovery of Novel PET tracer [$^{18}$F]F-diarylbisthiazoles for α-Synucleinopathies Imaging

***B. Hooshyar Yousefi***[1], *B. Uzuegbunam*[2], *S. Bagheri*[3], *G. B. Kotipalli*[3], *W. Paslawski*[4], *J. Li*[5], *E. Nasisi*[6], *F. Geibl*[6], *M. Henrich*[6], *P. Svenningsson*[4], *H. Ågren*[5], *M. Luster*[7], *W. Weber*[8], *T. Arzberger*[9], *D. Librizzi*[10];
[1]*Nuclear Medicine Department, Radiopharmacy section, Philipps University Marburg, Marburg, GERMANY,* [2]*Nuclear Medicine Department, Radiopharmacy section, Philipps University, Munich, GERMANY,* [3]*Nuclear Medicine Department, Radiopharmacy section, Philipps University, Marburg, GERMANY,* [4]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, SWEDEN,* [5]*Department of Physics and Astronomy, Uppsala University, Uppsala, SWEDEN,* [6]*Department of Neurology, Philipps University Marburg, Marburg, GERMANY,* [7]*Nuclear Medicine Department, Philipps University, Marburg, GERMANY,* [8]*Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY,* [9]*Neurobiobank Munich, Ludwig-Maximilians-University of Munich, Munich, GERMANY,* [10]*Nuclear Medicine Department, Philipps University Marburg, Marburg, GERMANY.*

***Aim/Introduction:*** Development of a specific $^{18}$F-labeled PET tracer for α-synucleinopathies imaging, based on diarylbisthiazole (DABTA), with high binding affinity to α-synuclein fibrils (α-syn), excellent selectivity over β-amyloid and tau fibrils and a suitable brain uptake kinetic. As an α-synuclein PET tracer, can specially monitor disease progression and evalute potetial disease modifying therapies for PD and DLB. ***Materials and Methods:*** We apply in silico, molecular dynamics and quantum/molecular mechanics approaches to design DABTAs with excellent binding properties and a favorable pharmacokinetics (PK). The precursors and $^{18}$F-labeled lead DABTAs, with high affinity to α-syn with excellent selectivity and PK, are synthesized and used for brain uptake kinetic and PET/CT in a group of 12 weeks post intrastriatal injection of preparation of human aSYN preformed fibrils (PFF) mice study. The leads with appropriate PK and in vivo stability were further studied within our translational research, screened via experimental lipophilicity and assays, plasma stability, biodistribution, in vivo metabolite analyses and postmortem autoradiography of human brain slices with α-Synucleinopathies. ***Results:*** Autoradiography of three promising DABTAs (with $K_i$ <3 nM and >>100 folds selectivity) show high density binding to α-Synucleinopathies in regions of PD, DLB and MSA postmortem brains then confirmed by IHC. The most promising tracer [$^{18}$F]F5 with excellent binding properties ($K_i$ ≤1 nM), logD 2.6, based on the biodistribution results in healthy mice showed initial brain uptakes of up to 7 %ID/g and with fast washout from brain at 120 mins p.i. down to 0.6 %ID/g. It shows an excellent plasma and brain stability. The PET/CT and kinetic modelling results of the PFF mice show elevated tracer retention where α-synuclein aggregates are in left brain hemisphere including striatum and amygdala but not in WT mice which fit to to the immunohistochemical results showing abundant α-Synucleinopathies. ***Conclusion:*** The in silico modeling helps rational design of the tracers with desired properties. The promising in vitro and in vivo results encourage us to further study the tracer by in vivo imaging nonhuman primate and translation to first in human investigation. [$^{18}$F]F5 is a groundbreaking tool to the highly desirable, but as yet unmet, medical need to detect and quantify the presence, severity, and regional distribution of α-syn and its clinical manifestations in individuals with α-synucleinopathies in vivo. ***References:*** This project was supported by ParkinsonFonds Deutschland.

## OP-563

### In vivo quantification of [$^{11}$C]BIO-1819578, a novel radioligand for O-GlcNAcase, in non-human primates using Positron Emission Tomography

***M. Bolin***[1], *S. Nag*[1], *P. Datta*[1], *R. Arakawa*[1], *Y. Khani Meynaq*[1], *E. Lin*[2], *N. Genung*[2], *H. Hering*[2], *K. Guckian*[2], *L. Martarello*[2], *M. Kaliszczak*[2], *L. Farde*[1], *P. Stenkrona*[1], *C. Halldin*[1], *A. Forsberg Morén*[1];
[1]*Centre for Psychiatry Research, Department of Clinical Neuroscience, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, SWEDEN,* [2]*BIOGEN MA Inc., 225 Binney St., Cambridge, MA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The novel radioligand [$^{11}$C]BIO-1819578 has been labelled from [$^{11}$C]CO and developed to study how drugs targeting O-GlcNAcase (OGA) interact with the enzyme in the CNS. The aim of the present study was to further validate [$^{11}$C]BIO-1819578 binding to OGA in the non-human primate brain. For that purpose, kinetic compartment analyses (1TCM and 2TCM) and a graphical analysis (MA1Logan) were evaluated using a radio-metabolite corrected arterial input function. The total volume of distribution ($V_T$) was the outcome estimate and used for comparisons between the models. ***Materials and Methods:*** Three cynomolgus monkeys were examined a total of seven times using a HRRT PET system (Siemens Medical Solutions). PET data were collected for 93 minutes immediately after injection of [$^{11}$C]BIO-1819578 (83.6±5.3 MBq, MA: 18.1±6.3 GBq/μmol); One pre-treatment scan was perform with a mass dose of the selective OGA inhibitor Thiamet-G. Arterial blood was measured continuously for the first 3 minutes followed with discrete samples at several time points. The fraction of unchanged radioligand in plasma was determined from HPLC analysis and used to produce the metabolite corrected input function. The outcome measure of the kinetic and graphical analyses was $V_T$ in hippocampus, frontal cortex, putamen, occipital cortex, and cerebellum. To guide method selection in future studies with [$^{11}$C]BIO-1819578, the second-order corrected Akaike Information Criterium (AICc) was calculated for all quantitative approaches. ***Results:*** The regional time activity curves were overall better described by the two-tissue compartment model (2TCM) in comparison with the one-tissue compartment model (1TCM), (mean AICc for 2TCM ~ 47.6±29.3 and 1TCM ~ 52.3±34.2). $V_T$s of OGA binding at baseline conditions obtained by 2TCM were (Hippocampus $V_T$ ~ 34 mL/cm$^3$, Frontal Cortex $V_T$ ~ 30 mL/cm$^3$, Putamen $V_T$ ~ 28 mL/cm$^3$, Occipital Cortex $V_T$ ~ 18 mL/cm$^3$ and Cerebellum $V_T$ ~ 16 mL/cm$^3$). The $V_T$ values obtained by the graphical method were a few percent lower in comparison with the estimates from 2TCM. Pre-treatment with Thiamet-G indicated a uniform reduction of uptake across the brain and a mean $V_T$ decrease of 89 %. ***Conclusion:*** The regional TACs could be described by the 2TCM which performed better than the 1TCM. The $V_T$s were similar for the kinetic and graphical approaches. Pre-treatment data indicates ~ 90 % specific binding of [$^{11}$C]BIO-1819578 to OGA. Furthermore, no region appeared to be devoid of specific binding and hence future studies with [$^{11}$C]BIO-1819578 will require an arterial plasma input function for quantification.

## Cutting Edge Science Track - TROP Session: Total Body PET Methods

### OP-564

**Application of the long axial field-of-view PET/CT with direct and indirect Patlak parametric imaging**

***L. Pan***, *C. Sachpekidis, A. Dimitrakopoulou-Strauss;*
*German Cancer Research Center, Heidelberg, GERMANY.*

***Aim/Introduction:*** Patlak imaging by $^{18}$F-FDG PET/CT is an important parametric imaging tool of disease diagnostics. The recent introduction and clinical application of long axial field-of-view (LAFOV) PET/CT scanners has yielded very promising results regarding image quality and sensitivity in oncological patients. We, herein, aim to evaluate whether Patlak imaging is feasible in a new LAFOV Biograph Vision 600 PET/CT (Siemens Healthcare) system and whether it improves lesion detectability as compared with the 55-60-min SUV images. ***Materials and Methods:*** 37 oncological patients (n= 23 melanoma, n= 7 lung cancer, n= 5 sarcoma, n= 1 lymphoma, n= 1 urothelial carcinoma) were enrolled in the study. All patients underwent PET/CT from the skull vertex to the upper leg in one bed position (each 60-min acquisition in list mode, field-of-view 106 cm) after i.v. injection of 2.0 MBq/kg $^{18}$F-FDG. Three sets of images were compared: direct Patlak $k_i$ images from Siemens e7-tools, indirect Patlak $k_i$ images from PMod software, as wells as static 55-60-min SUV images. Three sets of images were reviewed visually (qualitatively) by the reading physicians, and 260 individual tumor lesions were quantitatively analyzed using the target-to-background (TBR) metrics. ***Results:*** Concerning visual analysis, no significant differences were observed between the three applied imaging approaches (direct Patlak $k_i$, indirect Patlak $k_i$, static SUV images) regarding both number of pathologic scans and number of lesions. Quantitatively, direct Patlak $k_i$ TBR was significantly higher than SUV TBR in 255/260 lesions, and indirect Patlak $k_i$ TBR was significantly higher than SUV TBR in 259/260 lesions. Besides, indirect Patlak $k_i$ TBR was significantly higher than direct Patlak $k_i$ TBR in 179/260 lesions. All three set TBR are significantly different to each other according to Wilcoxon signed-rank test. ***Conclusion:*** Dynamic FDG PET/CT is feasible with the new LAFOV PET/CT scanner and produces Patlak $k_i$ images of good visual quality and better lesion contrast than SUV images regardless of the applied Patlak method (direct or indirect). In addition, indirect Patlak $k_i$ images are relatively better than direct Patlak $k_i$ image in terms of lesion contrast.

### OP-565

**Kinetic modeling and parametric imaging of 18F-PSMA-11: an evaluation based on total-body dynamic PET scan**

***H. Yuan***, *L. Jiang;*
*Guangdong Provincial People's Hospital, Guangzhou, CHINA.*

***Aim/Introduction:*** Despite the increasing clinical utilization of 18F-PSMA-11, the in vivo visualization of its kinetic feature in humans remains lacking, and hence the normal in vivo distribution of 18F-PSMA-11 remains unclear. With the recent advancement of long axial FOV total-body PET equipment, the whole-body dynamic scan enabled the visualization and quantification of radiotracer kinetics . Hence, this study aimed to evaluate the in vivo kinetic features of 18F-PSMA-11 in healthy volunteers and visualize these features using parametric imaging based on the total-body dynamic PET scan. ***Materials and Methods:*** A total of 8 healthy volunteers (7 males; 1 female) underwent total-bodyPET/CT imaging at 1 h and 2 h post-injection (p.i.) of 18F-PSMA-11, of which 7subjects underwent total-body dynamic PET scans lasting 30 min. Two-tissuecompartments (2TC) and Patlak models were fitted based on the voxel-based time activity curves (TACs), with the parametric images generated subsequently.Additionally, semi-automated segmentation of multiple organs was performed in the dynamic images to measure the SUVmean at different time points and in theparametric images to estimate the mean value of the kinetic parameters of theseorgans. ***Results:*** 18F-PSMA-11 was rapidly cleared from blood circulation and predominantly-excreted through the urinary system. High and rapid radiotracer accumulation was observed in the liver, spleen, lacrimal glands, and salivary glands, whereas gradual accumulation was observed in the skeleton. Net influx (Ki) values generated using Patlak models showed a good correlation with Ki values of 2TC models ($r=0.858$, $P<0.05$). However, the 2TC parametric images might suffer from estimation errors from moving artifacts (e.g., lungs) and variations of blood supply (e.g., liver). A scanning time point of 30-35 min p.i. was then suggested for decreased abdominal organ uptake and controlled skeletal background of the radiotracer. ***Conclusion:*** Patlak model-based Ki measurement showed good consistency with, thusis recommended over 2TC model-based Ki calculation on dynamic 18F-PSMA cans for substantially quicker calculation and less susceptibility to errors. Based on the dynamic imaging analysis, a shorter uptake time (30-35min) might be preferred for a better balance of background radioactive accumulation within the visceral organs vs. the bones.

### OP-566

**Multi-tracer image-derived input function validation using a long axial field of view PET scanner**

***X. Palard-Novello***[1,2], *D. Visser*[2], *N. Tolboom*[3], *C. Smith*[2], *G. Zwezerijnen*[2], *E. van der Giessen*[2], *M. den Hollander*[2], *F. Barkhof*[2], *B. Windhorst*[2], *B. N. M. van Berckel*[2], *R. Boellaard*[2], *M. Yacub*[2];
[1]*Centre Eugène Marquis, Rennes, FRANCE,* [2]*Amsterdam Universitair Medische Centra, Amsterdam, NETHERLANDS,*
[3]*Universitair Medisch Centrum Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Highly sensitive large axial field of view (LAFOV) PET scanners could avoid the need of an arterially measured input function by using an image-derived input function (IDIF) for kinetic modelling of dynamic PET studies. The aim of this study is to validate the use of IDIF for two different tracers. ***Materials and Methods:*** Four dynamic 70 minutes 18F-FDG scans and 10 dynamic 60 minutes [18F]DPA-714 scans were acquired on the Quadra PET/CT scanner. For [18F]DPA-714, continuous online arterial and manual arterial blood samples were acquired. Venous blood samples were available for the [18F]FDG study. PET images were reconstructed using a large variability of different reconstruction settings (number of iterations, matrix size, maximum ring difference, gaussian filter and scatter correction) with EARL2 as reference. IDIFs were taken from ascending aorta (AA), descending aorta (DA), and left ventricular cavity (LV) locations and calibrated using blood samples. Patlak linearization was performed to extract $K_i$ for [18F]FDG in striatum and Logan linearization was performed to extract $V_T$ for [18F]DPA714 in frontal region. To assess only the effects

of various IDIFs, frontal and striatum time-activity-curves were extracted from EARL2 reconstruction. ***Results:*** For [18F]FDG, the results showed a low variability of the calibration factors (CF) for the different IDIFs (AA_EARL2_IDIF: mean CF = 0.86 with standard deviation (SD) = 0.04). Compared to striatum $K_i$ extracted using AA_EARL 2 IDIF as reference, striatum $K_i$ mean differences were <10% using other locations or reconstruction settings to derive IDIFs. For [18F]DPA714, the results showed high variability of the CF for the different IDIFs (AA_EARL2_IDIF: mean CF = 0.87 with SD = 0.13). The CF improved to 1.0 using more iterations but the variability also increased (AA_10iterations_5subsets_nofilter_IDIF: mean CF = 0.99 with SD = 0.21). Compared to frontal $V_T$ extracted using continuous sampler input as reference, frontal $V_T$ mean differences were <10% for the other IDIFs, except for DA_EARL2_IDIF (frontal $V_T$ mean relative difference = +11% with SD = 6%) and LV_EARL2_IDIF (frontal $V_T$ mean relative difference = +16% with SD = 11%). ***Conclusion:*** EARL2-based IDIF from LAFOV PET scanner can replace venous samples for [18F]FDG. For [18F]DPA714, it can replace the use of continuous arterial sampling but may only be used in combination with recalibration using several manual arterial blood samples. So the accuracy and precision of IDIFs obtained with the LAFOV PET/CT system are tracer dependent and depend also on reconstruction settings and locations.

## OP-567

### The ENHANCE-PET Framework: An initiative to engage the imaging community in Advancements in Total-Body PET Analysis

***L. Shiyam Sundar***[1], *B. A. Spencer*[2], *J. Callahan*[3], *S. R. Cherry*[2], *R. D. Badawi*[2], *I. Buvat*[4], *D. Lewis*[5], *D. Ferrara*[1], *S. Gutschmayer*[1], *R. Hicks*[3], *M. Lassen*[6], *J. Mannheim*[7], *O. Muzik*[8], *M. Pires*[1], *J. Yu*[1], *T. Beyer*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*University of California-Davis, Davis, CA, UNITED STATES OF AMERICA,* [3]*Melbourne Theranostics Innovation Center, Melbourne, AUSTRALIA,* [4]*Institut Curie, Paris, FRANCE,* [5]*CRUK Glasgow, Glasgow, UNITED KINGDOM,* [6]*Rigshospitalet Copenhagen, Copenhagen, DENMARK,* [7]*Uniklinikum Tuebingen, Tuebingen, GERMANY,* [8]*Wayne State University, Detroit, MI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** With its wide field-of-view coverage and simultaneous tracking of physiological activities, total-Body PET (TB-PET) is revolutionising nuclear medicine and offers potential for novel insights into human physiology and disease processes. To effectively analyze large TB-PET datasets and foster collaboration among TB-PET stakeholders, we introduce the ENHANCE-PET framework. This approach supports the open sharing of tools, datasets, and experiences through the user-friendly, centralized enhance.pet web platform. The bespoke tools though aimed at TB-PET, works seamlessly for regular whole-body (WB) PET images as well. ***Materials and Methods:*** In a previous iteration of this framework, presented at EANM 2022, the platform featured open-access tools for automated image segmentation (MOOSE), motion correction (FALCON), and inter-organ connectivity assessment (PIGEON). Ongoing efforts and community collaboration have since resulted in four additional tools: voxelwise metabolic aberration mapping (OCELOT), a PET-CT image alignment tool for dual-modality, static and dynamic PET/CT scans (ORCA), a tool to generate non-kinetic modeling-based multi-parametric images from short-duration dynamic PET scans (STING-RAY), and a tool for evaluating voxel-/organ-wise metabolic changes during health-to-disease transitions (WOLF). To evaluate these tools, we analyzed several datasets from different vendors: For ORCA, we used 19 WB FDG PET/CT datasets; for STING-RAY, we analyzed 10 TB PSMA PET/CT datasets; for OCELOT, we examined 15 WB FDG PET/CT datasets; and for WOLF, we assessed 10 longitudinal WB FDG PET/CT datasets. The integration of these diverse datasets demonstrates the versatility and practicality of the ENHANCE-PET framework across various contexts. ***Results:*** We showcased the feasibility of these newly developed tools by applying them to various TB/WB-PET datasets from a range of clinical situations as proof-of-concept. OCELOT effectively identified voxelwise intensity and morphometric changes in a lung cancer patient with cachexia. ORCA improved the accuracy of image registration, while STING-RAY successfully produced informative non-kinetic modeling-based multi-parametric images from short-duration dynamic scans. WOLF proved to be useful in monitoring metabolic changes over time, thereby enhancing our understanding of disease progression and treatment response. ***Conclusion:*** The ENHANCE-PET framework, strengthened by contributions from a global community, offers an extensive set of tools for thorough TB/WB-PET analysis. The enhance.pet platform encourages collaboration and promotes open sharing, ultimately contributing to a better understanding of human physiology and disease mechanisms. We are excited to announce the launch of the enhance.pet community website at the EANM conference, fostering continued innovation and cooperation within the nuclear medicine community.

