***Aim/Introduction:*** Cervical carcinoma (CC) is one of the most common malignancies in women. Locally-advanced CC (LACC) are treated with pelvic external beam radiation (EBRT) in combination with cisplatin-based chemotherapy and subsequent brachytherapy, with a recurrence rate of 40%. The aim of this study is to evaluate whether radiomics, applied to baseline 18F-FDG-PET in LACC patients treated with chemoradiotherapy (CRT), can contribute in predicting response to therapy and in evaluating Disease-Free Survival (DFS) compared to standard clinical and radiological assessment. ***Materials and Methods:*** 56 patients with LACC, who performed 18F-FDG-PET/CT before CRT were included. Primary tumor volumes were delineated using iterative thresholds with PETVCAR™.A total of 157 radiomics features (intensity, shape, and texture) were extracted (according to IBSI recommendation) and evaluated for their prognostic value. A univariate analysis was performed to examine the association between radiomic features and response to therapy (clinical and imaging: defined as complete vs. non-complete) and DFS. In addition, Receiver Operating Characteristic (ROC) analyses were conducted.To investigate whether the addition of radiomic features could enhance the prediction of DFS compared to lymph-node invasion alone, a multivariate Cox analysis was carried out by combining radiomic features with lymph-node invasion.Kaplan-Meier curves were used to describe DFS stratified according to metabolic response, lymph-node invasion, and radiomic features. ***Results:*** In univariate analysis Szm Lzlge (p-value=0.007; AUC=0.77) and Cm Suv Avg (p-value=0.012; AUC=0.75) are strongly correlated with metabolic response. DFS is significantly correlated with metabolical response (p<0.001) and lymph-node invasion (p=0.034). No correlation was found between standard PET values (SUVmax, SUVmean, SUVpk, MTV and TLG) and these parameters. Applying Multivariate Cox Proportional Hazard Regression, the only improvement in predicting DFS without reaching statistical significance is obtained by adding the radiomic feature Szm Lzlge to lymph node invasion (p=0.077).Comparing the survival curves, patients with lymph-node metastases (N+) and Szm Lzlge<0.0198 had an oncological outcome overlapping with patients with negative lymph nodes (p<0.001). Conversely, N+ patients and Szm Lzlge >0.0198 had a 5.3 times higher probability of disease recurrence. ***Conclusion:*** Radiomics features are correlated to response to CRT in LACC and can improve the prediction of DFS, identifying high-risk patients when combined with standard prognostic factors. These results suggest that a more personalized approach to treatment planning could be achieved by identifying high-risk patients at the time of diagnosis.

## EP-0317

### Potential of baseline and early response FDG-PET/MRI to predict radiotherapy outcome in uterine cervical squamous cell carcinoma - a pilot study

***S. Strandberg***[1], *J. Jonsson*[1], *M. Zarei*[1], *K. Aglund*[1], *L. Blomqvist*[2], *K. Söderkvist*[1], *B. Zackrisson*[1];
[1]*Department of Radiation sciences, Umea University, Umea, SWEDEN,* [2]*Department of Molecular Medicine and Surgery, Karolinska Institute, Solna, SWEDEN.*

***Aim/Introduction:*** Assessment of early response using FDG-PET/MRI might improve prediction of radiotherapy (RT) outcome in uterine cervical squamous cell carcinoma (CSCC).The aim of this study was to investigate the association between FDG-PET/MRI features and outcome in CSCC. ***Materials and Methods:*** In this pilot study, all eligible participants from the prospective clinical trial MORRIS - Multimodal Monitoring of Radiotherapy Response in Squamous Cell Cancer (MORRIS; NCT02379039), with primary CSCC and completed imaging work-up, were included. The imaging consisted of baseline FDG-PET/MRI performed one week before start of RT and early treatment response FDG-PET/MRI performed on day 8 of RT. PET/MRI was performed with an integrated PET/MRI 3.0 T scanner during 2016-2021. The imaging protocols for FDG-PET and pelvic MRI were designed according to current clinical routines. From blinded single modality assessment of T2-weighted (T2W) sequences and semi-quantitative assessment with apparent diffusion coefficent (ADC) in MRI, gross tumor volume (GTV) of the primary tumors was manually delineated at baseline and at early treatment response PET/MRI. Quantitative imaging parameters were extracted from the manual segmentations: GTV from T2W and ADC, perpendicular lesion diameters (ccxllxap) measured in T2W and ADC, SUVmax, SUVmean and functional tumor volume (FTV). Additional delta (change) parameters were calculated for early treatment response examinations. Treatment response according to RECIST 1.1 was also reported. All study participants had at least 24 months clinical follow-up. Descriptive statistics were used. ***Results:*** Of the eligible twelve CSCC study participants from the MORRIS trial, one patient was excluded due to incomplete radiology. Visual decrease in tumor size was present in 9/11 participants (range 8.2-24.6% decrease in largest diameter on T2W or ADC). Relapse occurred in 2/11, with high FTV as the most conspicuous imaging characteristic. Also 2/11, of which one relapse, had an increase in largest diameter after one week of RT. Mean change in largest tumor diameter was -9,3% (SD 9,6%), but none qualified as significant according to RECIST 1.1. ***Conclusion:*** High FDG-PET FTV at baseline as well as unfavorable response in FTV at one week after start of RT may predict non-responders to RT in CSCC. RECIST 1.1 does not seem suitable for early treatment response evaluation in CSCC treated with RT.

### Metabolic tumour volume in Hodgkin lymphoma - a comparison between manual and AI-based analysis

***M. Sadik***[1], *S. F. Barrington*[2], *J. Ulén*[3], *O. Enqvist*[4], *E. Trägårdh*[5], *B. Saboury*[6], *A. Lerberg Nielsen*[7], *A. Loft Jakobsen*[8], *J. Loaiza Gongora*[9], *J. López-Urdaneta*[1], *R. Kumar*[10], *L. Edenbrandt*[1];
[1]*Molecular and Clinical Medicine, Gothenburg, SWEDEN,* [2]*Clinical PET Centre, London, UNITED KINGDOM,* [3]*Eigenvision AB, Malmö, SWEDEN,* [4]*Eigenvision AB and Electrical Engineering, Malmö and Gothenburg, SWEDEN,* [5]*Clinical Physiology and Nuclear Medicine, Malmö, SWEDEN,* [6]*Radiology and Imaging Sciences, Bethesda, MD, UNITED STATES OF AMERICA,* [7]*Nuclear Medicine, Odense, DENMARK,* [8]*Clinical Physiology, Copenhagen, DENMARK,* [9]*Diagnostic Imaging, Oslo, NORWAY,* [10]*Nuclear Medicine, Chandigarh, INDIA.*

***Aim/Introduction:*** Total metabolic tumour volume (tMTV) is recognised as a prognostic tool which is associated with progression-free and overall survival in Hodgkin lymphoma (HL) patients (1). Manual segmentation of tMTV however is time-consuming and subject to inter-reader variability. There is a clinical need for automated methods, which may be more objective and faster. The aim of this study was to compare tMTV, calculated using two artificial intelligence (AI)-based tools with measurements using manual segmentation by specialists as the reference. ***Materials and Methods:*** Forty-eight consecutive HL patients staged with [18F]FDG PET/CT were included. The median age was 35 years (range 7-75) and 46% of the patients were female. The tMTV was automatically measured using the AI-based tools PARS (from Siemens) and RECOMIA (recomia.org) without any manual adjustments. A group of eight nuclear medicine specialists manually segmented lesions for tMTV calculations; each of the 48 patients were independently segmented by two specialists. ***Results:*** The median of the manual tMTV was 146 $cm^3$ (inter quartile range (IQR) 79-568 $cm^3$) and the median difference between two tMTV values segmented by different specialists for the same patient was 26 $cm^3$ (IQR 10-86 $cm^3$). In 22 of the 48 patients, the manual tMTV value was closer to the RECOMIA tMTV value than to the manual tMTV value segmented by the second specialist. In 11 of the remaining 26 patients, the difference between the RECOMIA tMTV and the manual tMTV was small (<26 $cm^3$, which was the median difference between two manual tMTV values from the same patient). The corresponding numbers for PARS were 18 and 10 patients, respectively. ***Conclusion:*** The results of this study indicate that RECOMIA and Siemens PARS AI tools could be used without any major manual adjustments in 69% (33/48) and 58% (28/48) of patients, respectively. This demonstrates the feasibility of using AI tools to automate measurement of MTV for assessment of prognosis in clinical practice. ***References:*** 1. Barrington SF, Meignan M. Time to Prepare for Risk Adaptation in Lymphoma by Standardizing Measurement of Metabolic Tumor Burden. J Nucl Med 2019; doi:10.2967/jnumed.119.227249.

### C-X-C Motif Chemokine Receptor 4-directed PET/CT provides improved Diagnostic Performance relative to [18F]FDG in Newly Diagnosed Patients with Marginal Zone Lymphoma

***A. Kosmala***[1], *S. E. Serfling*[1], *S. Schneid*[1], *T. Higuchi*[1,2], *A. Weich*[3], *C. Lapa*[4], *P. E. Hartrampf*[1], *M. Raderer*[5], *H. Einsele*[3], *A. K. Buck*[1], *M. S. Topp*[3], *J. Duell*[3], *R. A. Werner*[1,6];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN,* [3]*Department of Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY,* [4]*Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY,* [5]*Department of Internal Medicine I, Medical University Vienna, Vienna, AUSTRIA,* [6]*Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Sciences, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** C-X-C motif chemokine receptor 4 (CXCR4) is overexpressed in marginal zone lymphoma (MZL) and thus, may emerge as a theranostic target. We aimed to evaluate the diagnostic performance of CXCR4-targeting [68Ga]Ga-PentixaFor when compared to [18F]FDG PET/CT in newly diagnosed MZL. ***Materials and Methods:*** 33 MZL patients (subtypes: nodal, n=20; extranodal, n=12; splenic, n=1) received [68Ga]Ga-PentixaFor and [18F]FDG PET/CT within median 2 days, without treatment between scans. We performed a visual and quantitative analysis of the total lymphoma volume by identifying target lesions (TL). For the latter investigation, maximum/peak standardized uptake values ($SUV_{max/peak}$), and target-to-background ratio (TBR) were calculated. TBR was defined as $SUV_{peak}$ from TL divided by $SUV_{mean}$ from blood pool serving as reference. ***Results:*** [68Ga]Ga-PentixaFor identified MZL manifestations in 33 (100%) patients (vs. [18F]FDG, 25/33 patients [75.8%]), and substantially more MZL manifestations were evident on CXCR4-directed imaging compared to [18F]FDG (274 vs. 154). For a quantitative head-to-head comparison, we identified 143 identical TL on both scans. For concordant lesions, $SUV_{peak}$ on [68Ga]Ga-PentixaFor was 7.1±4.0, which was significantly elevated when compared to [18F]FDG (5.3±4.3, P<0.0001). Similar results were observed for $SUV_{max}$ ([68Ga]Ga-PentixaFor, 11.2±5.4 vs. [18F]FDG, 7.8±5.7, P<0.0001), indicative that a substantial portion of patients may be eligible for CXCR4-directed therapy. TBR was also approximately 1.7-fold higher on [68Ga]Ga-PentixaFor (median, 3.8) when compared to [18F]FDG (2.1, P<0.0001), suggestive for an improved contrast on chemokine receptor PET. ***Conclusion:*** CXCR4-directed PET/CT identifies more sites of disease in patients with newly diagnosed MZL. On a quantitative assessment, a substantial portion of patients would also be suitable for "cold" or "hot" CXCR4-targeted treatment. Last, TBR-derived image contrast was markedly higher on [68Ga]Ga-PentixaFor PET, thereby suggesting improved diagnostic read-out when compared to [18F]FDG.

## EP-0320

### Development of prediction models for treatment response and prognosis in patients with diffuse large B-cell lymphoma based on 18F-FDG PET radiomics

***Y. Zhou****;*
*West China Hospital, Chengdu, CHINA.*

***Aim/Introduction:*** Biomarkers that can accurately predict outcome in diffuse large B-cell lymphoma (DLBCL) patients are urgently needed. Radiomics features extracted from baseline [$^{18}$F]-FDG PET/CT scans have shown promising results. This study aims to assess the influence of lesion selection and segmentation methods on the radiomics features of DLBCL in treatment response and prognosis prediction. ***Materials and Methods:*** A total of 533 patients pathologically diagnosed with DLBCL were enrolled. 112 radiomics features (n=3 conventional PET, n=12 morphology, n=43 intensity, n=54 texture) were extracted for all individual lesions and at patient level, where all lesions were aggregated into one VOI. Three lesion selection approaches were tested (largest or hottest lesion, patient level). Manual segmentation and four semiautomatic segmentation methods were applied (SUV threshold of 2.5 [SUV2.5], SUV threshold of 4.0 [SUV4.0], 25% of SUVmax, and 41% of SUVmax). To quantify the agreement between features extracted from different segmentation methods, the intraclass correlation (ICC) agreement was calculated for each method compared with SUV4.0. The predictive value of all models was tested using a fivefold cross-validation approach with 50 repeats, yielding the mean cross-validated AUC (CV-AUC) for all lesion selection combined with segmentation methods using eXtreme gradient boosting, which were compared by Delong test. Additionally, the relative importance of individual radiomics features was determined. ***Results:*** Both in treatment response and prognosis prediction, the percentage of features yielding an ICC of at least 0.75, compared with the SUV4.0 segmentation, was lowest for 41% of SUVmax both at the patient level and for

the hottest or largest lesion, with 43%, 59%, 56% and 46%, 57%, 57% of the features yielding an ICC of at least 0.75, respectively. In treatment response prediction, CV-AUC ranged between 0.606 and 0.768 at the patient level, between 0.618 and 0.704 and between 0.616 and 0.666 at the hottest or largest lesion level, respectively. In prognosis prediction, CV-AUC ranged between 0.583 and 0.699 at the patient level, between 0.584 and 0.636 and between 0.633 and 0.705 at the hottest or largest lesion level, respectively. Texture features had the highest relative importance in most of these models. However, the prediction performance gap was not significant for each model ($p > 0.05$). ***Conclusion:*** Even though there are differences in the actual radiomics feature values derived and selected features among lesion selection and segmentation methods, there is no substantial difference in the predictive power of radiomics features among lesion selection and segmentation methods.

## EP-0321

### Diagnostic performance of whole-body [18F]FDGPET/MRIwith diffusion-weighted imaging for detecting bone marrow involvement in lymphomas

***X. Chen***, *M. Wei, T. Yuan, B. Yu, N. Zhou, Z. Hua, Z. Yang, X. Wang; Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** This study aimed to investigate the diagnostic efficiency of whole-body [18F]FDG PET/MRI with diffusion-weighted imaging for detecting bone marrow involvement (BMI) in lymphomas. ***Materials and Methods:*** This single-centre prospective study recruited patients with different lymphoma pathological subtypes. Each patient underwent [18F] FDG PET/MRI and BMB. The diagnostic performance of FDG PET/MRI was assessed using visual evaluation and quantitative measurements. ***Results:*** Of the 120 patients, 39 (32.5%) had BMI (15 focal BMI and 24 diffuse BMI). PET/MRI images were divided into three groups (double-positive, double-negative and single-positive) according to visual evaluation. The accuracy of each group was 100%, 94.1% and 56.7%, respectively. The sensitivity, specificity, PPV and NPV were 66.7%, 90.1%, 76.5% and 84.9% for PET and 79.5%, 88.9%, 77.5% and 90.0% for MRI, respectively. The sensitivity and specificity of PET/MRI reached 89.7% and 100%, respectively, when compared with PET alone ($p = 0.004$) and MRI alone ($p = 0.004$). Similar results were obtained through quantitative measurements. The vertebral SUVmax, lesion-to-mediastinum ratio (LMR), lesion-to-liver ratio and ADCmean were significantly different between the lymphomas with BMI(+) and BMI(–) ($p < 0.05$). The strongest diagnostic factor of BMI was the vertebral LMR, with a cut-off value of 2.19. A moderate correlation was observed between vertebral LMR and ADCmean ($r = 0.536$, $p < 0.01$). ***Conclusion:*** WB [18F]FDG PET/MRI with DWI is a promising method for improving sensitivity and specificity by visual evaluation or quantitative parameters and stratifying the BMI risk of patients with lymphoma.

## EP-0322

### A focus on the impact of spleen involvement in total metabolic tumor volume measurements in Diffuse Large B-Cell Lymphoma patients.

***L. Rebaud***[1,2], *N. Capobianco*[3], *K. Girum*[2], *A. Cottereau*[4], *F. Morschhauser*[5], *B. Spottiswoode*[6], *I. Buvat*[2]; [1]*Siemens Healthcare SAS, Courbevoie, FRANCE,* [2]*LITO laboratory, U1288 Inserm, Institut Curie, University Paris-Saclay, Orsay, FRANCE,* [3]*Siemens Healthcare GmbH, Erlangen, GERMANY,* [4]*Cochin University Hospital, AP-HP, Department of Nuclear Medicine, Paris, FRANCE,* [5]*Service des Maladies du Sang, CHU Lille, Lille, FRANCE,* [6]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Quantifying Total Metabolic Tumor Volume (TMTV) from FDG PET/CT in Diffuse Large B-Cell Lymphoma (DLBCL) patients has sparked a debate on the inclusion of diffuse spleen uptake in TMTV measurement. Whether the uptake is due to an immune response or to tumor cells is not always easy to determine. This study aimed to explore the impact of excluding the spleen from TMTV measurements on the prognostic value of TMTV in DLBCL patients. ***Materials and Methods:*** A cohort of 375 patients diagnosed with DLBCL from two clinical trials, NCT01122472 and NCT00498043, was investigated. Tumors were segmented by experienced physicians, and the spleen was automatically segmented using TotalSegmentator[1], with subsequent manual correction in the rare cases of incorrect segmentation. For each patient, TMTV and Total Metabolic Tumor Volume Outside the Spleen (TMTVOS) were calculated. The cohort was divided into two groups based on the presence (SI) or absence (NSI) of spleen involvement (either focal or diffuse). The correlation between TMTV and TMTVOS was assessed using Spearman's correlation coefficient. Cutoff values that maximize Youden's index for 2-year Progression-Free Survival (PFS) and 2-year Overall Survival (OS) prediction were determined, and the significance of differences in survival rates was tested (log-rank tests). ***Results:*** In the total patient cohort, 127 patients had spleen involvement, with tumor volume in the spleen accounting for 26% of TMTV on average. TMTV and TMTVOS were strongly correlated in both the entire patient cohort ($r=0.94$) and the SI group ($r=0.86$). Median TMTV and TMTVOS were significantly higher in the SI group (662 mL and 414 mL, respectively) compared to the NSI group (186 mL). SI patients demonstrated significantly lower PFS ($p=0.04$) and OS ($p=0.04$) compared to NSI patients. Optimal cutoffs for PFS were 308 mL for TMTV and 316 mL for TMTVOS. For OS, optimal cutoffs were 388 mL for TMTV and 336 mL for TMTVOS. High TMTV and low TMTV groups had significantly different survival (PFS: $p<0.01$; OS: $p=0.01$). Similarly, high TMTVOS and low TMTVOS had significantly different survival (PFS: $p<0.01$; OS: $p=0.01$). No significant differences were found in the survival of high TMTV and high TMTVOS groups (PFS: $p=0.67$; OS: $p=0.98$), nor between low TMTV and low TMTVOS groups (PFS: $p=0.83$; OS: $p>0.99$). ***Conclusion:*** While spleen involvement is predictive of PFS and OS in DLBCL patients, TMTV excluding spleen involvement remains predictive, although this exclusion impacts the optimal cut-off value. ***References:*** [1] Wasserthal, et al., arXiv, 2022;2208.05868

## EP-0323

### The Role Of Baseline 18F-FDG PET/CT Metrics And Radiomics Features In Predicting Primary Gastric Lymphoma Diagnosis

***A. Calabro'***, *D. Albano, F. Dondi, P. Bellini, A. Tucci, F. Bertagna; ASST Spedali Civili of Brescia, University of Brescia, Brescia, ITALY.*

***Aim/Introduction:*** Diffuse Large B-Cell Lymphomas (DLCBL) and mucosa-associated lymphoid tissue (MALT) are the two most common primary gastric lymphomas (PGLs), but have strongly different features. DLBCL are more aggressive, are frequently diagnosed at an advanced stage and have a poorer prognosis. The aim of this retrospective study was to investigate the usefulness of fluorine-18-fluorodeoxyglucose positron emission tomography/CT ($^{18}$F-FDG PET/CT) metrics and radiomics features (RFs) in predicting the final diagnosis of patients with PGLs. ***Materials and Methods:*** Patients with newly diagnosed PGLs who underwent pre-treatment $^{18}$F-FDG PET/CT were included. We reviewed and analyzed the main clinical, epidemiological and PET/CT features to predict the final diagnosis. PET images were qualitatively and

semi-quantitatively analyzed by deriving maximum standardized uptake value body weight (SUVbw), maximum standardized uptake value lean body mass (SUVlbm), maximum standardized uptake value body surface area (SUVbsa), lesion to liver SUVmax ratio (L-L SUV R), lesion to blood-pool SUVmax ratio (L-BP SUV R), metabolic tumor volume (gMTV) and total lesion glycolysis of gastric lesion (gTLG), total MTV (tMTV), TLG, and first-order radiomics features (histogram-related and shape related). Student's t test, Wilcoxon's rank-sum test, and $\chi^2$ test were used to determine the statistical difference in the main continuous and categorical variables between patients with various histological subtypes. Receiver-operating characteristic (ROC) curve analyses were performed to determine the differential diagnostic values of PET parameters. A bivariate logistic regression model was performed to derive the best combination of parameters predicting the final diagnosis. ***Results:*** 91 patients with a histological diagnosis of PGL were recruited: 54 (59%) with DLBCL and 37 (41%) with gastric MALT. PGLs were FDG avid in 83 cases (90%) with a significant difference based on the histotype: 100% in DLBCL and 78% in gastric MALT.All PET/CT metrics, such as stage of disease and tumor size, were significantly higher in DLBCL than MALT; association with H. Pylori infection was more common in MALT. At univariate analysis, all PET/CT metrics were significantly higher in DLBCL than MALT lymphomas, while among radiomics features only Shape volume_vx and Shape sphericity showed a significant difference.The combination of SUVmax with L-L SUV R and L-BP SUV R was the best predictor of the final diagnosis with a AUC value greater than 0.8. ***Conclusion:*** $^{18}$F-FDG PET/CT can potentially discriminate between DLBCL and MALT lymphomas with high accuracy.SUV-related features seem to be superior to volumetric (MTV and TLG) and radiomics parameters in predicting the final diagnosis.