## OP-568

### Walk-Through Flat-Panel Total Body PET: System Design and Comparison of Body Motion with a standard PET-CT

***F. Muller***[1], *J. Maebe*[1], *N. Withofs*[2], *S. Vandenberghe*[1];
[1]*Medical Image and Signal Processing, Faculty of Engineering and Architecture, Ghent University, Ghent, BELGIUM,* [2]*Division of Nuclear Medicine and Oncological Imaging, Department of Medical Physics, CHU of Liege, Quartier Hôpital, Liège, BELGIUM.*

***Aim/Introduction:*** Current Total Body PET (TB-PET) scanners come at high costs which limits their acquisition in standard nuclear medicine departments. TB-PET systems have become so sensitive that 30-second torso acquisitions seem feasible, practical patient throughput is however limited by patient positioning. We describe the design of a new dual flat-panel Walk-Through (WT) TB-PET scanner for patient imaging in upright position; enabling fast and efficient patient throughput at lower component cost. The extent of motion, potentially larger for standing patients, was tested in a mock-up of the WT-TB-PET and compared to motion of patients lying on a conventional PET-CT scanner bed. ***Materials and Methods:*** To define the dimensions of the WT-TB-PET, patients size (vertex-ischium length, shoulder width, patient depth) were measured from 40 PET-CT scans. For the motion tests, healthy volunteers (n=9) and patients (n=13) were asked to step into the WT-TB-PET mock-up and stand still between the two flat-panels for 30s (feasible acquisition time). A Microsoft Kinect camera tracked motion of infrared markers placed on subjects' shoulders, head, chest and abdomen. After 30s normal breathing test, we investigated whether breath-hold or leaning back against the flat-panel can feasibly be associated with reduced patient movement. Motion results were compared with those of patients lying on a conventional Biograph Vision PET-CT (CHU Liège). ***Results:*** The WT-TB-PET system consists of two flat-panel detectors that are 70x106cm$^2$ in size and spaced 50cm apart, leading to a WT-TB-PET footprint (2-4m$^2$) much smaller than current PET-CTs (±35m$^2$). Motion of patients standing in the WT-TB-PET was larger (factor 1.5-3) compared with patients lying in the conventional PET-CT. When patients stood upright

in the WT-TB-PET for 30s, most movement was observed along the y-axis (front-back) which was ~2x the motion ranges seen along the x-axis (right-left); with head motion the largest (y-axis: 5.7mm). Motion was reduced by factor 1.7±0.2mm when patients held their breath; breath-hold was not possible for 1 out of 4 patients. When subjects were leaning back against a flat-panel while standing inside the WT-TB-PET, body motion was reduced to motion ranges comparable to those recorded on conventional PET-CT (in mm: $head_{WT\text{-}TB\text{-}PET(y)}$=0.52, $head_{PET\text{-}CT(y)}$=0.49, $head_{WT\text{-}TB\text{-}PET(x)}$=1.07, $head_{PET\text{-}CT(x)}$=0.52, $chest_{WT\text{-}TB\text{-}PET(y)}$=0.63, $chest_{PET\text{-}CT(y)}$=0.85, $chest_{WT\text{-}TB\text{-}PET(x)}$=0.36, $chest_{PET\text{-}CT(x)}$=0.43). ***Conclusion:*** A new TB-PET scanner was proposed with patients standing upright between two flat-panels. Motion tracking studies with the WT-TB-PET mock-up showed that body motion is limited (i.e., close to the expected spatial resolution of 2 mm) for a design configuration with leaning backwards.

## OP-569

### TOF Data Compression Strategies for 3D Fourier-Based Analytical Reconstruction of Long Axial Field of View (LAFOV) scanners data

***V. Panin****;*
*Siemens Medical Solutions United States Of America, Knoxville, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The Direct Inversion Fourier Transform Time-of-Flight (3D DIFTOF) algorithm is a tool for resolution and unbiased image assessment. However, analytical reconstruction on LAFOV scanners faces challenges due to suboptimal signal-to-noise ratio (SNR) resulting from poor quality oblique data, which are susceptible to noise amplification during attenuation correction. This is in contrast to iterative methods, which can statistically weight these data to improve SNR. This study aims to investigate different TOF data compression methods for LAFOV scanner data to improve the SNR while maintaining axial resolution in 3D DIFTOF reconstructed images. ***Materials and Methods:*** A long 20 cm diameter cylinder phantom that completely covered the axial scanner FOV (1 m) and was filled with F-18 was scanned on a Biograph Vision Quadra scanner (Siemens Healthineers) using two different TOF data compression schemes. The first, standard, method used uniform TOF axial line-of-responses (LORs) spanning, while the second added an additional axial compression on the most oblique tilts ($47^0$-$52^0$), combining them into one tilt. The reconstructed images were also evaluated using the NEMA resolution assessment data, which included a Na-22 point source located at various positions. ***Results:*** The standard data compression method led to a 20% decrease in SNR in the axial central part of the image using all data, compared to an "optimal" Maximum Ring Difference (MRD) of about $40^0$. However, the modified compression method reversed this trend, with the axial central part of the image showing a marginal increase in SNR. The axial resolution was not practically affected by additional compression of the most oblique tilts. ***Conclusion:*** A more extensive axial TOF compression scheme should be used to accurately reflect better SNR when more oblique data are being used. This is consistent with the idea of TOF down sampling, where worse axial resolution data should be compressed more to improve computational efficiency.

## OP-570

### Comparison of the standard and ultra-high sensitivity modes on a long axial FOV PET/CT system

***M. Roya****, J. van Sluis, J. H. van Snick, A. W. J. M. Glaudemans, C. Tsoumpas;*
*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Recently, long axial field of view (LAFOV) PET/CT systems have been introduced. Compared to short axial field of view systems, the image quality is superior due to the increased sensitivity in photon detection. This increase may allow very short scan duration in order to minimise motion artifacts[1]. This work aims to study the feasibility of ultra-fast protocols compared to routine scans. ***Materials and Methods:*** 6 patients referred for routine PET/CT were asked to participate in this study. The formal need for a METc approval was waived. The acquisition protocol was completed on a 106-cm long LAFOV in listmode. The data was used to reconstruct 15 and 30-second images with the full maximum ring distance (MRD322) and the routine 2-minute protocols with the standard setting (MRD85) using the e7tools. The vendor-recommended reconstruction settings were used, which are optimised for clinical diagnosis. The noise levels in healthy tissue were compared between the ultra-fast and routine protocols using the coefficient of variation (COV). The liver, spleen, abdominal aorta (blood pool) and bone marrow (spinal segment L4) were chosen as healthy tissue due to their proximity to the centre of the axial field of view, where the sensitivity profile is the highest[2]. ***Results:*** The mean COV for the 2-minute scan was .17. The mean COV for 30s (MRD322) scan was .25. The mean COV for 15s (MRD322) was .34. The COV was found to be significantly different for all healthy tissue between the three reconstruction durations ($p < 0.008$). ***Conclusion:*** This study suggests that with full maximum ring distance (MRD322) 15 and 30 seconds scans do not match the noise level of routine 2-minute acquisitions. However, the effect of ultra-short scan durations with full MRD on the standardised uptake in healthy tissue and lesions remains to be further explored in ongoing research. ***References:*** 1. ## OP-571

### Sub-minute acquisition with deep-learning reconstruction in the diagnosis of colorectal cancers using total-body 18F-FDG PET/CT

***E. Liu****, Z. Lyu, L. Jiang;*
*Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, CHINA.*

***Aim/Introduction:*** This study aimed to retrospectively evaluate the feasibility of total-body $^{18}$F-FDG PET/CT ultrafast acquisition combined with deep-learning reconstruction (DLR) in the diagnosis of colorectal cancers (CRCs). ***Materials and Methods:*** The clinical and preoperative imaging data of patients with CRCs were collected. All patients underwent a 300-second list-mode total-body $^{18}$F-FDG PET/CT. The entire dataset was divided into groups of durations of 10, 20, 30, 60, and 120-second. PET images were reconstructed using ordered subset expectation

maximisation (OSEM) and deep-learning reconstruction (DLR). Considering the 300-second OSEM reconstruction image as a standard, a 5-point Likert scale and semi-quantitative analysis were used to compare the effects of OSEM and DLR on image quality, detection rate, and uptake value of primary and liver metastases of CRCs at different acquisition durations. ***Results:*** All 34 recruited patients with CRCs had single colorectal lesions, and the diagnosis was verified pathologically. Of total patients, 11 had liver metastases, and 113 liver metastases were detected. The 10-second dataset cannot be evaluated because of high noise, whether it is reconstructed by OSEM or HYPER DLR. The signal-to-noise ratio (SNR) of the liver and mediastinal blood pool of 10, 20, 30, and 60-second acquisition duration images reconstructed with the same reconstruction parameters was lower than that of the 300-second OSEM reconstruction images ($P<0.01$). DLR significantly improved the SNR and visual image quality score compared to OSEM reconstruction ($P<0.01$). No significant difference was observed in the SNR of the liver and mediastinal blood pool, SUVmax and TBR of CRCs and liver metastases, and the number of detectable liver metastases between the 20 and 30-second DLR and 300-second OSEM reconstruction images ($P>0.05$). ***Conclusion:*** DLR can significantly improve the image quality of total-body $^{18}$F-FDG PET/CT ultrafast acquisition. Notably, without affecting the diagnosis of CRCs and liver metastases, DLR allowed decreasing the acquisition time of total-body PET images to 20-second. Compared with the standard acquisition, the 20-second and 30-second DLR images have the same accuracy in identifying and quantitatively evaluating CRCs and liver metastases.

## OP-572

### Diagnostic image quality and quantitative PET parameters of low-dose $^{18}$F-FDG-PET/CT in a total-body PET/CT scanner: How low can we go?

***E. Calderón***[1], *F. P. Schmidt*[1,2], *W. Lan*[1], *H. Dittmann*[1], *C. la Fougère*[1,3], *L. S. Kiefer*[1];
[1]*Department of Nuclear Medicine and Clinical Molecular Imaging, University Hospital Tübingen, Tübingen, GERMANY,* [2]*Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard-Karls University Tübingen, Tübingen, GERMANY,* [3]*Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tübingen, Tübingen, GERMANY.*

***Aim/Introduction:*** Total-body PET/CTs with a long axial field-of-view have a higher sensitivity and allow for a reduction of the injected activity while maintaining diagnostic image quality and quantitative PET parameters. Lower doses of injected activity reduce radiation exposure, which is especially beneficial for oncological patients routinely exposed during their radiological follow-up. This study aims to evaluate the lowest activity limits of $^{18}$F-FDG for standard clinical use in a total-body PET/CT. ***Materials and Methods:*** Twenty-two randomly selected oncological patients who underwent a clinically indicated $^{18}$F-FDG-PET/CT in a total-body PET/CT scanner were included in this study. Standard 5 min scans were acquired with an injected dose of 3 MBq/kg and subsequently rebinned for lower frame durations to simulate doses of 0.5 MBq/kg, 0.25 MBq/kg, and 0.125 MBq/kg for acquisition times of 5 and 10 min, respectively. The impact of limited and maximum acceptance angle modes was assessed by performing reconstructions with the manufacturer's proprietary software. Whole-body images were analyzed by two nuclear medicine physicians in consensus read using a 5-Point Likert scale, evaluating overall image quality, lesion conspicuity, and image noise. Afterwards, eighty-two tumor lesions were randomly selected for further analysis. Thereby, standard uptake PET parameters $SUV_{mean}$, $SUV_{max}$, $SUV_{peak}$, total-lesion-glycolysis (TLG), and tumor-to-background ratio (TBR) were measured for each lesion and normalized for analysis. TBR was determined as the ratio of $SUV_{max}$ to $SUV_{mean}$ of the background (a 14 $cm^3$ spherical VOI in the right liver lobe). ***Results:*** Subjective image rating showed degradation of diagnostic image quality and increased noise starting at 0.25 MBq/kg (5 min). A lesion detection rate of 95% was recorded for 0.5 MBq/kg (5 min), corresponding to 0.25 MBq/kg (10 min), which considerably decreased with the further reduction of simulated injected activity. Lesion conspicuity was significantly influenced by the size of tumor lesions and their contrast to background. $SUV_{max}$ and TBR increased by 24% and 29% for the lowest simulated injected activity compared to the original scan data at 3 MBq/kg. The maximum decrease of $SUV_{mean}$, $SUV_{peak}$, and TLG was recorded at 8%, 3%, and 8%, respectively (0.125 MBq/kg). ***Conclusion:*** This study indicates that the lowest activity dose for acquiring clinically diagnostic images in a total-body PET/CT is 1/12$^{th}$ of the standard injected activity using the maximum acceptance angle mode and an acquisition time of 10 minutes. Thereby, lesion detection was assured, and diagnostic image quality was maintained without any relevant deterioration of quantitative PET parameters.

***Aim/Introduction:*** Efficacy of the human epidermal growth factor receptor (HER)2-targeting trastuzumab emtansine (T-DM1) in breast cancer (BC) relies on HER2 status obtained on tissue samples. Heterogeneity in HER2 expression, however, generates interest in whole-body assessment using molecular imaging. Previously published interim results of a patient-based analysis demonstrated high negative predictive value (NPV) of zirconium-89 ($^{89}$Zr) trastuzumab (HER2)-PET/CT in identifying patients with metastatic BC who will not benefit from T-DM1 [1]. Here we present the final results of the study's primary objective, namely a lesion-based analysis to evaluate the role of HER2-PET/CT, early FDG-PET/CT response, and their combination in detecting lesions unlikely to respond to T-DM1. ***Materials and Methods:*** The ZEPHIR trial is an international, single-arm phase II trial, including patients with locally advanced or metastatic HER2-positive BC. Patients underwent HER2-PET/CT, FDG-PET/CT and diagnostic CT before T-DM1 initiation. Maximum 10 (5 per organ) unequivocally neoplastic lesions were selected as target lesions on baseline FDG-PET/CT. Based on $^{89}$Zr-trastuzumab uptake, target lesions were visually classified as HER2-positive (visible/high uptake) or HER2-negative (background/close to background activity). A week before the second treatment cycle, early metabolic lesion response was assessed on FDG-PET/CT (≥15% SUVmax decrease from baseline). After three T-DM1 cycles, lesion response was assessed anatomically on CT (size decrease ≥30% from baseline) and metabolically on late FDG-PET/CT (≥30% SUVmax decrease from baseline). NPVs of HER2-PET/CT, early FDG-PET/CT response, and combination of both, were evaluated for their prediction of the lesion anatomic and late metabolic non-responses post three T-DM1 cycles. ***Results:*** Ninety patients were included, median prior treatment lines of 3. 83/90p received median of 12 T-DM1cycles (1-114). In 383 target lesions, 148 (39%) were HER2-negative. In the anatomically evaluable lesions (265/383), 93 (35%) were classified as HER2-negative. HER2-PET/CT correctly identified 75/93 HER2-negative lesions as anatomically non-responding with NPV of 81%. NPV of HER2-PET/CT for the lesion late metabolic response was 63%. Early FDG-PET/CT predicted lesion anatomic and late metabolic response with NPV of 81% and 69%, respectively. Combination of both imaging modalities predicted lesion anatomic and late metabolic response with NPV of 91% and 84%, respectively. ***Conclusion:*** Molecular imaging can assess HER2 heterogeneity in HER2-positive BC and can predict very early on lesions not responding to T-DM1, further improved by adding an early metabolic response assessment. Similar efforts should be displayed for improved tailoring of the highly active but also toxic new generations of antibody-drug conjugates. ***References:***

***Aim/Introduction:*** Hypoxia in solid tumours is associated with increased tumour aggressiveness and resistance to chemoradiotherapy. Hypoxia in cervical cancer has been associated with a poor prognosis. Molecular markers and PET imaging methods have been investigated for assessing and mapping hypoxic lesions. Several $^{18}$F-labelled and $^{60/64}$Cu tracers have been studied for imaging hypoxia in cervical cancer with variable yet encouraging results. Over the years $^{68}$Ga labelled nitroimidazoles have been studied and have shown improved kinetics with improved tumour to background ratios. We present the first translational imaging of hypoxia PET in cervical cancer with $^{68}$Ga-Nitroimidazole derivative and $^{18}$F-FDG PET/CT. ***Materials and Methods:*** We prospectively recruited twenty women with histologically proven cervical cancer who underwent both $^{18}$F-FDG and $^{68}$Ga-Nitroimidazole PET/CT imaging. The $^{68}$Ga-Nitroimidazole PET was performed at 30 and 60-minutes post tracer injection. Qualitative and semi-quantitative analyses were performed on both scans, with $^{68}$Ga-Nitroimidazole scans being scored qualitatively from 0 - 3 and a score above 2 considered as positive. We also documented SUVmax and SUVmean of the primary lesions as well as tumour to muscle ratio (TMR), tumour to blood (TBR), metabolic tumour volume (MTV) and hypoxic tumour volume (HTV). ***Results:*** The mean age of the population was 44.65±11.43years. Twelve patients had uptake considered positive on $^{68}$Ga-Nitroimidazole PET. The median SUVmax, SUVmean, MTV, TMR, TBR of the primary tumour on $^{18}$F-FDG were 17.41, 6.78, 150.51cm$^3$, 28.50 and 9, respectively. The median SUVmax, SUVmean, HTV, TMR, TBR on $^{68}$Ga-Nitromimidazole PET were 3.63, 1.49, 60.85cm$^3$, 10.50 and 3.27, respectively. The areas of $^{68}$Ga-Nitroimidazole uptake in the primary lesion were smaller than the metabolic area on $^{18}$F-FDG PET, with the hypoxic subvolume as a percentage of the MTV ranging from 2% - 98% (median 37%). ***Conclusion:*** Two-thirds of the patients demonstrated hypoxia on $^{68}$Ga-Nitroimidazole PET imaging. $^{68}$Ga-Nitroimidazole PET may play a complementary role in patients with a high index of suspicion for hypoxia.

***Aim/Introduction:*** To demonstrate the preoperative predictive value of 2-[F]FDG -PET/CT in reducing the rate of mastectomy in high-risk breast cancer patients undergoing neoadjuvant chemotherapy (CTx), in addition to conventional staging methods, as a primary endpoint. Sensitivity and specificity of a partial/complete PET/CT early response for predicting pathological complete response (pCR) at the end of CTx, among others, were analyzed as a secondary endpoint. ***Materials and Methods:*** 94 patients (median age 48.5; with triple neg., HER2-pos. or high-risk HR+/HER2) from the prospective GeparOcto (NCT02125344) study were recruited for the Gepar-PET substudy. Within the main study protocol, randomization and subsequent adaptation of the treatment protocol within the study arms took place depending on the receptor status. The patients included in the sub-study underwent FDG-PET/CT before neoadjuvant CTx (PET1) and 2 weeks after the start of therapy (PET2) to assess the early response to therapy. Following a further randomization, a sub group of patients received a 3rd PET/CT (PET3) after the completion of neoadjuvant CTx. $\Delta SUV_{max}$ and $\Delta SUV_{peak}$ were assessed to evaluate treatment response according to the primary endpoint using histopathology as the reference. The statistical evaluation included the determination of cut-off values by means of ROC analysis (max. Youden's Index) and subsequently the corresponding sensitivities and specificities. ***Results:*** 53 of 94 (56%) patients were histopathological responder and 41 (44%) were histopathologic non-responder. A threshold of 70% decrease in $SUV_{peak}$ evaluation (PET2 - PET1) identified 25 of 53 responders. Histopathological responders were identified with a positive predictive value of 81%. ***Conclusion:*** The Gepar PET-study demonstrates that in patients with advanced breast cancer FDG PET/CT differentiates histopathologic responders from non-responders early in the course of neoadjuvant treatment. Thus, FDG-PET/CT may be helpful for improved patient management by reducing the rate of mastectomy in high-risk breast cancer patients.

***Aim/Introduction:*** Radiolabeled RM26 and RGD peptide analogs have been investigated for imaging gastrin releasing peptide receptor (GRPR) and integrin αvβ3 receptor expression in multiple types of tumors. In this study, we synthesized a novel RM26-RGD heterodimer, radiolabeled with [$^{68}$Ga]Ga and applied it for the first time in breast cancer patients to assess its clinical performance. ***Materials and Methods:*** RM26-RGD heterodimer was synthesized from GRPR antagonist RM26 and integrin αvβ3 antagonist RGD through conjugating with 1,4,7-triazacyclononanetriacetic acid (NOTA) and labeled with [$^{68}$Ga]Ga. The dual receptor binding affinity of [$^{68}$Ga]Ga-RM26-RGD was determined using cell uptake and competition binding assay. PET/CT imaging of [$^{68}$Ga]Ga-RM26-RGD was performed to identify the tumor targeting effect and pharmacokinetic properties. With institutional review board approval and informed consent, a total of 32 patients with breast cancer (24 patients with primary tumor confirmed by puncture pathology and 8 patients with suspected recurrence or metastasis) were recruited. 6 patients underwent 2-h dynamic acquisition of [$^{68}$Ga]Ga-RM26-RGD PET/CT for dosimetry estimation, and the other patients underwent [$^{68}$Ga]Ga-RM26-RGD PET/CT scan at 45 min after intravenous injection. ***Results:*** [$^{68}$Ga]Ga-RM26-RGD had GRPR and integrin αvβ3 dual receptor binding affinity in vitro and in vivo, which showed higher tumor uptake values and tumor/muscle ratios than [$^{68}$Ga]Ga-RM26 and [$^{68}$Ga]Ga-RGD in PC3 tumor model. In clinical applications, all patients tolerated the examination well and no significant adverse event was reported in correlation with the study in any of the patients. The total body absorbed dose and the effective dose of [$^{68}$Ga]Ga-RM26-RGD were 1.00E-02 ± 1.20E-03 and 3.25E-02 ± 7.94E-03 mSv/MBq, respectively. [$^{68}$Ga]Ga-RM26-RGD detected a total of 23 primary lesions in all 25 lesions of 24 patients (92%). The mean SUVmax of primary tumor lesions on [$^{68}$Ga]Ga-RM26-RGD PET/CT was 4.6 ± 2.1. In a recurrent breast cancer patient with brain metastases who also underwent [$^{18}$F]-FDG PET/CT, [$^{68}$Ga]Ga-RM26-RGD showed a superior tumor/background ratio (15.5 vs. 1.1) than [$^{18}$F]-FDG PET/CT. ***Conclusion:*** [$^{68}$Ga]Ga-RM26-RGD was synthesized and radiolabeled with high radiochemical purity and stability. This pilot study indicates the safety and the first clinical application of [$^{68}$Ga]Ga-RM26-RGD in breast cancer. Further investigation of the detection performance of [$^{68}$Ga]Ga-RM26-RGD in metastatic lymph nodes and the differences between dual- and single- target tracers in larger scale clinical studies are warranted

## OP-577

### Tumor and metastatic lymph nodes metabolic activity on $^{18}$F-FDG PET/CT to predict progression-free survival in locally advanced cervical cancer

***J. Song****;*
*Zhejiang Cancer Hospital, Hangzhou, CHINA.*

***Aim/Introduction:*** The present study investigated the predictive diseases progression value of preoperative fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) in patients with local advanced cervical cancer (LACC). ***Materials and Methods:*** In total, 267 patients [median age 58 (range: 27-85) years old] with LACC underwent $^{18}$F-FDG PET/CT prior to any treatment. The maximum standardized uptake values ($SUV_{max}$), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of the primary lesion and metastatic lymph nodes were measured on PET/CT and correlated with clinicopathological features and progression-free survival (PFS). ***Results:*** The median follow-up was 36.52 (range: 3.09-61.29) months. During the observation period, 80 (30.0%) patients exhibited disease progression. Univariate analysis showed that FIGO stage, concurrent chemoradiotherapy (CRT), serum level of carcinoembryonic antigen (CEA) and squamous cell carcinoma antigen (SCC-Ag), primary tumor MTV (pMTV) and TLG (pTLG), lymph nodes $SUV_{max}$ (n$SUV_{max}$) and TLG (nTLG), and total

metabolic activity (sMTV, sTLG) were associated with PFS. $nSUV_{max}$ ≥5.29, CEA≥7.11ng/ml and deficiency of concurrent CRT were independent risk factor for PFS (P = 0.006, P=0.008, P=0.014). The 3-year PFS for patients with high $nSUV_{max}$ were 42.2% compared to 56.3% for low $nSUV_{max}$ values. ***Conclusion:*** Pretreatment cervical and lymph nodes metabolic parameters were associated with PFS in patients with LACC.

## OP-578

### HER2-specific Affibody Molecule [$^{99m}$Tc]Tc-ZHER2:41071: phase I clinical trial

***V. Tolmachev***[1], *O. Bragina*[2], *M. Larkina*[3], *A. Rybina*[2], *R. Zelchan*[2], *M. Oroujeni*[1], *A. Loftenius*[4], *A. Orlova*[5], *J. Sörensen*[6], *F. Frejd*[1], *V. Chernov*[2];
[1]*Department of Immunology, Genetics and Pathology (IGP), Uppsala University, Uppsala, SWEDEN,* [2]*Cancer Research Institute, Tomsk National Research Medical Center, Tomsk, RUSSIAN FEDERATION,* [3]*Research Centrum for Oncotheranostics, Research School of Chemistry and Applied Biomedical Sciences, Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION,* [4]*Affibody AB, Solna, SWEDEN,* [5]*Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [6]*Radiology and Nuclear Medicine, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** Imaging of human epidermal growth factor receptor type 2 (HER2) expression in breast and gastric cancers may be instrumental for selection of patients responding to HER2-targeting therapy. Affibody molecules are small (58 amino acids) targeting proteins based on non-immunoglobulin scaffold, which provide highly sensitive molecular imaging at the day of injection. Contemporary SPECT/CT scanners provide good sensitivity and sufficient accuracy for quantitative measurements of activity in vivo. Implementation of a $^{99m}$Tc-labelled Affibody molecule would increase availability of HER2 imaging for clinical community. Affibody molecule [$^{99m}$Tc]Tc-ZHER2:41071 (affinity 68 pM ) was developed for SPECT/CT imaging of HER2 expression. The aim of this Phase I trial was an evaluation of safety, biodistribution and dosimetry of [$^{99m}$Tc]Tc-ZHER2:41071. ***Materials and Methods:*** A prospective, open-label, non-randomized Phase I diagnostic study was performed in patients with untreated primary breast cancer (ClinicalTrials.gov Identifier: NCT05203497). Thirty one patients were divided in three cohorts. Each cohort included at least five patients with high HER2 expression (immunohistochemistry (IHC) score 3+ or FISH-positive and IHC score 2+) and five patients with low HER2 expression in tumors (FISH negative and IHC score 2+ or lower). The injected protein mass was either 500, 1000, or 1500 µg ZHER2:41071 for cohort 1, 2 and 3, respectively. The injected activity was 451±71 MBq [$^{99m}$Tc]Tc-ZHER2:41071. Planar scintigraphy followed by SPECT/CT was performed after 2, 4, 6 and 24 h. Vital signs were monitored before, during and after the imaging. The imaging data were used for calculation of dosimetry using OLINDA/EXM 1.1 (female phantom). The uptake values were analyzed using one-way ANOVA (for comparison of different groups) or Mann-Whitney U test (comparison of tumor uptake). ***Results:*** Injections of [$^{99m}$Tc]Tc-ZHER2:41071 were not associated with any adverse events. The effective dose was 0.019±0.004 mSv/MBq. Injection of with 1000 µg enabled the best discrimination between HER2-positive and HER2-negative tumors. The uptake in tumors with high expression (SUVmax 16.9±7.6) was significantly (p<0.005, Mann-Whitney U test) higher than in tumors with low expression (SUVmax 3.6±1.4) in this case already 2 h post injection. The uptake of [$^{99m}$Tc]Tc-ZHER2:41071 in HER2-positive lymph node metastases was also significantly (p < 0.05) higher than in HER2-negative 2 h after injection of 1000 µg. ***Conclusion:*** Injections of [$^{99m}$Tc]Tc-ZHER2:41071 are safe. Dosimetry data permit multiple injections of [$^{99m}$Tc]Tc-ZHER2:41071. Injection of 1000 µg is ensures the best discrimination between tumors with high and low expression of HER2.

## OP-579

### HER2-targeting [$^{68}$Ga]Ga-ABY-025 PET Predicts Early Metabolic Response in Metastatic Breast Cancer

*A. Alhuseinalkhudhur*[1,2], *H. Lindman*[2], *P. Liss*[3], *T. Sundin*[4], *F. Y. Frejd*[2,5], *J. Hartman*[6,7], *V. Iyer*[1], *J. Feldwisch*[5], *M. Lubberink*[1,8], *C. Rönnlund*[6,7], *V. Tolmachev*[2], *I. Velikyan*[1], ***J. Sörensen***[1];
[1]*Nuclear Medicine and PET, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN,* [2]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN,* [3]*Radiology, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN,* [4]*Clinical Research and Development Unit, Uppsala University Hospital, Uppsala, SWEDEN,* [5]*Affibody AB, Solna, SWEDEN,* [6]*Department of Oncology-Pathology, Karolinska Institute, Stockholm, SWEDEN,* [7]*Department of Clinical Pathology and Cancer Diagnostics, Karolinska University Hospital, Stockholm, SWEDEN,* [8]*Medical Physics, Uppsala University Hospital, Uppsala, SWEDEN.*

***Aim/Introduction:*** Imaging using human epidermal growth factor receptor 2 (HER2) binding tracer [$^{68}$Ga]Ga-ABY-025 was shown to reflect HER2 status determined by immunohistochemistry and in situ hybridization (ISH) in metastatic breast cancer (MBC). This single-center open-label Phase II study aimed to investigate how [$^{68}$Ga]Ga-ABY-025 uptake corresponds to biopsy results and early treatment response in both primary breast cancer (PBC) planned for neoadjuvant chemotherapy and MBC. ***Materials and Methods:*** Forty patients with known positive HER2 status were included, 19 PBC and 21 MBC (median three previous treatments). [$^{68}$Ga]Ga-ABY-025 PET/CT, [$^{18}$F]F-FDG PET/CT, and core needle biopsies from targeted lesions were performed at baseline. [$^{18}$F]F-FDG PET/CT was repeated after two cycles of therapy to calculate the directional change in tumor lesion glycolysis (delta-TLG). Largest lesions (up to five) were evaluated in all three scans per patient. Standardized uptake values (SUV) from [$^{68}$Ga]Ga-ABY-025 PET/CT were compared to biopsied HER2 status and delta-TLG by receiver operating characteristics (ROC) analyses. ***Results:*** Trial biopsies were HER2-positive in 31, negative in six, and borderline-positive in three patients. [$^{68}$Ga]Ga-ABY-025 PET SUVmax 6.0 cut-off predicted delta-TLG lower than -25% with 86% sensitivity and 67% specificity in soft tissue lesions (AUC 0.74 [95% CI, 0.67-0.82] [P = 0.01]). Compared to HER2 status, this cut-off resulted in clinically relevant discordant findings in 12 of 40 patients. Metabolic response (delta-TLG) was more pronounced in PBC (-71% [95% CI, -58% to -83%]) than MBC (-27% [95% CI, -16% to -38%]) (P < 0.0001), but [$^{68}$Ga]Ga-ABY025 SUVmax values were similar in both with a mean SUVmax of 9.8 (95% CI, 6.3-13.3) and 13.9 (95% CI, 10.5-17.2), respectively (P = 0.10). In multivariate analysis, global delta-TLG was positively associated with the number of previous treatments (P = 0.0004) and negatively with [$^{68}$Ga]Ga-ABY025 SUVmax (P = 0.018), but not with HER2 status (P = 0.09). ***Conclusion:*** [$^{68}$Ga]Ga-ABY025 PET predicted early metabolic response to HER2-targeted therapy in HER2-positive BC. Metabolic response was attenuated in recurrent disease. [$^{68}$Ga]Ga-ABY025 PET appears to provide an estimate of the HER2-receptor expression required to induce tumor metabolic remission by targeted therapies and might be useful as an adjunct diagnostic tool.

***Aim/Introduction:*** The $^{68}$Ga-labelled gastrin-releasing peptide receptor (GRPR) antagonist NeoB is a novel PET tracer for imaging tumors with high target expression. Here we aim to assess $^{68}$Ga-NeoB-uptake in glioma and breast cancer patients. ***Materials and Methods:*** Eligible patients with glioma or breast cancer were offered clinical PET and subsequently enrolled in a prospective observational trial. PET data were acquired 81 min (mean) after injection of 95 MBq (mean) of $^{68}$Ga-NeoB. In glioma, lesion $SUV_{max}$ values were determined and compared among distinct entities according to the recently revised WHO Classification. In breast cancer, NeoB-uptake (NeoB-positivity defined as visually markedly higher uptake than local background) was reported in five regions ("breast", "lymph nodes", "liver", "bone", "other"). Only patients/regions with at least one clinically verified tumor lesion (by either histopathology, CT/MRI/PET, or tumor board) were included in a patient-/region-based analysis. Mean $SUV_{max}$ values from all NeoB-positive regions were calculated per breast cancer patient for global assessment of NeoB-uptake. ***Results:*** We investigated n=24 glioma patients (n=16 diagnosed with glioblastoma, n=6 with IDH-mutant astrocytoma, n=2 with IDH-mutant oligodendroglioma). Mean $SUV_{max}$ was 1.1 (range: 0.3-2.4) among all, 0.7 (0.3-1.9) among non-glioblastoma, and 1.3 (0.4-2.4) among glioblastoma patients. Highest $SUV_{max}$ values were measured in glioblastoma patients with histopathological relapse confirmation. In n=11 glioblastoma patients with relapse-suspicious MRI at NeoB PET examination, mean $SUV_{max}$ was 1.4 (0.6-2.4); n=7/11 (63.6%) of these patients underwent FET PET examination within two weeks with FET showing higher uptake (mean $SUV_{max}$: 2.2 versus 1.6; range: 1.2-3.5 versus 0.7-2.4). We investigated n=20 breast cancer patients with clinically verified tumor in at least one region (n=8 at initial staging, n=12 with advanced disease), n=14/20 (70%) were NeoB-positive. In a patient-based analysis regarding hormone receptor status, n=12/14 patients (85.7%) with estrogen receptor-positive/HER2-negative breast cancer (ER+/HER2-) and n=2/6 patients (33.3%) with other hormone receptor status were NeoB-positive. In NeoB-positive ER+/HER2- patients, mean $SUV_{max}$ was 12.3 (4.1-25.9) and n=7/12 (58.3%) patients showed high (mean $SUV_{max} \geq 10$), n=4/12 (33.3%) intermediate ($10 >$ mean $SUV_{max} \geq 5$), and n=1/12 (8.3%) low ($SUV_{max} < 5$) global NeoB-uptake. In the region-based analysis, n=20/26 (76.9%) of regions in ER+/HER2- patients were NeoB-positive (mean $SUV_{max}$: 14.3; range: 3.5-44.0). ***Conclusion:*** NeoB-uptake and lesion detection were low for glioma and heterogeneous for breast cancer. Glioblastoma showed higher uptake than other glioma. ER+/HER2- breast cancer demonstrated higher uptake than other hormone receptor status; more than 50% of those patients showed intense global uptake and could be candidates for GRPR-directed radioligand therapy.

## OP-581

### Prognostic Value Of [$^{18}$F]-FDG PET/CT In Patients With Metastatic Breast Cancer Treated With Cyclin-Dependent Inhibitors

***D. Maccora***[1], *A. Annovazzi*[1], *S. Rea*[1], *L. Pizzuti*[2], *G. Ferretti*[3], *P. Vici*[4], *F. Cappuzzo*[2], *R. Sciuto*[1];
[1]*Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [2]*Division of Medical Oncology 2, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [3]*Division of Medical Oncology 1, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [4]*Phase IV Clinical Trial Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.*

***Aim/Introduction:*** The addition of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) (i.e. palbociclib, ribociclib, abemaciclib) to endocrine therapy impressively improved the outcome of patients with hormone receptor-positive metastatic breast cancer. Despite their great efficacy, not all patients respond to treatment and many of them develop acquired resistance. We aimed to assess the role of [$^{18}$F]-FDG PET/CT in evaluating treatment response and in predicting progression-free survival (PFS) and overall survival (OS) in breast cancer patients treated with CDK4/6i. ***Materials and Methods:*** One hundred fourteen patients who performed an [$^{18}$F]-FDG PET/CT scan before (PET1) and 2-6 months after (PET2) starting treatment were retrospectively enrolled. Metabolic response was evaluated by EORTC criteria, PERCIST and Deauville score and correlated to PFS and OS. Four response groups were considered: complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD). The 5-point Deauville score was evaluated considering the hottest lesion at PET2 using the well-known scores according to background and liver uptake (1 to 5). In addition, pre-treatment Total Metabolic Tumour Volume (TMTV), a surrogate for tumour burden, as well as clinic-pathologic tumour variables were analysed and correlated to PFS or OS. ***Results:*** Disease progression occurred in 69 patients (median follow-up time 35.8 months). In patients who did not progress at PET2 (n = 90), PFS rates were not significantly different between classes of response by EORTC criteria and PERCIST. Conversely, patients showing a Deauville score ≤3 had a longer PFS (median PFS 42 vs 21 months; p = 0.008). A higher TMTV at PET1 (TMTV1) was associated with a shorter PFS (median PFS 18 vs 42 months; p = 0.0026). PMD at PET2 was associated with a shorter OS (36-month survival rate 29.8 vs 84.9%, median OS 24 months vs not reached; p<0.0001), as well as some baseline clinical features, such as ECOG status, administration of CDK4/6i therapy in second- or later line and liver metastases. Deauville score and TMTV1 were the only independent prognostic factors for PFS at multivariate analysis and their combination stratified the population in four definite classes of relapse risk. ***Conclusion:*** Metabolic response by Deauville score and TMTV were significant prognostic factors for PFS in patients with breast cancer treated with CDK4/6i, PMD and the presence of liver metastases for OS. Their determination could help physicians to select patients who may need a closer follow-up.

**Fibroblast activation protein staining in tissue samples of high-grade gliomas**

***N. Tolboom***, *S. Sabunchi, A. Muhlebner, P. A. J. T. Robe, T. J. Snijders;*
*University Medical Centre Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) shows low expression in normal tissue and high expression in certain types of cancer and is therefore a promising potential target for non-invasive imaging and treatment of patients. Limited information is available on expression in gliomas. The aim of this study was to examine the staining pattern of a FAP-specific antibody in high-grade glioma tissue samples, to determine the potential of FAP and [68Ga]FAPI-PET for glioma imaging and theranostics.
***Materials and Methods:*** Tissue samples from patients with high-grade gliomas (WHO grade 3-4) were primed on tissue microarrays (TMA) and immunohistochemically stained with a FAP-specific antibody. Samples were assessed consecutively and systematically on extent of staining by two readers and classified in a binary fashion as low/focal or high/diffuse. Furthermore, pattern of staining (perivascular and/or diffuse intraparenchymal) and heterogeneity of FAP expression across gliomas was examined. The association between isocitrate dehydrogenase (IDH) mutation status and extent of staining and expression pattern was tested with Chi-square tests or Fisher's exact test and regression models. ***Results:*** 418 samples from 191 patients (107 male, 84 female, mean age of 59 years) were available for analysis. The samples consisted of tissue, mostly from grade 4 gliomas (n=406), 9 grade 3 astrocytomas and 3 grade 3 oligodendrogliomas. IDH mutation status was available for 332 samples. In the total sample studied, negative FAPI staining was more common than positive staining (68% versus 32%). Of these positive cases, most tumour samples stained only perivascular but about a fifth of the samples did show diffuse intraparenchymal or a combination of diffuse intraparenchymal and perivascular staining. High/diffuse staining was seen in 27 out of 315 IDH wildtype glioma (mostly glioblastoma according to WHO2021) samples and 5 out of 17 IDH mutant glioma samples. Heterogeneity of staining was found within patients. FAP expression was not related to survival. ***Conclusion:*** In a large cohort of patients with high-grade gliomas, the majority of the samples did not stain with FAP. However, of the samples that did stain, a subset showed a high and diffuse intraparenchymal FAP expression pattern, suggesting a potential for [68Ga]FAPI-PET in a select set of patients. However, heterogeneity in staining pattern within patients was observed which needs to be further investigated. These findings give useful insights, in light of the recent interest in [68Ga]FAPI-PET based imaging and potential theranostic therapies in gliomas.

### OP-584

**Postoperative $^{68}$Ga-DOTATATE-/PET-CT imaging is prognostic for progression-free survival survival in meningioma WHO grade 1:A prospective single center study**

***N. Teske***, *A. Biczok, S. Quach, F. J. Dekorsy, R. Forbrig, R. Bodensohn, M. Niyazi, J. Tonn, N. L. Albert, C. Schichor, M. Ueberschaer;*
*Munich University Hospital, LMU Munich, Munich, GERMANY.*

***Aim/Introduction:*** Microsurgical tumor resection represents the first-line treatment for symptomatic meningiomas, and extent of resection has been shown to be of prognostic importance. Assessment of tumor remnants with somatostatin receptor PET proves to be superior to intraoperative estimation with Simpson grading or MRI. However, prognostic relevance of postoperative PET for progression-free survival in meningiomas remains unclear.
***Materials and Methods:*** We conducted a prospective study including patients with surgically removed meningioma WHO grade 1 and collected clinical and imaging data. All patients received postoperative MRI and $^{68}$Gallium-DOTATATE/PET, and were followed regularly with MRI surveillance scans for detection of tumor recurrence/progression. ***Results:*** We included 46 patients with 49 tumors. Mean age at diagnosis was 57.8 ± 1.7 years with a male-to-female ratio of 1:1.7. Local tumor progression occurred in 7/49 patients (14%) after a median follow-up of 52 months. Positive PET was associated with an increased risk for progression (*p = 0.015) and a lower progression-free survival (*p = 0.029) whereas MRI was not. 20/20 patients (100%) with negative PET findings remained recurrence-free. Location of recurrence/progression on MRI was adjacent to regions where postoperative PET indicated tumor remnants in all cases. Gross tumor volumes were higher on PET compared to MRI (*p = 0.032). ***Conclusion:*** Our data show that $^{68}$Ga-DOTATATE/PET is highly sensitive in revealing tumor remnants in patients with meningioma WHO grade 1. Negative PET findings were associated with a higher progression-free survival, thus improving surveillance. In patients with tumor remnants, additional PET can optimize adjuvant radiotherapy target planning of surgically resected meningiomas.