## EP-0324

### 18F-FDG PET/CT radiomics features and MYC protein expression predict progression in Diffuse Large B-cell Lymphoma

***C. Cui***, *B. Li, X. Mu, Z. Wu;*
*SXMU, Tai Yuan, CHINA.*

***Aim/Introduction:*** The prognosis of diffuse large B-cell lymphoma (DLBCL) varies greatly among patients, in part due to genetic abnormalities such as MYC oncogene rearrangement, BCL2 and/or BCL6 gene translocation. Our study aimed to analyze the relationship between high-risk molecular protein expression and DLBCL prognosis, and to investigate the additional value of radiomics features in predicting progression in DLBCL. ***Materials and Methods:*** A retrospective analysis was performed on clinical and pathological data from 91 consecutively confirmed DLBCL patients. PET and CT radiomics features were extracted, and a total of 328 radiomics features were obtained for each patient. The least absolute shrinkage and selection operator (Lasso) was used to select the radiomics features, and the radiomics score (RS) was constructed. XGBoost ensemble learning models were constructed based on clinopathological combined with PET features, RS combined with clinopathological and PET features to predict progression after 2 years. Receiver operating characteristic (ROC) curves were drawn, and the area under the curve (AUC), sensitivity, and specificity were used to evaluate the performance of the models. The Delong test was used to compare the differences in AUC between the two models. ***Results:*** A total of 91 DLBCL patients met the inclusion criteria. There were no statistically significant differences in clinical data between the two groups . 7 radiomics features were selected by Lasso. Significant intergroup differences were observed in Ann Arbor stage, IPI, MTV, TLG, and MYC (all P <0.05). The XGBoost model based on clinopathological and PET features had an AUC of 0.74 in the training set, and 0.54 in the validation set; While the XGBoost model based on RS combined with clinopathological and PET features had an AUC of 0.81 in the training set and 0.74 in the validation set. The performance of the RS combined with clinopathological-PET model was better than that of the clinopathological-PET model (P <0.05). ***Conclusion:*** MYC is a risk factor for disease progression after 2 years in DLBCL patients. Adding radiomics features to the clinopathological-PET prediction model, including IPI and MYC, improves the model's performance and positive predictive value, thereby helping to identify poor prognosis patients. ***References:*** [1]Siegel R L, Miller K D, Wagle N S. ## EP-0325

### Prognostic value of baseline 18F-FDG PET/CT metabolic tumour volume and total lesion glycolysis in Diffuse Large B Cell Lymphoma patients

***A. Doma***[1,2], *A. Studen*[3,4], *B. Jezeršek Novaković*[1,2];
*[1]Ljubljana Oncology institute, Ljubljana, SLOVENIA, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [3]Experimental Particle Physics Department, Jožef Stefan Institute, Ljubljana, SLOVENIA, [4]Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** To assess the prognostic value of the $^{18}$F-FDG PET/CT- based pretreatment metabolic tumour volume (MTV) and total lesion glycolysis (TLG) in Diffuse Large B Cell Lymphoma (DLBCL) patients treated with standard immunochemotherapy regimen. ***Materials and Methods:*** Baseline $^{18}$F-FDG PET/CT scans of 157 histologically proven stage II-IV DLBCL patients (64 female, 93 male, median age 67.0 years; range 20.0- 85.0), without a history of other malignancies, were retrospectively analysed and correlated with overall survival (OS) data (median follow up: 3.75 years ; range 0.16- 7.12). The maximum standardised uptake values ($SUV_{max}$), mean standardised uptake values ($SUV_{mean}$), MTV and TLG of all lesions were analysed. 3- dimensional segmentations with a threshold SUV>2.5 were performed by a single experienced nuclear medicine physician using Slicer 3D software. Areas of increased bone marrow activity were identified as pathological if the infiltration was not homogeneous, indicating a reactive bone marrow. Total MTV of each patient was defined as the sum of metabolic volumes of all focal lesions. A value of <0.05 was considered statistically significant. ***Results:*** The data for OS for 3 and 5 years were available for 126 (survivors n= 94) and 81 (survivors n=46) patients, respectively. Differences between groups were analysed by the Mann-Whitney U test. 3 and 5 years OS was significantly associated with lower baseline MTV (497± 706 ml and 405± 619 ml vs. 1378± 1387 ml and 1293± 1359 ml, respectively, p<0.001) and TLG (4110± 5866 g and 3571± 4913 g vs. 10852± 10598 g and 10194± 10389 g, respectively, p<0.001). No statistical correlation was found between OS and baseline $SUV_{max}$ and $SUV_{mean}$.The MTV and TLG cutoff values for predicting 3 and 5 years OS were determined by ROC analysis, and the optimal thresholds found were 480 ml (AUC: 0.72), 520 ml (AUC: 0.74), 2614 g (AUC: 0.71) and 2614 g (AUC: 0.71), respectively. By Kaplan-Meier analysis, OS at follow-up was significantly better in patients with MTV and TLG lower than the cutoff compared to patients having MTV and TLG value above the cutoff (p<0.001).

***Conclusion:*** Baseline $^{18}$F-FDG PET/CT measurements of tumour burden obtained by calculating MTV and TLG may be used in the prediction of OS in DLBCL patients prior to treatment initiation.

## EP-0326

### PET-Based Volumetric Biomarkers for Risk Stratification in Pediatric Hodgkin's Lymphoma

***M. Dunaykin***, *M. Yadgarov, G. Shestopalov, K. Chaurasiya, E. Kireeva, Y. Likar;*
*Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The five-point Deauville score is known to be a predictive factor in Hodgkin's lymphoma (HL), identifying children with a poor prognosis. A study by Milgrom SA et al. showed an association between baseline metabolic tumor burden, as measured by pretreatment metabolic tumor volume (MTV) and the total lesion glycolysis (TLG), with event-free survival in children and adolescents with intermediate-risk HL [1]. Despite this, it is still controversial whether baseline or interim PET/CT volumetric parameters can predict survival in children with HL.The aim of our study was to assess the prognostic significance of the baseline and interim (after two cycles of chemotherapy) MTV and TLG values for prediction of progression-free survival (PFS). ***Materials and Methods:*** This single-center retrospective study included patients with newly diagnosed HL who underwent pretherapeutic and interim PET / CT scans. The examinations were reviewed and processed with commercially available software to obtain MTV and TLG using fixed absolute (SUV 2.5) and fixed relative (41% of SUVmax) thresholds. Patients were treated in accordance with EuroNet-PHL-C1. Multivariable Cox regression was performed for clinical and radiological parameters. ***Results:*** 47 patients with HL were included (30 boys, median age 14 years, range 4-17). Median follow-up was 19 months (interquartile range 12-36), 8 patients had disease progression at longest follow-up. In multivariable analysis, only baseline MTV41% (cut-off: ≥310 ml) (hazard ratio [HR] = 26.4; 95% CI 2.3-131.1; p < 0.001) and bulky disease (HR = 5.1, 95% CI 1.1-24.7; p = 0.043) were significantly associated with worse PFS when controlling for other important clinical covariates, including age and response to chemotherapy. ***Conclusion:*** Volumetric PET/CT parameters can provide prognostic value for progression-free survival in pediatric patients with HL. Patients with baseline MTV41% ≥310 ml could be classified as at high risk of unfavorable outcome. The results of this study indicate that further research is warranted, including longer follow-up periods and larger sample sizes. ***References:*** 1. ## EP-0327

### Prognostic value of interim FDG PET/CT in Extranodal Natural Killer/T-Cell Lymphoma, nasal type : comparison of Deauville scores, deltaSUVmax and qPET

***W. Hou***, *R. Tian;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** This retrospective study aimed to compare prognostic value of three criteria interpretating interim FDG PET/CT for patients with Extranodal natural killer/T-cell lymphoma, nasal type (ENKTL) following a full course of asparaginase-based chemotherapy: DS, deltaSUVmax and qPET. ***Materials and Methods:*** Patients admitted to our hospital between December 2013 and December 2019, and newly diagnosed with ENKTL by pathology were enrolled in this retrospective study. DS, deltaSUVmax and qPET on interim PET/CT scans were calculated for each patient. Progression-free survival (PFS) and overall survival (OS) were used as endpoints for progression evaluation. Receiver operating characteristic(ROC) curve was used to determine the best cut-off values of qPET and deltaSUVmax for predicting PFS and OS. Univariate analysis and multivariate Cox proportional hazards models were used to assess the potential independent variables for PFS and OS. ***Results:*** One hundred and sixty-two ENKTL patients with a mean follow-up time of 50.0±22.0 months (2-89 months) were enrolled in this study. ROC curve analysis showed that the best cut-off values of qPET for predicting PFS and OS were 1.95 (AUC 0.737, P<0.001, 95% CI=0.645-0.833) and 2.17 (AUC 0.668, P =0.005, 95% CI=0.562-0.815), respectively. The best cut-off value of deltaSUVmax for predicting PFS was 43.39% (AUC 0.660, P =0.002, 95% CI=0.565-0.755). deltaSUVmax (AUC 0.604, P =0.126, 95% CI=0.485-0.722) and ΔSUVpeak (AUC 0.602, P=0.131, 95% CI=0.475-0.730) were not statistically significant to predict OS. Kaplan-Meier analysis showed DS (PFS, P <0.001; OS, P =0.004), qPET (PFS, P <0.001; OS, P <0.001), and Ann Arbor stage (PFS, P <0.001; OS, P =0.004) were significant predictors for PFS and OS, while deltaSUVmax (P<0.001) and IPI (P=0.003) were the significant predictors for PFS, but not OS. Multiple analysis showed qPET (PFS, P <0.001; OS, P =0.001) and Ann Arbor stage (PFS, P =0.003; OS, P =0.047) were independent predictors for PFS and OS. ***Conclusion:*** qPET and Ann Arbor stage were independent predictors of PFS and OS. Using qPET to analyse the interim PET/CT, combined with Ann Arbor stage, may be beneficial for distincting between patients with good and poor prognosis.

## EP-0328

### Deep learning-based fully automatic segmentation of whole-body [18F]FDG PET/CT images from lymphoma patients: addition of CT data has poor impact on networks performance

***C. S. Constantino***[1,2], *F. P. M. Oliveira*[1], *S. Leocádio*[1], *M. Silva*[1], *C. Oliveira*[1], *J. C. Castanheira*[1], *Â. Silva*[1], *S. Vaz*[1], *R. Teixeira*[1], *M. Neves*[1], *P. Lúcio*[1], *C. João*[1], *S. Vinga*[2], *D. C. Costa*[1];
[1]*Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*INESC-ID, Instituto Superior Técnico, Universidade de Lisboa, Lisbon, PORTUGAL.*

***Aim/Introduction:*** Segmentation is paramount for the quantification of [$^{18}$F]FDG avid lymphoma lesions in clinical practice and research. Our aim is to investigate the added value of anatomic low-dose CT information on the performance of a fully automatic deep learning-based (DL-based) segmentation on whole-body [$^{18}$F]FDG PET/CT images from lymphoma patients. ***Materials and Methods:*** A training set of 144 whole-body [$^{18}$F]FDG PET/CT images from lymphoma patients and the corresponding lesions' manual segmentation was obtained from The Cancer Imaging Archive [1] published by autoPET MICCAI challenge [2,3]. Images were acquired on Siemens Biograph mCT PET/CT scanner. An independent set of 65 [$^{18}$F]FDG PET/CT images acquired on Philips Gemini TF 16 PET/CT from lymphoma patients was used for external validation. All visible lesions were identified by nuclear medicine physicians and manually segmented independently by two experienced observers (Obs1 and Obs2) [4]. Two networks were trained using the nnU-Net framework [5]: one-channel (PET) and two-channel (PET and low-dose CT). A standard 3D U-Net architecture was chosen and hyperparameters were estimated based on heuristic rules. Training was performed with five-fold cross-validation (80% train; 20% internal validation). The

proportion of overlap between segmentations was calculated using Dice coefficient (DC). Sensitivity and positive predictive values (PPV) using manual segmentations as ground truth were calculated. Wilcoxon test was used for statistical inference (significance level of 5%). Adjusted p-values were calculated using Bonferroni method. ***Results:*** Median DC, sensitivity and PPV achieved between observers' manual segmentation and one-channel U-Net was 0.82, 0.77 and 0.91 and 0.74, 0.84 and 0.83 respectively for Obs1 and Obs2. Median DC, sensitivity and PPV achieved between observers' manual segmentation and two-channel U-Net was 0.83, 0.81 and 0.92 and 0.78, 0.86 and 0.82 for Obs1 and Obs2, respectively. Median inter-observer manual segmentation DC was 0.84. The difference between the DC of manual vs one-channel segmentation and manual vs two-channel segmentation was not statistically significant: $p_{adj}$=0.06 (Obs1) and $p_{adj}$=0.22 (Obs2). Inter-observers manual segmentation DC was significantly superior to DC obtained with both DL-based approaches. ***Conclusion:*** The added value expected with the integration of the CT component in the network is not statistically proven with our data. However, a trend for better results was observed. Both DL-based networks had an outstanding performance compared to literature. Funding: LyRaCAD (Ref.:LISBOA-01-0247-FEDER-039885); OLISSIPO (H2020, No:951970); UIDB/50021/2020 (FCT) ***References:*** [1] Clark et al., https://doi.org/10.1007/s10278-013-9622-7; [2] Gatidis et al., https://doi.org/10.7937/gkr0-xv29; [3] Gatidis et al., https://doi.org/10.1038/s41597-022-01718-3; [4] Constantino et al., https://doi.org/10.1007/s10278-023-00823-y; [5] Isensee et al., https://doi.org/10.1038/s41592-020-01008-z

## EP-0329

### Assessment of the metabolic volume of the tumor as a marker of response to therapy with CAR-T Cells in patients with B-cell non-Hodgkin lymphoma, our experience.

***M. CASALLAS CEPEDA****, J. Montalva Pastor, S. Salcedo, I. Gomez Fernandez, J. Alonso Farto;*
*Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.*

***Aim/Introduction:*** To assess the correlation between metabolic tumor volume (MTV), prior to infusion of therapy with CAR-T Cells, and survival (disease-free progression (PFS) and overall survival (OS)) as a prognostic marker of response in patients with refractory or relapsed non-Hodgkin lymphoma. ***Materials and Methods:*** Retrospective descriptive observational study, in which MTV and TLG were evaluated in the baseline $^{18}$F-FDG-PET/CT study, prior to the infusion of CAR-T Cells therapy; with the intention of assessing disease-free progression and overall survival. Body metabolic images were quantitatively assessed manually by two nuclear medicine doctors, using GE AW Server 3.2 software. The data obtained with the subsequent $^{18}$F-FDG-PET/CT and clinical history were compared, evaluating the disease-free progression and overall survival from the infusion of the therapy with cut-off until April 1, 2023. ***Results:*** 73 patients were included, of which 4 were excluded because they did not have access to the baseline $^{18}$F-FDG-PET/CT for quantification (39 men and 30 women; 56.52% and 43.47% respectively) with a median age 61 years. 29 were infused with tisagenlecleucel (Kymriah®) and 40 with axicabtagene ciloleucel (Yescarta®) with a median follow-up of 447 days. Median survival data were 92 days for PFS and 447 days for OS. Therefore, we stratified the cohort according to the median MTV (114.40 cm $^{3)}$ in two groups: high tumor volume (HMTV) and low tumor volume (LMTV) (35 and 34 patients respectively), evidencing a lower number of days until PFS and OS in the HMTV group (69 and 446 days vs 94.5 and 466 days). ***Conclusion:*** A high MTV value in the $^{18}$F-FDG-PET/CT prior to infusion of CAR-T Cell therapy is related to worse progression-free survival and overall survival in patients with refractory or relapse of non-Hodgkin's lymphoma. ***References:*** 1. doi: 10.1182/bloodadvances.2020001900/2. doi: 10.1182/bloodadvances.2020002394/3. doi: 10.1016/S1470-2045(18)30864-7/4. doi: 10.1016/S1470-2045(18)30864-7

## EP-0330

### 18F-FDG PET/CT Volumetric and Radiomic Features for lesions/patients' characterization in CAR-T therapy

***E. Abenavoli****[1], F. Linguanti[1], I. Cutini[2], L. Nassi[3], B. Puccini[3], M. Palazzo[3], B. Sordi[4], R. Saccardi[2], A. Vannucchi[4], R. Sciagrà[1], V. Berti[1];*
*[1]Nuclear Medicine Unit, Experimental and Clinical Biomedical Sciences Department "Mario Serio", AOU Careggi, Florence, Italy, Florence, ITALY, [2]Department of Cellular Therapies and Transfusion Medicine, Careggi University Hospital, Florence, ITALY, [3]Hematology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY, [4]Department of Experimental and Clinical Medicine, CRIMM, Center Research and Innovation of Myeloproliferative Neoplasms, Azienda Ospedaliera Universitaria Careggi, University of Florence, Florence, ITALY.*

***Aim/Introduction:*** 18F-FDG PET/CT(PET/CT)is currently used to assess non-Hodgkin lymphoma patients eligible to chimeric antigen receptor T cell(CAR-T)therapy.We sought to identify precocious and specific metabolic radiomic PET features measured at time of CAR-T transfusion(TT),1 month (M1) and 3 months (M3) post-CAR-T therapy,which can identify relapsed/refractory lesions(R/R). ***Materials and Methods:*** A total of 50 PET/CT (17 TT,16 M1,17 M3)from 17 patients were reviewed. Lesions were delineated using an automated preselection of 18F-FDG avid structures defined by a SUV ≥ 2.Lesions without avid uptake were drawn manually using CT as reference.Volumetric and radiomic parameters were measured on PET/CT using LIFEx software both for Reference lesion (RL) and for all lesions(nodal and extranodal).Mann-Whitney test was used to assess the difference in features between R/R and not-R/R.We performed factor analysis to remove redundancy of cross-correlated variables and discriminant analysis to examine the power of the potential independent predictors.At patient level,GLM repeated measures analysis was used to assess longitudinal changes in radiomic features derived from both global disease and RL. ***Results:*** A total of 112 lesions were segmented and analysed for radiomic features extraction.We divided lesions into 3 groups according to tissue type: nodal (18TT, 22M1, 30M3), muscle-bone (5TT, 2M1, 3M3), and soft tissue (10TT, 8M1, 14M3).R/R lesions were 72 and not-R/R lesions were 40.Biopsy has been considered gold standard to distinguish R/R from pseudoprogression. Regarding nodal lesions,SUVmax at TT,IntensityBased Local-Intensity-Peak at M1 and GLCM joint-maximum with SUVmax and TLG at M3 exhibited significant predictive power of R/R. Regarding soft tissue lesions,GLZM Small-Zone-Grey-Level-Emphasis associated with TLG,IntensityBased 25$^{th}$percentile at M1 and GLCM dissimilarity with NGTDM contrast at M3, significantly predicted R/R status. No variable exhibited significant predictive power for muscle-bone tissue lesions, probably because of small sample size. At patient level,in R/R group,the variance of SUVmean indicated a significant time effect,with reduction at TT-M1 and subsequent increase at M1-M3.Moreover,the SUVmax variance was similar to SUVmean, but with significant results only at TT-M1.No significant variance of metabolic and volumetric variables was found in not-R/R group. ***Conclusion:*** Our study demonstrated that metabolic radiomic

PET/CT parameters could provide a significant predictive power in identification of R/R status in CAR-T therapy.Interestingly,-features related to metabolic activity at all time points resulted particularly significant in nodal lesions examination.On the other hand, in soft tissue lesions,the significant predictive power was related to features evaluating heterogeneity.Longitudinal analyses demonstrated significant variation in SUVmean and SUVmax only in R/R patients. ***References:*** Nioche C,et al. Cancer Research.2018;78:4786-4789; www.lifexsoft.org

## EP-0331

### Is [18F]FDG PET/CT at one month of chimeric antigen receptor T-cell therapy (CAR-T) in lymphomas necessary in the early treatment response assessment?

***P. Stefaneli Mormandi***, *C. Soldevila-Lozano, A. Caballero-Gonzalez, S. Abouzian Senhaji, P. Torres-Quintana, A. Fernández-León, R. Valverde-Jorge, M. Velasco-Nuño, J. Duch, V. Camacho, A. Flotats;*
*Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

***Aim/Introduction:*** The importance of [$^{18}$F]FDG PET/CT in the staging and follow-up of lymphomas has been internationally accepted for several years. The new treatments force us to rethink the follow-up protocols in the response assessment in all immunotherapies. The aim of this study is to retrospectively evaluate the early metabolic response of patients with diffuse large B-cell lymphoma (DLBCL) treated with CAR-T cell therapies and to analyze current PET/CT follow-up protocols. ***Materials and Methods:*** Retrospective study of 21 patients (13 men, 8 women; mean age 50.4 years) with DLBCL, refractory to at least 2 therapeutic lines and who were treated with CD19 CAR-T therapy. A [$^{18}$F]FDG PET/CT was performed prior to CAR-T infusion, as well as at one (M1) and three months (M3) post-infusion. Images were assessed using the Lugano classification and the LYmphoma Response to Immunomodulatory Therapy Criteria (LYRIC). The total follow-up time was 6 months (M6). ***Results:*** The number of patients who presented complete response (CR) was 8 pts in M6, 6 pts in M3 and 4 pts in M1. A progression disease (PD) was seen in 13 pts, 12 pts and 2 pts for M6, M3 and M1 respectively. No patients presented partial response (PR) in M6, 2 pts did in M3 and 10 pts in M1 (of whom 1 pt evolved to CR in M3; 4 pts maintained PR and underwent adjuvant radio/chemotherapy; 1 pts presented an indeterminate response and the other 4 pts had a PD). Finally, indeterminate response was only seen in M3 (1 pt) and M1 (5 pts, all confirmed as PD in M3). ***Conclusion:*** The assessment made by [$^{18}$F]FDG PET/CT 3 months after the infusion of CAR-T cells is similar to the real evolution of the patients in the short term. In the series presented, the [$^{18}$F]FDG PET/CT carried out one month after CAR-T therapy was not a good predictor of response and may not be necessary.

## EP-0332

### Head-to-head comparison between 68Ga-Pentixafor and 18F-FDG PET/CT in diffuse large B cell lymphoma

***P. Palanivelu***, *H. Goyal, D. Halanaik, P. Ganesan;*
*Jawaharlal Institute of Postgraduate Medical Education and Research, Pondicherry, INDIA.*

***Aim/Introduction:*** Positron emission tomography with computed tomography (PET/CT) using the standard radiotracer 18F-FDG is the most recommended method for imaging patients with diffuse large B cell lymphoma (DLBCL). However, there is significant over-expression of the CXCR4 chemokine receptor noticed in the DLBCL and marker of disease aggressiveness. Furthermore, it has the potential for theranostics and CXCR4-targeted radionuclide therapy. We evaluated in vivo expression of the CXCR4 chemokine receptor using novel tracer 68Ga-Pentixafor PET/CT in DLBCL and compared it to 18F-FDG PET/CT. ***Materials and Methods:*** Morphologically proven treatment-naive DLBCL patients were enrolled in this prospective study. The institute's ethics committee approved this study, and informed consent was obtained from all the patients. Twenty-seven patients (17 Males; 10 Females, Median age 55 years, Range 25- 73 years) underwent 18F-FDG PET/CT and 68Ga-Pentixafor PET/CT. Evaluated separately for 23 anatomic regions (12 lymph node stations and 11 organs/tissues). For lesion-to-lesion analysis, SUVmax was calculated. Concordance between 18F-FDG and 68Ga-Pentixafor PET/CT was assessed based on standard Lugano's staging. Cohen's Kappa statistics were used to analyze the agreement. ***Results:*** From the analysis of 27 patients, the mean number of nodes detected by FDG was 24.78 ± 30.56 (mean ± SD) and 23.22 ± 29.51 for Pentixafor (p-value 0.155). The mean number of extranodal sites was detected by FDG 2 ± 0.96 and 1.93 ± 1.00 for Pentixafor. A substantial agreement (Kappa 0.804) was achieved between FDG & Pentixafor in detecting the number of nodal and extranodal sites of lymphoma involvement. In visual comparison by maximum intensity projection images, 68Ga-Pentixafor shows more intense uptake than F-18 FDG in 3 (11%) patients, equal uptake in 8 (29%), and superior FDG uptake in 16 (60%) patients. The intensity of the tracer uptake in the nodal lesions was higher in 18F-FDG PET/CT, which is statistically significant. The mean SUVmax reflects this in the nodes 3.96 ± 2.44 (mean ± SD) for FDG and 2.13 ± 1.11 for Pentixafor ($p < 0.001$). Even with statistically significant differences in the SUVmax, overall Lugano staging showed a statistically significant correlation (p-value 0.001) between 68Ga-Pentixafor and 18F-FDG PET/CT. ***Conclusion:*** 68Ga-Pentixafor PET/CT showed good concordance and comparable diagnostic performance to 18F-FDG PET/CT for baseline staging in patients with DLBCL. 68G-Pentixafor PET/CT may help to select patients who might benefit from CXCR4-directed therapy.