### OP-585

**$^{18}$F-DOPA PET imaging in re-irradiation with proton therapy of recurrent glioblastoma.**

***D. Donner***[1], *D. Amelio*[2], *D. Scartoni*[2], *L. Picori*[1], *S. Agostini*[1], *F. Magnani*[1], *A. Palermo*[1], *M. Cianchetti*[2], *F. Chierichetti*[1];
[1]*Nuclear Medicine Unit, Azienda Provinciale per i Servizi Sanitari, Trento, ITALY,* [2]*Centro di Protonterapia, Azienda Provinciale per i Servizi Sanitari, Trento, ITALY.*

***Aim/Introduction:*** After Photon Therapy, recurrent glioblastoma (rGBM) may be treated again with re-irradiation by Proton Therapy (PT). We evaluated the impact of adding 18FDOPA PET data, with respect to MRI planned treatment, in defining the target volumes for PT. ***Materials and Methods:*** 54 patients (pts) with rGBM underwent morphological MRI with Gadolinium-based contrast agent and 18F-DOPA PET imaging at baseline. 18F-DOPA tumor uptake, using a tumor-to-normal brain ratio > 2, identified the so-called Biological Tumor Volume (BTV). We investigated the differences in volume and relationship of MRI vs. 18F-DOPA PET-derived gross tumor volumes (GTVs). MRI T1 positive for contrast enhancement was used for MRI-based GTV (MRGTV). Definitive GTV included MRGTV plus BTV. Finally, clinical target volume was generated by adding to GTV a 3mm uniform margin in the proximity of anatomical barriers. All pts received 36 GyRBE

in 18 fractions. We also evaluated the median PFS at 4th and 6th month after PT and where the recurrence occurred. ***Results:*** MRGTV (mean 17.8 ± 16.07 cc) was smaller than BTV (mean 23.41 ± 21.28 cc) although this difference was not statistically significant (p = 0.11). The PT irradiation of PET-integrated target volumes provided a median progression-free survival (PFS) of 4 months; 6-month PFS rate was 28%; median survival after PT was 8.5 months. After re-irradiation with protons, the recurrence occurs in the re-irradiated field in 70% of cases and 30% of cases in the marginal outfield regions. ***Conclusion:*** 18F-DOPA PET helped detect the rGBM intratumoral heterogeneity, more accurately defining the tumor burden and catching non-enhancing pathological areas in rGBM, outside the conventional MRGTV. This provided larger volumes in treatment planning. The possible effect on outcome and survival needs further evaluation. ***References:*** 1) Heikki Minn, Saila Kauhanen, Marko Seppänen, Pirjo Nuutila. 18F-FDOPA: A Multiple&#8211Target Molecule. ### Amino-acid PET for monitoring temozolomide adjuvant therapy after a Stupp protocol in gliomas

***T. Zaragori***[1,2], *S. Ahrari*[1,2], *A. Zinsz*[2], *A. Mortada*[2], *L. Taillandier*[3,4], *M. Blonski*[3,4], *F. Rech*[5,4], *L. Imbert*[1,2], *A. Verger*[1,2];
[1]*Université de Lorraine, IADI, INSERM, UMR 1254, Vandoeuvre-lès-Nancy, FRANCE,* [2]*Department of Nuclear Medicine & Nancyclotep Imaging Platform, CHRU-Nancy, Université de Lorraine, Vandoeuvre-lès-Nancy, FRANCE,* [3]*Department of Neuro-Oncology, CHRU-Nancy, Université de Lorraine, Nancy, France, Vandoeuvre-lès-Nancy, FRANCE,* [4]*Centre de Recherche en Automatique de Nancy CRAN UMR 7039, CNRS, Université de Lorraine, Vandoeuvre-lès-Nancy, FRANCE,* [5]*Department of Neurosurgery, CHRU-Nancy, Université de Lorraine, Vandoeuvre-lès-Nancy, FRANCE.*

***Aim/Introduction:*** Studies investigating the value of amino-acid PET for monitoring temozolomide adjuvant therapy (TMZ) in literature are scarce with limited and heterogeneous populations. The aim of this study was to evaluate the performances of amino-acid PET to monitor adjuvant therapy in gliomas within a homogeneous population of patients having beneficiated from TMZ after a Stupp protocol. ***Materials and Methods:*** Consecutive patients with grades II-IV gliomas who performed a dynamic $^{18}$F-FDOPA PET imaging within 3 months of the end of a TMZ after a Stupp protocol were included. Clinical and histo-molecular factors, responses to RANO criteria for MRI and static and dynamic PET parameters were correlated to progression-free and overall survivals (PFS and OS). The biological tumor volumes (BTV) were defined semi-automatically with a 1.6 threshold from the healthy brain. ***Results:*** Sixty-seven patients (57.1±14.4 years old, 27 women) from whom 59 (88%) with IDH-wildtype glioblastomas, having beneficiated from 3 to 24 cures of TMZ, were included. In a subgroup of 19 patients with multiples PET during TMZ cures, decrease in tumor-to-background ratios were associated to PFS at 1 year with an accuracy of 84% (p=0.03). In the overall population, the presence of a BTV was associated to significant lower PFS and OS (respectively 9.0 vs. 22.4 months, p<0.001 and 21.7 vs. 50.0 months, p=0.01). In multivariate analysis, the combination of the presence of a BTV, RANO criteria, the grade of the tumor and the slope were associated to PFS. ***Conclusion:*** Amino-acid PET is an efficient tool to monitor TMZ therapy in patients with gliomas. In a homogeneous population of patients having beneficiated from TMZ after a Stupp protocol, the presence of a BTV is an independent predictor of survivals.

## OP-587

### Predictive values of preoperative [$^{68}$Ga]Ga-PSMA-11 PET/CT in patients with suspected brain tumours of glial origin.

***K. Pelka***[1,2], *K. Koczyk*[3], *L. Koperski*[4], *T. Dziedzic*[3], *A. Nowak*[3], *L. Królicki*[1], *P. Kunert*[3], *J. Kunikowska*[1];
[1]*Nuclear Medicine Department, Medical University of Warsaw, Warsaw, POLAND,* [2]*Laboratory of Centre for Preclinical Research, Department of Research Methodology, Medical University of Warsaw, Warsaw, POLAND,* [3]*Department of Neurosurgery, Medical University of Warsaw, Warsaw, POLAND,* [4]*Department of Pathology, Medical University of Warsaw, Warsaw, POLAND.*

***Aim/Introduction:*** PET/CT targeting the prostate-specific membrane antigen (PSMA) is commonly used in patients with prostate cancer, however its expression has been found in other solid tumors like renal cell carcinoma, hepatocellular carcinoma, and primary brain tumors like glioblastoma (GB). It has been found in the recurrence of GB. The aim of this study to evaluate usefulness of preoperative [$^{68}$Ga]Ga-PSMA-11 PET/CT of patients with suspected brain tumours of glial origin. ***Materials and Methods:*** In this prospective study we screened patients as a consecutive series, which were referred to the hospital for surgery with suspicion of a tumor of glial origin in previously performed imaging examinations. The PET/CT image acquisition was performed from the skull to the mid-thigh with a CT scan for anatomic correlation and attenuation correction 60 min post injection of [$^{68}$Ga]Ga-PSMA-11 (2 MBq per kg body weight). Additional acquisition of 5 min was used for brain imaging. The PET/CT qualitative and quantitative results were compared to the histological examination. The collected results were compared to GB diagnostics or differentiation between high-grade (HGG) and low-grade gliomas (LGG). Additional histopathological staining for PSMA has been performed to gain more data. ***Results:*** 44 patients met the inclusion criteria. 20 of them had positive and 24 negative PET/CT scan. The sensitivity, specificity, positive predictive value and negative predictive value for HGG diagnosis 71.4 (95% confidence interval - 51.3-86.8), 100.0 (79.4-100.0), 100.0 (83.1-100.0), 66.7 (44.7-84.4) respectively. Due to tracer uptake in all lesions finally diagnosed as HGG, for the quantitative analysis the area under the receiver operating characteristic curve was used for differentiation GB vs non-GB, with the best results for tumor-to-backgound ratio parameter: 0.81 (0.66-0.96; 42.2) (95% CI; cut-off). The comparison with immunohistochemical examination showed a correlation in qualitative and quantitative analysis. ***Conclusion:*** The PSMA PET/CT showed a great potential in detection of HGG. More prospective trials are still needed for a differentiation between GB and non-GB. the proposed interpretation of the study allows to distinguish a high-risk group from patients with suspected tumor of glial origin, which may allow better treatment planning.

## OP-588

### Tumoral TSPO-radioligand uptake on PET prior to radiotherapy is associated with overall survival in glioblastoma patients

***A. Holzgreve***[1], *D. V. Nelwan*[1], *D. F. Fleischmann*[2], *S. Quach*[3], *K. von Rohr*[1], *L. Kaiser*[1], *N. Teske*[3], *L. M. Unterrainer*[1], *L. M. Bartos*[1], *V. C. Ruf*[4], *M. ***Aim/Introduction:*** PET imaging targeting the 18-kDa translocator protein (TSPO) is increasingly applied in glioblastoma patients. Data correlating TSPO-PET imaging results with survival in glioblastoma patients, however, are lacking. Therefore, we here investigated the prognostic value of TSPO-PET imaging in patients with proven glioblastoma prior to radiotherapy. ***Materials and Methods:*** 45 patients (median age 63.3 years, range 30.6-84.2) with newly-diagnosed glioblastoma (CNS WHO Grade 4) prior to radiotherapy were included. 23/45 (51.1%) patients received conventional chemoradiotherapy (60 Gy dose and temozolomide), and 22/45 (48.9%) patients received hypofractionated radiotherapy (40.05 Gy dose, either with or without temozolomide). Pre-therapeutic image analysis included assessment of tumoral uptake intensity on TSPO-PET ($SUV_{max}$) and delineation of tumor volumes on MRI (ceT1 and T2/FLAIR). Additionally, the TSPO binding affinity status of each patient was assessed using polymorphism genotyping. Further clinical parameters included MGMT status and TERT status. Univariate survival analysis was performed using Kaplan-Meier estimation and Log-rank test regarding progression-free survival (PFS) and overall survival (OS) for all imaging-based and further clinical data. Parameters found to be prognostic in the univariate analysis were subsequently included in a multivariate survival analysis using Cox proportional hazards model. A two-tailed p-value $< 0.05$ was considered as statistically significant. ***Results:*** On TSPO-PET, the median tumoral $SUV_{max}$ was 2.2 (range, 1.0-4.7). $SUV_{max}$ was associated with clinical outcome: Patients with a high tumoral uptake intensity on TSPO-PET prior to radiotherapy (i.e., median split $SUV_{max} > 2.2$) had a significantly shorter survival than patients with a lower $SUV_{max}$ (8.3 vs. 17.8 months, p=0.037). No such correlation was found regarding PFS. Other parameters with a significant association to overall survival in the univariate analysis included the T2w-tumor volume on MRI (p=0.031), age (p=0.046), and MGMT status (p=0.032). Contrast-enhancement on MRI was present at a higher proportion in patients with $SUV_{max} \geq 2.2$ (p=0.022), otherwise there were no group differences between patients with low vs. high tumoral uptake on TSPO-PET (for each other imaging-based or clinical parameter, p>0.05). Tumoral $SUV_{max}$ on TSPO-PET was still significantly associated with overall survival when performing multivariate survival analysis (p=0.023). The hazard ratio for death in cases with a $SUV_{max} > 2.2$ was 2.212 (95% CI, 1.115-4.386). ***Conclusion:*** In patients with newly-diagnosed glioblastoma, a high tumoral TSPO-radioligand uptake on PET prior to radiotherapy is associated with significantly shorter survival. TSPO-PET seems to add prognostic insights in glioblastoma beyond established clinical parameters.

## OP-589

### Imaging PD-L1 in the brain - journey from the lab to the clinic

***G. Kramer-Marek***[1,2], *D. Dar*[1], *M. Rodak*[2], *C. Da Pieve*[1], *M. Niedbala*[3], *G. Sharma*[1], *I. Gorczewska*[2], *P. Bzowski*[2], *A. d'Amico*[2], *E. Chmielik*[2], *B. Bobek-Bilewicz*[2], *E. Nowicka*[2], *R. Tarnawski*[2], *W. Kaspera*[3];
[1]*The Institute of Cancer Research, London, UNITED KINGDOM,* [2]*Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice, POLAND,* [3]*Medical University of Silesia, Katowice, POLAND.*

***Aim/Introduction:*** Patients with glioblastoma (GBM) eventually relapse, mainly due to a relatively immune-depleted ("cold") tumour microenvironment. High levels of programmed death ligand-1 (PD-L1) have been associated with GBM invasiveness and immuno-resistance. Presently, there is no standardised assessment of PD-L1 expression level that would help in predicting the response to immune checkpoint inhibitors. To fulfil this exigency, we investigated the suitability of $^{89}$Zr-radiolabelled Atezolizumab (anti-PD-L1 mAb) to measure the expression of PD-L1 in xenograft and syngeneic mouse models and patients with GBM. ***Materials and Methods:*** The immunoreactivity, binding affinity, and specificity of $^{89}$Zr-DFO-Atezolizumab were assessed in vitro using GBM cell lines with different PD-L1 expression levels. Mice with human and murine orthotopic GBM tumours were injected with ~2 MBq (110 µg) of the radioconjugate and PET/CT images were acquired 24, 48 and 72 h post-injection. Biodistribution studies, IHC staining of brain sections and immunophenotyping of tumour samples using flow cytometry (FC) were performed. GBM patients (n=6) enrolled in the clinical trial (NCT05235737), with and w/o neoadjuvant pembrolizumab treatment, received ~37 MBq of $^{89}$Zr-DFO-Atezolizumab (1 mg) together with unlabelled antibody (10 mg) and underwent PET/CT scans 48 and 72 h post-injection. Following the surgery, the tumour samples were collected for IHC and FC analysis. $^{89}$Zr-DFO-Atezolizumab uptake was measured in the VOIs placed in the tumour mass and normal tissues. The data, expressed as the standardised uptake value ($SUV_{max}$/$SUV_{mean}$/$SUV_{peak}$) were correlated with PD-L1 IHC staining and tumour lymphocytes infiltration. ***Results:*** Atezolizumab was radiolabelled with high radiochemical yield (RCY=88-92%) and purity (RCP>98%). The cell-associated radioactivity in vitro corroborated PD-L1 expression levels assessed by FC. $^{89}$Zr-DFO-Atezolizumab specifically recognised PD-L1 expressing brain tumours in vivo providing high contrast images at 24 and 48 h post-injection. Patients experienced no $^{89}$Zr-DFO-Atezolizumab-related side effects. High radioconjugate accumulation was observed in the vital part of the tumours 48 h post-administration. However, the radioconjugate uptake varied between the patient's with and w/o neoadjuvant pembrolizumab ($SUV_{max}$: 3.4 vs 6.9). In normal tissues, uptake was seen in the spleen, liver, and intestines. The radioconjugate tumour targeting was associated with PD-L1 expression assessed by IHC and was consistent with an increased T-cell infiltration. ***Conclusion:*** $^{89}$Zr-DFO-Atezolizumab detects with high specificity different expression levels of PD-L1 in the preclinical GBM models and patients with newly diagnosed GBM. It also provides complementary tumour-specific and/or immune-specific information to ex vivo methods.

## OP-590

### Profiling Functional Clusters of Short Chain Fatty Acids Metabolism in Primary Brain Gliomas for Phenotype Prediction

***M. Inglese***[1,2], *T. Boccato*[1], *M. Ferrante*[1], *S. Islam*[2], *M. Williams*[2], *A. D. Waldman*[3], *K. O'Neill*[4], *E. O. Aboagye*[2], *N. Toschi*[1,5];
[1]*University of Rome "Tor Vergata", Rome, ITALY,* [2]*Imperial College London, London, UNITED KINGDOM,* [3]*University of Edinburgh, Edinburgh, UNITED KINGDOM,* [4]*Imperial College Healthcare NHS Trust, London, UNITED KINGDOM,* [5]*Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Glioblastoma multiforme (GBM) genetic profiling significantly influences diagnosis, therapy, and patient survival. The primary GBM biomarker is isocitrate dehydrogenase (IDH), with IDH mutations(mu) associated with markedly improved survival compared to the wild-type(wt)[1]. Pathological sampling, the gold standard for GBM diagnosis, poses risks due to spatial heterogeneity and variable genetic expression. Additionally, technical limitations hinder IDH mutation pathological testing, necessitating non-invasive diagnostic techniques to supplement pathologic data[2]. However, IDH mutation currently lacks a distinct radiologic signature[3]. This study aims to classify GBMs' genetic profiles using 18F-fluoropivalate(FPIA) PET tracer kinetics, targeting brain gliomas' specific mechanism involving short-chain fatty acid(SCFA) oxidation for energy production and proliferation4,5. ***Materials and Methods:*** Ten primary brain glioma patients(5 IDH1mu, 5 IDHwt) were recruited. $^{18}$F-FPIA PET/MR images were obtained using a Signa PET/MR scanner. For each patient, an average of 25202(±14337) time activity curves(TACs) were extracted voxelwise from dynamic PET data using a lesion mask generated manually by an expert radiologist. A K-means clustering approach for time series grouped standardized TACs into k=4 clusters (k defined by optimizing distortion score using the elbow method), generating four lesion subregions (DynamicFPIA_clustering). For each patient and subregion, the percentage of voxels and average MRI-derived diffusion/perfusion parameters were assessed for classification. A support vector machine(SVM) model was trained on in a 5-fold nested cross validation fashion, which comprised hyperparameter optimization(inner loop) and perforamnce quantification (outer loop). This approach was compared to two others: one using parameters evaluated in subregions defined by clustering SUV voxels (StaticFPIA_clustering), and another assessing average MRI parameter values across the entire lesion(standard approach). ***Results:*** The DynamicFPIA_clustering approach classified GBM phenotypes with 80%(±20) accuracy (AUC=0.8±0.2), with the 3rd subregion's percentage dimension and the 2nd subregion's CBF as the most significant features. Accuracy decreased to 70%(±24) (AUC=0.7±0.2) using StaticFPIA_clustering and 60%(±37) (AUC=0.6±0.4) with the standard approach without subregions. Average and standard deviation evaluated across outer folds. ***Conclusion:*** This study leverages the inherent spatial heterogeneity of GBMs, which significantly affects biopsy, diagnosis, and survival outcomes, to non-invasively identify four distinct profiles of SCFA kinetics. By combining these profiles with MRI-derived parameters, our approach classifies GBM phenotypes with 80% accuracy. The findings demonstrate the potential of integrating dynamic FPIA PET/MR imaging with machine learning techniques as a valuable, non-invasive diagnostic tool. Moreover, this innovative method could contribute to more accurate and personalized treatment strategies for GBM patients, minimizing the risks associated with invasive biopsies. ***References:*** 1.Wang,doi: 10.1016/j.gde.2014.12.002.2.Pasquini,doi: 10.3390/jpm11040290.3.Johnson,doi: 10.1148/rg.2017170037.4.Kant,doi: 10.1038/s41419-020-2449-5.5.Mashimo,doi: 10.1016/j.cell.2014.11.025

### Development of deep learning model for generalized utilization to restore short-scanning PET images using three radiopharmaceuticals

***Y. Jeong***[1], *S. Cheon*[1], *H. Park*[2], *K. Jeon*[2];
[1]*Dong-A University Hospital, Busan, KOREA, REPUBLIC OF,* [2]*National Institute for Mathematical Science, Daejeon, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** We proposed a deep learning (DL) model that restores 2-minute amyloid positron emission tomography (PET) images as 20-minute standard images and recently developed this model to be commonly applicable to amyloid PET images using three radiopharmaceuticals. The performance of the DL model commonly applicable to three radiopharmaceuticals for amyloid PET was evaluated. ***Materials and Methods:*** We enrolled a total of 873 F-18 florbetaben (FBB), 415 F-18 flutemetamol (FMM), and 208 F-18 florapronol (FPN) PET images of our hospital. These PET images were divided into training, internal validation, and temporal validation sets as follows: 734,119, and 20 for FBB-PET, 365, 30, and 20 for FMT-PET, and 173, 15, and 20 for FPN-PET, respectively. For all PET images, 20-minute images were used as ground truth images, and the first 2-minute images among 20-minute data were used

as short-scanning images. Using our DL network, we generated a 20-minute PET-like image from a 2-minute PET image. We verified our model by measuring peak signal-to-noise ratio (PSNR), structural similarity (SSIM), and root-mean-square error (RMSE). We also compared these quantified results with other DL models. ***Results:*** In internal and temporal validation datasets, our DL model showed better performance than the existing models in restoring short-scanning PET images. (Table 1, 2). In addition, it was confirmed that the performance of our DL model was commonly stable for various types of amyloid PET images obtained with three radiopharmaceuticals. ***Conclusion:*** It was confirmed that our image restoration DL model could be applied to all amyloid PET images using three different radiopharmaceuticals and that the image quality is well maintained. The proposed method using domain labels for short-scanning amyloid PET image restoration can be a promising approach to overcoming the challenges of multi-domain learning in PET imaging. ***References:*** Jeong YJ, Park HS, Jeong JE, Yoon HJ, Jeon K, Cho K, Kang DY. Restoration of amyloid PET images obtained with short-time data using a generative adversarial networks framework. Sci Rep. 2021 Mar 1;11(1):4825.