## EP-0333

### 18F-FDG PET/CT features as potent imaging biomarkers of efficacy and toxicity in large-B-cell lymphoma treated with CAR-T cell therapy

***D. Leithner***[1], *J. R. Flynn*[1], *A. Mauguen*[1], *S. M. Devlin*[1], *T. Fei*[1], *B. S. Imber*[1], *H. Hubbeling*[1], *M. E. Mayerhoefer*[1], *D. Lafontaine*[1], *L. Michaud*[2], *M. Perales*[1], *H. Schöder*[1], *R. Shouval*[1];
[1]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Lausanne University Hospital, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** Chimeric antigen receptor T (CAR-T) cell therapy has transformed the care of patients with large B cell lymphoma (LBCL). However, toxicity and disease recurrence or progression after CAR-T remain a barrier and effective quantitative biomarkers for their outcomes represent an unmet clinical need. Our aim was to evaluate whether 18F-FDG PET/CT imaging features can inform the likelihood of response and developing immune toxicity (i.e. cytokine release syndrome [CRS] and neurotoxicity) in LBCL patients treated with CD19-directed CAR-T cell therapy. ***Materials and Methods:*** 18F-FDG PET/CT scans performed before CAR-T for LBCL were retrospectively analyzed by a board certified radiologist. Metabolic tumor volume (MTV), SUVmax, total lesion glycolysis (TLG), and presence of bulky disease were recorded using the PET-CT plugin for FIJI. Response to CAR-T cell therapy was defined according to the Lugano

criteria. CRS and neurotoxicity were graded according to ASTCT guidelines. Progression-free survival (PFS) was measured from time of CAR-T cell infusion; PFS events included death, relapse, and disease progression. Association between PET imaging features and outcomes were studied in univariable logistic regression and Cox regression models. ***Results:*** A total of 181 LBCL patients, with a median age of 65 years, treated with autologous CD19-directed CAR-T (94 axi-cel, 52 tisa-cel, 35 liso-cel) were included. We considered two time points of evaluation: 1) pre-apheresis scans (n=161; median SUVmax 19, MTV 56, TLG 427, maximum diameter 7.8 cm), and 2) latest disease evaluation before CAR-T infusion which includes post-apheresis and post-bridging scans, as well as pre-apheresis scans for patients who did not have additional imaging afterwards (n=181; median SUVmax 15, MTV 44, TLG 333, maximum diameter 7.8 cm). At the pre-apheresis point, increasing SUVmax, MTV, and TLG were associated with a higher likelihood of non-complete remission (CR) and grade 2-4 neurotoxicity (P-values 0.003, 0.021, 0.036 and 0.011, 0.04, 0.024, respectively). Similarly, the same pattern of association was observed when evaluating radiologic features measured at most recent disease assessment before CAR-T infusion. Finally, increasing SUVmax, MTV, and TLG at latest disease assessment were strongly associated with shorter PFS (HR 1.28 [95% CI 1.11-1.48], HR 1.05 [1.03-1.07], HR 1.06 [1.04-1.09], respectively, all P<0.001). ***Conclusion:*** This is the one of the largest studies demonstrating that quantitative radiologic features in LBCL may serve as biomarkers for CAR-T cell therapy toxicity and likelihood of treatment failure. These results may guide preventive interventions to increase the efficacy and safety of CAR-T cell therapy.

## EP-0334

### Effect of chemotherapy-related hepatic steatosis on liver 18F-FDG uptake in lymphoma patients

***Y. Wang***, *M. Su, L. Li;*
*West China Hospital, Sichuan University, Chengdu City, CHINA.*

***Aim/Introduction:*** Nonalcoholic fatty liver disease is the most common liver disorder in the developed countries. Although typically associated with obesity and metabolic syndrome, it can also be secondary to drug toxicity. Liver uptake activity is used as a semi-quantitative reference to assess treatment response among lymphoma patients by positron emission tomography-computed tomography (PET/CT) with 2-deoxy-2-[F-18]fluoro-D-glucose ($^{18}$F-FDG). However, hepatic steatosis after chemotherapy may affect hepatic glucose metabolism. The aim of our study was to evaluate the impact of chemotherapy-related hepatic steatosis on liver $^{18}$F-FDG uptake in lymphoma patients. ***Materials and Methods:*** We conducted a retrospective analysis of 56 lymphoma patients (23 diffuse large B cell lymphoma, 33 extranodal natural killer/T-cell lymphoma and 1 Hodgkin lymphoma) with de novo hepatic steatosis after chemotherapy. Patients with chemotherapy-related steatosis (steatosis group) were matched 1:1 to controls (non-steatosis group) by histologic type. All of them underwent a baseline whole-body PET/CT (B-PET) and interim or end-to-treatment PET/CT (I/E-PET) after chemotherapy. Patients with liver disease or steatosis on baseline PET/CT scans were excluded. Steatosis was diagnosed on the unenhanced CT part of PET/CT examinations using a cut-off value of 42 Hounsfield units (HU). The mean and maximum standardized uptake values (SUVmean and SUVmax) were recorded on the liver and the tumor target lesion. Data were analyzed by paired samples t-test and linear regression. ***Results:*** No significant differences in terms of age, gender, histologic type and Ann Arbor staging between steatosis group and non-steatosis group. In the steatosis group, liver SUVmax and SUVmean were significantly lower in I/E-PET (2.53±0.42 and 2.06±0.41, respectively) as compared with B-PET (2.84±0.35, P<0.005 and 2.32±0.32, P<0.005, respectively). But in the non-steatosis group, there were an increased liver SUVmax and SUVmean in I/E-PET(2.82±0.38 and 2.28±0.32, respectively) as compared with that of B-PET (2.62±0.37, P<0.005 and 2.12±0.35, P<0.005, respectively). CT density of liver was found to be an independent factor that correlated with liver SUVmax and SUVmean, while BMI, blood glucose level, $^{18}$F-FDG dose and incubation period were not. ***Conclusion:*** PET/CT scans showed that chemotherapy-related hepatic steatosis in patients with lymphoma had decreased liver $^{18}$F-FDG uptake. These alterations should be noted when a metabolic response to therapy in the interim and end-to-treatment PET/CT is determined.

## EP-0335

### Classical Hodgkin's Lymphoma: does baseline 18F-FDG PET/CT radiomics from the largest and hottest lesions add value to conventional prognostic models?

***E. Triumbari***[1,2], *D. Morland*[3], *R. Gatta*[4], *A. Collarino*[4], *E. Maiolo*[4], *A. Cuccaro*[4], *M. De Summa*[4], *S. Chiesa*[4], *L. Boldrini*[4], *M. E. Mayerhoefer*[5], *L. Nardo*[6], *S. Hohaus*[4], *S. Annunziata*[4];
[1]*1Department of Radiology, Radiotherapy and Hematology, Fondazione Policlinico Universitario A.Gemelli IRCCS, Rome, ITALY,* [2]*Radiopharmacy Research Core Facility, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY,* [3]*Service de médecine nucléaire, Institut Godinot and CReSTIC EA 3804, Université de Reims Champagne-Ardenne, Reims, FRANCE,* [4]*Department of Radiology, Radiotherapy and Hematology, Fondazione Policlinico Universitario A.Gemelli IRCCS, Rome, ITALY,* [5]*Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [6]*Department of Radiology, UC Davis, Sacramento, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Aim of this study was yo investigate the predictive role of baseline $^{18}$F-FDG PET/CT (bPET/CT) radiomics from two target lesions in patients with classical Hodgkin's Lymphoma (cHL) and its value in combination with clinical and conventional PET/CT prognostic models. ***Materials and Methods:*** cHL patients with bPET/CT between 2010 and 2020 were retrospectively included and randomized into training and validation sets (60%-40%). Two target lesions were chosen: Lesion_A, with the largest axial diameter ($D_{max}$); Lesion_B, with the highest $SUV_{max}$. The total metabolic tumor volume (TMTV) was also calculated for each patient, and 212 radiomic features were extracted from each target lesion. All PET/CT features were harmonized using ComBat method across two scanners. Two outcomes were chosen: progression free survival (PFS), and Deauville Score (DS) at interim PET/CT. For each outcome, three models (and their combinations) were constructed using training data, then validated: radiomic model "R", with features selected by cross-validated LASSO regression; conventional PET/CT model "P", based on $D_{max}$, $SUV_{max}$ and TMTV; and clinical model "C", based on the International Prognostic Score (IPS) and early/advanced stage. ***Results:*** 197 patients were included (training set: n=118; validation set: n=79). During a mean follow-up of 53.8±29.8 months, 38/197 (19%) patients had adverse events and 42/193 (22%) had DS≥4. Only one radiomic feature was selected for PFS prediction (F_cm.corr from Lesion_B, C-index 66.9% [56.3-77.5]) and constituted the model "R". The optimal Cox clinical model "C" was identified as a combination of stage and IPS (C-index 74.8% [66.0-83.6]), while the optimal PET/CT model "P" was composed of TMTV and $D_{max}$ (C-index 63.3% [51.5-75.1]). At validation, models

"C", "C+R", "R+P" and "C+R+P" were significant for PFS. The best model was "C+R" (C-index 66.3% [55.9-76.7]). No model was found significant at validation for the prediction of DS. ***Conclusion:*** cHL bPET/CT radiomic features from the largest and hottest lesions may have a prognostic value in combination with clinical and conventional PET/CT data.

## EP-0336

### Comparison of Low dose Vs standard dose 18F-FDG PET/CT in Lymphoma Patients using Conventional PET/CT Scanner

***N. Kumar***, *J. Yadav, G. Arora, S. A. Shamim;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT plays a pivotal role in detection of lymphoma and broadly utilized in diagnosis, staging, restaging, and response evaluation of lymphoma patients. Repeated PET/CT scans are required for current disease status and response assessment. Present study aimed to develop a new protocol by using by comparing low-activity with standard $^{18}$F-fluorodeoxyglucose (FDG) PET/CT in lymphoma patients using conventional PET/CT scanner without compromising the image quality and clinical information and hence decreasing the radiation exposure to the radiation worker and general public. ***Materials and Methods:*** Histopathologically confirmed lymphoma patients were prospectively included for randomized scan using low vs standard activity FDG PET/CT scan. $^{18}$F-FDG PET/CT acquisition was performed after intravenous injection of low activity (group-1) 3-5mCi (111-185MBq) or standard activity (10mCi) (group-2) $^{18}$F-FDG and scanning with 2-3 min. per bed at 60 minutes post-injection. Two nuclear medicine physicians with experience of more than 3 years analysed the acquired scans and suggested five-point Likert scale based on image quality. The Likert scale with score ≥ 3 was assigned as acceptable image during PET/CT reporting. The inter-reader concordance and discordance on Likert score was also evaluated. ***Results:*** A total of 30 patients, 15 in each group (16 male; 14 female) with mean age of 44.7 ± 16.4 years were enrolled prospectively and injected with mean dose of 146.76±15.92Mbq (3.96±0.43mCi) in group-1 patients while 370MBq (10mCi) in group-2 patients. Of 15 patients in each group, baseline scans were performed in only 3 patients in each group. The median SUVmax; SUVmean of lesion was 6.5 (range 1.55-23.73); 2.5 (range 1.1-6.25) and 6.8 (range 1.13-11.06); 2.1 (range 0.91-4.24) in group-1 and 2 respectively. The median TBRmax; TBRmean of lesions was 4.24 (range 1.20-20.45); 3.32 (range 0.98-6.79) and 3.84 (range 1.13-9.81); 2.28 (range 1.02-3.79), for group-1 and 2, respectively. During image analysis, all the patients of both group 1 & 2 had scores ≥3 points that fulfilled the clinical needs for diagnosis/disease status. On subjective scoring, the inter reader concordance in Likert scoring was present only in ten patient while remaining 20 were discorded. ***Conclusion:*** Whole-body PET/CT scan in both groups had comparable image quality. Thus, low-dose $^{18}$F-FDG activity could maintain a satisfactory image quality with conventional PET/CT scanners and also reduces patient's as well as personnel radiation dose.

## EP-0337

### Do FDG PET metrics have a role for predicting the response to BeGeV therapeutic scheme in refractory Hodgkin lymphoma? A pilot study.

***D. Pizzuto***[1], *N. Messina*[2,3], *E. Maiolo*[2], *F. D'Alò*[2,3], *S. Hohaus*[2,3], *S. Annunziata*[1];
[1]*Nuclear Medicine Unit, GSteP Radiopharmacy, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [2]*Hematology Unit, Diagnostic Imaging, Radiation Oncology and Hematology Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [3]*Hematology Institute, University Department of Radiological and Hematological Sciences, Università Cattolica del Sacro Cuore, Rome, ITALY.*

***Aim/Introduction:*** BeGeV is an effective salvage regimen with high rate of complete response in Relapsed/Refractory Hodgkin Lymphoma (R/R HL). FDG PET metrics and Deauville score (DS) represent well-established parameters for the clinical management of HL patients; however, their role should be better defined in R/R HL undergoing BeGeV scheme. The study aimed to explore if DS and semiquantitative parameters, assessed on interim 18F-FDG PET/CT after 2 BeGeV cycles (interimPET), could predict DS of BeGeV end-of-treatment PET (EOT-PET) and the patients' outcome. ***Materials and Methods:*** From a large PET dataset, patients with R/R HL completing BeGeV scheme were retrospectively included from April 2017 to October 2022. All patients underwent a 18F-FDG PET/CT before BeGeV (prePET), after two (interimPET) and four BeGeV cycles (EOT-PET). For each patient, progression-free-survival (PFS as interval from starting BeGeV scheme to the recurrence/change of therapeutic scheme) and following PET variables were collected: prePET and interimPET LesionSUV$_{max}$, deltaSUV$_{max}$ (i.e. the variation between prePET and interimPET), interimPET DS, SUV$_{peak}$, SUV$_{mean}$, MTV, TLG, LiverSUV$_{max}$, LiverSUV$_{mean}$, rPET, qPET (i.e. Lesion SUV$_{max}$/LiverSUV$_{mean}$ and LesionSUV$_{peak}$/LiverSUV$_{mean}$, respectively). Within the cohort with persistent/progression disease at interimPET (DS≥4), the patients were dichotomized into two subgroups, according to the EOT-PET DS, as follows: DS≤3 and DS≥4. Differences of PFS and interimPET metrics were assessed between the EOT-PET DS≤3 and DS≥4 subgroups. ROC analyses were performed for assessing best PET metric cut-off value, with EOT-PET DS as outcome. A p value ≤ 0.05 was considered significant. ***Results:*** 23 patients were recruited. 11/23 patients (48%) had interimPET DS≤3; among them, 10/11 (90%) showed no PFS. Conversely, 12/23 patients (52%) presented a interimPET DS≥4; among them, 6/12 patients (50%) converted to a EOT-PET DS≤3, although all of them (6/6, 100%) presented a PFS at 20 months. The remaining 6/12 patients (50%) presented PFS at 20 months in 3/6 patients (50%). Within the interimPET DS≥4 cohort, SUV$_{max}$ ,SUV$_{mean}$, SUV$_{peak}$ , rPET, qPET were found significantly different among EOT-PET DS≤3 and DS≥4 subgroups (Mann Whitney U-Test; p=0.004, p=0.002, p=0.02, p=0.006, p=0.02, respectively). SUV$_{mean}$ cut-off value ≥ 3.50, rPET cut-off value ≥ 1.97 and qPET cut-off values ≥ 1.90 showed a sensitivity and specificity of 100% and 100% (AUC=1.00), 100% and 83.3% (AUC=0.97), 83% and 100% (AUC=0.89), respectively. ***Conclusion:*** DS and PET metrics applied on interimPET seemed to be effective to predict PFS and EOT-PET DS, respectively, so hypothesizing their usefullness for monitoring BeGeV therapeutic response in patients with R/R HL.

## EP-0338

### Normalization and 2-bit-quantization of FDG-PET using the Deauville Score for training an deep learning AI for lymphoma staging

***B. Schemmer***;
*Uniklinik Bonn, Bonn, GERMANY.*

***Aim/Introduction:*** Lymphoma is a common cancer in young adults and children worldwide. Regular staging is crucial for therapy planing and patient outcome. Positron Emission Tomography (PET) is a widely used imaging modality for lymphoma staging with the standard uptake value (SUV) commonly used as a measure of tumor activity. However, SUV has limitations, and methods improve the clinical value of PET imaging have been developed. One such method is the Deauville Score, which uses a visual qualitative scoring system for the interpretation of tumor uptake before and during therapy with blood-pool(mediastinum) and liver as references. ***Materials and Methods:*** We included 25 patients (median age 26 years (range, 12-34 years)), with histologically confirmed Hodgkin/NHL cancer who underwent FDG-PET/CT imaging for primary or follow-up staging with at least two FDG-PET studies (whole body and dedicated neck), to train and validate our AI model. The majority had visible brown fatty tissue (86%) and other unspecific uptake forms of uptake from inflammation, sarcoidosis and vaccination. The AI was based on deep learning and provided with whole-body PET-images. The AI was specifically not trained to find any subtle lesions with uptake below blood-pool. The PET-images were preprocessed, uptake values below blood-pool were no longer present in the training images. Detection was evaluated as successful when there was a corresponding labeled lymph-node in the data. To increase the amount of training data, the whole bodies were presented as single image slices (~50*100 images). ***Results:*** The results of the study showed that using the Deauville Score (stage 1 and 2 combined) as quantization/normalization method for AI training a reliable detection of suspicious lesions is possible with a small dataset. We achieved a good sensitivity of 92% (mainly due to lymphnodes close to each other). However specificity was only 27% due to misinterpretation of unspecific findings such as brown fatty tissue, inflammation and vaccination, on the other hand only findings that needed human interpretation where detected. ***Conclusion:*** This study demonstrates the potential of normalization/quantization of FDG-PET using the visual Deauville Score for deep learning AIs as a method to eliminate irrelevant image findings from PET images, thus reducing the workload of the reader. The AI itself currently suffers from the detection of unspecific findings which we hope to remove from the final results by using a second post processing AI.

## EP-0339

### Total metabolic tumor volume (TMTV) at baseline 18F-FDG PET/CT and Laboratory Prognostic Index (LAB-PI) as outcome predictors in Large B-Cell Lymphoma (LBCL).

***L. García Belaústegui***, *S. Borwne, L. Sancho Rodríguez, R. Figueroa, F. Minguez, M. Canales, S. Huerga, V. Betech-Antar, E. Pena, C. Grande, M. Garcia-Velloso;*
*Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** Aggressive LBCL is the most common subtype of non-Hodgkin's lymphoma and consists of a heterogeneous group of disorders with variable clinical presentation. LAB-PI is a recently validated prognostic index for LBCL that analyzes three pretreatment laboratory parameters: lactate dehydrogenase, hemoglobin and beta-2 microglobulin. This study aimed to correlate baseline PET-derived metabolic tumor volume (MTV) and LAB-PI score (LAB-PIs) with progression-free survival (PFS) and overall survival (OS) in a sample of LBCL patients to identify those with higher risk of early relapse or refractory disease. ***Materials and Methods:*** Patients with LBCL treated with R-CHOP(-like) regimens who had previously undergone a baseline $^{18}$F-FDG PET/CT were retrospectively reviewed. MTVs were obtained by an experienced nuclear medicine physician using Syngo.via software, with automatic threshold equal to 1.5 times the average standardized uptake value of the liver. The extent of the disease was evaluated considering the presence of unique lymph node involvement or the existence of extranodal extension. Correlation between LAB-PIs and MTV divided into three categories - nodal, extranodal and total- was assessed. ***Results:*** 56 patients (38 male, 18 women) with a mean age of 65 years (SD:15) were selected. LAB-PIs values were divided into low (0, 1, 2) and high (3,4), with 52 patients (59.8%) in the low LAB-PIs group and 35 patients (40.2%) in the high LAB-PIs one. The median of total MTV was 144.27 cm3 (Q1=64.07 cm3, Q3=543.63 cm3). Spearman's rank test was used to study correlation between LAB-PIs and MTV groups, with the highest correlation coefficient between LAB-PIs and extranodal MTV ($\rho$= 0.65; p<0.001). An unexpected finding was that all patients with a total MTV higher than 100cm$^3$ had a greater LAB-PIs. The median follow-up was 27 months, with OS and PFS of 96.3% and 97.3% in low LAB-PIs patients and 71.5% and 68.8% in high LAB-PIs ones. A log rank test between LAB-PIs groups was performed and showed statistical significance for both OS and PFS (p=0.005 and p=0.019, respectively). Regarding the total MVT, both OS and PFS were 100% for patients with a MTV bellow the median (144.27 cm3) and 73.4% and 70.4% respectively for those patients above it. ***Conclusion:*** Despite the small sample size, this initial study proposes pretreatment MVT and LAB-PI as a set of prognostic criteria for outcome in LBCL. Further validation in larger series is needed.

## EP-0340

### Prognostic Value of Volumetric Parameters with 18F-FDG PET/TC in Follicular Lymphoma

***P. Sarandeses***[1], *M. Poza*[1], *S. Pedraza*[1], *A. Medina Benito*[2], *A. Peter Seiffert*[2], *A. Jimenez*[1], *D. Vega*[1], *P. Zaragoza*[1], *S. Angiolillo*[1], *X. Guarnizo*[1], *S. Ruiz*[1], *A. Gomez*[1], *E. Martinez*[1], *A. Saviatto*[1], *A. Galiana*[1], *S. Barrio*[1], *M. Tabuenca*[1];
[1]*HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, Madrid, SPAIN,*
[2]*Universidad Politécnica Madrid, Madrid, SPAIN.*

***Aim/Introduction:*** Follicular lymphoma (FL) is the second most common no-Hodgkin lymphoma in developed countries. It is considered an indolent disorder with a relatively favorable course. However, a subset of patients has a more aggressive course and a worse outcome. Currently, there is no established method to identify patients at risk of early disease progression at the time of diagnosis of FL.The early identification is the main purpose of moderm-day prognostic tools to consequently modulate treatment intensification and maintenance therapies in an early phase.18F-FDG PET/CT (PET/CT) provides valuable prognostic information. Specifically, Tumor Metabolic Volume (TMV) and Total Lesion Glycolysis (TLG) at diagnosis are considered an independent prognostic factor for Progression-Free Survival (PFS) and Overall Survival (OS).Our objective is to evaluate the prognostic value of TMV and TLG at diagnosis. ***Materials and Methods:*** 69 FL patients were retrospectively enrolled from

December 2012 to september 2020, who underwent PET/CT at staging before immunochemotherapy.The TMV was obtained by summing the metabolic volumes of all individual nodal and extranodal lesions, using the 41% SUVmax threshold method. The most suitable cut-off to dichotomize patients regarding outcome was determined by receiver operating characteristic (ROC) analysis. Following that, both PFS and OS were estimated with Kaplan-Meier curves based on the optimal MTV threshold. ***Results:*** 69 patients were included, 34 men and 35 women; aged 35-98 (mean 67.9). 92.7% of them with a 3-4 Ann Arbor stage. The TMV and TLG are quantitative variables with non-parametric distribution with a median of 205.75 (range 0.5-1989) and SD 1161.12 (range 2-12916) respectively.In our sample, the ROC analysis could not demonstrate an optimal cut-off point for TMV, with an area under the curve of 0.6; Furthermore, no significant relationship was observed between VMT and TLG with PFS and OS.We have observed an association between TMV and stage III-IV, the presence of a bulky mass, bone marrow infiltration, elevated LDH and increased risk (Follicular Lymphoma International Prognostic Index FLIPI). ***Conclusion:*** Although most authors reflect that TMV and TLG are independent predictors of PFS and OS in patients with FL, in our sample it has only been significantly associated with a more advanced stage of the disease and with higher risk (FLIPI). ***References:*** Tatsumi, Mitsuaki et al. "Volumetric and texture analysis on FDG PET in evaluating and predicting treatment response and recurrence after chemotherapy in follicular lymphoma." **18F-FDG PET/CT maybe not so helpless in detection leptomeningeal metastasis- a case report**

***T. Stoeva****, M. Dyankova, S. Chausheva, T. Yordanova, Z. Dancheva, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** Leptomeningeal metastasis represents secondary infiltration by neoplastic cells in meningeal space. The gold standard for diagnosing the involvement of the meninges is cerebrospinal fluid analysis and contrast enhanced-magnetic resonance imaging (MRI). Herein, we aimed to report the usefullness of 18F-FDG PET/CT for finding out leptomeningeal carcinomatosis in a patient with extraosseous plasmocytoma. ***Materials and Methods:*** We present the rare case of a 52-years-old female patient with leptomeningeal carcinomatosis from extraosseous plasmocytoma. The patient visited hospital due to complaints of severe headache and disorientation which started two weeks ago. After performing brain computed tomography (CT) a tumor lesion was found in the cerebellum. Biopsy showed involvement from a plasma cell neoplasm. Patient was referred to 18F-FDG PET/CT because of the observation for multiple myeloma. ***Results:*** Whole body 18F-FDG PET/CT was performed with a complimentary protocol for better visualization, scanning only head and neck regions. The study showed multiple metabolically active lesions on brain surface. Also a FDG-avid lesion was found in the spinal cord on S1/S2 vertebrae level. Those findings raised a great suspicion for leptomeningeal involvement from a plasma cell neoplasm. Numerous metabolically active neck and mediastinal lymph nodes were found as well. There were no evidence of bone lesions. MRI was performed and confirmed the suspicions of leptomeningeal carcinomatosis. The patient was referred for a radiotherapy. ***Conclusion:*** This case report shows that head and neck as well as whole body $^{18}$F-FDG PET/CT can be used as an additional diagnostic tool for raising a suspicions of leptomeningeal carcinomatosis or as a primary diagnostic method in cases when cerebrospinal fluid analysis or contrast enhanced-magnetic resonance imaging can`t be performed.