## EPS-169

### Deep-learning based classification of dual-phase 18F-FP-CIT PET images for the diagnosis of Parkinsonism

***D. Kim***[1], *K. Choo*[1], *D. Kim*[2], *H. Lim*[2], *M. Yun*[2];
[1]*Yonsei University, Seoul, KOREA, REPUBLIC OF,* [2]*Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** With new cases of Parkinsonism being reported at an accelerating rate, physicians are under pressure to study tens of PET images a day. To alleviate this burden, this study aims to develop a deep-learning based framework that helps with the analysis of dual-phase 18F-FP-CIT PET images to detect persons with normal condition (NC), idiopathic Parkinson's disease (IPD), progressive supranuclear palsy (PSP), and multiple system atrophy (MSA). ***Materials and Methods:*** This retrospective study involved 388 cases collected internally from 2015 to 2022. Labels were assigned on the consensus of two experts, one nuclear medicine physician and one clinician. The data were split into train, validation, and test set by the ratio 8:1:1 to assess the effects of model architecture, regularization, and dual-phase imaging. Candidate models were then selected based on F1 score and accuracy, upon which 5-fold cross validation was performed. Finally, the performance of each of the five models was compared with their ensemble. The best-performing ensemble model has been prospectively examined for one month on 76 cases. ***Results:*** DenseNet, EfficientNet, and a custom convolutional neural network are chosen as candidate architectures, among which the custom CNN showed best performance (F1 score, accuracy: 0.90, 0.90) in single model. Regularization on the custom CNN improved its accuracy to 0.92. However, when trained only on each of delay-phase and early-phase images, the custom CNN's F1 score and accuracy dropped to 0.62, 0.77 and 0.83, 0.82 respectively. Among the candidates, DenseNet showed best performance in 5-fold cross-validation, with an average F1 score of 0.90 (std 0.05) and an average accuracy of 0.92 (std 0.04). In ensemble, the F1 score and the accuracy improved to 0.94 and 0.95. This ensemble model yielded a F1 score of 0.71 and an accuracy of 0.92 during the prospective study. ***Conclusion:*** Convolutional neural network has shown to be capable of classifying 18F-FP-CIT PET images at the level of a skilled nuclear medicine physician. Further research may explore the possibility of performing classification on data from different PET devices.

## EPS-170

### Feasibility of transfer learning in decoding hibernating myocardium from rest myocardial perfusion images

***B. Khangembam****, J. Jaleel, A. Roy, P. Gupta, C. Patel;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** To assess the feasibility of a transfer learning approach to automatically predict hibernating myocardium from rest myocardial perfusion imaging (MPI). ***Materials and Methods:*** Data of patients who underwent 99mTc-sestamibi MPI and 18F-FDG cardiac PET/CT for myocardial viability assessment from January 2017 to September 2022 were assessed. Replicable and stratified data sampling allocated 70% (146) of the dataset to the training set and the remaining 30% (62) to the testing set. The gold standard for defining hibernating myocardium was the presence of mismatched perfusion-metabolism defect with impaired myocardial contractility at rest. Rest MPI data were processed on ECToolbox and polar maps were saved using NFile PMap tool. Image embedding was implemented on the polar map images using VGG-16, a 16-layer deep neural network model trained on the ImageNet dataset. Image features in the vector space were ranked by Gini Index scoring method. The 17 best-ranked features were selected for training the machine learning (ML) algorithms. 13 supervised ML algorithms were trained with 10-fold stratified cross-validation on the training set with hyperparameter optimization to yield optimal performance. The trained ML algorithms with a LogLoss of <0.693 were then tested on the testing set. Various performance matrices of the algorithms were assessed including area under the curve (AUC), classification accuracy (CA), F1 score, precision, recall, and specificity. ***Results:*** A total of 208 patients (186 males; mean age 56 ± 11 years) were enrolled in the study. Among the 13 ML algorithms, Naive Bayes and Decision Tree had a LogLoss of >0.693 in the cross-validation step while 9 ML algorithms had AUC >0.800. These were Gradient Boosting (scikit-learn), Stochastic Gradient Descent (SGD), Support Vector Machine (SVM), Gradient Boosting (xgboost), Logistic Regression (LR), Neural Network (NN), Random Forest (RF), Gradient Boosting (catboost), and Gradient Boosting Random Forest (xgboost). On testing, 8 ML algorithms had AUC >0.750 which included k-Nearest Neighbours (kNN) and all the above algorithms with the exception of SGD and LR. Gradient Boosting (xgboost) and Gradient Boosting (catboost) were the most optimal models (AUC 0.813 and 0.803 respectively) with similar F1 Score (0.762), precision (0.750), specificity (0.742) and could decode hibernating myocardium in 24/31 (77.4%) patients with an overall CA of 75.8% (47/62). ***Conclusion:*** Machine learning using a transfer learning approach can decode the presence of hibernating myocardium from rest myocardial perfusion images. Gradient Boosting (xgboost) and Gradient Boosting (catboost) were the most consistent and optimal models for the purpose.

## EPS-171

### Synthetic Attenuation Correction Maps for SPECT Imaging using Deep Learning: A Study on Myocardial Perfusion Imaging

***M. Namías***[1], *M. A. Prieto Canalejo*[2], *A. Palau San Pedro*[1], *R. Geronazzo*[1], *D. M. Minsky*[3], *L. E. Juarez Orozco*[4];
[1]*Fundación Centro Diagnóstico Nuclear, Buenos Aires, ARGENTINA,* [2]*Universidad Tecnológica Nacional, Facultad Regional Buenos Aires, Buenos Aires, ARGENTINA,* [3]*Comisión Nacional de Energía Atómica, San Martín, ARGENTINA,* [4]*University Medical Center Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** CT-based attenuation correction of SPECT images is essential for obtaining quantitative images of the activity concentration inside the human body. However, there are many SPECT systems that do not have an associated CT scanner. Performing additional CT scans also implies larger radiation doses for patients. The objective of this work is to estimate linear attenuation coefficient maps from SPECT emission images reconstructed without attenuation correction, using deep learning methods. ***Materials and Methods:*** 398 myocardial perfusion studies with $^{99m}$Tc-sestamibi SPECT were included. A deep convolutional neural network (DCNN) based on a 2D U-Net architecture was trained using information from 312 patients. The quality of the synthetic attenuation correction maps (ACM) and reconstructed emission values was evaluated using three metrics and compared to standard of care data using Bland-Altman plots. Finally, a quantitative evaluation of myocardial uptake was performed, followed by semi-quantitative evaluation of myocardial perfusion (summed stress score) using the Emory Cardiac Toolbox. ***Results:*** For 66 test patients, the ACM quality metrics were: MSSIM = 0.97 ± 0.001 and NMAE = 3.08 ± 1.26 (%), and the reconstructed emission quality metrics were MSSIM = 0.99 ± 0.003 and NMAE = 0.23 ± 0.13 (%). The 95% limits of agreement (LoA) at the voxel level for reconstructed SPECT images were: [-9.04; 9.00] %, and for the segment level were [-11; 10] %. The 95% LoA for the Summed Stress Score values between images reconstructed were [-2.8, 3.0]. When the global perfusion scores were assessed, it was observed that 2 out of 66 patients showed changes in categories. The 95% LoA for percent myocardium abnormal were [-4.2, 4.4]%. ***Conclusion:*** We implemented a generative deep learning model to estimate attenuation correction maps from non-attenuation corrected SPECT images. This method can produce high-quality attenuation maps suitable for attenuation correction in myocardial perfusion SPECT imaging.

## EPS-172

### Human vs Machine: Comparison of manual and deep learning semantic segmentation algorithm generated tumour volumes on [177Lu]Lu-PSMA-617 post therapy SPECT/CT images

***R. Karri***, *P. Jackson, L. McInstosh, J. P. Buteau, G. Kong, T. Akhurst, A. S. Ravi Kumar, D. G. Murphy, S. Sandhu, M. S. Hofman; Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** [177Lu]Lu-PSMA-617 is a new life-prolonging treatment in patients with metastatic castrate-resistant prostate cancer following at least one line of chemotherapy and androgen receptor pathway inhibitors. Post therapy imaging can provide information on biodistribution and tumour response to treatment. Tumour volume and intensity of PSMA uptake on the post therapy SPECT/CT images (potential prognostic biomarkers) can be estimated with advanced image processing. This is a time consuming manual process and not all centres have software to facilitate. We compared the accuracy and agreement of manually contoured and AI generated tumour volumes on the post therapy SPECT/CT images ***Materials and Methods:*** Post-therapy quantitative SPECT CT images 24 hrs post administration of cycle 1 of [177Lu]Lu-PSMA-617 in a 50 patient single-centre phase II study were analysed[1,2]. Manual contouring of tumour excluding any physiologic uptake was performed using a standardised uptake value (SUV) threshold of 3. Molecular Tumour Volume (MTV), SUVmax and SUVmean were recorded. Contours were also generated using a novel semantic deep learning segmentation workflow called Global Threshold Regional Consensus Network (GTRC-Net). The similarity of the parameters using the two techniques was estimated using dice scores and Pearson's correlation. Bland Altman analysis were also performed. ***Results:*** The mean dice coefficient for the MTV was 0.965. The Pearson correlation was 0.99 for TTB, SUVmax and SUVmean. Bland Altman analysis demonstrated bias between the two techniques of 35.61 ± 338.8 for MTV, 0.07±0.64 for SUVmax and 0.04±0.64 for SUVmean. The plot shows excellent agreement between both techniques with few outliers. A difference in contours of more than 100ml was noted in 9 scans. These were due to incorrect contouring by expert in 2 and false positive or false negative contours by AI in 7 scans. False positive contours by AI were predominantly in the bowel loops, lacrimal / salivary glands while false negatives were in proximity to kidney and in the liver. Processing time of the tumour contour by the AI workflow is about a minute per scan. ***Conclusion:*** The novel deep-learning enabled algorithm has excellent agreement in delineating tumour burden on post therapy SPECT/CT images; potentially permitting large-scale clinical use. Further work is required to define the role of SPECT-based quantitative parameters as predictive or prognostic biomarkers. ***References:*** Lancet Oncology. Jun;19(60) 2018:825-833. J Nucl Med. 2020 Jun;61(6):857-865.

## EPS-173

### Primary tumour type impacts 3D U-Net for [$^{18}$F]FDG PET lesion segmentation performance in cases of lung cancer, melanoma, and lymphoma

***M. Sobral***[1,2], *M. Oliveira*[1,3], *C. Constantino*[1], *F. Oliveira*[1], *N. Matela*[4], *D. C Costa*[1];
[1]*Champalimaud Foundation, Lisboa, PORTUGAL,* [2]*Departamento de Física, Faculdade de Ciências, Universidade de Lisboa, Lisboa, PORTUGAL,* [3]*Escola Superior de Biotecnologia, Universidade Católica Portuguesa, Porto, PORTUGAL,* [4]*Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisboa, PORTUGAL.*

***Aim/Introduction:*** We aim to evaluate the importance of the type of primary tumour used to train a deep learning network to segment different types of tumours. ***Materials and Methods:*** This study includes 432 whole-body [$^{18}$F]FDG PET images and corresponding manual tumour segmentations, from the MICCAI AutoPET Challenge [1-3]. There are three cohorts: 144 images of lung cancer, 144 of melanoma, and 144 of lymphoma. Each cohort was divided into 114 images for training, 15 for internal validation, and 15 for testing. All images and segmentations were resampled to isotropic voxels of 4×4×4 mm$^3$. A 3D U-Net with a depth of 4 convolutional blocks, and a patch size of 128×128×128 voxels was chosen for the deep learning-based segmentation. The optimal weights were obtained by minimising the generalised Dice loss while using the Adam optimiser, over 600 epochs. Therefore, 3 networks were trained, one for each cohort. Each network was applied to the three test sets and the Dice similarity coefficient (DSC) was calculated, using the manual segmentations as gold standard. The Wilcoxon signed-rank test was used for statistical inference. P-values were adjusted for multiple comparisons using the Bonferroni method. ***Results:*** The segmentations of the test set from lymphoma patients achieved median DSC of 0.43, 0.57, and 0.68 when using the networks trained with the lung, melanoma, and lymphoma patients, respectively. The network trained with the lymphoma patients had significantly higher DSC values when compared to the others ($p_{adj}$<0.05). The median DSC regarding the segmentation of the lung cancer patients' test set were 0.79, 0.64, and 0.54 using the networks trained with lung cancer, melanoma, and lymphoma patients, respectively. When comparing the DSC

values, the network trained with lung cancer patients originated statistically higher values than the others ($p_{adj}$<0.01). The median DSC obtained from the melanoma test dataset were 0.45, 0.64, and 0.41, for the networks trained with lung cancer, melanoma, and lymphoma patients, respectively, without statistically significant difference between them ($p_{adj}$>0.05). ***Conclusion:*** Tumour segmentation of [$^{18}$F]FDG PET images using the 3D U-Net should be trained with images from patients with the same tumour type as per case under evaluation. This seems to be more important in the cases of lung cancer and lymphoma than melanoma. ***References:*** [1] Gatidis et al. (2022), The Cancer Imaging Archive. ### A systemic analysis of [18F]FDG PET/CT data for early detection of cachexia in lung cancer patients

***D. Ferrara***[1], *A. Frille*[2], *E. Abenavoli*[3], *T. Beyer*[1], *S. Duke*[4], *S. Gruenert*[5], *M. Hacker*[5], *S. Hesse*[2], *L. Hofmann*[2], *S. Holm*[4], *M. Rullmann*[2], *R. Sciagrà*[3], *L. Shiyam Sundar*[1], *A. Tönjes*[2], *H. Wirtz*[2], *J. Yu*[1,5], *O. Sabri*[2];
[1]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*University Hospital of Leipzig, Leipzig, GERMANY,* [3]*Division of Nuclear Medicine, Azienda Ospedaliero Universitaria Careggi, Florence, ITALY,* [4]*University of Copenhagen, Copenhagen, DENMARK,* [5]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Cancer-associated-cachexia (CAC) substantially decreases quality of life and survival of cancer patients, especially those with lung cancer. Early detection of CAC can aid in identifying lung cancer patients (LCP) requiring increased multi-professional clinical support at the time of LC diagnosis and treatment planning. Using a multi-organ analysis, we sought to extract distinct "metabolic fingerprints" from [18F] FDG-PET images of LCP who subsequently developed CAC. ***Materials and Methods:*** A retrospective cohort included LCP (N=209, 59F/150M) who underwent [18F]FDG-PET/CT imaging for initial clinical staging. The body mass index (BMI)-adjusted weight loss (WL) grading system (WLGS) helped stratify LCP into two metabolic phenotypes: a non-cachectic (WLGS-0: N=121, 32F/89M, 68±9 years) and a cachectic (WLGS-3-4: N=88, 27F/61M, 62±12 years). Abdominal organs, muscles, subcutaneous and visceral adipose tissue were segmented automatically from PET/CT data [1]. Standardized-uptake-values normalized to lean body mass ($SUV_{lbm}$) and organ volumes were extracted from each segmented organ and their averages reported across both cohorts. A multi-organ network analysis was conducted to study inter-organ connectivities using Spearman correlations. Significant (p<0.05) correlations were visualized in a chord plot for both WLGS-0 and WLGS-3-4 groups. The individual organ degree of centrality (i.e., the number of inter-organ connections) was investigated. A machine-learning model was trained to classify the LCP in WLGS-0 or WLGS-3-4 respectively. Techniques of explainable artificial-intelligence (AI: feature importance plots and SHAP analysis) were employed to identify the parameters that primarily contributed to disease development for each patient. ***Results:*** $SUV_{lbm}$ of visceral and subcutaneous adipose tissue were higher in patients with WLGS-3-4 than in WLGS-0. Corresponding volumes were smaller in the WLGS-3-4 cohort than in the WLGS-0 cohort. The multi-parametric correlation analysis revealed a lower degree of centrality for gluteus muscle $SUV_{lbm}$ and fat volumes in WLGS-3-4. Machine-learning based classification into cachectic and non-cachectic phenotypes was 88% accurate. Feature importance plots and SHAP analysis identified volumes of fat segmentations and $SUV_{lbm}$ of gluteus regions as the parameters that mainly influenced the prediction. ***Conclusion:*** The multi-organ networks in LCP were distinct for patients without (WLGS-0) and with (WLGS-3-4) cachexia phenotype. The inter-organ analysis highlighted differences in adipose tissue and gluteus connectivity profiles between the two clinical phenotypes. Explainable AI helps extract a "metabolic fingerprint" for LCP at risk of developing CAC. ***References:*** [1] L. K. Shiyam Sundar et al. ### Comparison of a deep learning model to denoise low dose 18F-FDG PET images trained using synthetic image versus acquired low dose images

***L. Sibille****, R. Chamberlain;*
*Subtle Medical, Menlo Park, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Recently, deep learning techniques have emerged as a promising solution for enhancing low photon count image quality, thus facilitating faster acquisitions. State of the art methods to denoise low dose 18F-FDG PET images rely on a large number of paired images (low dose, full dose) which are difficult and expensive to collect. This study investigated the capabilities of a diffusion model to capture the degradation process to generate realistic synthetic low dose PET from a full dose image applied to low dose image denoising. ***Materials and Methods:*** A 2.5D Convolutional Neural Network was trained to denoise synthetic low dose images (sCNN) and compared against an identically trained network using the acquired low dose images (rCNN). Synthetic low dose images were generated from a full dose image using a conditional diffusion probabilistic model (cDDPM) trained from pairs of low dose (50%, 25%, 10%, 5% and 1% of dose) and full dose images. Additionally, the cDDPM used an extra embedding based on scanner manufacturer and dose level to control the generative process. Evaluation was performed using acquired low dose image. Regions suspicious for cancer were manually delineated using 41% of SUVmax and manually adjusted if necessary. SUVmax and SUVmean quantification was performed on these regions. ***Results:*** 192 patients were retrospectively used to train (N=160) the the cDDPM, sCNN and rCNN and evaluated (N=32) on an independent dataset. The mean difference of SUVmax quantification between synthetic and acquired images was not significant (P>0.93) and similarly for SUVmean (P>0.12). L1 (sCNN=0.140, rCNN=0.120) and SSIM (sCNN=0.985, rCNN=0.987) were comparable. SUVmax error (sCNN=0.149, rCNN=0.176) and SUVmean error (sCNN=0.130, rCNN=0.151) were lower for the CNN trained using synthetic images. ***Conclusion:*** cDDPM was found to be a promising approach to generate realistic synthetic images to be used for low count image denoising. Our results indicate training a PET denoising model using synthesize low dose data could improve the quantitative accuracy the denoised images.