### EP-0342

**18F-FDG PET/CT assessment of metabolic activity of the osteolytic lesions in patients with multiple myeloma after treatment for evaluation tumor vitality**

***T. Stoeva****, Z. Dancheva, M. Dyankova, S. Chausheva, T. Yordanova, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** We aimed to determine the cut-off value of the glucose metabolism, assessed by value of SUVmax and 5-point scale (FPS), to evaluate the vitality of multiple myeloma (MM) after treatment. ***Materials and Methods:*** We examined 31 patients with MM with 18F-FDG PET/CT after treatment. We estimated the cut-off value of the glucose metabolism evaluated by SUVmax and FPS by ROC curve and chi-square analysis. For a reference study, we used the highest SUVmax value measured in a patient with complete response. We determined the metabolic response as: incomplete metabolic response (IMR) - a SUVmax greater than 3.12 and a score greater than 3 as assessed by FPS. Complete metabolic response from the treatment (CMR) had a SUVmax less than 3.12 and less than score 3. ***Results:*** The results of the ROC curves of the SUVmax showed that the method is reliable and have a high degree of predictability (p=0.000) with area under the curve and confidence interval as follows: AUC 91.2% and CI 0.810-1.000. The threshold value for establishing an IMR is an uptake estimated as SUVmax between the values 2.95-3.12 with a corresponding sensitivity of 0.824; 0.706 and specificity 0.071; 0.071.Most patients evaluated with score 4 and 5 have established IMR. On the other hand, all patients evaluated with score 2 and 3 fall into the group with established CR. It was observed that 1 patient with proven stable disease was evaluated with a score 3. The determined threshold value for establishing an IMR from treatment is a focal uptake evaluated as score 3 (activity above the mediastinum or equal to the liver).We determined that CMR can be predicted for a SUVmax below 2.95, and an IMR - for a SUVmax equal to or above 3.12. A CMR with a high probability can be predicted with a visual assessment score of 1-2, and an IMR - with a score 3 and higher (score 4 and 5). We advise that with a result in the gray zone of a borderline metabolic response (FPS=3 and SUVmax between 2.95-3.12) it is appropriate to repeat the test in the shortest possible time (up to 2-3 months) in correlation with laboratory tests. ***Conclusion:*** 18F-FDG PET/CT is considered as a standard technique for evaluating and monitoring the metabolic response to therapy in patients with MM. In this regard, standardization of interpretation criteria and determination of positive/negative thresholds are of great importance.

## EP-0343

### 18F-FDG PET/CT in unknown primary suspected of multiple myeloma

***T. Stoeva**, Z. Dancheva, M. Dyankova, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** In the present study, we aim to evaluate the role of 18F-FDG PET/CT in patients with osteolytic lesions of unknown origin, suspecious of multiple myeloma. ***Materials and Methods:*** We retrospectively reviewed 33 patients who underwent 18F-FDG PET/CT because of osteolytic lesions suspect to be caused by multiple myeloma (MM) detected by conventional imaging studies. We used histological verification to confirm the diagnoses. The gender distribution of patients was 57.6% (n=19) males and 42.7% (n=14) females with an average age of 62 years (44-85 years). Magnetic resonance tomography (MRT) was performed on 24.2% (n=8), 66.7% (n=22) had a computer tomography scan (CT), and 9.1% (n=3) had a bone radiography (X-ray). All of the patients had no imaging findings or medical history of malignant disease. ***Results:*** According to 18F-FDG PET/CT was found that 57.6% (n=19) were true positive with subsequent histological verification for MM, 27.3% (n=9) were true negative, and 15.2% (n= 5) were false positives. The specificity and positive predictive value of the 18F-FDG PET/CT for detecting MM in patients with osteolytic lesions were 64.29% and 79.17%, respectively. We found that 15.8% (n=3) of patients had up to 5 osteolytic lesions, 15.8% (n=3) had between 5 and 10 lesions, and in 68.4% (n=13) - more than 10 metabolically active osteolytic lesions. The average SUVmax measured in all patients was 6.8. According to the 5-point scale evaluation- 38.1% (n=8) were with score 4 (metabolic activity above the hepatic level), and 61.9% (n=13) - with 5 (metabolic activity exceeding the hepatic level). In one of the patients, the bone lesions were located in the axial skeleton, and in the remaining 18- in the axial and appendicular skeleton. In 63.2% (n=12) a soft tissue component was also found. Extramedullary spread of the disease in the pleura was found in one patient. Pathological fractures occurred in 57.9% (n=11). ***Conclusion:*** 18F-FDG PET/CT is a non-invasive and highly sensitive examination of the whole body, allowing not only the detection of the primary tumor, but also its simultaneous staging and 18F-FDG PET/CT directed biopsy. In patients with unknown primary carcinoma, it should be used as the first imaging modality of choice. In the present study, we found that 18F-FDG PET/CT helped in the diagnosis of 57.6% (n=19) of the patients and the specificity and positive predictive value of 18F-FDG PET/CT method were 64.29% and 79.17%.

## EP-0344

### 18F-FDG PET/CT assessment of metabolic activity of the osteolytic lesions in newly diagnosed multiple myeloma patients as predictive factor for overall survival

***T. Stoeva**, Z. Dancheva, M. Dyankova, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** Our aim was to assess the impact of metabolic activity of osteolytic lesions found by staging 18F-FDG PET/CT and assessed by visual scale or semiqualitative value (SUVmax) as a predictor for overall survival (OS) in newly diagnosed multiple myeloma (MM) patients. ***Materials and Methods:*** A total of 19 patients with histologically proven multiple myeloma and a staging 18F-FDG PET/CT were included in the present study. We used a qualitative assessment of the metabolic activity of bone lesions by a 5-point scale (5-PS). On the other hand a semi-qualitative evaluation was performed using the SUVmax value. As a cut-off value we accepted the average SUVmax of all the malignant osteolytic lesions in this group obtained by us - 4,20. By using Kaplan-Meier survival analysis and the Log Rank test, we compared the OS of the group. ***Results:*** After the comparison, a tendency towards a longer overall survival was found in the patients with a SUVmax value lower than 4,20 (p=0.082), as only one of the patients with higher SUVmax value survived longer- 40 months after diagnosis. The average survival time after 18-FDG-PET/CT of patients with SUVmax less than 4,20 was 27 months. The OS after 18-FDG-PET/CT of patients with SUVmax equal to or greater than 4,20 was only 13,3 months. The Kaplan Meier analysis and Log Rank test revealed a statistically significant relationship between the evaluation of metabolic activity of osteolytic lesions assessed by 5-PS and overall survival (p=0.026). A shorter survival time was observed for patients with score 5 than those with scores 3 and 4. The average survival time after 18-FDG-PET/CT of patients with scores 3 and 4 was 26,67 months and in patients with score 5 was 8,5 months. ***Conclusion:*** In our study, we found that patients evaluated with score 5 (5-PS) of osteolytic lesions had significantly lower OS than those with scores 3 and 4. Also an average value of SUVmax of 4,20 showed a trend in patient stratification, with those with a lower SUVmax cut-off having greater overall survival.

## EP-0345

### Impact of the Segmentation Method on the Correlation between Metabolic Tumor Volume and Total Circulating Tumor DNA

***C. D. Ramos**[1], G. Duffles[1], M. S. Takahashi[1], E. Napolitano[2], F. Lupinacci[2], L. Pereira[2], J. Maues[1], M. Chauffaille[1], I. Lorand-Metze[1];*
*[1]University of Campinas, Campinas, BRAZIL,*
*[2]Laboratorio Fleury, Sao Paulo, BRAZIL.*

***Aim/Introduction:*** Total Metabolic Tumor Volume (TMTV) and total circulating tumor DNA (ctDNA) at baseline have been shown to be relevant prognostic factors for patients with diffuse large B-cell lymphoma (DLBCL), both positively associated with worse outcomes. Recent studies have demonstrated a strong correlation between ctDNA and TMTV [1,2]. However, there is currently no consensus on the optimal methodology for calculating TMTV. This study aimed to investigate whether the choice of the threshold used for tumor segmentation to calculate TMTV might influence its correlation with total ctDNA load in patients with DLBCL. ***Materials and Methods:*** Twelve patients (7 males, 57±17.1 years old) with DLBCL who underwent [$^{18}$F]FDG PET/CT imaging and ctDNA analysis before treatment were studied. TMTV was calculated using semi-automatic segmentation of attenuated corrected [$^{18}$F]FDG PET images, performed with the freely available Beth Israel plugin for Fiji (a distribution of ImageJ). Three different thresholds were used for tumor segmentation: absolute fixed thresholds using standardized uptake values (SUVs) of 2.5 (TMTV_2.5) and 4.0 (TMTV_4.0), and fixed relative threshold based on 41% of the maximum SUV (TMTV_41%). The representation of the tumor contour was visually analyzed for the three methods. Total ctDNA was measured by next-generation sequencing (NGS) with a panel of 11 genes and quantified in haploid genome equivalents per mL (hGE/mL). The Spearman correlation coefficient was used to assess the relationship between ctDNA and TMTV, with significance level of 5% ($p<0.05$). ***Results:*** The median (min-max) ctDNA load was 1335.1 hGE/ml (175.8 - 4862.4hGE/ml). The median (min-max) of TMTV_2.5, TMTV_4.0 and TMTV_41% were respectively 130.8mL (0-1654.5 mL), 96.8mL (0-1580.6

mL) and 164.5 mL (0-1454.9 mL). The Spearman correlation coefficient revealed a strong correlation between ctDNA and all TMTV calculation methods: TMTV_4.0 (r=0.7881; p=0.0023), TMTV_2.5 (r=0.7040; p=0.0106), and TMTV_41% (r=0.6480; p=0.0227). At visual analysis, the representation of tumor contour appeared to be more accurate for TMTV_2.5 and TMTV_4.0 than for TMTV_41%, particularly in areas with non-homogenous [$^{18}$F] FDG uptake. ***Conclusion:*** TMTV shows a strong correlation with ctDNA in DLBCL patients even using different thresholds for tumor segmentation. The correlation was higher for threshold of SUV=4.0 than for thresholds of SUV=2.5 or 41% of the maximum SUV. Methods that use absolute fixed threshold seems to present greater visual outline of the tumor. ***References:*** [1] Le Goff E, et al. Br J Haematol. 2023 Apr 10. doi: 10.1111/bjh.18809. Epub ahead of print.[2] Rivas-Delgado A, et al. Clin Cancer Res. 2021 Jan 15;27(2):513-521. doi: 10.1158/1078-0432.CCR-20-2558.

## EP-0346

### End of treatment FDG PET CT in patients with Langerhans cell histiocytosis as a predictor of disease recurrence and survival.

***P. Bochev***[1], *Z. Dancheva*[2];
[1]*Acibadem Cityclinic Mladost UMBAL, Sofia, BULGARIA,* [2]*Medical University "Prof.Dr Paraskev Stoyanov", Varna, BULGARIA.*

***Aim/Introduction:*** To evaluate the value of end of treatment (EOT) FDG PET CT in patients with Langerhans cell histiocytosis (LCH) as a predictor of disease recurrence and as a prognostic factor for survival. ***Materials and Methods:*** Inclusion criteria: Histologically confirmed LCH. At least one FDG PET CT performed after any treatment completed - surgery, chemotherapy, radiotherapy or targeted therapy or after spontaneous remission. Minimum follow up after completion of treatment and a negative PET was 24 months (24 to 242 months) Exclusion criteria: Single system-skin and lung forms Criteria for PET positivity: any lesion, consistent with possible LCH involvement with above background activity (may be equalized to Deauville >2) Retrospective review of the database of the two participating centers from 2010-2020 identified 22 patients with LCH (1y10mo to 66y). Two patient with skin only and lung only disease on staging and one patient under active therapy were excluded. One patient wasa excluded due to inconsistent follow up. Of the remaining 18 patients 8 patients were with multisystem LCH (MS LCH), 5 patients with multifocal single system LCH (SS-MF) and 5 patients with single system single site (bone)- SS-SS LCH. All SS-SS were treated locally by excision. All MS and SS-MF LCH were treated by at least one line of chemotherapy ***Results:*** 16 patients achieved PET negative scan after treatment or (one) - spontaneous remission. Three of them recurred: one SS-SS recurred locally after 5 months (alive, no further data on consecutive treatment) and two patients with MS-LCH recurred 19 and 20months after chemotherapy. Furthermore the latter two achieved remission after consecutive lines of chemotherapy.Two patients with MS LCH never achieved a PET negative scan and died of the disease (both with risk organ involvement) ***Conclusion:*** The negative end of treatment FDG PET CT in patients with LCH does not necessarily guarantee durable remission, but recurrence rate is comparatively low and consecutive recurrences were eligible for successful treatment. In cases of MS-LCH, failure to achieve a PET negative scan under treatment bears a poor prognosis.

## EP-0347

### Unresolved Challenges in Functional Imaging of Multiple Myeloma: F-18 Fluorocholine PET/CT or F-18 FDG PET/CT? A Single Center Experience

***G. KAYA***[1], *S. Akın*[2], *Y. Büyükaşık*[3], *M. Tuncel*[1], *M. F. Bozkurt*[1], *P. Özgen Kıratlı*[1];
[1]*Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University Medical School Department of Medical Oncology, Ankara, TÜRKIYE,* [3]*Hacettepe University Medical School Department of Hematology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The role of FDG-PET/CT in Multiple Myeloma (MM) is well-established. In certain groups of MM, especially those with low-hexokinase enzyme expression, false negative findings are seen with FDG-PET/CT, which decreases the sensitivity of the test to 50%. In the preliminary studies, F18 Fluorocholine (FCH) PET/CT has been shown to be a good candidate in the evaluation of MM. This study aims to compare the diagnostic performance of FDG and FCH-PET/CT imaging in MM patients. ***Materials and Methods:*** FDG and FCH-PET/CT (early 10 and late 60min imaging) whole-body images of biopsy-proven MM patients performed within a 30-day period were evaluated retrospectively. IMPeTUs-criteria were used for FDG-PET/CT and also modified for FCH-PET/CT. Any focal FCH uptake higher than the physiological biodistribution was accepted as positive for MM. The sensitivity and accuracy of each imaging modality were evaluated and a ROC analysis was done. Images of both FCH and FDG-positive patients were compared with each other. Evaluation with laboratory correlation was performed as well. ***Results:*** A-total-of 75 PET-CT scans of 25 patients (F/M: 11/14; mean age: 61.4y (SD 2.4)) diagnosed with MM composed the study group. Twelve examinations were performed for newly-diagnosed patients and 13 for restaging purposes. Clinical and laboratory results showed, 24/25 patients were secretory, thus evaluated as positive for at least minimal residual disease. FCH-PET/CT scans were accepted positive in 22 of 25 patients; while 14 patients were positive on FDG-PET/CT scans. All FDG-positive patients were also FCH-positive. FDG&FCH were both positive in 14 patients; of whom 9 were FCH>FDG, but none were FDG>FCH. The sensitivity of FCH and FDG-PET/CT scans were calculated as 90% and 59%, respectively. The accuracy of FCH and FDG scans were calculated as 92% and 60%, respectively. ROC analysis showed that the AUC of FCH is higher than FDG (0.96 vs 0.79). There was no significant difference between the detection performance of early 10min and late 60min FCH scans. ***Conclusion:*** The results of this study suggest that the diagnostic performance of FCH-PET/CT is superior to FDG-PET/CT in the evaluation of patients with MM. Our data should be confirmed in larger series with different clinical scenarios.

## EP-0348

### Prognostic utility of baseline 18F-FDG PET/CT in relapsed and refractory Multiple myeloma patients treated with T-cell redirecting bispecific antibodies.

***F. MINGUEZ***[1], *V. Betech-Antar*[1], *L. Tamariz-Amador*[1], *A. Bronte Viedma*[1], *J. Rosales*[1], *J. Bastidas*[1], *C. von Gall*[2], *M. Romera*[1], *P. Echegoyen*[1], *F. Pareja del Rio*[1], *T. Cuenca*[1], *S. Menendez-Sanchez*[1], *L. García Belaustegui*[3], *L. Sancho*[3], *E. Guillen*[3], *E. Prieto*[1], *R. Ramos*[3], *J. Simon*[1], *M. Panizo*[1], *S. Huerga*[1], *J. San-Miguel*[1], *P. Rodriguez Otero*[1], *M. García-Velloso*[1];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,* [2]*Siemens Healthineers, Molecular Imaging, Knoxville, TN, UNITED STATES OF AMERICA,* [3]*Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** [$^{18}$F]FDG PET/CT is an accepted imaging technique for staging and monitoring patients with relapsed/refractory multiple myeloma (RRMM). Its prognostic value in patients treated with bispecific antibodies (BsAbs) has not been explored. We investigated the prognostic value of PET/CT before therapy with BsAbs in patients with RRMM. ***Materials and Methods:*** Forty-six patients with RRMM who had performed an FDG PET/CT before initiation of treatment with BsAbs were reviewed according to the IMPeTUS criteria with the 5-point Deauville score (DS) in bone marrow (BM) and focal lesions (FL), presence of paramedullary (PMD) and extramedullary (EMD) disease. Metabolic tumour volume (MTV) and total lesion glycolysis (TLG) were obtained using three-dimensional volume-of-interest isocontouring and bone was automatically segmented using work in progress syngo.via MI General Anatomy Segmentation software (Siemens Healthineers, Knoxville, TN). MTV and TLG for bone (BMTV and BLG), EMD (EMTV and ELG), and total (TMTV and TLG) were each calculated separately. Patients' outcome was analysed using the Kaplan-Meier method and Cox regression. ***Results:*** Median age was 64.2 years (IQR, 56 - 72 years) and 27 (58.7%) were male. PET/CT results were positive in 42 (91.3%) patients. Twenty (43.5%) patients had diffuse BM uptake with DS ≥ 4. FL were detected in 38 (82.6%) patients, with DS ≥ 4 in 35 (92.1%). PMD was present in 22 (47.8%) patients and EMD in 20 (43.5%). PET biomarkers are presented in Table 1 (PET BIOMARKERS).In the whole cohort of patients, EMD had no prognostic value. However, among patients with EMD, those with a EMTV >100 (n =7 [35%]) had shorter PFS (median 1.6 months [95% CI 0.7 - 2.7] versus 2.7 [95% CI 1.2 - 7.3] (p = 0.21); HR 3.9 [95% CI 1.2 - 12.4] (p=0.02) and shorter OS (median 2.8 months [95% CI 2.1 - 5.4] versus 6 [95% CI 2.9 - 11.9] (p = 0.16); HR 5.3 [95% CI 1.2 - 24.2] (p=0.03) than those with EMTV<100 (n = 13 [65%]). ***Conclusion:*** Baseline presence of EMTV >100 had significant impact on PFS and OS before therapy with BsAbs in patients with RRMM. In this series, neither TMTV nor TLG show prognostic impact regarding survival.

## EP-0349

### Comparison of C-11 Methionine and F-18 FDG PET/CT findings in evaluation of Multiple Myeloma: First Turkey Experience

*E. Özkan[1], **B. Demir**[1], G. Cengiz Seval[2], M. Araz[1], C. Soydal[1], M. Beksac[2], N. O. Kucuk[1];*
*[1]Ankara University School of Medicine Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Ankara University School of Medicine Department of Hemotology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Despite advances in the treatment of Multiple Myeloma(MM), it stays as a disease that cannot be cured. The extent of the disease in diagnosis and follow-up, accurate evaluation of therapy response are important in terms of management and extending the survival. Although $^{18}$F-FDG PET/CT is valuable in predicting disease prognosis, it does not have the enough sensitivity and specificity to determine disease activity. Methionine(MET), an amino acid labeled with carbon-11(C-11), performs better than $^{18}$F-FDG in determining active lesions. In this study, the first $^{11}$C-MET PET experience in Turkey and comparison with $^{18}$F-FDG PET/CT findings was shared. ***Materials and Methods:*** Thirty-five PET images of 31 patients who underwent prospective $^{11}$C-MET PET imaging with the diagnosis of multiple myeloma were evaluated. A total of 15 $^{11}$C-MET and $^{18}$F-FDG PET images were simultaneous in 13 of 31 patients. PET indication was for staging in 6 patients, treatment response in 2 patients, and restaging in 7 patients. For $^{11}$C-MET PET, imaging was performed at 20th minute after activity injection of 6-10 MBq/kg. For $^{18}$F-FDG, after 3-5 MBq/kg activity injection, imaging was performed at 60th minutes. Both methods were compared in terms of number of focal lesions, extramedullary disease, SUV and metabolic tumor burden. ***Results:*** While MET and FDG were positive in 12 examinations, more foci were detected with MET in 8 (67%) examinations. While active disease could not be detected with FDG in 1 case, it was shown to be positive with MET (MET+/FDG-). In one patient, FDG + lymph nodes suggestive of nodal disease were MET negative and myeloma involvement was also excluded histopathologically (MET-/FDG+). In 1 patient, FDG uptake in the ribs were MET negative and interpreted as false positive due to fracture. The mean SUV was 10.13 for MET and 4.83 for FDG (p=0.017). The mean metabolic tumor burdens determined by MET and FDG were 215.95 and 44.18, respectively (p=0.001). Disease foci that could not be detected by FDG in the paramedullary area in 5 examinations, in the extramedullary area in 2 examinations and in the medullary area in 4 examinations were demonstrated with MET PET. ***Conclusion:*** Although the study has significant limitations in terms of patient number and heterogeneity, it shows that MET is a more sensitive method than FDG PET in detecting myeloma lesions. The prognostic value and treatment response of MET need to be included in the assessment of a larger number of homogeneous patients.

## EP-0350

### Role of 18F-FDG PET/CT in patients with Castleman disease

***R. Goel**, N. Damle, Y. Dharmashaktu, C. Bal, M. Tripathi, R. Kumar, P. Kumar;*
*All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.*

***Aim/Introduction:*** Castleman disease (CD) is a rare, nonclonal lymphoproliferative disorder. Due to its ability to affect lymph nodes of any part of the body, Castleman disease is a great mimic of both benign and malignant conditions. This study aims to evaluate the role of 18F FDG PET/CT in patients with clinical suspicion of Castleman disease. ***Materials and Methods:*** We retrospectively reviewed 15 18F-FDG PET/CT scans in 12 patients with clinical suspicion of Castleman disease at our institution between January 2017 and April 2023. The lesion SUVmax and lesion-to-liver uptake ratios were also measured. ***Results:*** There were 12 patients (4 females, 8 males; age 9-63 years) who underwent a total of 15 18F-FDG PET/CT scans. Out of the 15 scans, 6 were performed for diagnosis, 6 for response assessment, and 3 for surveillance/suspected recurrence. Out of the 6 scans done for diagnosis, 5/6 patients were confirmed to have Castleman disease on histopathology. Histopathology of 1/6 patients revealed a T cell lymphoma. Lymphadenopathy with increased FDG uptake was seen in 4/5 patients with CD and they had involvement of two or more nodal groups (MCD). 1/5 patients demonstrated involvement of single group of lymph nodes (UCD). The average size of lymph nodes involved was 2.1 cm (short axis dimension). Two patients with MCD also demonstrated hepatosplenomegaly. The median SUVmax and median lesion-to-liver ratios of the 5 patients with CD were 2.6 (range 1.5-14.7) and 0.87 (range 0.66-4.6) respectively. Out of the 6 scans performed for response assessment, 4 showed stable disease and 2 showed partial response. Of the three scans performed for surveillance/suspected recurrence 1 revealed metabolically active right cervical, right axillary, mesenteric and abdominopelvic lymph nodes, later confirmed to be recurrent disease. ***Conclusion:*** 18F-FDG PET/CT may play an important role in

identifying lymph nodes and lesions that are more likely to yield a definitive diagnosis on biopsy, defining extent of disease (UCD versus MCD), monitoring response to treatment, and detection of suspected recurrence in patients with Castleman disease which would help in their overall management. However, more studies on a larger patient population are required to validate the same.