## EPS-176

### Multi-tracer Deep Learning-based Time-of-Flight (DL-ToF) Image Enhancement of non-TOF PET Scans

***A. Mehranian***[1], *S. Wollenweber*[2], *K. Bradley*[3], *M. Walker*[4], *K. Su*[2], *R. Johnsen*[2], *F. Jansen*[2], *D. McGowan*[4,5];
[1]*GE HealthCare, Oxford, UNITED KINGDOM,* [2]*GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA,* [3]*Wales Research and Diagnostic PET Imaging Centre, University Hospital of Wales, Cardiff, UNITED KINGDOM,* [4]*Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM,* [5]*Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.*

***Aim/Introduction:*** To evaluate the generalizability of a deep learning time-of-flight (DL-ToF) model trained using fluorodeoxyglucose (FDG) and non-FDG PET images in order to provide ToF like image quality for multi-tracer non-ToF PET scans ***Materials and Methods:*** A multi-tracer DL-ToF model was trained using 315 (289 training, 26 validation) whole-body PET exams scanned on GE Discovery MI (DMI) ToF (3-5 ring) scanners from eleven different sites (US, Europe and Asia). The training and validation pairs consisted of ToF (target) and non-ToF (input) Q-Clear reconstructions using site-preferred regularisation parameters (beta values). The tracer distribution of training and validation pairs was 74% FDG and 26% with four different non-FDG tracers (68Ga-PSMA, 68Ga-Dotatate, 18F-Fluciclovine and 18F-Fluorine). A total of 25 FDG and 7 non-FDG whole-body DMI exams were selected for quantitative analysis based on standardised uptake value (SUV) in selected regions of interest (ROI). A subset of 15 exams (8 FDG and 7 non-FDG) were further selected for blinded clinical readings based on diagnostic confidence, lesion detectability and image noise/quality on a 5-point Likert score ***Results:*** Quantitative analysis of 67 lesions identified on 25 FDG test exams showed that the non-ToF and DL-ToF images resulted in -36±17% and -10±24% difference in SUVmax, respectively, compared to target ToF images. The SUVmean percent difference, averaged over 5 ROIs per organ per exam, were 7±13% and 1±11% for lungs and 5±5% and 0±4% for liver, respectively. For 7 non-FDG test exams (4 different tracers), results for non-TOF and DL-ToF were as follows: SUVmax percent difference for 12 identified lesions of -27±19% and -1±20%, lung SUVmean percent difference of -1±23% and -5±19%, and liver SUVmean percent difference of -5±5% and -0±5%, respectively. Clinical readings of all 15 selected exams were as follows: ToF, non-ToF and DL-ToF scored 4.6±0.6, 3.3±0.6 and 4.9±0.3 for diagnostic confidence, 4.9±0.5, 3.3±0.6 and 4.9±0.4 for lesion detectability and 3.8±0.7, 4.4±0.8 and 4.4±0.6 for image noise/quality metrics, respectively. Additionally, DL-ToF showed the reduction of photopenic areas caused by attenuation mismatch artefacts similar to ToF reconstruction method ***Conclusion:*** This study demonstrated that the DL-ToF model developed is generalizable to both FDG and non-FDG tracers and could be utilized for BGO-based PET scanners to provide ToF like image quality. This work will be extended by including multi-tracer exams from GE Discovery IQ and OMNI Legend PET/CT scanners and more readers

## EPS-177

### Deep learning based missing data retrieval of small animal PET using a conditional GAN (Pix2Pix)

***Z. Karimi***[1], *A. Ghafari*[2], *M. Farahani*[2], *P. Sheikhzadeh*[3], *M. Ay*[2]; [1]*Faculty of Physics, University of Isfahan, Isfahan, IRAN, ISLAMIC REPUBLIC OF,* [2]*Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment Institute (AMTEI), Tehran University of Medical Sciences (TUMS), Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The Pix2Pix conditional generative adversarial network (Pix2Pix cGAN) is used to retrieve and fill missing data in preclinical PET sinograms caused by inter-block gap. Missing areas in sinogram domains can cause distortions in the resulting reconstructed image and can lead to errors in quantitative data analysis. ***Materials and Methods:*** The Pix2Pix cGAN model was trained on a total of 4700 2D PET sinograms with gaps from the real moused scanned by animal PET scanner. The sinograms filled with interpolation method were modified as target. The artificial gaps were applied on the target sinograms with different width (3 - 4 - 5 pixels) similar to original gaps pattern. These artificial gaps were also located at different places except the interpolation areas as input of the network and tested on a separate set of 300 original sinograms. The quality of the generated sinograms was quantitatively assessed using normalized mean square error (NMSE) and structural similarity index (SSIM) metrics. ***Results:*** The SSIM and NMSE of the generated sinograms from the model trained was 0.99 ± 0.000024 and 0.0026 ± 0.000082 considering the corresponding interpolated sinograms as target, respectively. So, the predicted sinograms demonstrated improvements quantitatively compared to input sinograms. This approach can recover missing data in sinograms prior to reconstruction which indicates more accuracy and consistency than the conventional interpolation method. ***Conclusion:*** This proposed approach can retrieve the missing data present in the sinograms by learning a mapping derived from the whole sinogram compared to the adjacent pixels used in the conventional interpolation method used. ***References:*** Shiri, I., Sheikhzadeh, P., & Ay, M. R. (2019). Deep-fill: Deep learning based sinogram domain gap filling in positron emission tomography. arXiv preprint arXiv:1906.07168.

### Enhanced characterization of functionally significant coronary lesions using machine learning techniques with radiomics-based analysis

***G. Kalykakis***[1,2], *F. V. Driest*[3], *A. Broersen*[4], *D. Terentes-Printzios*[5], *A. Antonopoulos*[5], *N. Anousakis Vlachichristou*[1], *R. Liga*[6], *D. Visvikis*[7], *A. Scholte*[8], *J. Knuuti*[9], *D. Neglia*[10], *C. D. Anagnostopoulos*[1]; [1]*Biomedical Research Foundation Academy of Athens, Athens, GREECE,* [2]*Ionio University, Corfu, GREECE,* [3]*Leiden University Medical Center, Department of Cardiology, Leiden, NETHERLANDS,* [4]*University Medical Center, Division of Image Processing, Leiden, NETHERLANDS,* [5]*Hippocration General Hospital of Athens, Athens, GREECE,* [6]*University of Pisa, Pisa, ITALY,* [7]*University of Bretagne Occidentale, Brest, FRANCE,* [8]*Leiden University Medical Center, Leiden, NETHERLANDS,* [9]*Turku University Hospital, Turku, FINLAND,* [10]*Institute of Clinical Physiology, Pisa, ITALY.*

***Aim/Introduction:*** Computed Tomography Coronary Angiography (CTCA) is an effective non-invasive imaging modality for anatomo-functional assessment of coronary artery disease (CAD). Radiomics features have been used for diagnosis or outcome prediction, however, their potential value for characterizing flow limiting coronary lesions has not been explored. The aim of the study is to assess whether application of novel radiomics and machine learning (ML) techniques on CTCA derived datasets improves characterization of functionally significant coronary lesions. ***Materials and Methods:*** Consecutive patients with stable chest pain and intermediate pre-test likelihood for CAD, who underwent CTCA and PET-or SPECT-Myocardial Perfusion Imaging (MPI) respectively, were prospectively evaluated and included in the analysis. PET-MPI was considered abnormal when >1 contiguous segments showed both stress Myocardial Blood Flow ≤ 2.3mL/g/min and Myocardial Flow Reserve (MFR) ≤ 2.5 for 15O-water or < 1.79 mL/g/min and ≤ 2.0 for 13N-ammonia respectively. Defect reversibility (DR) was defined as a summed difference score (SDS) between stress and rest images ≥ 2. CTCA and functional images were fused to assign each myocardial segment to the pertinent coronary territory. Stenosis severity, plaque characteristics and radiomic

plaque features were assessed in the total length of the 3 main coronary vessels. In total, 1765 features were extracted from each vessel and a feature reduction and model creation pipeline was constructed. Two separate datasets: a) coronary stenosis (≥ 50%) + plaque characteristics and b) coronary stenosis (≥ 50%) + plaque characteristics + radiomics were formulated and compared in terms of AUCs accordingly. ***Results:*** The study analyzed 140 vessels having corresponding PET-MPI data and 152 vessels having SPECT MPI data. For PET-MPI, plaque burden and stenosis severity were identified as the only independent predictors of impaired myocardial perfusion, with an area under the curve (AUC) of 0.749 (95% CI: 0.658-0.826). However, when additional radiomics features were combined with stenosis severity, the prediction performance improved significantly, with an AUC of 0.854 (95% CI: 0.775-0.914, p-diff: 0.02, 95% CI: 0.0165-0.194). For SPECT-MPI, stenosis severity was the only predictor of a reversible perfusion defect, with an AUC of 0.624 (95% CI: 0.542-0.702). However, combining additional radiomics features with stenosis severity significantly improved the prediction performance, with an AUC of 0.816 (95% CI: 0.745-0.875, p-diff: 0.006, 95% CI: 0.152-0.329). ***Conclusion:*** Radiomic futures can be combined with anatomical and morphological characteristics of coronary lesions in CTCA imaging and provide valuable complementary information for characterizing functionally significant coronary lesions.

## EPS-179

### Volume dependence and repeatability of $^{99m}$Tc SPECT radiomic parameters

***A. Gemmell***[1,2,3], *C. Brown*[1,2], *S. Ray*[3], *S. Small*[1,2];
[1]*Nuclear Medicine, Gartnavel General Hospital, Glasgow, UNITED KINGDOM,* [2]*Department of Clinical Physics & Bioengineering, Glasgow, UNITED KINGDOM,* [3]*School of Mathematics & Statistics, University of Glasgow, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** Guidelines on radiomics in Nuclear Medicine [1] have recommended that users test for volume dependence and repeatability of radiomic parameters, including proposing the use of a "revolver" phantom, originally applied to PET imaging by Forgacs et al [2]. This study applies a modified version of the suggested methodology to identify reproducible SPECT radiomics parameters using $^{99m}$Tc. ***Materials and Methods:*** A uniform phantom containing 297 MBq of $^{99m}$Tc was imaged and 15 Volumes of Interest (VoI) of increasing size ranging from 0.9 ml to 1021 ml were placed in the reconstructed image. 67 radiomics parameters (IBSI compliant) were calculated and correlated against the VoI size. Due to the poorer resolution of SPECT relative to PET, three "revolver" inserts were tested, each using 7 syringes of 2.5 ml, 5 ml and 10 ml syringes respectively. Each were filled with $^{99m}$Tc in syringe:background concentrations of: 4:1, 8:1 and 16:1. The inserts were placed into a phantom and SPECT imaging performed four consecutive times. VoIs were drawn around the inserts using a $SUV_{max}$ threshold of 2.5 times background. The mean and standard deviation for the 67 parameters was recorded and Coefficient of Variation (CoV) was calculated for comparison to the recommended criteria of CoV <10%. ***Results:*** For volume dependence, 32 features showed convergence above a minimum VoI size of 50 ml. 35 features showed increasing, decreasing or a random distribution with increasing VOI size. 4 parameters exceeded 10% CoV for the "revolver" insert constructed of 2.5 ml syringes, 6 parameters for the 5ml insert and 1 parameter for the 10 ml insert. Parameters in common across the three insert sizes that would be excluded from any future studies are Excess Kurtosis and multiple Grey Level Zone Length Matrix parameters. ***Conclusion:*** The guideline recommendation for phantom studies to assess volume dependence and repeatability of radiomics parameters can be applied to $^{99m}$Tc SPECT imaging and can help to exclude features that will not prove reliable in radiomics patient studies.

### The biological counterpart of radiomics in pancreatic cancer: a preliminary simulation study

***L. Cavinato***[1], *J. Hong*[2], *S. Reinhard*[2], *M. Wartenberg*[2], *F. Ieva*[1,3], *K. Shi*[2];
[1]*Politecnico di Milano, Milano, ITALY,* [2]*University of Bern, Bern, SWITZERLAND,* [3]*Human Technopole, Milan, ITALY.*

***Aim/Introduction:*** Radiomics extracts quantitative features from medical images and use them to predict clinical outcomes. However, to fully realize the potential of radiomics, these features need to be associated with a biological meaning. Linking radiomics features to underlying biological processes is still an open matter, yet crucial to achieve a deeper understanding of disease mechanisms and identify potential biomarkers. In this work, we employ a multidisciplinary approach that integrates radiomics and other fields, to correlate radiomics features with biological characteristics of different tissues affected by pancreatic cancer at different stages. ***Materials and Methods:*** We analysed the histopathological samples (Whole Slide Imaging - WSI) of four patients affected by different stages of pancreatic cancer. Three different markers were used to stain patients' specimens to highlight different biological structures: CD31 antigen (Cluster of Differentiation 31) to marks (micro)vessels; the FAP (Fibroblast Activation Protein) that is usually expressed by stromal cells; the Ki67 antigen that is a marker of active cell proliferation in both normal and tumoral cell populations. We developed and implemented a simulation framework for estimating the spatiotemporal uptake throughout the tissues of the 18F-fluorothymidine tracer ([18F] FLT).The framework consisted of several steps including the creation of the computational domain from CD31 WSI and the implementation of a spatiotemporal model to describe the [18F]FLT uptake via Partial Differential Equations (PDE). From time-varying uptake maps of the tissues, we simulated the dynamic PET imaging and extracted 43 radiomic feature maps describing the tissue texture. Each of these feature maps was correlated with tissue biological characteristics (spatial location of vessel, stroma, and cell density), cell proliferation index and overall tracer uptake, and the overall tracer uptake with carcinoma grade describing tumour aggressiveness. We used Pearson correlation to quantify the relationship between the variables. ***Results:*** The overall uptake was higher in carcinomas with higher grades and lower in slides with no or reduced cancer. GLCM_features_Entropy (0.27), NGTDM_features_Complexity (0.26) and GLCM_features_Homogeneity (0.25) correlated the most with stromal tissue; GLCM_features_AutoCorrelation (0.15), GLSZM_features_LZHGE (0.13) and NGTDM_features_Complexity (0.12) correlated with cell density; GLCM_features_Entropy (0.54) , GLCM_features_Homogeneity (0.53) and GLRLM_features_LRE (0.51) with cells proliferation index. ***Conclusion:*** The proposed framework

represents a sound pipeline for evaluating the biological meaning of radiomics. With a properly extended sample size, this work can provide valuable insights into the biological counterpart of the texture analysis.

## EPS-181

### A machine learning approach based on rest myocardial perfusion image radiomics to detect the presence of hibernating myocardium: a single institutional experience on 239 patients with 371 perfusion defects

***C. Patel***, *B. Khangembam, J. Jaleel, A. Roy, P. Gupta;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** To assess the feasibility of a machine learning (ML) approach using radiomics features of perfusion defects on rest myocardial perfusion imaging (MPI) to detect the presence of hibernating myocardium. ***Materials and Methods:*** Data of patients who underwent 99mTc-sestamibi MPI and 18F-FDG cardiac PET/CT for myocardial viability assessment were retrieved. Rest MPI data were processed on ECToolbox and polar maps were saved using NFile PMap tool. The gold standard for defining hibernating myocardium was the presence of mismatched perfusion-metabolism defect with impaired myocardial contractility at rest. Radiomics analysis was performed on LIFEx-7.3.21. Perfusion defects on the polar maps were delineated with regions of interest (ROIs) after spatial resampling and intensity discretization. Replicable random sampling allocated 80% (257) of the perfusion defects of the patients from January 2017 to September 2022 to the training set and the remaining 20% (64) to the validation set. An independent dataset of perfusion defects from 29 consecutive patients from October 2022 to January 2023 was used as the testing set for model evaluation. A total of 110 first and second-order texture features were extracted for each ROI. After feature normalization and imputation, 26 best-ranked features using Information Gain scoring were selected to train the ML algorithms. 13 ML algorithms were trained with 10-fold stratified cross-validation on the training set and validated on the validation set. The ML algorithms with a Log Loss of <0.688 and <0.672 in the cross-validation and validation steps respectively were evaluated on the testing set. Performance matrices of the algorithms assessed included area under the curve (AUC), classification accuracy (CA), F1 score, precision, recall, and specificity. ***Results:*** In total, 239 patients (214 males; mean age 56 ± 11 years) were enrolled in the study. On cross-validation, 6 ML algorithms had AUC >0.800. These were Support Vector Machine, Gradient Boosting (xgboost), Neural Network (NN), Random Forest (RF), Gradient Boosting (catboost) and Gradient Boosting Random Forest (xgboost). On validation, 5 ML algorithms had AUC >0.800 with RF achieving the highest AUC of 0.842. On model evaluation on the testing set, 7 ML models had AUC >0.800 with NN achieving the highest AUC of 0.877 and could decode hibernating myocardium in 21/29 (72.4%) perfusion defects with a precision of 87.5% (21/24), specificity 85.7% (18/21), CA 78.0% (39/50) and F1 Score 0.792. ***Conclusion:*** Machine learning using radiomics features of perfusion defects on rest myocardial perfusion images can decode the presence of hibernating myocardium.

## EPS-182

### Clinical Evaluation of $^{18}$F-FDG PET Radiomics Stability to Respiratory Motion Using a Data-Driven Respiratory Gating Algorithm

***K. Lue***[1], *K. Kan*[2,3], *Y. Chen*[2,4], *S. Liu*[1,2], *I. Shih*[5], *H. Lin*[6,7];
[1]*Tzu Chi University of Science and Technology, Hualien, TAIWAN,* [2]*Hualien Tzu Chi Hospital, Hualien, TAIWAN,* [3]*Fu Jen Catholic University Hospital, New Taipei City, TAIWAN,* [4]*Tzu Chi University, Hualien, TAIWAN,* [5]*GE HealthCare, Taipei, TAIWAN,* [6]*Chang Gung University, Taoyuan, TAIWAN,* [7]*Keelung Chang Gung Memorial Hospital, Keelung, TAIWAN.*

***Aim/Introduction:*** $^{18}$F-FDG PET-based quantitative features are susceptible to respiratory motion. However, few studies have explored the impact of respiratory motion on $^{18}$F-FDG PET radiomic features using clinical patient data. In this study, we investigated the stability of radiomics features in clinical $^{18}$F-FDG PET images using a data-driven respiratory motion correction technique. ***Materials and Methods:*** Oncological pathologies of 65 patients who underwent whole-body $^{18}$F-FDG PET scans using a digital PET/computed tomography system (Discovery MI, GE Healthcare, Milwaukee, USA) were retrospectively included in this study. A commercially available data-driven gating algorithm combined with a motion-correction technique (MotionFree, GE HealthCare, Milwaukee, USA) was used to extract the PET images with respiratory motion correction. $^{18}$F-FDG-avid lesions from the lower lung to the upper abdomen were analysed using motion-corrected and non-motion-corrected images. The lesions were segmented with a 40% threshold of the maximum standardised uptake value to define the metabolic tumour volume (MTV). A total of 725 radiomic features were computed from the segmented images, including first-order, shape, texture, and wavelet features. The intraclass correlation coefficient (ICC) and coefficient of variation (COV) were calculated to evaluate feature reproducibility and variability. An ICC above 0.9 and a COV below 5% were considered high stability. All images were analysed using the PMOD image processing software version 4.2 (PMOD Technologies Ltd., Zurich, Switzerland). The Pyradiomics software package version 3.0.1 (Harvard Medical School, Boston, USA) was used to compute the radiomic features. Statistical analyses were performed using MedCalc 20.218 (MedCalc Software, Ostend, Belgium). ***Results:*** In total, 133 lesions with and without respiratory motion correction were analysed. The median MTV was 2.60 mL (interquartile range: 1.69-6.28 mL). Our results indicated that $^{18}$F-FDG PET radiomics features are sensitive to respiratory motion. For lesions with MTV larger than 3 mL, 13 radiomic features were very stable, including first-order_entropy, shape_sphericity, grey-level cooccurrence matrix (GLCM) sum entropy, three grey-level run length matrix (GLRLM) features (run_entropy, run_percentage, and short_run_emphasis), and seven wavelet features (first-order_entropy, GLCM_joint_entropy, GLCM_sum_entropy, GLRLM_run_entropy, GLRLM_run_length_nonuniformity_normalized, GLRLM_run_percentage, GLRLM_short_run_emphasis) in the three axes of PET images in low-pass filtering (wavelet-LLL). For all lesions, only six features (GLRLM_run_entropy, shape_sphericity, wavelet-LLL_first-order_entropy, wavelet-LLL_GLCM_joint_entropy, wavelet-LLL_GLCM_sum_entropy, and wavelet-LLL_GLRLM_run_entropy) were highly stable for respiratory motion. ***Conclusion:*** Respiratory motion has a significant impact on $^{18}$F-FDG PET radiomic stability. Several highly stable features were identified that may be potential candidates for machine-learning modelling.

## EPS-183

### Does fdg pet-based radiomics have an added value for prediction of overall survival in non-small cell lung cancer?

***G. Giovacchini***[1], *E. Giovannini*[1], *F. Tutino*[1], *A. Milano*[1], *L. Florimonte*[2], *E. Bonatto*[3], *C. Bareggi*[2], *L. Dellavedova*[4], *A. Castello*[5], *C. Aschele*[1], *M. Castellani*[2], *A. Ciarmiello*[1];
[1]*S. Andrea Hospital, La Spezia, ITALY,* [2]*Fondazione IRCCS Ca' Granda, Milano, ITALY,* [3]*University of Milan, Milano, ITALY,* [4]*ASST Ovest Milanese, Legnano, ITALY,* [5]*IRCCS Ca' Granda, Milano, ITALY.*

***Aim/Introduction:*** Machine-learning and radiomics are promising approaches to improve the clinical management of NSCLC. However, the additive value compared to clinical and standard imaging variables is less investigated. We aimed to assess the prognostic role of combined use of machine-learning and radiomics in NSCLC patients. ***Materials and Methods:*** 320 NSCLC patients underwent PET/CT with FDG. A total of 49 predictors, including 43 textural features extracted from PET studies, and SUVmax, MTV, TLG, TNM stage, age and gender. A least absolute shrinkage and selection operator (LASSO) regression was used to select features with highest predictive value. Overall survival were calculated with Kaplan-Meier curves. ***Results:*** Five variables including one textural feature (NGTDM coarseness), SUVmax and TNM stage (stage II, stage III, stage IV) showed highest predictive value at LASSO regression analysis. These variables were used to create a test model (TNM, SUVmax and NGTDM Coarseness) and a reference model (TNM, SUVmax). The test model did not significantly better predict survival in NSCLC patients than the reference model. ***Conclusion:*** These data indicate that radiomics, as selected and assessed by our study design, should not be used as an additional tool in clinical practice to predict prognosis when tumor stage and SUVmax, as derived by FDG PET, are available

## EPS-184

### Improving Outcome Prediction in Multicentric Data: Novel harmonization and clustering Techniques for Radiomic Feature Analysis

***N. Abdallah***[1], *J. Marion*[2], *C. Tauber*[1], *T. Carlier*[3], *P. Chauvet*[2], *M. Hatt*[4];
[1]*Imaging & Brain, INSERM, Tours, FRANCE,* [2]*LARIS, Angers, FRANCE,* [3]*CRCINA, INSERM, CNRS, Université d'Angers, Université de Nantes, Nantes, FRANCE,* [4]*LaTIM, INSERM, Brest, FRANCE.*

***Aim/Introduction:*** This study aimed at developing a survival analysis pipeline incorporating innovative clustering and harmonization techniques, explicitly addressing the multicentre nature of the data to maximize outcome prediction. ***Materials and Methods:*** We introduced a linear regression (RL) harmonization approach and compared it to ComBat. We also developed two novel methods for training separate models for two sub-populations of the cohort: one based on a latent feature generated from a Partial Least Squares (PLS) Regression model, the other based on clustering according to the feature most correlated with progression-free. IBSI-compliant features were extracted with PyRadiomics, followed by feature selection. Survival analysis employed Random Survival Forest (RSF) and Gradient Boosting (GB), with performance evaluated using the concordance index (C-index). We evaluated our pipeline using the HECKTOR 2021 dataset containing 325 head and neck cancer patients from six clinical centers. FDG PET/CT images with expert-defined GTV masks were provided for Pyradiomics feature extraction. Clinical variables with missing values were imputed using a Logistic Regression Model trained for each variable. ***Results:*** The base model (without clustering) achieved a c-index of 0.64 using the RSF method and our RL harmonization approach on CT features. The c-index increased to 0.69 when combining CT features, PET features, and clinical variables with imputed values. Using PLSRegression clustering, a maximum weighted c-index of 0.70 was reached with ComBat harmonization and the RSF method on concatenated CT and PET features with imputed clinical variables. For the first cluster, the highest c-index of 0.82 was achieved using our RL harmonization approach on PET images concatenated with imputed clinical variables. For the second cluster, the highest c-index was 0.69, utilizing concatenated CT and PET features with imputed clinical variables and ComBat harmonization. We also investigated clustering using features most correlated with time, achieving a maximum weighted c-index of 0.682 based on the c-index of 0.642 (RSF) in cluster 1 and 0.728 in cluster 2. ***Conclusion:*** Relying on models trained specifically on sub-populations of the cohorts automatically determined through clustering improved the overall model, as demonstrated in this study. The base model had a c-index of 0.68, while our novel clustering approaches combined with harmonization achieved a maximum c-index of 0.70. Additionally, we emphasized the importance of using imputed clinical variables for survival analysis, as shown by the increase in c-index from 0.64 to 0.69.

## EPS-185

### [18F]FDG-PET/CT Tumor Spread and Dissemination Measured from the Spleen in Lymphoma: How Predictive of the Outcome?

***K. Girum***[1], *A. Cottereau*[2], *J. Clerc*[2], *L. Vercellino*[3], *O. Casasnovas*[4], *F. Morschhauser*[5], *C. Thieblemont*[6], *I. Buvat*[1];
[1]*LITO laboratory, U1288 Inserm, Institut Curie, University Paris-Saclay, Orsay, FRANCE,* [2]*Department of Nuclear Medicine, Cochin Hospital, AP-HP, Paris Descartes University, Paris, FRANCE,* [3]*Department of Nuclear Medicine, Saint-Louis Hospital, AP-HP, Paris, FRANCE,* [4]*Department of Hematology, University Hospital of Dijon, Dijon, FRANCE,* [5]*Department of Hematology, Claude Huriez hospital, University Lille, EA 7365, Research Group on Injectable Forms and Associated Technologies, Lille, FRANCE,* [6]*Department of Hematology, Saint Louis Hospital, AP-HP, Paris, FRANCE.*

***Aim/Introduction:*** To investigate the predictive value of new baseline [18F]-FDG PET/CT features that characterize how tumor spreads and disseminates in Diffuse Large B-Cell Lymphoma (DLBCL) patients. Assuming the spleen plays a particular role in DLBCL, we assessed whether spleen-based features improved the prediction of progression-free survival (PFS) and overall survival (OS) when combining them with the total metabolic tumor volume (TMTV). ***Materials and Methods:*** This is a retrospective analysis of DLBCL patients from the REMARC (NCT01122472) cohort. Experts delineated lymphoma lesions on the [18F]-FDG PET/CT images, from which the TMTV and recently introduced tumor dissemination features (Dmax (distance between two farthest lesions) and Dbulk (the maximum distance between the largest lesion and another lesion)) were calculated. Artificial intelligence method was used to segment the spleen from the CT images [1]. An image-processing pipeline was developed to check the quality of the spleen segmentation and correct it. The distance between the centroid of the spleen and all other lesions was measured. The standard deviation (SD) of the measured distances was defined as the lesion spread (LS). The maximum distance of a lesion from the spleen for each patient (DLS) was computed. Univariate and multivariate survival analyses were evaluated using Kaplan-Meier estimates and time-dependent receiver-operating-characteristic curves (tdAUC).

***Results:*** 282 patients (mean age ± SD, 68.33 ± 5.42, y; 164 men) were evaluated. LS and DLS were uncorrelated with TMTV (Pearson r<0.23) and moderately correlated with Dmax and Dbulk (r≤0.78). The median values, used as a cut-off value in the Kaplan-Meier survival analysis, were 6.67 and 32.43 cm, respectively. LS and DLS classified patients into two-risk groups significantly for PFS and OS (P<0.001). The hazard ratios (95% confidence interval) for OS were DLS: 19.4 (2.9-90.7), LS: 10.3 (1.6-46.1), TMTV: 17.6 (2.1-82.5), Dmax: 6.4 (1.0-18.7), Dbulk: 7.9 (1.2-28.6), and IPI: 5.9 (1.3-16.3). The tdAUC (95% confidence interval) for OS were DLS: 0.6 (0.6-0.7), LS: 0.6 (0.6-0.7), TMTV: 0.7 (0.6-0.7), Dmax: 0.6 (0.5-0.7), Dbulk: 0.6 (0.5-0.7), and IPI: 0.6 (0.5-0.7). Combining TMTV with LS or DLS can classify the patients into three-risk groups for both OS and PFS significantly (P<0.001). ***Conclusion:*** The two introduced simple LS and DLS PET/CT features characterizing the lesion locations with respect to the spleen are predictive of PFS and OS in DLBCL. Both biomarkers complement TMTV to characterize the disease. Further evaluation on an external cohort and other lymphatic diseases is underway. ***References:*** [1] Wasserthal et al., arxiv, 2022

### Quantitative Analysis of Dual Time Point in FDG PET/CT images

***N. Reshtebar***[1], *S. Hosseini*[1], *A. Rahmim*[2], *p. Sheikhzadeh*[3];
[1]*Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*University of British Columbia, Vancouver, BC, CANADA,* [3]*Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** In single-time-frame whole-body PET/CT, the SUV parameter is commonly utilized for assessment of disease. By contrast, dynamic imaging can provide significant information via extraction of kinetic features and quantitative analysis based on temporal information. We aimed to assess textural features in parametric Patlak $K_i$ images as generated from dual time point images in comparison with $K_i$ from entire data (Standard Patlak ) and SUV images. ***Materials and Methods:*** The XCAT human torso phantom was used to simulate dynamic whole-body FDG PET imaging. Thirty-nine realistic tumors were modeled in lung tissue with various irregularly shaped heterogeneities and varying levels of uptake. Finally, the texture features in parametric $K_i$ (Patlak-DTP) images (at 60-min post injection for early and 90-min post injection for the late scan) in comparison with $K_i$ (Patlak-full) $^{18}$F-FDG WB PET and SUV images were assessed. ***Results:*** Using the 40% threshold segmentation, The average value of MTV in $K_i$ (Standard Patlak ) and $K_i$ (Pat-DTP) images was smaller than (28%) average value of this parameter in SUV images. It was also observed that most mean radiomics features did not significantly differ between $K_i$ (Standard Patlak ) and $K_i$ (Pat-DTP) images, and there was high correlation (>80%) between the evaluated texture features in $K_i$ (Standard Patlak ) and $K_i$ (Pat-DTP) images. ***Conclusion:*** A simulation study was used to assess performance of heterogeneity metrics in parametric $K_i$ (Pat-DTP) images (at 60-min post injection for early and 90-min post injection for the late scan). Quantitative analysis indicated that parametric $K_i$ (Pat-DTP) images may have larger heterogeneity than SUV images. We concluded that parametric $K_i$ (Pat-DTP) images from dual-time-point imaging can be an alternative to more common parametric $K_i$ (Standard Patlak) images, and can provide complementary images with respect to conventional SUV. ***References:*** Kotasidis FA, Tsoumpas C, Rahmim A. ## EPS-188

### Predicting overall survival in non-Hodgkin lymphoma patients using baseline $^{18}$F-FDG PET radiomic features

***T. Husevåg****, A. M. Løndalen, J. Blakkisrud, C. Stokke;*
*Oslo University Hospital, Oslo, NORWAY.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-lilotomab satetraxetan was developed as an anti CD37 radioimmunotherapy and investigated in a phase 1/2a study for relapsed / refractory indolent non-Hodgkin B-cell lymphoma. This study aims to investigate the relationship between radiomic features extracted from tumour volumes in positron emission tomography (PET) images at baseline and the patient outcome, to identify potential imaging biomarkers with prognostic potential. ***Materials and Methods:*** The LYMRIT37-01 activity escalation study included administration of 10-20 MBq per kg of body weight of [$^{177}$Lu]Lu-lilotomab satetraxetan to non-Hodgkin lymphoma patients, with varying pre-treatment and pre-dosing of rituximab and lilotomab, across five study arms. Using 2-[ $^{18}$F]FDG PET-images at baseline from 28 patients, 107 radiomic features (RFs) were extracted following the imaging biomarker standardization initiative [1]. The tumour volumes of interest (VOIs) were segmented by thresholding in the SUV3.0 to SUV4.0 range, with manual corrections for physiological uptake in collaboration with a nuclear medicine physician. First-order, shape-based and texture-features were extracted from a single VOI for each patient. The patients were followed up until 10.4 years post-treatment to assess overall survival (OS). Clinical factors such as age, bodyweight, and gender were also assessed as covariates. An elastic-net regularized cox proportional hazard model was used for predicting overall survival. Using leave-one-out cross-validation with nested 3-fold cross-validation for hyperparameter tuning, the RFs having stable non-zero coefficients were identified and used for prediction. ***Results:*** The median survival for all patients was 6.09 years. Using clinical factors, only age obtained a non-zero model weight with a hazard ratio of 1.043. The model scored a concordance-index (c-index) of 0.578, an integrated brier score (IBS) of 0.207, and a cumulative dynamic area under the receiver operating characteristic (CDAUC) of 0.506. Age and three texture-features were selected, scoring a c-index of 0.736, IBS of 0.170, and CDAUC 0.709. Stratifying the survival data by median predicted risk yielded significantly different survival probabilities under the log-rank test (p=0.039). NGTDM-busyness had the highest hazard rate at 1.370, while GLCM-IMC had the lowest at 0.629. ***Conclusion:*** Radiomic features from 2-[ $^{18}$F]FDG PET images at baseline demonstrated the potential to predict overall survival, with three texture-features identified as stable predictors having complementary information to the baseline age. As the patient cohort is small, there are treatment variations across study arms and subsequent treatments, validation is needed to assess the reproducibility of the results. ***References:*** [1] Zwanenburg et al., "Image biomarker standardisation initiative - feature definitions", Dec. 2016.

**Radio-theragnostics targeting CXCR4 based on the endogenous ligand EPI-X4 for oncological applications**
***R. Gaonkar***[1], *J. Millul*[1], *R. Mansi*[1], *M. Harms*[2], *J. Münch*[2], *M. Fani*[1];
*[1]University Hospital Basel, Basel, SWITZERLAND, [2]Institute of Molecular Virology, Ulm University Medical Center, Ulm, GERMANY.*

***Aim/Introduction:*** The C-X-C chemokine receptor 4 (CXCR4) is highly expressed in various cancers and plays an important role in proliferation and metastasis, while its level of expression is correlated with poor prognosis. Previously we had reported on radiolabeled derivatives (work presented in EANM 2022) from Endogenous Peptide Inhibitor of CXCR4 (EPI-X4), a human serum albumin fragment (1). The derivative $^{68}$Ga-/$^{177}$Lu-JMF-04 (dILRWSRKK($^{68}$Ga-/$^{177}$Lu-DOTA)-$NH_2$) was able to visualize CXCR4 expressing tumors in xenografted mice. However, it had undesirably high kidney uptake and therefore in a follow-up structure optimization study, we developed two optimized derivatives, JMF-10 and JMF-11, reported herein. ***Materials and Methods:*** JMF-10 and JMF-11 were labeled with Lu-177 and compared against the lead $^{177}$Lu-JMF-04. Their hydrophilic nature was assessed via log D values, and the shelf-life was determined at room temperature at 1 up to 24h. SPECT/CT images (200 pmol, 15MBq) and biodistribution studies (200 pmol, 1MBq) were performed in CXCR4-expressing Jurkat T cell xenografts at 1 h post injection (p.i.) followed by performing blocking studies using AMD3100 in high excess. Additionally, in vivo the metabolic stability of $^{177}$Lu-JMF-10 was evaluated in blood, while PET/CT imaging and biodistribution studies were performed with $^{68}$Ga-JMF-10, in a theragnostic approach. ***Results:*** Radiochemical yield of the radioligands was >95% and remained >90% after 4h. At 24h, $^{177}$Lu-JMF-10 showed higher stability than $^{177}$Lu-JMF-11 and $^{177}$Lu-JMF-04 (79±1% vs. 72±2% vs. 66±0%, respectively). $^{177}$Lu-JMF-10 and $^{177}$Lu-JMF-11 displayed similar lipophilicity (log D = -2.99±0.1 and -2.88±0.3, respectively), being higher than that of $^{177}$Lu-JMF-04 (-3.45±0.1). Both, $^{177}$Lu-JMF-10 and $^{177}$Lu-JMF-11 were able to visualize CXCR4-expressing tumors and showed significant reduced accumulation in the kidneys as compared to $^{177}$Lu-JMF-04 in SPECT/CT imaging studies. Biodistribution studies at 1h, revealed a 15-fold reduction in the kidneys for $^{177}$Lu-JMF-10 and $^{177}$Lu-JMF-11 (~5% %IA/g), as compared to $^{177}$Lu-JMF-04 (83±25 %IA/g), without hampering the tumor uptake (1.5-2 %IA/g). $^{177}$Lu-JMF-10 displayed the best tumor-to-background ratios and remained ~50% intact in the blood 30 min p.i. Its $^{68}$Ga-counterpart, $^{68}$Ga-JMF-10, behaved identically to $^{177}$Lu-JMF-10 in the PET/CT imaging and biodistribution studies. ***Conclusion:*** Structural optimization of the endogenous CXCR4 antagonist EPI-X4 led to the identification of new radioligands with significantly improved biodistribution profile and lower unspecific accumulation in non-targeted organs without compromising the tumor uptake. Among the developed derivatives, $^{177}$Lu/$^{68}$Ga-JMF-10 was identified as the best theragnostic pair for CXCR4-expressing malignancies. ***References:*** 1.Zirafi O et al., Cell Reports 11, 737-747, 2015.

***Aim/Introduction:*** Radiolabeling with $^{18}$F/$^{211}$At employs complex radiosynthesis with multi-step purifications. Procedures are typically not quantitative and not compatible with aqueous media. In particular, no easily implementable method exists for employing $^{18}$F/$^{211}$At as a theranostic pair. Last year´s Nobel Prize in chemistry highlighted the promise of click chemistry in addressing such challenges. Unfortunately, conventional click chemistry is too slow to reach completion for micromolar scale reactions. Reaction times of month would be needed. Recently, the tetrazine ligation has been explored as next generation click chemistry with rate constants suitable for quantitative radiolabeling within 5-10 minutes. [1, 2] However, this reaction results in a complex

mixture of isomers which can be an unsurmountable challenge for regulatory approval. [3] Here, we present a new radiolabeling technology, which provides just a single isomeric product from the tetrazine ligation within 20 minutes, without the need for any purification. This methodology holds the promise of labeling any targeting vector with $^{18}$F/$^{211}$At. ***Materials and Methods:*** In order to avoid the formation of multiple isomers, a new trans-cyclooctene (T4CO) was developed. T4CO was synthesized and conjugated to two established vectors; PSMA and octreotate. $^{18}$F/$^{211}$At-tetrazines were synthesized[4, 5] and clicked to the vectors. The procedure was performed at room temperature using micromolar starting amount of the vectors. All $^{18}$F-structures were µPET scanned in naïve and tumor bearing mice. Different linkers were employed to optimize the excretion profile. The lead PSMA analogue was labeled with $^{211}$At and evaluated in ex vivo biodistribution studies. ***Results:*** Radiolabeled tetrazines were clicked quantitively to the T4CO-vectors resulting in ready-to-inject radiopharmaceuticals within 20 minutes. All products were isomerically pure with a RCP ≥ 95%, thus avoiding the need of HPLC purification. $^{18}$F-derivatives demonstrated tumor uptake in vivo. Careful design of the linkers with respect to polarity and overall net charge allowed to steer the excretion profile of these radiopharmaceuticals. Our best $^{18}$F-PSMA targeting ligand showed a comparable tumor and excretion pattern as $^{68}$Ga-PSMA-11/$^{18}$F-PSMA-1007. The $^{211}$At version of our lead showed promising results in ex vivo biodistribution studies in tumor bearing mice indicating that it can be used as a therapeutic. ***Conclusion:*** We have demonstrated that the tetrazine ligation can be used to $^{18}$F/$^{211}$At-labelel any targeting vector. Our platform can produce ready-to-inject radiopharmaceuticals within minutes without the need of purification. ***References:*** 1. BioconjugateChem. 2022, 1393. 2. Bioorg.Med. ## OP-616

### CD83 as a Theranostic Target for Acute Myeloid Leukemia

***K. Ott***[1], *A. J. Robertson*[1], *J. P. Gallant*[1], *K. K. Walton*[2], *B. C. Betts*[2], *A. M. LeBeau*[1];
[1]*The University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*The University of Minnesota, Minneapolis, MN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Acute Myeloid Leukemia (AML) is the most common form of acute leukemia among adults, accounting annually for the majority of leukemia related deaths in the US. Patients with AML are additionally at an increased risk of developing myeloid sarcomas (MS). MS is reported in 2-8% of AML patients as a single or multifactorial tumor and has been increasingly seen as an initial manifestation of relapse in previously treated AML patients in remission. Patients presenting with MS concurrent with AML is traditionally considered a marker for poor clinical outcome and shorter survival (5-year survival: 28%). Management and treatment of the disease is often hindered by dose limiting toxicity and drug resistance. In an effort to overcome these issues, we have identified the target antigen, CD83, which is uniquely overexpressed across AML subtypes. Using phage display we identified an anti-CD83 camelid antibody (C10) and engineered into a number of constructs. Here, we aim to use these novel camelid constructs as a platform theranostic technology for the imaging of AML associated MS as well for the development of a novel CD83 drug conjugate treatment. ***Materials and Methods:*** Biolayer interferometry (BLI) and Flow Cytometry were used to assess binding ability of the camelid antibody constructs for CD83. For imaging studies, mice bearing subcutaneous U937 xenografts were injected with $^{89}$Zr-labeled C10-Fc and imaged for up to 144H post-injection. Injected dose per gram quantities were determined for non-specific and tumor-specific tissues. Cell viability assays using the AML cell line, U937, were used to determine the specificity, efficacy, and potency of the developed C10-Fc anthracycline based drug conjugate. ***Results:*** Engineering the C10 camelid antibody into a human Fc scaffold (C10-Fc) increases affinity for CD83 by 16-fold ($K_D$ = 39.8 nM:2.60 nM) as determined by BLI. C10-Fc binds cellularly expressed CD83 with even greater affinity ($K_D$ = 44.98 pM) making the construct suitable for in vivo experimentation. As an nuclear imaging agent, [$^{89}$Zr]Zr-C10-Fc rapidly localizes to the tumor site at 4h and largely remains up to 48h with little background from non-specific tissues. The C10-Fc drug conjugate is highly potent against the U937 AML cell line with an $IC_{50}$ of 0.308 nM. ***Conclusion:*** We conclude that our anti-CD83 camelid antibody construct, C10-Fc, is an effective theranostic tools for PET imaging of AML as well as for the delivery of highly potent drugs.