## EP-0351

### Talquetamab, a Novel Anti-Myeloma GPRC5DxCD3 Bispecific Antibody, is Associated with Increased Oropharyngeal FDG Uptake

***J. Trak***, *T. Mouhieddine, G. Lancman, L. Sanchez, A. Chari, M. Ghesani;*
*Mount Sinai Hospital, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Talquetamab (JNJ-64407564) is a first-in-class bispecific antibody that directs CD3+ T cells to G protein-coupled receptor class C group 5 member D (GPRC5D), which is highly expressed on primary multiple myeloma cells. However, up to 36% and 48% of patients receiving the recommended phase 2 dose (RP2D) (≥400 mcg/kg), reported dysgeusia. Nevertheless, the rate of talquetamab discontinuation secondary to oral toxicity remained less than 5%. While GPRC5D has limited expression in normal human tissues, RNA sequencing data has revealed GPRC5D expression in resident plasma cells of the salivary glands and tonsils. In order to better understand the potential pathophysiology underlying talquetamab-related oropharyngeal symptomatology, we characterized changes in 18F-fluorodeoxyglucose (FDG) uptake on positron emission tomography/computed tomography (PET/CT) imaging in patients enrolled in clinical trials of talquetamab. ***Materials and Methods:*** Eighty-seven patients that received talquetamab monotherapy between January 2018 and 2023 were evaluated by collecting the following parameters from PET/CTs and patient charts prior to and during/within 60 days of talquetamab discontinuation: bilateral parotid and submandibular gland SUVmax, radiotracer injected dose and circulation time, talquetamab dose(s), dysgeusia, and xerostomia. 58 patients had complete PET/CT profiles (non-I&C-adjusted). 29 patients had injected doses and FDG circulation times within a 20% margin (I&C-adjusted). Two sets of paired t-tests were performed. ***Results:*** Radiologically, paired t-test of the I&C-adjusted cohort (n=29) demonstrated a statistically significant increase in FDG uptake in the left submandibular gland in PET/CT imaging acquired during/after talquetamab therapy compared to that acquired prior to initiation of talquetamab (p=0.041). Paired t-test of the non-I&C-adjusted sample (n=58) demonstrated a statistically significant increase in FDG uptake in the right and left parotid, and left submandibular glands in PET/CT imaging acquired during/after talquetamab therapy compared to that acquired prior to talquetamab (p=0.006, 0.039, and 0.001, respectively). Clinically, in the I&C-adjusted sample, 34.5% (10/29) of patients reported grade 2 dysgeusia, 37.9% (11/29) reported grade 1, and 27.6% (8/29) did not report any dysgeusia. 17.2% (5/29) reported grade 2 xerostomia, 34.5% (10/29) reported grade 1, and 48.3% (14/29) did not report any xerostomia. ***Conclusion:*** While patients did not have clinically apparent changes in salivary glands on physical exam, the increase in FDG uptake in the bilateral parotid and left submandibular glands may suggest an ongoing inflammatory process. We hypothesize that this may reflect off tumor/on-target mediated T cell trafficking and hence a potential mediator of dysgeusia and xerostomia that warrants further detailed clinical characterization and tissue sampling.

## EP-0352

### A follow up of 30 patients with multiple myeloma confirmed: prognostic role of number of focal lesions and SUV max at diagnosis in 18F-FDG PET/CT

***I. López Villar***[1], *V. Castillo Morales*[1], *I. Hernández Pérez*[1], *A. García Noblejas*[2], *S. Hernández Muñiz*[3], *I. Salmerón Beliz*[3], *J. Alonso Farto*[4], *D. Zamudio*[4], *N. Gómez de Leon*[3];
[1]*Princesa University Hospital, Nuclear Medicine Service, Madrid, SPAIN,* [2]*Princesa University Hospital, Hematology Service, Madrid, SPAIN,* [3]*Princesa University Hospital, Radiology Service, Madrid, SPAIN,* [4]*Gregorio Marañón University Hospital. Nuclear Medicine Service, Madrid, SPAIN.*

***Aim/Introduction:*** Flurodeoxyglucose Positron Emisión Tomography (18F-FDG-PET/CT) is a useful molecular imaging in staging and follow up of multiple myeloma patients. ***Materials and Methods:*** A baseline and follow -up study of 30 MM was carried out in University Hospital (January 2018-January 2023), Male 19 Female 11; age range:36-91 years, mean 65+/- 11.0 years). We were referred by hematologist for baseline PET/CT, after induction PET/CT and after autologous transplant PET/CT.The PET criteria for active MM were defined as focal bone lesions with visually increased 18F-FDG uptake and/or SUV max superior to 4.0 and/or diffused bone marrow metabolism superior to liver. We then correlated with number of focal lesions, SUV max and if there is extramedullary disease at baseline. ***Results:*** 30 patients with pathohistochemical examinations confirmed with MM. Of this 30 MM patients: 18F-FDG PET-CT baseline identified 20/30 p (66.7%). PET false negative was seen in 10/30 p (33,3%).Of the 20/30 patients detected by FDG tracer, the number of focal lesions were superior to 3 in 20/30, SUV max at diagnosis were superior to 4.5 in 18/20 and SUV max focal inferior or equal 4,5 in 2/20.None of the 20/30 patients had extramedullary disease at baseline. Complete FDG supresión after induction was seen in 20/30 p.Of the 20 patients detected by FDG PET, 15/20 patientsunderwent autologous transplant. Complete FDG supresión after transplant was seen in all the patientes (15) with follow up range 5 months-5 years, therefore is required longer follow-up and more studies are needed to detect the role of novel therapies (antibodies, chimeric antigen receptor (CAR) T cells etc. ***Conclusion:*** In our study: sensitivity of 18F-FDG PET-CT for detecting myeloma bone disease was 66.7% (20/30 p). False negative was seen in 10/30 (33,3%) patients with MM confirmed and could be associated with low hexokinase-2 expression.None of the 20 p (20/30) identified by PET had extramedullary disease at baseline.Complete FDG supresión after induction was seen in the 20 patients identified by PET.There is no significant associattion between SUV max and response after induction and response after transplant. Long term studies are needed.

## EP-0353

### [11C]-Methionine as Novel Image Biomarker of Disease Activity in Newly Diagnosed Multiple Myeloma Patients - Comparison with [18F]-FDG

***S. Serfling***[1], *M. Bittrich*[1], *A. K. Buck*[1], *T. Higuchi*[1], *S. Samnick*[1], *K. M. Kortüm*[1], *L. Rasche*[1], *H. Einsele*[1], *R. A. Werner*[1], *S. Knop*[2];
[1]*University Hospital Würzburg, Würzburg, GERMANY,*
[2]*Klinikum Nürnberg Nord, Nürnberg, GERMANY.*

***Aim/Introduction:*** Based on accumulation in altered immunoglobulin productions, [11C]-Methionine has demonstrated improved read-out in patients with multiple myeloma (MM) in retrospective settings. We aimed to determine the diagnostic performance of [11C]-Methionine relative to [18F]FDG in patients enrolled in a prospective Phase III trial.

***Materials and Methods:*** 11 newly diagnosed, symptomatic multiple myeloma (MM) patients have been scanned as part of the clinical Phase III DSMM XVII trial (NCT03948035). At baseline, all subjects were scheduled for a dual-tracer approach using [11C]-Methionine and [18F]FDG. Individuals remained treatment-naïve between both scans. We then conducted a visual and quantitative assessment, determining maximum standardized uptake ($SUV_{max}$) values and target-to-background ratios (TBR) in sites of disease. $SUV_{max}$ was then compared to serologic markers at time of imaging, including M component, serum free light chains (FLC), Bence-Jones-protein (BJ), lactate dehydrogenase (LDH), and Beta-2 microglobulin (B2M). Correlative analyses were performed using Spearman's Method. ***Results:*** On a visual assessment, [18F] FDG and [11C]-Methionine were rated positive in all patients (11/11 [100%], respectively). In 4/11 instances (36.4%), the latter radiotracer provided a higher detection rate on lesion-based level. On a quantitative assessment, we recorded increased $SUV_{max}$ for [11C]-Methionine (10.0 ± 5.0 vs [18F]FDG, 6.3 ± 3.5; P=0.058). Indicative for improved image contrast, TBR were also substantially elevated for [11C]-Methionine (12.1 ± 7.9 vs [18F]FDG, 4.1 ± 2.8, P<0.01). When compared to markers of disease activity, [18F] FDG-derived $SUV_{max}$ failed to reach significance (M component, FLC, BJ, LDH, B2M, P≥0.34). [11C]-Methionine, however, exhibited relevant associations with M component (R=0.7 [95% CI, -0.38-0.77], P<0.05), along with improved associations with other serologic markers (FLC, BJ, LDH, B2M, P≥0.2). ***Conclusion:*** [11C]-Methionine provides improved image contrast when compared to [18F]FDG in newly diagnosed MM patients and thus, allows for a more comprehensive read-out of myeloma manifestations. Future analyses of this cohort will investigate whether [11C]-Methionine also emerges as an image biomarker to monitor disease activity under novel targeted therapies.

## EP-0354

### Multiple Myeloma: a comparison between 18F-FDG-PET/CT and 68Ga-PSMA-PET/CT

***D. Bezzi***[1], *E. Zamagni*[2], *S. Fanti*[3], *L. Vetrone*[1], *M. Talarico*[2], *C. Malizia*[3], *C. Nanni*[3];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Seràgnoli Institute of Hematology, Bologna University, Bologna, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** The aim of this study was to assess the possible added value(especially in the light of theranostic approaches) and limitations of 68Ga-PSMA-PET/CT(PSMA-PET) to that of 18F-FDG PET/CT(FDG-PET) in the evaluation of myelomatous disease. ***Materials and Methods:*** We prospectively enrolled 21 consecutive patients with newly diagnosed symptomatic multiple myeloma(MM) who underwent FDG-PET and PSMA-PET, performed 0-14 days apart. The results of the two scans were compared in terms of the number of focal bone lesions(FL) and paramedullary lesions(PM), SUVmax of the hottest FL and hottest PM, and presence of diffuse pathologic bone marrow(BM) involvement. Wilcoxon rank test was used to compare SUVmax of FDG-PET and PSMA-PET. ***Results:*** A total of 245 focal lesions were detected, of which 235 were FL and 10 PM. FDG-PET detected 229/245(93%) lesions in 13 patients and PSMA-PET 61/245 (25%) lesions in 12 patients. Sixteen(7%) lesions were detected by PSMA-PET alone and 184(75%) by FDG-PET alone. FDG-PET and PSMA-PET identified 10 and 9 PM respectively, while isolated BM involvement was detected in 2 and 1 patient respectively. Seventeen patients(80%) had concordant FDG-PET and PSMA-PET scans while 4 patients(20%) had discordant scans. Regarding concordant scans, 5 patients had both negative scans while 12 patients had both positive scans. Six patients(29%) had positive FDG-PET and PSMA-PET scans identifying the same number and sites of myelomatous lesions. The remaining six patients(29%) had positive FDG-PET and PSMA-PET scans, but identified different number of lesions; indeed in 4 patients FDG PET identified more lesions (203 vs 25), while PSMA-PET did so in 2 patients (22 vs 7). Regarding discordant scans, 3 patients(14%) had a positive FDG-PET scan and a negative PSMA-PET, while 1 patient had a positive PSMA-PET and a negative FDG-PET. The highest FL-SUVmax of FDG-PET and PSMA-PET had a median(min-max) of 5,8(2,2-34,4) and 5,4(2-8,6) respectively, the highest PM-SUVmax had a median of 5,1(2,7-14,4) and 5,1(1,2-10), both with no significant difference at statistical analysis(pFL= 0,3,pPM= 0,93). Notably, the hottest SUV max in PSMA scans was higher than liver uptake in only 2/13 positive PSMA scans(SUVmax 10 and 9,1 vs liverSUVmax of 7,9 and 8,5 respectively). ***Conclusion:*** According to these preliminary data, FDG-PET appears to be more sensitive than PSMA-PET for the detection of myelomatous lesions; furthermore the PSMA uptake was low in the majority of cases (lower than the liver). These data need to be confirmed in larger series to evaluate the role of PSMA in the MM.

## EP-0355

### Sarcopenia and metabolic parameters of [18F]-FDG PET/CT in patients with multiple myeloma. Preliminary results.

***Aim/Introduction:*** Multiple myeloma (MM) is a malignant neoplasm of plasma cells in the bone moarrow, classified as an obesity-associated cancer. Sarcopenia, defined by a reduction in muscle mass, occurs commonly with aging ad it has an overall poor clinical outcome. The aim of our work was to evaluate sarcopenia and metabolic parameters obtained in [18F]-FDG PET/CT, in patients with MM. ***Materials and Methods:*** The IMMAGE study consists of quantifying body composition in patients with MM that underwent a staging [18F]-FDG PET/CT and examine its association with prognosis factors. Skeletal muscle (SM) and musculoskeletal index (SMI defined by skeletal muscle mass area/height$^2$) measured at the L3 level on the CT image were coupled with glycidic quantification from PET images using the MIM Encore® software. Maximum and mean standardized uptake value (SUVmax and SUVmean), metabolic volume and total lesion glycosis (TLG) at skeletal muscle were all categorized into 2 categories based on the median (low/high). Sarcopenia was estimated using cut-off points: males BMI≥25; SMI<53 cm$^2$ /m$^2$;

males BMI<25; SMI<43 cm2 /m$^2$; females SMI<41 cm$^2$ /m$^2$). Odd Ratios (OR) and 95% confidence intervals (CI) were estimated using logistic regression models adjusted by age and sex using Stata v16. ***Results:*** We analysed a total of 49 patients (32 males, mean age 67 years old -SD 12 range 39 to 87 years old-), 33 (67%) of them were overweight or obese. Twenty-one patients (43%) present sarcopenia and age mean was higher among patients with sarcopenia (69 years old SD: 12) than those without sarcopenia (65 years old, SD: 12) and no differences by sex (among 47% female and 41% male). In patients with sarcopenia the mean SUVmean and metabolic volume values were 0.75 and 26.6 while in non-sarcopenic patients they were 0.64 and 37.42 respectively. Sarcopenia was associated with high SUVmean values (OR: 4.64; 95% CI, 1.29 to 16.71), high metabolic volume values (OR: 0.09; CI95% 0.01 to 0.54), while no differences were found with SUVmax (p = 0.14) and TLG (p = 0.07). ***Conclusion:*** This preliminary results show high prevalence of sarcopenia in MM patients. The [18F]-FDG PET/CT variables, SUVmean and metabolic volume, could be useful to classify patients with sarcopenia and to evaluate further the prognosis of MM patients. ***References:*** Sergentanis TN et al, Clin Lymphoma Myeloma Leuk 2015; Martin L et al, J Clin Oncol, 2013

***Aim/Introduction:*** The aim of this study is to describe the outcome of relapsed/refractory multiple myeloma (RRMM) patients treated with Chimeric antigen receptor T-Cell therapy (CAR-T) and to evaluate the prognostic value of baseline [18F]-FDG PET/CT visual parameters . ***Materials and Methods:*** Forty-six patients with RRMM treated with CAR-T from a multicentre study were included. Visual parameters based on the Italian Myeloma for PET use (IMPeTUs) were used for the baseline PET/CT evaluation. We assessed the presence of bone marrow (BM) diffuse uptake, more than 3 osteolytic lesions with FDG uptake (>3L) and the type of plasmacytoma (paramedullary vs. extramedullary). We analysed the contribution of baseline PET variables in the prediction of progression-free survival (PFS) and overall survival (OS) in the whole group. Statistical analysis was performed using SPSS software. Survival analysis was calculated using the log-rank test. ***Results:*** The results showed 39% of patients (18/46) with an increased diffuse BM uptake and 52% (24/46) with >3L. Plasmacytomas were present in 48% of patients (22/46), 33% (15/46) paramedullary and 15% (7/46) extramedullary. After a mean follow-up of 23 months the median PFS was 21.8 months (95%CI 14.7-29.1) and median OS was not reached with an OS rate at 18 months of 74%. An increased diffuse BM uptake or the presence of >3L did not have an impact in PFS or OS. The presence of plasmacytomas did not impact PFS (p=0.49), but median OS in patients with and without plasmacytomas was 18.8 months (95%CI 14.9-22.7) vs. not reached (NR), respectively, reflecting the difficulties in treating these subset of patients after CAR-T. In terms of the type of plasmacytoma, patients with paramedullary plasmacytomas had a similar PFS and OS compared to patients without plasmacytomas, but patients with extramedullary plasmacytomas had a shorter PFS [7.5 months (95%CI 1.6-13.3) vs. 22.3 months (95%CI 13.7-30.9); p=0.026] and OS [9.2 months (95%CI 4.8-13.6) vs. NR (95%CI NR-NR); p=0.002]. ***Conclusion:*** An increased diffuse BM uptake or the presence of >3L do not have an impact in PFS and OS in this cohort. The presence of extramedullary plasmacytomas has prognostic impact in terms of both PFS and OS. No differences were observed between patients with paramedullary vs. without plasmacytomas. These results highlight a potential value of baseline PET/CT for the evaluation of response after BCMA CAR-T therapy and the identification of high-risk patients.

## EP-0357

### Prognostic value of 18F-FDG PET/CT biomarkers in patients with diffuse large B-cell lymphoma treated with chimeric antigen receptor T-cell therapy Preliminary results.

***J. Cañadas Salazar****, A. Martín Lopez, L. G. Díaz González, C. Montes fuentes, A. Martín García-Sancho, P. Tamayo Alonso; Sacyl, Salamanca, SPAIN.*

***Aim/Introduction:*** Evaluate the prognostic value of PET biomarkers, such as metabolic tumor volume(MTV), total lesion glycolysis(TLG) and standard maximum uptake value(SUVmax), on the outcome of patients diagnosed with diffuse large B-cell lymphoma treated with chimeric antigen T-cell receptor (CART). ***Materials and Methods:*** We prospectively analyzed patients diagnosed with diffuse large B-cell lymphoma who received CD19-targeted CAR-T cell therapy at our center between March 2019 and January 2022. Patients underwent PET/CT studies with 18F-FDG before treatment and at 28 days post infusion. Pre-treatment serum lactate dehydrogenase (LDH) values and the presence of bulky tumor (<7cm) were defined. Treatment response was assessed by 18F-FDG PET/CT 28 days after infusion using the Deauville criteria. Two nuclear medicine specialists measured PET biomarkers with MIM(v7.0.6) software at each time point, and statistical analysis was performed with IBM_SPSS(v.25) statistical software. ***Results:*** 44 patients were selected, 25 men and 19 women, with a mean age of 60 years (range 32-76). Before treatment 36 (81%) patients had advanced stage, 26 (59%) an increased LDH level and 17 (38%) had bulky disease. The mean values of baseline PET/CT biomarkers obtained in the complete response group were MTVcr:229.6 ml, TLGcr:1903.59 and SUVmaxcr: 16.07; and of the group that did not achieve complete response MTVpr: 448.47ml, TLGpr: 4072.05 and SUVmaxpr: 24.09 demonstrating higher values in the groups that did not achieve complete response. The Mann-Whitney U test was performed on each biomarker for the presence or absence of complete metabolic response, without observing statistical significance in any of them (p>0.05) ***Conclusion:*** PET biomarkers, in this instance, do not appear to show a relationship in predicting response to CART therapy. Although they do not show a statistically significant relationship in this study, this may be due to the small sample size. Further follow-up and number of patients is required.

### EP-0358

**Dual time point [18F]FDG PET/CT can differentiate benign from malignant soft tissue tumors and outperforms the diagnostic performance of conventional PET/CT acquisition**

***P. D'Abadie***, *O. Gheysens, R. Lhommel, T. Kirchgesner, A. De Roo, T. Schubert;*
*Cliniques universitaires Saint Luc, Brussels, BELGIUM.*

***Aim/Introduction:*** $^{18}$F-FDG-PET/CT can be used for the workup of soft tissue tumors (STT) but it ability for differentiating malignant from benign tumors remains controversial, with risks of false positive and negative results[1]. The aim of this study is to evaluate if dual time point PET/CT can predict with higher accuracy malignant STT. ***Materials and Methods:*** Patients with undetermined STT were prospectively enrolled in this study. $^{18}$F-FDG PET/CT imaging was performed at 1h (t1) and 3h (t2) post [$^{18}$F]FDG injection. Delta SUV max ((SUVmax$_{t2}$ - SUVmax$_{t1}$)/ SUVmax$_{t1}$) x 100) was calculated for each tumor. Metabolic parameters were compared to histological results. The diagnostic performance of delta SUV max and SUVmax$_{t1}$ were measured using ROC curves and cutoffs defined using the Youden index. ***Results:*** 62 patients were included corresponding to 20 benign and 42 malignant tumors. Delta SUV max was significantly higher in malignant STT compared to benign STT (mean: + 16.6 % versus - 6.7 %, p <0.001). Delta SUVmax > 14% predicts tumor malignancy with a specificity (Sp) of 90% and a sensitivity (Se) of 67%. SUVmax$_{t1}$ >4.5 was less accurate with a Sp of 80% and a Se of 57%. In a subgroup of tumors with at least a slight metabolism activity at t1 (SUVmax> 2.5; n= 44), delta SUVmax significantly outperformed the diagnostic performance of SUVmax$_{t1}$ with a Sp of 100% (vs 70%) and a Area Under the ROC Curve of 0.82 (vs 0.63, p: 0.007). ***Conclusion:*** Dual time point [$^{18}$F]FDG PET/CT identifies malignant STT tumors with high specificity and outperforms the diagnostic performance of conventional PET/CT acquisition. ***References:*** 1- Shin et al. The clinical efficacy of $^{18}$F-FDG-PET/CT in benign and malignant musculoskeletal tumors. Ann Nucl Med (2008) 22: 603-609.

### EP-0359

**Prognostic Value of Pre-Treatment F-18 FDG PET/CT Parameters in Soft-Tissue Sarcomas**

***I. Ak Sivrikoz***, *H. Deveci, E. Çinçin;*
*ESOGU School of Medicine Department of Nuclear Medicine, Eskisehir, TÜRKIYE.*

***Aim/Introduction:*** Soft-tissue sarcomas (STSs) are cancerous growths of mesenchymal tissues, most commonly arising from fat, muscles, and other connective tissues. Most soft tissue sarcoma (STS) has a high affinity for 18F-FDG, which is why 18F-FDG PET/CT has been proposed as a non-invasive method, useful in diagnosis and follow-up. The aim of the present study was to investigate the value of PET parameters of pre-treatment F-18 FDG PET/CT as prognostic factors in overall survival (OS) and progression-free survival (PFS) in patients with STSs. ***Materials and Methods:*** A retrospective study was conducted on 76 consecutive patients with primary locally advanced or distant metastatic STS, who underwent an F-18 FDG PET/CT before surgery or neoadjuvant treatment at our Institute between June 2014 and December 2020. A final cohort of 31 patients (mean age 61,87±17, 21 Male, 10 Female) was finally analysed. PET parameters (SUVmax, SUVmean, MTV and TLG values) were calculated according to the literature and tested as predictive factors for progression-free survival (PFS) and overall survival (OS), defined as the period starting from the date of first treatment and disease relapse or death, respectively. ***Results:*** There were 5 Liposarcoma, 4 fibrosarcoma, 7 malignant fibrous histiocytoma, 4 synovial sarcoma, 2 leiomyosarcoma, 2 rabdomyosarcoma and 7 other sarcomas. All tumors showed a significantly high and variable degree of FDG uptake, with a mean SUVmax of 12.39 ± 6.23 (range 4.3-49.4). The mean MTV and TLG were 388.61 cm3 (1.8-2115 cm3 ) and 1876.84 (6.82-9756), respectively. The mean follow-up time for all patients was 36 mounts. The mean PFS was 17.44 mounts. There was no significant correlation between SUVmax, SUVmean, MTV and TLG values and PFS (0.34, 0.63, 0.15 and 0.08, respectively). In total, 18 out of 31 patients died during the observation period. The mean OS was 21.6 months (95% CI: 16-not reached), with a survival rate of 58% at 1 year. There were no significant correlation between SUVmax, SUVmean, MTV, TLG values and both PFS (0.34, 0.63, 0.15 and 0.08, respectively) and OS (0.3, 0.6, 0.44, 0.26, respectively). ***Conclusion:*** In conclisuon; There were no significant association for PET parameters with PFS and OS in patients with STSs. If the prognostic value of this feature is confirmed in prospective studies with larger populations, it could be proposed to predict PFS and OS in high-risk patients with STSs.

### EP-0360

**Association of 'Hot Kidneys' on Bone Scintigraphy and Serum Ferritin Levels**

***I. Kuji***[1], *K. Watanabe*[1], *E. Ryuta*[1], *Y. Matsusaka*[1], *A. Seto*[1], *I. Matsunari*[2];
[1]*Department of Nuclear Medicine, Saitama Medical University International Medical Center, Hidaka, Saitama, JAPAN,* [2]*Department of Nuclear Medicine, Saiatama Medical University Hospital, Saitama Medical University, Moroyama, Saitama, JAPAN.*

***Aim/Introduction:*** The mechanism of 'hot kidneys' on bone scintigraphy is not well understood[1]. Renal accumulation is influenced by various factors, like renal function, nephritis, bone metabolism abnormalities, etc. We found high serum levels of ferritin in patients with autoimmune and malignant diseases who had high renal accumulation on bone scintigraphy. Therefore, we investigated the association. ***Materials and Methods:*** We retrospectively analysed data of patients who underwent bone scintigraphy and serum ferritin measurement within 1 month. Serum ferritin level was measured for anaemia scrutiny, except in cases of polyarthritis. Bilateral renal cortex counts were measured on the posterior whole-body image avoiding the ribs, and lumbar spine counts were measured avoiding degenerative changes. The renal to vertebral bone accumulation ratio of the average count per pixel was calculated as the K/V ratio, and its correlation with the blood levels of ferritin, iron, creatinine, C-reactive protein, haemoglobin, and alkaline phosphatase, as well as white and red blood cell counts was analysed using Spearman's rank correlation coefficient. Renal accumulation was also visually evaluated on a five-point scale compared to the rib and lumbar accumulation on bone scintigraphy. ***Results:*** A total of 22 patients with high renal

accumulation were included, 8 with suspected polyarthritis, 2 with amyloidosis, and 12 with malignant tumours. The mean interval between bone scintigraphy and blood collection for ferritin level measurement was 7.8±8.9 days. There was a significant correlation between the K/V ratio and ferritin level (r=0.66, p<0.001), red blood cell count (r=0.56, p=0.007), and haemoglobin level (r=0.58, p=0.005). However, there was no correlation with the following parameters, which are thought to be related to nephritis, and iron and bone metabolism: creatinine (r=0.27, p=0.22), C-reactive protein (r=-0.11, p=0.61), white blood cell count (r=-0.19, p=0.41), iron (r=0.33, p=0.21), and alkaline phosphatase (r=-0.038, p=0.88). There was also a significant correlation between the K/V ratio and the visual evaluation score (r=0.86, p<0.001). ***Conclusion:*** There was a significant correlation between serum ferritin levels and increased renal accumulation on bone scintigraphy. The detailed mechanism is unknown, but it was suspected to be related to changes in the red blood cell count caused by the red blood cell destruction unrelated to iron deficiency. ***References:*** 1. Bernard MS, Hayward M, Hayward C, et al. Evaluation of intense renal parenchymal activity ("hot kidneys") on bone scintigraphy. Clin Nucl Med. 1990; 15: 254-6.

## EP-0361

### Prognostic value of metabolic parameters of 18F-FDG PET-CT in the staging of adult soft tissue sarcomas

***A. Berardinelli***[1], *M. Meneses Navas*[1], *G. Cuesta Domingo*[1], *P. Nespral Torres*[1], *P. Romero Fernández*[1], *P. Dauden Oñate*[1], *P. Bascuñana*[1], *A. Crespo*[2], *M. Cabrera Martín*[1];
[1]*Department of Nuclear Medicine, Instituto de Investigación Sanitaria San Carlos (IdISSC), Hospital Clínico San Carlos, Universidad Complutense, Madrid, SPAIN,* [2]*Department of Radiology, Hospital Clínico San Carlos., Madrid, SPAIN.*

***Aim/Introduction:*** Our purpose was to study the prognostic value of metabolic parameters of pre-treatment 18F-FDG PET/CT in adult patients with soft tissue sarcomas diagnosis, and their relationship with distant disease and overall survival. ***Materials and Methods:*** Seventy-six patients with pathologically confirmed soft tissues sarcomas who underwent 18F-FDG PET/CT for initial staging before treatment were retrospectively analyzed. Histological grade, percentage of necrosis, age at diagnosis, stage, and tumour recurrence were recorded as variables, as well as the maximum standardized uptake value (SUVmax), metabolic tumour volume (MTV), and total lesion glycolysis of the primary tumour (TLG). These parameters were measured using syngo.via software. The threshold at which these biomarkers correlated with the presence of distant disease was determined using ROC curves, and the relationship between these variables and overall survival (OS) was then evaluated using Kaplan-Meier analysis. Multivariate analysis was perform for survival prediction and Hazards Regression Plot. ***Results:*** Of the 76 patients, 68.4% were male with a mean age of 58.03±17.58 years; range 21-90. The maximum standardized uptake value (>12.3) and total lesion glycolysis of the primary tumour (>504) showed the best correlation with M1 (AUC 0.72). Patients with >10.5 SUVmax had worse survival, with a mean of 14 months (9-44;95% CI) compared to patients with lower SUVmax, with a mean of 89 months (95% CI). ***Conclusion:*** Initial 18F-FDG PET/CT in soft tissue sarcomas offers a more accurate TNM staging, and metabolic biomarkers appear to provide prognostic information, which could favour a more personalized treatment for each patient.

## EP-0362

### Utility of metabolic indices in 18F-FDG-PETCT for prediction of presence, patterns and sites of metastases in patients with osteosarcoma

***N. Kundu***, *S. Sagar, D. Khan, A. Roy, R. Goel, M. Y S, R. V, R. Kumar; AIIMS New Delhi, Delhi, INDIA.*

***Aim/Introduction:*** 18F-FDG-PET/CT is widely used for staging of osteosarcoma based on increased glucose uptake by malignant cells. The degree of 18F-FDG uptake, as expressed by standardized uptake value (SUV), can be measured and quantified by 18F-FDG-PET/CT. The role of metabolic indices, such as SUVmax, MTV and TLG in predicting presence of metastases and patterns of spread of osteosarcoma is unknown. Our study aims to assess the utility of metabolic indices in 18F-FDG-PET/CT to predict the presence and pattern of metastases in osteosarcoma patients. ***Materials and Methods:*** At our center in India, we conducted a retrospective study that included 20 patients referred to our department with known osteosarcoma for baseline staging or tumour recurrence between January 2019 and December 2022. All patients underwent $F^{18}$FDG-PETCT according to department protocol. Imaging parameters like maximum standardized uptake value (SUV max), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of primary lesion were measured. Two experienced nuclear medicine physicians reviewed the scans, and presence of metastases was recorded such as presence of soft tissue component (STC), skip lesions(SL), lymph node (LNM), lung (LM) and distant bony metastases(DBM) and muscle deposits (MD) and the data was analysed. ***Results:*** Out of 20 patients included in the study, 13 were male and 7 were female, with average age of 18.9±12.5 years (range 7-62 years). Out of 20 patients, 10 had soft tissue component,7 had distant metastases, , 4 had skip lesions, 5 had lung metastases, 6 had lymph node metastases, 6 had muscle deposits/infiltration, 3 had bony metastases. The SUV max, MTV and TLG of patients with metastases were 63.40±40.6, 107.47±127.58 $cm^3$ and 30.77±20.31kBq/ml respectively. The SUV max, MTV and TLG of patients with STC were 73.06±55.13, 124.64±152.27 $cm^3$and 34.21±18.72 kBq/ml respectively. The SUV max, MTV and TLG of patients with SL were 99.91±56.16, 71.96±74.51$cm^3$ and 35.66±9.64kBq/ml respectively. The SUV max, MTV and TLG of patients with LM were 65.64±40.64,114.93±127.58$cm^3$ and 32.74±20.3kBq/ml respectively. The SUV max, MTV and TLG of patients with LNM were 64.67±50.31, 115.42±139.98$cm^3$ and 32.26±19.65kBq/ml respectively. The SUV max, MTV and TLG of patients with DBM were 63.34±56.16, 116.59±74.5$cm^3$ and 31.45±9.64kBq/ml respectively. SUV max, MTV and TLG of patients with MD were 64.16±39.59, 116.29±125.26$cm^3$and 31.81±21.05kBq/ml respectively. ***Conclusion:*** Our data concluded that TLG can be used to predict distant bony metastases and skip lesions as they showed values with compact standard deviation whereas parameters like SUVmax and MTV can show highly variable results.

## EP-0363

### The Relationship Between Staging F-18 FDG PET/CT Parameters and Survival in Patients Diagnosed with Soft Tissue Sarcoma

***N. Aydin***, *G. Mütevelizade, G. Gümüşer, E. Sayıt Bilgin; Celal Bayar University, Manisa, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study is to investigate the prognostic value of metabolic parameters obtained from staging PET/CT of patients with STS and their effects on overall survival (OS) and progression-free survival (PFS). ***Materials and***

***Methods:*** 34 patients (49 ± 23 years) who underwent staging F-18 FDG PET/CT examination with the diagnosis of STS in our clinic between 2017-2022 were included in our study. SUVmax, SUVmean, MTV and TLG were obtained from F-18 FDG PET/CT images. The presence of lymph nodes and/or distant metastases was evaluated in PET/CT images. The relationship between the metabolic parameters of the primary tumor and clinical data was evaluated with Mann-Whitney U and Chi-square tests. Prognostic values of metabolic parameters in predicting overall survival and progression-free survival were evaluated using the Kaplan-Meier method. ROC analysis was performed ***Results:*** A total of 34 patients (13 female, 21 male) with a mean age of 49±23 were included. A statistically significant correlation was found between the presence of distant metastases and the TLG value of the primary tumor (p=0.025). However, no statistically significant correlation was found between SUVmax, SUVmean values and the presence of distant metastases at the time of diagnosis. According to Kaplan-Meier analysis, the presence of distant metastases in staging PET/CT was associated with both overall survival (p=0.019) and progression-free survival (p=0.035). No statistically significant correlation was found between SUVmax, SUVmean, MTV and TLG values of the primary lesion and OS and PFS. To predict the presence of distant metastases according to Youden index, a cut-off value of 104.2 cm3 (sensitivity: 78%, specificity: 68%) was obtained for MTV and 350 (sensitivity : 89%, specificity : 56%) was obtained for TLG. ***Conclusion:*** According to the results of our study, the presence of distant metastases at the time of diagnosis is associated with overall survival and progression-free survival was found to be the main determinant of survival. Among the metabolic parameters obtained in the staging PET/CT of patients with STS, a statistically significant correlation was observed between TLG and the presence of distant metastases. ***References:*** von Mehren M, Randall RL, Benjamin RS, et al. soft Tissue Sarcoma , Version 2.2018, NCCN Clinical practice Guidelines in Oncology . ## EP-0364

### Additional diagnostic contribution of bone SPECT/CT in foot and ankle pathology

***K. Bayardo****, L. F. Portugal, F. Carrera, O. Alonso, R. Ferrando;*
*University of the Repubic, Montevideo, URUGUAY.*

***Aim/Introduction:*** The complex anatomy and function of the foot can make it difficult to diagnose the cause of the symptoms in patients with pathologies of the region. SPECT/CT offers considerable advantages in these cases. The objective is to evaluate the diagnostic impact of the hybrid images with respect to planar images. ***Materials and Methods:*** Retrospective study that included 63 consecutive patients (38 men, age 41 ± 13.5 years (mean ± SD), range 6-75) from 2016 to date, studied with 99mTc-MDP bone scintigraphy with whole body images, early and late sectorial planar and SPECT/CT of the feet on a GE Infinia Hawkeye 4 and a Mediso AnyScan 16 gamma cameras. All patients presented with clinical data of spontaneous or post-traumatic onset pain in the foot or ankle. ***Results:*** In 33 of the 63 patients, SPECT/CT provided additional information that allowed a diagnosis to be made compared to inconclusive planar images. The greatest impact was observed in the tarsal bones (28/33 patients). Only 3 patients had completely normal studies and in only 5 cases it was not possible to reach a final diagnosis due to nonspecific findings. Planar images revealed 164 bone lesions, while SPECT/CT detected 214 lesions. The final diagnosis was degenerative arthropathy in 12 cases, inflammatory in 8 and traumatic in 6, osteomyelitis in 16, stress fracture in 3, osteoid osteoma in 3, osteochondritis dissecans in 1, osteochondral lesion in 1, active synchondrosis in 1, coalitions tarsals 2, osteonecrosis 1 and bone viability 1. ***Conclusion:*** Bone SPECT/CT has a high impact on foot and ankle pathologies, allowing a diagnosis to be reached in 87% of cases, including 51% of patients with inconclusive planar images. Hybrid imaging should be considered in all patients presenting with foot or ankle pain whenever it is available.

## EP-0365

### Assessing the role of 18F-FDG PET-CT in the initial staging of soft tissue sarcomas: bone infiltration and distant metastasis

***Y. Abadi Sedraoui****, J. Cordero García, E. Ortiz Cruz, I. Barrientos Ruiz, J. Pozo Kreilinger, C. Lancha Hernández, M. Coronado Poggio, S. Rizkallal Monzón, E. López LLobet, D. Monachello Araujo, L. Giraldo González, P. Portilla Merino, S. Rodado Marina, C. Escabias Del Pozo, L. Domínguez Gadea;*
*Hospital Universitario La Paz, Madrid, SPAIN.*

***Aim/Introduction:*** Bone infiltration at diagnosis is one of the most important prognostic factors in diagnosing the extension of soft tissue sarcomas (STS) in adults. Likewise, the distant dissemination of STSs limits surgery, the only potentially curative treatment. We analyzed the usefulness of 18F-FDG-PET/CT in initial staging to assess the presence or absence of tumor infiltration in the adjacent bone and its value in distant staging, establishing the prognosis of the disease at diagnosis. ***Materials and Methods:*** We retrospectively reviewed STSs diagnoses between 2012 and 2021, selecting patients with an initial staging with MRI and PET/CT before surgery and assessing bone infiltration in each. We compared the findings with diagnostic CT when we suspected lung involvement with 18F-FDG. We considered positive PET/CT in case of focal deposit of the radiotracer with infiltration of the cortical bone near the lesion. We compared all the findings with the ones of surgical biopsies. Additionally, we evaluated other local anatomical structures. Any focal activity on 18F-FDG-PET/CT greater than that of the vascular pool in the mediastinum was considered suspicious of malignancy. A subsequent follow-up was carried out, with control at six months and a year. ***Results:*** We included 20 patients, ten men and ten women between the ages of 22 and 75 (mean 49), whose pathology revealed three myxofibrosarcomas, six spindle cell sarcomas, one undifferentiated synovial sarcoma, one myxoid liposarcoma, one alveolar sarcoma, two malignant fibrous histiocytomas, 1 Ewing-like tumor, one malignant tumor of the peripheral nerve, three pleomorphic sarcomas, and one fibroblastic monophasic synovial sarcoma. Among them, 15 were of high grade, 3 of intermediate grade, and 1 of low grade. We observed bone infiltration in one patient. The results were consistent with the MRI and the biopsy. None of the cases had local relapses in the first year after surgery. 2/20 patients presented pulmonary disease at diagnosis, observed by both PET/CT and diagnostic CT. We did not find other metastatic localizations. Additionally, two patients with nonspecific micronodules in diagnostic CT and negative 18F-FDG-PET/CT presented pulmonary progression at follow-up at six months (one of them with new lymph node metastasis). Finally, one patient with two synchronous malignant tumors (both spindle cells) presented bone progression in control at six months. ***Conclusion:*** 18F-FDG-PET/CT seems to show good reliability for detecting bone infiltration and metastatic involvement in our series. Our results indicate that PET/CT could be the one-stop shop for the initial staging of STS.

## EP-0366

### Evaluation of F-18 FDG PET-CT based parameters in prediction of histopathological response to neoadjuvant chemotherapy in patients with Osteosarcoma

***S. Maitra***, *N. Singh;*
*P.D. Hinduja National Hospital and MRC, Mumbai, INDIA.*

***Aim/Introduction:*** To evaluate F-18 FDG PET-CT based parameters in prediction of histopathological response to neoadjuvant chemotherapy in patients with Osteosarcoma ***Materials and Methods:*** 30 patients diagnosed with osteosarcoma who underwent FDG PET-CT scan at baseline and post neoadjuvant chemotherapy(NACT), followed by surgery (between 2011 - 2016) were assessed. SUVmax, metabolic tumor volume(MTV) and total lesion glycolysis(TLG) of the primary lesion was recorded at baseline and post NACT along with post/pre NACT ratios. MTV was calculated with threshold of 45% SUVmax ; MTV(45%) and by summing the volume of voxels with SUV higher than threshold SUV 2 ; MTV(2). TLG(45%) and TLG(2) was also calculated. Histopathological reports post-surgery were obtained, necrosis fractions and response was catalogued. Histopathological necrosis fractions (HNF) were correlated with post NACT parameters and post/pre NACT ratios. Receiver operating characteristic(ROC) curve analysis was done to determine cut off, sensitivity and specificity for post/pre NACT ratios which could predict good histopathological response from poor response. Post/pre NACT ratios were compared to find out which is a better predictor of histopathological response. ***Results:*** 16 patients were good histopathological responders and 14 were poor histopathological responders. Post NACT SUVmax , MTV(2) , TLG(2) , post/pre NACT ratios of SUVmax, MTV(2), and TLG(2) showed difference between good and poor responders. Among post/pre NACT ratios, all parameters except MTV(45 %) showed correlation with HNF. TLG(2) ratio showed strong, MTV(2) ratio showed moderate and SUVmax ratio showed weak correlation. On post NACT PET-CT scan, absolute values of SUVmax and MTV(45 %) did not show correlation with HNF and MTV(2), TLG(2) and TLG(45 %) showed weak correlation. ROC curve analysis and comparing AUCs(area under curve), revealed MTV(2) ratio and TLG(2) ratio to be equally good predictors of histopathological response. MTV(2) ratio is a better predictor of histopathological response than SUVmax ratio. The sensitivity and specificity for predicting a good response was 92.8% and 75% using a MTV(2) ratio cut off of 0.17 and using a TLG(2) ratio cut off of 0.10. ***Conclusion:*** In our osteosarcoma population, the change in F-18 FDG PET-CT based parameters post NACT were useful in predicting tumor response. The change in combined metabolic/volumetric parameters like MTV and TLG (measured at threshold of SUV 2) post NACT were better predictors of histopathological response than change in the metabolic parameter, SUVmax post NACT .

## EP-0367

### Usefulness of SPECT/CT 99mTc MIBI for the evaluation of lesions suggestive of bone sarcomas.

***F. Lemus Ramírez***[1], *A. López Méndez*[2], *D. Arguelles Pérez*[1], *D. Orendain Novoa*[1];
[1]*Instituto Nacional De Rehabilitación Luis Guillermo Ibarra Ibarra, México, MEXICO,* [2]*J&J, México, MEXICO.*

***Aim/Introduction:*** To evaluate the diagnostic utility of $^{99m}$Tc-MIBI SPECT/CT, for the evaluation of lesions suggestive of bone sarcomas. ***Materials and Methods:*** Cases were retrospectively evaluated within the Instituto Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra that by $^{99m}$Tc-MIBI-SPECT/CT were suggestive of bone sarcoma, compared with histopathology, both primary tumor and of the metastases, in patients seen from January 2018 to March 2023. ***Results:*** A total of 24 patients were studied, of which 15/24 are men and 9/24 women, with a mean age of 24 years, the maximum age 75 years and the minimum age 8 years, all were positive results by $^{99m}$Tc-MIBI-SPECT/CT and when comparing with histopathology were positive for bone sarcomas in 22 of 24 cases, giving a sensitivity of 100% for $^{99m}$Tc-MIBI-SPECT/CT and a positive predictive value of 91%, pathologies that were not sarcoma are: hodgkin lymphoma and other unspecified tumors. Of these 22 positives for bone sarcoma, the most frequent primary tumor sites were the extremities in 21/22 and the sacrum in 1/22. 15/22 had positive metastases with $^{99m}$Tc-MIBI-SPECT/CT at diagnosis, the most frequent sites being regional metastases 11/15, lung 3/15 and brain 1/15, 15/15 metastases were positive by histopathology, giving a sensitivity for the $^{99m}$Tc-MIBI-SPECT/CT when evaluating bone sarcoma metastasis of 100% and a positive predictive value of 100%. ***Conclusion:*** $^{99m}$Tc-MIBI-SPECT/CT with is a very sensitive tool to evaluate bone sarcomas as well as their regional or distant metastasis sites. Being a very useful tool for staging. Given the low incidence, it is important to carry out multicenter studies where we can correlate the prognostic role of $^{99m}$Tc-MIBI-SPECT/CT, as well as expanding the already known studies where they evaluate the predictive role of $^{99m}$Tc-MIBI-SPECT/CT in response to therapies. The next step is to evaluate the semi-quantitative parameters such as the uptake index (UR) and the alteration of the uptake index (AUR) and the tumor necrosis rate (TNR) (1,2), to reinforce the evidence of its usefulness as a model predictive.

***References:*** • Huang Z, Lou C. Application of the alteration uptake ratio of $^{99m}$Tc-MIBI scintigraphy for evaluating the efficacy of neoadjuvant chemotherapy in osteosarcoma patients. ## EP-0368

### 18F-NaF PET/CT in diagnosis and response assessment to Radiofrequency Ablation (RFA) in Osteoid Osteoma patients

***S. Shamim***, *N. Kumar, J. Pathak, G. Arora, S. Gamanagatti, S. Khan;*
*AIIMS New Delhi, Delhi, INDIA.*

***Aim/Introduction:*** The CT-guided Percutaneous Radiofrequency Ablation (RFA) is the current treatment of choice for patients with osteoid osteoma. RFA is found to be a safe, minimally invasive and highly effective treatment with high success rates in these patients. Response assessment is done with clinical assessment and on Visual Analogue Scale (VAS) scores and is accepted as standard method following RFA. $^{99m}$Tc-MDP (Methylene Diphosphonate) bone scan/SPECT-CT can be used for diagnosis but has disadvantage that it remains positive for long time limiting its use for post-procedure treatment assessment. With the widespread use of $^{18}$F-Fluoride as bone-seeking PET radiotracer, we aimed to evaluate the role $^{18}$F- NaF PET-CT for diagnosis and response assessment in post-RFA osteoid osteoma patients. ***Materials and Methods:*** Patients with clinical suspicion of osteoid osteomas were considered for the study. A total of 15 patients were prospectively included in this study. At baseline all patients were clinically evaluated for symptoms that included VAS

pain scale and other pain characteristics. All patients underwent $^{18}$F-NaF PET-CT and $^{99m}$Tc-MDP bone scan with SPECT-CT at baseline. All patients were followed up after RFA to evaluate for clinical recurrence. In patients with clinical suspicion of disease recurrence, $^{18}$F-NaF PET-CT was done after at least 3 months of RFA. Analysis and interpretation of SPECT/CT and PET/CT images were done by two separate experienced nuclear medicine physicians. ***Results:*** Fifteen patients (11 male, 4 female) with mean age 19±1.8 years (range 11- 31 years) were recruited in this study. All 15 patients were presented with pain at baseline. Typical bone scan presentation of positivity in all the 3-phases of bone scan were noted in 66.6% (10/15) while, atypical bone scan presentation were noted in rest of the 33.3%. SPECT-CT was found to be positive in all the patients (15/15). Similarly, pre-RFA $^{18}$F-NaF PET-CT were positive in all patients. Post-operative pain assessment after at least 3 months of RFA was positive in 13.33% (2/15). Thus, post-treatment PET-CT was performed in 2 symptomatic patients, both of whom showed $^{18}$F-NaF uptake in which one was categorized as recurrence and one as residual disease. $^{18}$F-NaF PET-CT was not done in asymptomatic patients in view of increased radiotracer uptake secondary to post-operative changes and sclerosis. ***Conclusion:*** $^{18}$F-NaF PET/CT is a complementary modality to $^{99m}$Tc-MDP bone scan/SPECT-CT in diagnosis and has an additional role in response assessment in post-RFA patients of osteoid osteoma.