### Development of [$^{18}$F]F-[$^{nat}$Lu]Lu-/[$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-84, a Radiohybrid-Based Minigastrin Analogue With High Tumour and low Kidney Accumulation: A Viable Clinical Option for Imaging and Radioligand Therapy of Medullary Thyroid Carcinoma?

***T. Günther***[1], *N. Holzleitner*[1], *I. Maniyankerikalam*[1], *L. Greifenstein*[2], *R. Beck*[1], *D. Di Carlo*[1], *R. P. Baum*[2], *H. Wester*[1];
[1]*Technical University of Munich, Garching, GERMANY,* [2]*CURANOSTICUM Wiesbaden-Frankfurt, Wiesbaden, GERMANY.*

***Aim/Introduction:*** To address kidney retention issues of previous radiohybrid-based minigastrin analogues, such as [$^{18}$F]F-[$^{nat}$Lu]Lu-/[$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-18 ([$^{18}$F]F-[$^{nat}$Lu]Lu-/[$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-dap(SiFA)-(γ-glu)$_8$-Ala-Tyr-Gly-Trp-Asp-Nle-Phe-NH$_2$), we substituted negatively charged D-γ-glutamate by hydroxyproline (Hyp) moieties and introduced a polyethylene glycol moiety, which yielded DOTA-rhCCK-84 (DOTA-dap(SiFA)-γ-glu-(Hyp)$_6$-γ-glu-(PEG)$_3$-Trp-(N-Me)Nle-Asp-1-Nal-NH$_2$). In vitro and in vivo properties of [$^{18}$F]F-[$^{nat}$Lu]Lu-/[$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-84 were investigated via state-of-the-art experiments and compared to internal ([$^{18}$F]F-[$^{nat}$Lu]Lu-/[$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-18) and external references ([$^{68}$Ga]Ga-/[$^{177}$Lu]Lu-DOTA-MGS5) to pave the way for a first-in-man application. ***Materials and Methods:*** $^{177}$Lu-labelling was performed at 90°C within 15 min (1.0 M NaOAc buffer, pH=5.5). $^{18}$F-labelling was conducted via isotopic exchange reaction at 60°C within 5 min (ammonium formate in anhydrous DMSO) using previously dried [$^{18}$F]fluoride (~400 MBq) with subsequent purification by cartridge. CCK-2R affinity ($IC_{50}$, n=3) was evaluated on AR42J cells. In vivo stability was investigated at 30 min post-injection (p.i.) in CB17-SCID mice (n=3). Biodistribution studies were carried out at 1 and 24 h p.i. in AR42J tumour-bearing CB17-SCID mice (n=4, 100 pmol each). ***Results:*** $^{177}$Lu-labelling resulted in radiochemical yields (RCY) and purities (RCP) of >99% and molar activities of 30-40 GBq/µmol. $^{18}$F-labelling resulted in RCYs and RCPs of 15-45% and >95%, respectively, and molar activities of up to 85 GBq/µmol. [$^{19}$F]F-[$^{nat}$Lu]Lu-DOTA-rhCCK-84 showed a slightly lower CCK-2R affinity than [$^{19}$F]F-[$^{nat}$Lu]Lu-DOTA-rhCCK-18 and [$^{nat}$Lu]Lu-DOTA-MGS5 ($IC_{50}$ (nM): 7.9±0.3 versus 4.7±0.6 and 5.2±0.8, respectively). Lipophilicity (expressed as n-octanol/PBS distribution coefficient, log$D_{7.4}$, n ≥5) of [$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-84 was comparable or slightly higher than those

of [19F]F-[177Lu]Lu-DOTA-rhCCK-18 and [177Lu]Lu-DOTA-MGS5 (−2.14±0.06 versus −2.69±0.06 and −2.21±0.08, respectively). In vivo, [18/19F]F-[nat/177Lu]Lu-DOTA-rhCCK-84 revealed high stability at 30 min p.i. (94±2% intact in serum, 55±9% in urine) and a noticeably higher tumour accumulation than [18/19F]F-[nat/177Lu]Lu-DOTA-rhCCK-18 at 1 h p.i. (36.3±3.7 versus 24.1±4.2 %ID/g, respectively), while kidney uptake was distinctly lower (16.8±1.1 versus 97.2±14.0 %ID/g, respectively). At 24 h p.i., [19F]F-[177Lu]Lu-DOTA-rhCCK-84 exhibited slightly lower activity levels in the tumour than [19F]F-[177Lu]Lu-DOTA-rhCCK-18 and higher levels than [177Lu]Lu-DOTA-MGS5 (18.8±1.4 versus 25.4±4.7 and 10.9±1.2 %ID/g, respectively), while activity levels in the kidneys were distinctly lower than those of [19F]F-[177Lu]Lu-DOTA-rhCCK-18 and only slightly higher than those of [177Lu]Lu-DOTA-MGS5 (9.5±1.7 versus 134±18 and 1.3±0.4 %ID/g, respectively). Based on these encouraging results, clinical translation of [18F]F-[natLu]Lu-/[19F]F-[177Lu]Lu-DOTA-rhCCK-84 has already been initiated. ***Conclusion:*** In contrast to previous radiohybrid-based minigastrin analogues, [18F]F-[natLu]Lu-/[19F]F-[177Lu]Lu-DOTA-rhCCK-84 displayed distinctly lower activity levels in the kidneys, while high tumour accumulation and retention was retained. A first-in-man application of [18/19F]F-[nat/177Lu]Lu-DOTA-rhCCK-84 will elucidate whether this compound could be a viable option for imaging and radioligand therapy of medullary thyroid cancer.

## OP-618

### Construction and preclinical evaluation of a 124/125Ilabeled specific antibody targeting CD147 in pan-cancer

***X. Ma***, *T. Liu, H. Zhu, Z. Yang;*
*Peking University Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction: Objectives:***Tumor microenvironment (TME) is a multifaceted and dynamic environment that surrounds tumors, consisting of immune cells, signaling molecules, blood vessels, and extracellular matrix (ECM). Recent studies have demonstrated that extracellular matrix metalloproteinase inducer (CD147) contributes to pan-cancer immunity and progression. The purpose of this study is to provide guidance for the noninvasive detection of CD147 in pan-cancer. ***Materials and Methods:*** Flow cytometry (FCM), Western blot (WB), and Immunofluorescence (IF) were used to verify the expression of CD147 on the surface of human colon cancer cells LS174T, human pharyngeal squamous cell carcinoma cells FADU, human prostate cancer cells 22RV1, human pancreatic cancer cells ASPC1 and human gastric cancer cells BGC823. 124/125I-anti-CD147 was prepared using N-bromine succinimide (NBS) as oxidant and purified by PD-10 column. The physicochemical properties, affinity, metabolic characteristics, biodistribution and immunoPET imaging of 124/125I-anti-CD147 were performed. 124I-IgG and 18F-FDG were used as controls. Finally, the correlation analysis between tumor uptake and CD147 expression level was established. ***Results:*** LS174T, FADU and 22RV1 cells showed high CD147 expression, while ASPC1 and BGC823 showed low expression of CD147. The radiochemical purity was over 99% and maintained over 85% in saline or 5% Human Serum Albumin (HSA) for more than 7 d. The $K_d$ value of 125I-anti-CD147 to CD147 protein was 6.344 nM, while that of 125I-IgG was over 100 nM. 125I-anti-CD147 showed significantly higher uptake in CD147 high-expression cells than that in CD147 low-expression cells (P<0.001). The biological half-life of distribution and clearance phases were 0.63 h and 19.60 h, respectively. 125I-anti-CD147 showed high initial uptake in blood pool and liver, and the uptake was decreased with time. The effective dose of 124I-anti-CD147 estimated from the biodistribution data was 0.104 mSv/MBq. In vivo immunoPET imaging showed that the tumor-to-muscle ratio of 124I-anti-CD147 were higher than that of 124I-IgG and 18F-FDG (P<0.01) in CD147 (+) tumors. The expression levels of CD147 in cells and tumors had positive correlation with $SUV_{max}$ values (P<0.01). ***Conclusion:*** 124/125I-anti-CD147 showed high targeting and affinity to CD147, which represents a tremendous potential for the imaging of CD147 positive tumors. The development of 124I-anti-CD147 may provide new insights for the regulation of TME and the formulation of precision diagnosis and treatment programs for tumors.

## OP-619

### CD47-targeted nanobody theranostics

***W. Wei****;*
*Shanghai Jiao Tong University, Shanghai, CHINA.*

***Aim/Introduction:*** Overexpression of CD47 is frequently found in various types of human malignancies. By mapping biomarker expression, immuno-positron emission tomography has been increasingly used for patient screening and response monitoring in clinical settings. However, molecular imaging tracers targeting human CD47 remain to be developed. Moreover, CD47-targeting radionuclide therapy may provide alternative treatment options for CD47-expressing malignancies. ***Materials and Methods:*** By immunization alpacas with recombinant human CD47, we prepared a CD47-targeting nanobody C2 and further engineered a nanobody deriative termed as ABDC2, which simutaneously targeting human CD47 and human/murine serum albumin. Following this, we carried labeling with C2/ABDC2 with 68Ga, 89Zr, and 177Lu and theranostic studies in CD47-humanized mice models. ***Results:*** Both C2 and ABDC2 specifically reacted with human CD47 with a high K D value of 23.50 and 84.57 pM, respectively. [68Ga]Ga-NOTA-C2 was developed with high radiochemical purity (99 >%, n = 4) and visualized CD47 expression in the nude mice and CD47-humanized NCG models. In comparison to the rapid renal clearance and short half-life of [68Ga]Ga-NOTA-C2, both [68Ga]Ga-NOTA-ABDC2 and [89Zr]Zr-DFO-ABDC2 showed prolonged circulation and increased tumor uptake, with the highest uptake of [89Zr]Zr-DFO-ABDC2 occurring at 72 h post-injection. Moreover, [177Lu]Lu-DOTA-ABDC2 radioimmunotherapy suppressed the tumor growth but was associated with toxicity, warranting further optimization of the treatment schedules. ***Conclusion:*** Taken together, we reported a series of nanobody-derived CD47-targeted agents, of which [68Ga]Ga-NOTA-C2 and [89Zr]Zr-DFO-ABDC2 are readily translatable. Optimization and translation of CD47-targeted theranostic pair may provide new prospects for CD47-targeted management of solid tumors. ***References:*** 1. Wei et al. Med. 2023 Feb 10;4(2):69-74.2. ## OP-620

### Preclinical Evaluation of [18F]F-[natLu]Lu-/[19F]F-[177Lu]Lu DOTA-rhCCK-18, a Radiohybrid-Based Minigastrin Analog With High Target Affinity and Tumor Accumulation: First Steps Towards Clinical Translation

***N. Holzleitner***[1], *T. Günther*[1], *L. Greifenstein*[2], *N. Urtz-Urban*[1], *D. Di Carlo*[1], *C. Lapa*[3], *R. Baum*[2], *H. Wester*[1];
[1]*Technical University Munich, Munich, GERMANY,* [2]*Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY,* [3]*University of Augsburg, Augsburg, GERMANY.*

***Aim/Introduction:*** In comparison to a recently introduced radiohybrid-based minigastrin analogue, [177Lu]Lu-(R)-DOTAGA-rhCCK-16 ([177Lu]Lu-(R)-DOTAGA-dap(SiFA)-(D-γ-Glu)$_6$-Ala-Tyr-Gly-

Trp-Asp-Nle-Phe-$NH_2$), the novel [$^{177}$Lu]Lu-DOTA-rhCCK-18 ([$^{177}$Lu]Lu-DOTA-dap(SiFA)-(D-γ-Glu)$_8$-Ala-Tyr-Gly-Trp-Asp-Nle-Phe-$NH_2$) revealed a significantly increased CCK-2R affinity (~4-fold improved $IC_{50}$) by a simple DOTA-for-(R)-DOTAGA substitution. In this study, we investigated the human serum albumin (HSA) and plasma protein binding and in vivo properties of [$^{18/19}$F]F-[$^{nat/177}$Lu]Lu-DOTA-rhCCK-18 to pave the way for a first evaluation in humans. ***Materials and Methods:*** All compounds were synthesised via automated Fmoc-based solid phase peptide synthesis (SPPS). $^{177}$Lu-labelling was performed at 90°C within 15 min (1.0 M NaOAc buffer, pH = 5.5). $^{18}$F-labelling was conducted at 60°C within 5 min (ammonium formate in DMSO) using previously dried [$^{18}$F] fluoride with subsequent purification by cartridge. Human serum albumin (HSA) and plasma protein binding was determined via an ultrafiltration method (3200 rpm, 40 min). Biodistribution studies were carried out at 1 and 24 h post-injection (p.i.) in AR42J tumor-bearing CB17-SCID mice. ***Results:*** Automated SPPS with concomitant purification via RP-HPLC yielded 5-20% peptide precursor. $^{177}$Lu-labelling resulted in high radiochemical purity (RCP, >95%) and molar activity of $A_m$ = 40 GBq/μmol. $^{18}$F-labelling proceeded in radiochemical yields of 10-30%, RCP >95% and molar activities of $A_m$ ~85 GBq/μmol. High HSA (62±3%) and plasma protein (95±1%) binding in vitro was determined for [$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-18. In vivo at 1 h p.i., [$^{18}$F]F-[$^{nat}$Lu]Lu-DOTA-rhCCK-18 revealed high activity levels in the tumour and the kidneys (31.2 and 146 %ID/g, respectively) but a low bone uptake (<1.7 %ID/g), underlining the high stability of the Si-$^{18}$F bond in vivo. Apart from high activity accumulation in the kidneys overall background was low in non-target tissues. At 24 h p.i., [$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-18 exhibited high activity retention in both the AR42J tumour xenograft and the kidneys (25.4±4.7 and 134±18 %ID/g, respectively), while further off-target retention was low, leading to superior tumour-to-background ratios for [$^{19}$F]F-[$^{177}$Lu]Lu-DOTA-rhCCK-18 compared to the reference compound [$^{177}$Lu]Lu-DOTA-PP-F11N ([$^{177}$Lu]Lu-DOTA-(D-Glu)$_6$-Ala-Tyr-Gly-Trp-Asp-Nle-Phe-$NH_2$). Based on these encouraging results, clinical translation of [$^{18}$F]F-[$^{nat}$Lu]Lu-DOTA-rhCCK-18 has already been initiated. Apart from the general pharmacokinetics it will be investigated whether the unfavourable high kidney uptake is obtained in humans as well. ***Conclusion:*** [$^{18/19}$F]F-[$^{nat/177}$Lu]Lu-DOTA-rhCCK-18 demonstrated favourable in vitro and in vivo properties, particularly high tumor accumulation and retention. A first-in-human application using either [$^{18}$F]F-[$^{nat}$Lu]Lu-DOTA-rhCCK-18 or [$^{19}$F]F-[$^{68}$Ga]Ga-DOTA-rhCCK-18 will elucidate if elevated kidney uptake observed in animals is reflected in humans. If not, the radiohybrid-based DOTA-rhCCK-18 could be a viable theranostic agent for positron emission tomography imaging and radioligand therapy of medullary thyroid cancer.

## OP-621

### In vitro and in vivo evaluation of BCY18469, a novel EphA2-targeting Bicycle® for radiotheranostic applications

***M. El Fakiri***[1,2,3], *G. E. Mudd*[4], *J. Mitschke*[5,1], *P. Huxley*[4], *K. McDonnell*[4], *A. R. Regupathy*[4], *N. Klemm*[5], *L. Domogalla*[2,1], *A. C. Eder*[1,2], *T. Reinheckel*[5,1], *M. Eder*[1,2];
[1]*German Cancer Consortium (DKTK), Partner Site Freiburg, and German Cancer Research Center (DKFZ), Freiburg, GERMANY,* [2]*Department of Nuclear Medicine, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [3]*Faculty of Biology, University of Freiburg, Freiburg, GERMANY,* [4]*BicycleTx Limited, Cambridge, UNITED KINGDOM,* [5]*Institute of Molecular Medicine and Cell Research, University of Freiburg, Freiburg, GERMANY.*

***Aim/Introduction:*** Targeting specific and selective binding sites with radioisotope bearing molecules offers immense value in the personalized management of cancer patients, enabling imaging and treatment of a wide range of tumours. EphA2, a tyrosine kinase involved in cell-cell interactions, is overexpressed in various tumours and has been linked to poor prognosis. To target cancer-overexpressed receptors, bicyclic peptides have gained attention due to their constrained nature, high tissue penetration, and improved stability compared to their linear counterparts. This work presents an in vitro and in vivo preclinical evaluation of BCY18469, a novel bicyclic peptide-based radiotheranostic that targets EphA2. ***Materials and Methods:*** To evaluate the preclinical efficacy of BCY18469, the bicyclic peptide was radiolabelled with gallium-68 and lutetium-177, and its stability assessed in mouse and human plasma. In vitro properties such as binding affinity and internalization were evaluated using the EphA2-overexpressing cell line HT1080. The peptide demonstrated a favourable in vitro profile, and was subsequently evaluated in vivo. Firstly, through μPET/MR imaging and biodistribution studies in an HT1080 mouse xenograft (BALB/c nu/nu), and secondly, in a μPET/MR longitudinal study on a transgenic immunocompetent breast cancer mouse model (MMTV-PyMT). ***Results:*** The EphA2-targeting bicyclic peptide BCY18469 was labelled with gallium-68 and lutetium-177 (RCY's ≥ 98%). Following 24 hours of incubation, ~90% of BCY18469 remained intact in human plasma, while 30% degradation was observed in mouse plasma. In vitro assays demonstrated specific binding of BCY18469 to EphA2-expressing cells, with nanomolar binding affinity. In vivo μPET/MR imaging of [$^{68}$Ga]Ga-BCY18469 on HT1080 xenograft mice showed high tumour enrichments at early time-points, with an SUV value of 1.18 g/mL 2 hours post-injection. Biodistribution studies with [$^{177}$Lu]Lu-BCY18469 in the HT1080 xenograft were consistent with μPET/MR imaging results, demonstrating high tumour accumulation at early time-points (19.50 ± 3.50 %ID/g 1 hour post-injection, n = 3). Additionally, [$^{68}$Ga]Ga-BCY18469 was able to stage and image disease progression from the formation of the first palpable tumours until end-point in MMTV-PyMT breast cancer mice. ***Conclusion:*** Targeting the EphA2 receptor has the potential to enable imaging and treatment of various cancerous diseases that overexpress it. The high tumour accumulation observed for BCY18469 at early time-points makes it a promising candidate for molecular imaging using short-lived radionuclides. Furthermore, the capacity of BCY18469 to detect cancerous lesions over time in an immunocompetent mouse model strengthens the hypothesis that bicyclic peptides are an effective tool for PET imaging of solid tumours during all the disease stages.

## OP-622

### Theranostic role of$^{89}$Zr/$^{177}$Lu-labeled aflibercept in triple-negative breast cancer

***L. Kang****, Q. Yang, Z. Chen, Y. Qiu, W. Huang, L. Song;*
*Peking University First Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Breast cancer is the most common cancer among women around the world. Although systemic therapy has improved outcomes for patients, the development of new molecularly targeted drugs and treatment regimens is imperative. Vascular endothelial growth factor (VEGF) represents a growth factor with important pro-angiogenic activity. Targeting and blocking angiogenesis could help the diagnosis and treatment of breast cancer. Aflibercept (Abe), a chimeric recombinant protein, contains the ligand-binding domains of both VEGFR-1 and VEGFR-2 and can sequester all isoforms of VEGF-A, PlGF, and VEGF-B, therefore affecting pathological and physiological