**The value of 18F-FDG PET/MR in the metastasis and re-stage of melanoma after operation**

***F. Wang***;
*Hangzhou Universal Imaging diagnostic center, Hangzhou, CHINA.*

***Aim/Introduction:*** To investigate the value of 18F-FDG PET/MR whole-body imaging in the metastasis and re-phase of melanoma after operation. ***Materials and Methods:*** The clinical data of 56 patients with melanoma after operation were retrospectively analyzed, and the PET/MR manifestations were analyzed. The PET/MR staging was compared with the traditional clinical staging based on CT and MR, and the difference between the detection rate and re-stage of metastatic lesions after operation was compared. The gold standard is clinical and pathological diagnosis. ***Results:*** Of 56 patients with melanoma after operation, 39 cases were found to have regional lymph node metastasis (N stage), a total of 128 lesions; There were 28 cases of distant metastasis (M stage), 194 lesions in total, including 35 lung metastasis, 41 liver metastasis, 17 brain metastasis, 76 bone metastasis, and 25 lymph nodes. The detection rate of regional lymph nodes by PET/MR was the same as that by conventional imaging (CT and MR) (98.4%), and the diagnostic coincidence rate of PET/MR was 97.6% higher than that of CT and MR (89.4%), with no statistical difference (P>0.05). Compared with conventional imaging (CT and MR), PET/MR found 69 more distant metastatic lesions in 28 patients, with significant statistical difference(P<0.05).Among them, 65 lesions were positive for PET-MR, negative for CT, and partial positive for MR, including 8 brain metastases, 22 liver metastases, 4 pancreas, 19 bones, 10 soft tissues, 2 lymph nodes, and 4 lesions were negative for PET uptake, but MR diagnosis was metastasis, including 1 brain metastasis, 1 liver metastasis, and 2 bone metastasis. The coincidence rate of PET/MR and MR diagnosis was 100% and 81%, respectively, with statistically significant difference (P<0.05).The detection rate and diagnostic coincidence rate of PET/MR in liver, brain, bone, muscle and soft tissue metastasis were higher than those of traditional CT and MR, with statistical significance (P<0.05). Through PET/MR examination, a total of 17 patients changed the traditional clinical stage, with significant statistical difference (P<0.05) .Among them, 8 patients increased from stage I to stage III, 3 patients increased from stage II to stage IV, and 6 patients increased from stage III to stage IV. ***Conclusion:*** 18F-FDG PET/MR is of high value for the metastasis and re-stage of melanoma after operation. The detection rate and accuracy of liver, brain, bone and soft tissue metastasis are higher than those of CT and MR, and lung lesions still need CT assistance diagnosis.

**Utility of 68Ga FAPI 46 PET CT scan in oncology patients with indeterminate 18 FFDG PET CT findings- A single institute study**

***V. Malasani***, *s. dash, d. pendharkar, n. singhal, a. raj, m. mehndiratta, d. parwan, n. n. begum, a. tomar, a. javed; sarvodaya hospital and research center, faridabad, INDIA.*

***Aim/Introduction:*** F18- FDG PET-CT is now the stranded imaging modality for tumor detection. It's not a tumor specific agent leading to false positive and false negative findings. We aim to look for the utility of Ga68 FAPI-46 (fibroblast activation protein inhibitor) PET-CT scan in these patients. Additionally, we tried to look for the utility of dual tracer study to differentiate benign from malignant pathologies. ***Materials and Methods:*** All the oncological patients who had indeterminate or negative findings in F18 FDG PET CT scan had underwent Ga 68 FAPI PET CT scan. Results were grouped based on quantification marker SUV max (maximum standard uptake value). Category 1: high likely benign (FDG positive, FAPI negative or both negative); Category 2 : Probably benign (both positive but the SUV max of FAPI is < 50% of SUV max of FDG; Category 3: indeterminate significance (both positive with SUV max of FAPI ranging from 50-70 % of SUV max of FDG), Category 4: high likely malignant (both positive with SUV max of FAPI ≥70% FDG SUV max or only FAPI positive). Histopathology or follow-up imaging served as the standard for the final diagnosis. ***Results:*** Of 40 patients with indeterminate FDG PET CT scan findings 21 were treatment naive and 19 had suspicious disease recurrence. FAPI PET CT scan alone could detect primary lesion in 5/21 (≈24%), suspicious lesions as benign in 4/21(≈19%), down staged 4/21 (≈19%) and upstaged

1/21(≈5%) patients; further dual tracer study reduced false positive rate in 4/21 (≈19%) patient. Rest 3 /21 (≈14%) patient was true positive in both the scans. In the recurrent group, FAPI PET CT scan alone detected true recurrence in 3/ 19 (≈16%) patients and prevented false positive in 5/19 (≈26%); however dual tracer study additionally prevented false positive cases in 5/19 (≈26%) patients. 2/19 (≈10.5%) patients of "indeterminate group" turned out to be tubercular in pathology. Rest 4/19 (≈21%) were true recurrence in both. ***Conclusion:*** 68 Ga FAPI PET -CT scan do have additional great advantage in reducing false negative and positive rate in various oncological scenarios pertaining to solid tumors. However, careful evaluation of benign pathologies having fibrotic sequalae may be challenging in some cases. We found that dual tracer study may help in differentiating benign vs malignant in these settings to a substantial extent. Our major limitation is the low study population; so additional studies with larger population groups are further required.

## EP-0371

### Comparison of Diagnostic Value between18F-FDG PET/CT and Immunohistochemistry in Lymph Node Metastatic Cancer with Unknown Primary site

***Y. Yu***, *S. Xu, X. Han;*
*the First Affiliated Hospital,Zhengzhou, Zhengzhou, CHINA.*

***Aim/Introduction:*** To investigate the diagnostic values of $^{18}$F-FDG PET/CT and immunohistochemistry of metastatic lymph nodes in patients with nodal metastatic carcinoma of unknown primary site (NCUP). ***Materials and Methods:*** A total of 190 patients (127 males,63 females, average age (57.68±11.72) years) with histological proven NCUP who underwent $^{18}$ F-FDG PET/CT imaging to find primary tumors from January 2011 to December 2020,133 patients who underwent preoperative lymph node immunohistochemistry were retrospectively analyzed. The histopathology of the primary lesion was taken as the gold standard for diagnosis. Calculate the sensitivity, specificity, false positive rate, false negative rate, positive predictive value, and negative predictive value of PET/CT and immunohistochemistry for exploring the primary lesion of NCUP.The correlation between gender, age, pathological classification, size (maximum diameter) of the metastatic lesion, SUVmax of the metastatic lesion, and whether the primary lesion has been found or not was analyzed using binomial classification logistic regression analysis. ***Results:*** The sensitivity, specificity, positive predictive value, and negative predictive value of PET/CT and metastatic lymph node immunohistochemistry in the diagnosis of primary lesions in NCUP patients were 88.89%/41.03%, 83.90%/69.15%, 77.11%/35.56%, and 92.52%/73.86%, respectively. Univariate logistic regression did not find any clinical factors significantly correlated with the presence or absence of the primary lesion ($P<0.05$). ***Conclusion:*** Although NCUP patients have early clinical staging, $^{18}$F-FDG PET/CT imaging still has high sensitivity and specificity in exploring their primary lesion, and is significantly superior to tumor markers and metastatic lymph node immunohistochemistry.

## EP-0372

### Diagnostic Efficacy of 68Ga-NY104 PET/CT in Patients With Clear Cell Renal Cell Carcinoma

***W. Zhu***, *X. Li, Y. Zhang, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Clear cell renal cell carcinoma (ccRCC) highly expresses carbonic anhydrase IX (CAIX) due to VHL mutation and upregulation of hypoxia inducible factor. CAIX-targeted PET imaging has been proved effective in REDECT trial, a prospective, phase III multicenter study describing the diagnostic performance of $^{124}$I labeled cG250, a CAIX-targeting antibody, for preoperative assessment of patients with renal masses. Nevertheless, small molecule CAIX-targeting imaging probes are still needed considering the superiority of pharmacokinetics of small molecule agents compared to intact antibody. Our team has demonstrated promising preclinical data of $^{68}$Ga-NY104, a small molecule CAIX-targeting PET agent, in animal models. The purpose of this study was to evaluate $^{68}$Ga-NY104 in patients with ccRCC suspicion. ***Materials and Methods:*** The study was approved by the institutional review board of Peking Union Medical College Hospital (approval NO. ZS-3089). Patients were prospectively recruited in the study. They were further divided into two groups: group 1, patients with a primary renal mass who were scheduled for surgery, group 2, patients with suspected/metastatic ccRCC. All patients received an intravenous injection of $^{68}$Ga-NY104 (200Mbq ± 20%) and underwent whole body PET/CT scan at 45-75 min after injection. In selective patients, comparative $^{18}$F-FDG PET/CT was performed to assist clinical evaluation. The efficacy of $^{68}$Ga-NY104 PET/CT scan was calculated using a final diagnosis as ground truth, which was based on pathological results or comprehensive clinical evaluation. ***Results:*** A total of 39 patients were recruited, including 16 patients in group 1 and 23 patients in group 2. The sensitivity, specificity, and accuracy of $^{68}$Ga-NY104 PET scan was 69% (9/13), 33% (1/3), 62% (10/16) for group 1, 94% (17/18), 100% (5/5), 95% (22/23) for group 2, and 83% (26/31), 75% (6/8), 82% (32/39) for all patients recruited, respectively. The tumor SUVmax of $^{68}$Ga-NY104 PET in patients with final diagnosis of ccRCC is 17.2 ± 11.4 for group 1, 26.1 ± 15.9 for group 2, and 22.5 ± 14.7 for all patients recruited. Of them, 22 patients (12 in group 1 and 10 in group 2) had comparative $^{18}$F-FDG PET/CT scan. The tumor SUVmax is 4.4 ± 4.1 for group 1, 9.2 ± 6.7 for group 2, and 6.3 ± 5.7 for all patients recruited. ***Conclusion:*** $^{68}$Ga-NY104 PET/CT scan is a powerful tool in ccRCC evaluation, especially in those with suspected/metastatic ccRCC.

## EP-0373

### The added values of 18F-FAPI over 18F-FDG in patients with oncologic diseases for evaluation of malignant lesions and management of incidental pathologic uptake

***X. Mu***, *M. Li, W. Fu;*
*Department of Nuclear medicine, Affiliated hospital of Guilin medical university, Guilin, CHINA.*

***Aim/Introduction:*** The objective of our study was to compare the quantitative parameters and tumor detection rates of malignant lesions between $^{18}$F-FAPI and $^{18}$F-FDG PET/CT in patients diagnosed with malignancies. Additionally, we investigated the differences in uptake between $^{18}$F-FAPI and $^{18}$F-FDG in incidental pathological uptake of $^{18}$F-FDG, and assessed whether $^{18}$F-FAPI PET/CT influenced the final decision for these lesions. ***Materials and Methods:*** A total of 78 participants from December 2021 to July 2022 who underwent paired $^{18}$F-FDG and $^{18}$F-FAPI PET/CT within 1 week were analyzed from a prospective clinical trial. The lesion detection rates and quantitative parameters of malignant lesions were compared between two scans. For incidental pathological uptake, the uptake grade and quantitative parameters were compared between the two radiotracers. Additionally, the pitfall lesions of $^{18}$F-FAPI were collected and the SUV was compared with that of the primary tumor. ***Results:*** $^{18}$F-FAPI demonstrated higher lesion detection rates compared to $^{18}$F-FDG, and showed similar or higher $SUV_{max}$ values in most lesion types, except for primary tumors. Moreover, the lower normal tissue uptake distribution resulted in significantly higher TBR for $^{18}$F-FAPI

compared to $^{18}$F-FDG. In cases of incidental pathologic uptake of $^{18}$F-FDG, $^{18}$F-FAPI showed significantly lower uptake grade and SUV compared to $^{18}$F-FDG in most lesion types. Therefore, the combination of $^{18}$F-FAPI and $^{18}$F-FDG dual radiotracers can significantly decrease the rate of further examinations by utilizing the distinct radiotracer uptake patterns of $^{18}$F-FDG and $^{18}$F-FAPI, reducing it from 40.2% to 8% in our cohort. ***Conclusion:*** In comparison to $^{18}$F-FDG, $^{18}$F-FAPI demonstrated higher detection rates of lesions and improved imaging contrast in both primary and metastatic lesions. In cases of incidental pathologic uptake of $^{18}$F-FDG, the use of $^{18}$F-FAPI can aid in determining the nature of these lesions, thereby influencing the diagnostic decision and avoiding unnecessary costly further examinations and false management decisions. ***References:*** 1.Riester M, Xu Q, Moreira A, Zheng J, Michor F, Downey RJ. ### Using dual-time 18F-FAPI PET/CT to distinguishing the nature of lesion and avoid digestive pitfalls

***X. Mu***;
*Department of Nuclear medicine, Affiliated hospital of Guilin medical university, Guilin, CHINA.*

***Aim/Introduction:*** The aim of this study was to evaluate the biodistribution, diagnostic performance and digestive pitfalls of dual-time 18F-FAPI PET/CT to detect the malignant and benign lesions in cancer patients, and compared the difference of uptake in malignant and benign lesions between two scans. ***Materials and Methods:*** Twelve cancer patients underwent dual-time $^{18}$F-FAPI PET/ CT for initial assessment or recurrence detection. Detection rate of lesions was compared between two scans. Normal organ uptake was quantified as the mean standardized uptake value (SUVmean). Lesion uptake was quantified as the maximum standardized uptake value (SUVmax). The Wilcoxon matched pairs signed-rank test was used to compare quantitative parameters between PET modalities. ***Results:*** In most of tissues, the SUVmean was observed decreasing from early time to normal time($P<0.05$). whereas, the SUVmean was no significant difference in muscle(1.8 ±0.4 vs 1.2 ±0.3,P= 0.67) and bone(1.0 ±0.4 vs 1.0 ±0.4,P= 0.34) between early time and normal time. All lesions can be observed in early and normal time scans. For malignant lesions, no significant difference between early and normal time in SUVmax(5.9 ±2.8 vs 5.7±2.8, P=0.09). For benign lesions, SUVmax of early time scan was significant higher than that of normal time(5.6 ± 3.4 vs 3.3± 1.9, $P<0.001$). In addition, malignant lesion depicted higher SUVmax than that of benign lesion in normal time(5.7±2.8 vs 3.3± 1.9,$P<0.001$). ***Conclusion:*** Dual-time 18F-FAPI PET/CT can detect all lesions, yet benign lesions show decrease of SUVmax from early to normal time on 18F-FAPI PET/CT that can help physicians to distinguish the nature of lesions. ***References:*** Kratochwil C, Flechsig P, Lindner T, Abderrahim L, Altmann A, Mier W, et al. (68)Ga-FAPI PET/CT: Tracer Uptake in 28 Different Kinds of Cancer. Journal of nuclear medicine: official publication, Society of Nuclear Medicine. 2019;60:801-5. doi:10.2967/jnumed.119.227967.

## EP-0375

### Does Brown Adipose Tissue represent a double-edged sword with mixed effects?

***W. Jalloul***[1], *D. Jalloul*[1], *R. Tibu*[2], *I. Grierosu*[1,2], *T. Ionescu*[1], *C. Stolniceanu*[1,2], *V. Ghizdovat*[1,2], *M. Moscalu*[1], *C. Stefanescu*[1,2];
[1]*University of Medicine and Pharmacy U.M.F „Grigore T. Popa" Iasi, Romania, Iasi, ROMANIA,* [2]*Nuclear Medicine Laboratory, County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA.*

***Aim/Introduction:*** Brown Adipose Tissue (BAT) has long been considered "a potential lifesaver" against metabolic pathologies, such as obesity and diabetes, however, its involvement in the development of Cancer induced Cachexia has also been reported. Through analysing the 18F-FDG BAT pattern, we aimed to study the implication of this fat on the weight status in a group of oncological patients. ***Materials and Methods:*** After investigating the total number of 18F-FDG PET/CT performed for various malignities during the period of 4 years, we selected the scans with active BAT. The patients with active brown fat were divided into non-obese (NO) (BMI≤25 kg/m$^2$) vs. overweight or obese (OOB) (BMI>25 kg/m$^2$). Moreover, SUVmax has been used to quantify this fat's activity. ***Results:*** Out of the total number of 62 patients who presented active BAT, 40 (64.5%) were NO. The mean value (mv) of patients' age showed a slight predominance among OOB with 36.1±12.9 years vs. NO with 31.5±10.6 years. We reported no significant differences between genders in the BMI groups. An important BAT expression in NO during spring, summer and autumn was recorded when compared to winter in OOB. The BMI mv was 24.62±6.12 (NO: 22.72±1.6 vs. OOB: 28.93±5.81). Our data showed that 35.5% of patients were diagnosed with Hodgkin's Lymphoma (HL), 17.7% with Non-Hodgkin's Lymphoma (NHL), 12.9% with Lung Cancer (LC), 11.3% with Cervical Cancer (CC), 11.3% with Breast Cancer (BC) and 11.3% with Gastrointestinal cancers (GCs). We noticed the predominance of each of these diagnoses in NO. 86.1% of NO presented 18F-FDG BAT uptake in multiple localisations. Brown fat was non-homogeneous in 54.9% of the scans with a greater prevalence in OOB. BAT showed a symmetric distribution of 76.6% in NO. The highest SUVmax mvs were recorded in OOB patients with 6.12±2.9 g/ml in supraclavicular, 5.1±2.82 in latero-cervical and 3.32±5.1 g/ml in paravertebral spots vs. 2.78±3.97 g/ml in mediastinal and 3.13±2.98 g/ml in latero-thoracic regions in NO group. BMI was positively correlated with latero-cervical and supraclavicular SUVmax, while this index showed a negative correlation with latero-thoracic and abdominal SUVmax. Furthermore, SUVmax decreased significantly in latero-cervical, paravertebral and abdominal spots during the increasing age of the patients. Men showed a significant lower BAT activity in the paravertebral region. ***Conclusion:*** BAT's biodistribution has an impact on the weight status of oncology patients, therefore, it is essential to consider the BAT pattern while developing treatment strategies based on this type of fat.

## EP-0376

### Prognostic value of volumetric and metabolic 18F-FDG indices in patients with Merkel cell carcinoma: a multicentric retrospective study

***M. Ricci***[1], *F. Zarrelli*[1], *B. Carabellese*[1], *A. Marzullo*[2], *M. Tudini*[3], *B. Criscuoli*[4], *G. A. Follacchio*[4], *L. Travascio*[5], *A. D. Di Nicola*[5], *E. Giovannini*[6], *F. Calabria*[7], *M. Leporace*[7], *A. Bagnato*[7], *A. Cimini*[2];
[1]*Nuclear Medicine Unit, Cardarelli Hospital, Campobasso, ITALY,* [2]*Nuclear Medicine Unit, St. Salvatore Hospital, L'Aquila, ITALY,* [3]*Medical Oncology Unit, St. Salvatore Hospital, L'Aquila, ITALY,* [4]*Nuclear Medicine Unit, Macerata Hospital, Macerata, ITALY,* [5]*Nuclear Medicine Unit, P.O. Pescara, Pescara, ITALY,* [6]*Nuclear Medicine Unit, S. Andrea Hospital, La Spezia, ITALY,* [7]*Department of Nuclear Medicine and Theragnostics, "Mariano Santo" Hospital, Cosenza, ITALY.*

***Aim/Introduction:*** Merkel Cell Carcinoma (MCC) is a rare and aggressive skin malignancy in which positron emission tomography/computed tomography (PET/CT) with 18F-Fluorodeoxyglucose (18F-FDG) imaging is often used in the management of patients. To our knowledge, there is not a definite literature regarding the possible role of 18F-FDG volumetric and metabolic indices in prognostic stratification. The aim of this Italian multicentric study is to investigate if Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG), derived from PET/CT with 18F-FDG, are correlated with overall survival (OS) and Progression Free Survival (PFS) in Patients affected by MCC. ***Materials and Methods:*** 107 consecutive scans of 61 patients with MCC (41 men and 20 women; mean age 72,09 ± 10,23) have been retrospectively examined in 6 Italian nuclear medicine units, in different stages of disease (staging, restaging or follow up). Each scan has been reviewed by 2 expert nuclear medicine physicians; MTV and TLG values have been obtained from the most active lesion in each scan (skin, lymph node, or metastatic lesion). The Shapiro test has been performed for the assessment of distribution. Then, the Mann-Whitney (U test) has been performed for the comparison of MTV and TLG values and OS and PFS indices. ***Results:*** The results reported a significant correlation between MTV and OS ($p<0.05$), between MTV and PFS ($p<0.05$), between TLG and OS ($p<0.05$), and between TLG and PFS ($p<0.05$). ***Conclusion:*** The major limitations of the present study regard the heterogeneous setting of 18F-FDG PET imaging (staging, restaging or follow up) and further prospective studies should be performed in a more homogeneous setting: however, our findings support the possible role of MTV and TLG derived from PET/CT with 18F-FDG in prognosis stratification in patients with MCC.

## EP-0377

### 68Ga-FAPI-04 PET/CT in Renal Cell Carcinoma: A Preliminary Study

***C. Civan***[1], *S. Kuyumcu*[1], *D. Has Simsek*[1], *O. Sanli*[2], *Z. Ozkan*[1], *O. Hurdogan*[3], *Y. Sanli*[1];
[1]*Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE,* [2]*Istanbul Faculty of Medicine, Urology Department, Istanbul, TÜRKIYE,* [3]*Istanbul Faculty of Medicine, Pathology Department, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** In this study, we aimed to evaluate the role of 68Ga-FAPI-04 PET/CT (FAPI) in patients with known metastatic renal cell carcinoma (RCC) or with suspected primary renal mass and to compare our results with 18F-FDG PET/CT (FDG). ***Materials and Methods:*** Our cohort included 14 patients (7 female, 7 male, mean age: 66 years) who underwent FAPI and FDG with a median interval of 7 days (IQR=6). Indication was restaging due to metastatic disease in ten patients, while it was initial assesment in four patients who had suspicious renal mass. We compared FAPI and FDG-PET parameters including SUVmax and tumor-to-background ratio (TBR) of primary lesion, local recurrence and lymph node, lung, bone and other metastasis. ***Results:*** One patient, who had xanthogranulomatous pyelonephritis showing high uptake on both PET/CT (SUVmax; FAPI: 13.1; FDG: 14.4) was excluded from further analyses. 10 out of 13 patients had clear cell RCC, 2 patients had papillary RCC and 1 patient had chromophobe RCC. A total of 68 lesions including 4 primary lesions, 5 local recurrences and 59 metastases were analysed. Minimum and maximum FAPI-SUVmax were 1.1 and 26.1, respectively. In all lesions, FAPI-SUVmax and FAPI-TBR was higher than FDG-SUVmax (6.3 vs 5.1, $p=0.17$) and FDG-TBR (6.7 vs 2.5, $p<0.001$). In primary tumor, local recurrence, lung and bone metastases FAPI-SUVmax was higher than FDG-SUVmax, while statistically significance was present in only lung metastases (7.6 vs 2.8, $p<0.001$). FAPI-TBR was significantly higher in local recurrence, lymph node and other metastases. Contrary, FDG-SUVmax was significantly higher than FAPI-SUVmax in lymph node metastases (7.6 vs 5.7, $p=0.001$). In patient based analyses, FAPI-SUVmax was higher than FDG-SUVmax in 7 patients (54%), while FDG-SUVmax was higher in 3 patients (23%). FAPI-SUVmax was higher than 6 in 57% of all lesions and 11 patients (85%) had at least one lesion with SUVmax higher than 6. ***Conclusion:*** In this preliminary study, our first clinical experience showed that 68Ga-FAPI-PET/CT could have potential role in primary lesion and metastatic disease of RCC. Further prospective studies were needed to confirm our results.

## EP-0378

### 68Ga-NY104 PET/CT helps discriminate metastatic clear cell renal cell carcinoma from post-surgical inflammation: compared with18F-FDG

***W. Zhu***, *X. Li, Y. Zhang, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** $^{68}$Ga-NY104 is a novel small molecule tracer targeting carbonic anhydrase IX (CAIX), which is overexpressed in clear cell renal cell carcinoma (ccRCC) but not expressed in inflammatory process. Therefore, $^{68}$Ga-NY104 PET/CT can be used to discriminate metastatic lesions from post-surgical inflammation in patients with ccRCC. ***Materials and Methods:*** A 50-year-old male had partial nephrectomy due to ccRCC of the right kidney in 2020. In Sep 2022, an avidly-enhancing right kidney mass was found on ceCT during follow-up, as well as multiple perirenal lesions. In Feb 2023, he underwent radical nephrectomy and metastasectomy. After surgery, the surgeon wanted to know if he had all lesions resected in order to help make the following treatment plan. $^{68}$Ga-NY104 PET/CT, as well as a comparative $^{18}$F-FDG PET/CT, was performed one month after surgery. The study was approved by the institutional review board of Peking Union Medical College Hospital (approval NO. ZS-3089). ***Results:*** A total of 14 lesions were detected on either PET, 7 of which were in the surgical area while the other 7 lesions were outside surgical area. $^{18}$F-FDG PET/CT detected 10 lesions, 7 in the surgical area (considered inflammatory) and 3 outside surgical area (considered metastatic). The $^{18}$F-FDG uptake is similar between inflammatory (average SUVmax 4.6) and metastatic lesions (average SUVmax 3.6). $^{68}$Ga-NY104 PET/CT detected 9 lesions, 3 in the surgical area and 6 outside surgical area (all considered metastatic). The $^{68}$Ga-NY104 uptake in these 9 lesions was extremely high (SUVmax, 36.8 ± 14.5, range, 13.2 - 57.8). On the contrary, the other 5 lesions that were FDG-avid

demonstrated no $^{68}$Ga-NY104 accumulation (SUVmax, 1.8 ± 0.7, range, 1.0 - 2.7). Although these lesions were not confirmed by follow-up pathological results, such huge SUV difference between NY104-avid lesions and NY104-indolent lesions, meaning huge CAIX expression differences, gave us enough confidence that $^{68}$Ga-NY104 PET/CT could help discriminate metastatic ccRCC lesions from post-surgical inflammatory process. Taking the results of $^{68}$Ga-NY104 PET/CT as reference, the lesion-level sensitivity, specificity, and accuracy of $^{18}$F-FDG were 22% (2/9), 80% (4/5), and 43% (6/14), respectively. Given the results of PET/CT, the patient was considered in metastatic status and went on lenvatinib and pembrolizumab combination therapy afterward. ***Conclusion:*** $^{68}$Ga-NY104 PET/CT is better than $^{18}$F-FDG PET/CT in discriminating metastatic ccRCC lesions from post-surgical inflammatory process.

## EP-0379

### A Rare Case of Adrenal Hemangioma with CT, MRI and Pathology Findings.

***B. Karasah Erkek***, *A. Akgün, Y. Ertan, M. Harman;*
*Ege University, Izmir, TÜRKIYE.*

***Aim/Introduction:*** Adrenal hemangiomas (AH) are extremely rare, non-functioning benign tumors that originate from endothelial cells. They account for 0.01% of all adrenal tumors. While a small portion of these tumors can cause symptoms such as abdominal pain, nausea, and vomiting, 70-80% of them are asymptomatic. These tumors are typically incidentally detected during imaging performed for other reasons. ***Materials and Methods:*** Our patient is a 62-year-old male who was found to have a mass in the right adrenal gland during routine check-up ultrasound (US). After the US findings, the patient underwent an MRI which revealed a hyper-vascular lesion measuring 2.5 cm in the right adrenal gland, without macroscopic or microscopic fat. The findings indicated that the lesion was likely not an adenoma and suggested considering neurogenic tumors (such as pheochromocytoma) in the differential diagnosis. Additionally, it was noted that the possibility of a primary malignancy with the potential for hypervascular metastasis should not be overlooked. Subsequently, the patient underwent a FDG PET/CT scan which showed that the FDG uptake of the well-defined and cystic lesion in the right adrenal gland was similar to that of the liver parenchyma (SUV max: 3.9, liver: 4). FDG PET/CT has a sensitivity of 93% to 100% and a specificity of 90% to 94% for characterizing malignant and benign adrenal lesions. While the FDG uptake ruled out malignancy, neuroendocrine tumors could not be excluded. The patient underwent the necessary metabolic and biochemical tests, and the results ruled out neurogenic tumors. As in our case, if there is no history of malignancy, surgical resection can be performed after careful exclusion of pheochromocytoma with imaging and biochemical tests to prevent hypertensive crisis. ***Results:*** Due to the rarity of AH, there are no established treatment guidelines, and surgical resection is often the preferred method in the literature. The laparoscopic adrenalectomy performed with the patient's consent confirmed the diagnosis of AH on histopathological examination. On gross pathological examination, a yellow-brown colored tumor with distinct demarcation from the normal adrenal parenchyma was seen. The tumor measured 3 cm in diameter and was composed of multiple vascular channels lined by a single layer of endothelial cells. The tumor was well circumscribed from the adrenal gland parenchyma that was hyperplastic. ***Conclusion:*** We believe that the imaging, clinical, and pathological findings used to arrive at the definitive diagnosis for our rare case of AH will contribute to the literature.

## EP-0380

### Comparison of 18F-FDG and 68Ga-FAPI PET/CT in the diagnosis of lung metastasis in different malignant tumors

***Z. Yang***;
*Fudan University Shanghai Cancer Center, Shanghai, CHINA.*

***Aim/Introduction:*** To evaluate the diagnostic value of $^{18}$F-FDG and $^{68}$Ga-FAPI PET/CT in lung metastasis of different malignant tumors. ***Materials and Methods:*** A retrospective analysis was performed on 20 patients with lung metastasis from May 2020 to March 2022 in Fudan University Cancer Center [13 males and 7 females, median age 58 (20-71 years old). 11 cases were confirmed as epithelial-derived malignancies and 9 cases as mesothelial-derived malignancies. The clinical, pathological and 18F-FDG and 68Ga-FAPI PET/CT images were analyzed. Wilcoxon sign rank test was used to compare the statistical difference of semi-quantitative metabolic parameters (SUVmax and TBR) between the two probes. Linear correlation was used to analyze the correlation between the semi-quantitative parameters of the two probes and the short diameter of lung metastatic lesions. ***Results:*** Among 81 lung metastases (51 cancers and 30 sarcomas), 72 were positive for 18F-FDG PET/CT, and 70 were positive for 68Ga-FAPI PET/CT. Compared with 68Ga-FAPI, lung metastatic lesions had a higher value of 18F-FDG, especially those of cancer origin ($P < 0.001$). The results of linear correlation analysis showed that the semi-quantitative metabolic parameters of the two probes were positively correlated with the short diameter of lung metastatic lesions ($P < 0.001$). ***Conclusion:*** 18F-FDG PET/CT is more advantageous than 68Ga-FAPI PET/CT in the diagnosis of lung metastasis from different types of malignant tumors.

## EP-0381

### Bone scan with technetium 99m-methyl diphosphonate, the missing link in the initial staging of muscle-invasive bladder carcinoma

***A. Aghaee***[1], *S. Soltani*[2], *H. Ghorbani*[2], *H. Ghorbani*[1], *S. Zakavi*[1], *K. Aryana*[1];
[1]*Nuclear Medicine Research Center,Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,*
[2]*Kidney Transplantation Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Accurate staging is crucial to determine the type of treatment for patients with bladder cancer (BCa), especially in high-risk cases. We aimed to assess the role of bone scan in the initial staging of muscle-invasive bladder carcinoma (MIBC). ***Materials and Methods:*** Forty-five patients with MIBC were referred to our tertiary clinic to perform a technetium 99m-methyl diphosphonate (Tc99m-MDP) bone scan from January 2019 to March 2020. The patients underwent bone scintigraphy with pelvic SPECT/CT before radical cystectomy. Whole-body scanning was performed 4 hours after Tc99m-MDP injection in both anterior and posterior views. Since the most common bone involvement site in these patients is the pelvic bones and the spine, pelvic SPECT/CT was performed in all patients. ***Results:*** Frequency of skeletal metastasis was 26.7%. Only 19% of the metastases were detected by previous pelvic CT/MRI images performed for routine staging. All the reported skeletal metastases by previous anatomical imaging methods were detected in the bone scan. There was no statistically significant correlation between bone metastasis and the patient's age, lymph nodes metastasis (LNM), hydronephrosis, and muscle-invasive type. The mean serum calcium level was 8.7 ± 0.57 in patients with bone metastasis and 8.87 ± 0.99 in patients without bone metastasis, which was not statistically significant.

***Conclusion:*** Bone scan has higher diagnostic performance than conventional imaging methods for detecting bone metastases. It changed the management plan in 8.8% of our patients, so we conclude that performing a whole-body bone scan in the initial staging of MIBC would be helpful.

## EP-0382

### The Role of Integrin αvβ6-PET/CT for Patients with Different Cancer-Preliminary Clinical Experience

***L. Li***, *Z. Xiao, D. Zeng, D. Xing, H. Wu, Y. Tian, C. Li, Y. He; Department of Nuclear Medicine, Zhongnan Hospital, Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** The αvβ6-integrin is an exclusive marker of epithelial cells and plays a critical role in the invasion and metastasis of carcinomas. The latest advancement of integrin αvβ6 tracers demonstrated promising preclinical and clinical outcomes. Specifically, $^{68}$Ga-Trivehenxin, a Ga68labeled αvβ6-integrin selective PET tracer, which was synthesized by trimerization of the cyclic nonapeptide Tyr2 (c[YRGDLAYp(NMe)K]) on the triazacyclononane-triphosphinate (TRAP) chelator TRAP chelator core, has shown encouraging outcomes in accurately demarcating head-and-neck tumors and detecting primary and metastatic pancreatic cancer. Here we present an initial clinical investigation focused on $^{68}$Ga-Trivehexin PET imaging in a spectrum of tumor types. ***Materials and Methods:*** A total of 17 patients (12 males and 5 females; median age, 60 years; age range, 40-80 years) with a diagnosis of 12 different cancers, including lung cancer, gastrointestinal malignancies, glioma, nasopharyngeal carcinoma, esophageal cancer, hepatobiliary and sarcoma, underwent both $^{18}$F-FDG and $^{68}$Ga-Trivehexin PET/CT scans. The median time interval between the two scans was 2 days (range, 1-3 days). Standardized uptake values (SUV) and tumor-to-background ratios (TBR) were generated from the contoured tumor and source organ volumes. Spherical volumes in the liver, blood pool, or normal brain were also obtained for TBR. ***Results:*** Compared to $^{18}$F-FDG imaging, Trivehexin exhibited a lower uptake in normal organs including the liver and mediastinal blood pool (1.59 vs 3.32 and 1.74 vs 2.62, respectively, both $p<0.001$), rendering it rationale to enhance TBR in order to detect minute lesions. Especially when using the liver as a background, the TBR of primary lesions is significantly higher with $^{68}$Ga-Trivehexin than with $^{18}$F-FDG (5.18 vs 2.45, $p=0.003$). $^{68}$Ga-Trivehexin has also shown a remarkable TBR advantage in detecting brain lesions, specifically in cases of gliomas and brain metastases. However, in the current solid tumor cases, $^{68}$Ga-Trivehexin exhibited lower SUVmax than $^{18}$F-FDG(8.97 vs 12.29, $p=0.03$), potentially due to the role of αvβ6-integrin in promoting invasive growth of malignant epithelial neoplasms. Moreover, the spillover effect of $^{18}$F-FDG is not a reliable indicator of tumor malignancy level. Therefore, it is essential to collect more pathological data in the future to verify these hypotheses. ***Conclusion:*** $^{68}$Ga-Trivehexin PET/CT imaging was able to demonstrate promising results and high clinical value with regard to intense tumor uptake and image contrast. We are currently conducting a large-scale cohort study and pathological analysis to further expand the applications of $^{68}$Ga-Trivehexin, such as staging or non-invasive tumor characterization for patients with malignant tumors.

## EP-0383

### Tumor Uptake of a Bi-specific Antibody which Binds to CD137 and FAP is Shown Using 89[Zr]Zr-BI 765179 PET-imaging

***M. Stavenga***[1,2], *M. C. Huisman*[3,2], *G. J. C. Zwezerijnen*[3,2], *J. J. Eertink*[1,2], *K. Ridler*[4,5], *Ö. Yalkinoglu*[6], *H. Maas*[4], *D. Radonjic*[7], *J. Pasek*[8], *D. J. Vugts*[3,2], *C. W. Menke-van der Houven van Oordt*[1,2]; [1]*Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Medical Oncology, Amsterdam, NETHERLANDS,* [2]*Cancer Center Amsterdam, research program, Amsterdam, NETHERLANDS,* [3]*Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Radiology and Nuclear Medicine, Amsterdam, NETHERLANDS,* [4]*Boehringer Ingelheim Pharma GmbH & Co. KG, Department of Translational Medicine & Clinical Pharmacology, Biberach, GERMANY,* [5]*Invicro, A Konica Minolta Company, London, UNITED KINGDOM,* [6]*Boehringer Ingelheim International GmbH, Department of Translational Medicine & Clinical Pharmacology, Ingelheim am Rhein, GERMANY,* [7]*Boehringer Ingelheim International GmbH, TA Oncology Medicine, Ingelheim am Rhein, GERMANY,* [8]*Boehringer Ingelheim Pharmaceuticals, Early Clinical Operations, Ridgefield, CT, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** BI 765179 is a bi-specific antibody binding to CD137 on immune cells and to Fibroblast Activation Protein (FAP) frequently upregulated in the tumor environment of many cancer types. It is postulated that CD137 agonism with required concomitant binding to FAP expressed on cancer-associated fibroblasts allows for tumor-restricted T-cell activation. Knowledge regarding target availability and saturation in tumors and in healthy tissues will improve dose selection. In this study, we aim to assess the tumor accumulation and biodistribution of [$^{89}$Zr]Zr-BI 765179 as well as its change upon applying BI 765179 treatment doses in patients with advanced and/or metastatic solid tumors using PET imaging. ***Materials and Methods:*** This sub-study is part of the phase 1 trial (NCT04958239) and has an adaptive design. Patients undergo three PET scans (at 2/24, 48, 72 hours) after each i.v. administration of 37 MBq [$^{89}$Zr]Zr-BI765179 containing a low dose (selected using available PK data) at baseline and on a treatment dose two weeks later. Blood samples are drawn for PK analyses immediately after each injection and after each PET scan. Biodistribution in organs as well as tumor uptake is assessed by normalizing tissue uptake (Bq/mL) with the plasma uptake (Bq/mL), resulting in the tissue to plasma ratio (TPR). ***Results:*** The results from the 72-hour time points of the first patient are presented here. For the low mass dose, highest TPR were 0.50 (liver), 0.27 (spleen), 0.21 (kidneys), 0.13 (lungs), 0.15 (bone marrow) and 0.02 (brain). TPR slightly decreased after the high mass dose in liver (0.45) and spleen (0.24), but not in the other organs (respectively 0.20, 0.14, 0.14 and 0.02). In the lungs uptake based on the low mass dose was visually detected in two lesions, whereas in a third lesion the uptake was borderline. When comparing low dose and treatment dose the $TPR_{peak}$ value in the largest lesion was reduced from 0.81 to 0.55, however, in the smaller lesion as well as the one with borderline uptake no difference was seen. ***Conclusion:*** Tumor uptake was variable in a patient with advanced cancer after administration of the bi-specific antibody [$^{89}$Zr]Zr-BI 765179. The uptake in the largest lesion could be reduced by a treatment dose, but no reduction was observed in the smaller lesions. Data analysis of subsequent participants will be presented and used to optimize the low dose, in order to capture quantitative information on lesion uptake and its change by treatment doses.

## EP-0385

### Diagnostic Accuracy of 18F-Flurodeoxyglucose Positron Emission Tomography-Computed Tomography in the Evaluation of Carcinoma of Unknown Primary Against Computed Tomography; Experience of Single Centre

***M. Numair Younis***, *U. B. Zahra, A. Shahid;*
*Institute of Nuclear Medicine and Oncology-INMOL, Lahore, PAKISTAN.*

***Aim/Introduction:*** Carcinoma of unknown primary can be characterized as most heterogeneous group of cancers thus it is considered to have an extremely aggressive behaviour and has high resistance regarding therapeutic aspect. We hypothesize that if $^{18}$F-FDG PET-CT is used earlier then CT, it is appropriate for the detection of primary location.Study was performed to determine the diagnostic accuracy of $^{18}$F-flurodeoxyglucose positron emission tomography-computed tomography in the evaluation of carcinoma of unknown primary and compare with CT scan. ***Materials and Methods:*** The prospective study of CUP Syndrome patients was performed on those that underwent ($^{18}$F-FDG PET-CT) scan between October 2022 and February 2023. The primary site localized on $^{18}$F-FDG PET-CT scan was proven through needle biopsy and histology which was considered as gold standard. ***Results:*** Of total 63, 57.1% men while 42.9% women with the average age of 56.27 years. The overall detection rate of $^{18}$F-FDG PET/CT was 88.8% for primary sites. The positive hypermetabolic lesion indicative of primary malignancy were correctly identified in 79.36% that were true positive. The scan was false negative in 4.76% patients though malignancy was proven through other investigations. While 6.36% had true negative and 9.52% showed false positive results on the scan. The overall diagnostic accuracy was 85.7%, sensitivity 94%, specificity 40%, positive predictive value 89.2% and the negative predictive value 57.1% against CT which showed sensitivity of 67.3%, specificity of 38.1%. ***Conclusion:*** $^{18}$F-FDG PET-CT is pivotal imaging modality for localization of primary site in CUP syndrome patients and may be used prior to CT alone in work up of these patients.

## EP-0386

### The utility of PET/CT with 18F-FDG in the localization of unknown primary tumors and its correlation with anatomopathological findings: Experience of the University Hospital of Salamanca.

***J. Badell***[1], *P. García-Talavera San Miguel*[2], *F. Gómez-Caminero López*[1], *A. C. Peñaherrera Cepeda*[1], *E. Campaña Díaz*[1], *S. Rama Alonso*[1], *J. G. Villanueva Curto*[1], *L. G. Díaz González*[1], *P. Tamayo Alonso*[1];
[1]*Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** To determine the utility of PET/CT with $^{18}$F-FDG in the detection of the primary lesion in patients studied for high suspicion of tumor of unknown origin and to establish its correlation with anatomopathologic findings. ***Materials and Methods:*** We included in the study 150 patients (81 men; 65.85 years ± 11.85 years) with suspected primary tumor of unknown origin, who were referred to our service for $^{18}$F-FDG PET/CT between October 2014 to September 2017. The most frequent reasons for request were: lymph node disease 41/150 (27.33%) and the presence of pulmonary lesions 37/150 (24.66%). A full-body tomographic image was acquired 60 minutes after intravenous administration of a calculated dose of 5 MBq per kg/weight of $^{18}$F-FDG. The PET/CT results were correlated with the anatomopathologic findings of pathologic hypermetabolic lesions suggestive of malignancy. The detection rate (DR) and the proportion of false positives (FP) were calculated. ***Results:*** PET/CT with $^{18}$F-FDG presented at least one pathological hypermetabolic focus in 132/150 patients studied, suggestive of malignancy in 79 of them (52.66%). In 67/79 patients (84.81%) malignant etiology was confirmed by anatomopathological study and the most frequent histological subtype was low-grade adenocarcinoma. The most common primary sites of location were: lung (26/79), ENT region (9/79), ovary (6/79), thyroid (6/79), non-Hodgkin's lymphomas (6/79), breast (5/79), pancreas (3/79), urothelial (1/58), Hodgkin's lymphoma (1/79), prostate (1/79), right iliac psoas muscle (1/79) and two patients had synchronous malignancies: lung/breast (1/79) and NHL/colon (1/79). The remaining patients (12/79), with hypermetabolic lesions suggestive of malignancy, the anatomopathologic result was negative for malignancy or a benign infectious/inflammatory cause was identified, resulting in false positives: sarcoidosis (4), cryptogenic organizing pneumonia (1), cervical schwannoma (1), cervical desmoid fibromatosis (1), pulmonary hamartoma (1), pulmonary granulomas (1), pulmonary bronchiectasis (1) diverticulosis (1) and ischemic colitis (1). The detection rate obtained was 44.66% and the false positive rate was 15.18%. ***Conclusion:*** PET/CT with $^{18}$F-FDG is of great value for the investigation of patients with suspected primary tumor process of unknown origin and is very useful for both localization and staging of malignant tumor disease.

## EP-0387

### The relevance of 18FDG-PET/CT in the therapeutic assessment of recurrent leimyosarcoma of the inferior vena cava

***K. Ben Ahmed***, *M. Maaloul, H. Noomen, F. Chaltout, M. Ouachem, I. Jardak, S. Charfeddine, K. Chtourou, F. Guermazi;*
*Nuclear medicine department , Habib bourguiba hospital, Sfax, TUNISIA.*

***Aim/Introduction:*** Leiomyosarcoma (LMS) of the inferior vena cava (IVC) is an extremely rare malignant tumor emerging from the tunica media of the venous wall accounting for 2% of all LMSs. Since Perl and Virchow's first description in 1871, less than 400 cases have been reported in literature. ***Materials and Methods:*** Here we report the case of a 57-year-old woman with history of LMS of IVC evolving for 4 years. She was initially operated by a complete resection of the tumour which envaded the renal veins (R0) followed by reconstruction of the latter. After 3 years of control, the patient presented diffuse abdominal pain and a full body CT scan was performed revealing an enlarged mass centered on the IVC which was thrombosed with locoregional invasion associated to retroperitoneal lymph nodes and pulmonary nodules suggestive of tumour recurrence. The patient then underwent 6 courses of chemotherapy. The post-therapeutic CT scan concluded that the initial lesions were stable. Then ,18FDG-PET/CT was performed in order to evaluate the therapeutic response. ***Results:*** 18FDG-PET/CT showed a hypermetabolic mass (SUVLbm max = 4) centered on the IVC and extended to the renal hilium. There was no evidence of metabolically active lesions neither in the lungs nor in retroperitoneal lymph nodes ***Conclusion:*** IVC leiomyosarcomas are retroperitoneal neoplasms with different growing patterns : extraluminal (major proportion), intraluminal or mixed patterns.18FDG-PET/CT plays a crucial role in defining the tumor extent and assisting with appropriate treatment approach. Benz et al study of 50 patients, of which 8% had a LMS, showed that 18FDG-PET/CT was significantly more accurate than size based criteria at assessing histopathologic response to adjuvant therapy. Add to that, reduction in FDG-uptake from baseline to

end of chemotherapy by 60% were used as cutoff point to predict treatment responses in sarcoma patients. As for the prognostic impact, a recent study of Dilly et al concluded that SUVmax, MTV and TLG in baseline are predictive of overall survival, delta SUVpeak in early therapeutic evaluation is significantly correlated with progression-free survival in advanced leiomyosarcoma patients. Also it is worth mentioning the effectiveness of 18FDG-PET/CT in determining safe surgical margins for soft tissue sarcoma reported by Yokouchi et al. This is prominent for large tumors requiring extensive resection including normal tissue, accompanied by reconstruction-assisting surgery, involving high cost and long hospital days. In the present study, areas with SUV-max less than 1.0 were free of viable tumor cells.

### PSMA Theragnostic beyond prostate cancer. A monocentric prospective observational study on the diagnostic performance of PSMA PET/CT in patients with metastatic Renal Clear Cell Carcinoma

***F. Serani***[1], *A. Farolfi*[2], *P. Castellucci*[2], *L. Vetrone*[1], *R. Mei*[2], *S. Fanti*[3]; *[1]Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** Prostate-specific membrane antigen positron emission tomography (PSMA PET/CT) is nowadays almost a certainty for staging and restaging of prostate cancer. However, it is well known that expression of PSMA it is not a prerogative of prostate cancer.Other malignant tumors overexpress this protein and renal clear cell carcinoma (ccRCC) has been found to be one of these.The aim of this study was to evaluate the diagnostic performance of PSMA PET/CT in patients at first evaluation of suspect metastatic ccRCC, and its potential use in a theragnostic intent. ***Materials and Methods:*** This monocentric prospective observational study included 4 patients with metastatic ccRCC who underwent PSMA PET/CT for restaging purposes within one month of the restaging contrast enhanced computed tomography (ceCT), used as a reference standard. A positive PSMA scan was defined when at least one lesion had a mean standardized uptake value (SUV mean) above the liver mean SUV. The active tumor volume (ATV) and the total lesion activity (TLA) were calculated with a semiquantitative method. ***Results:*** PSMA PET/CT was positive in all the 4 patients showing a total of 54 multiple pathological foci in all patients (median lesion number 11, IQR 8,8-15,8); in ceCT the total number of pathological foci was 39 (median 8,5, IQR 7,8-10,5). In one patient, PSMA PET/CT detected additional soft tissue uptakes, which were not detected on ceCT; however, in another patient showed less localization than ceCT (lung). In all patients, PSMA expression was highly positive at metastases, with a median SUV mean of 17,7 g/mL (IQR 16,1-19,3 g/mL) at the most avid metastases.The median ATV was 59,7 cm3 (IQR 35,9-64,7 cm3) and the TLA was 567,4 g/mL/ cm3 (IQR 830,1-306,8 g/mL/ cm3).The median SUVmean of parotid gland was 16,1 g/mL (IQR 14,3- 16,9 g/mL) and the median SUVmean of liver parenchyma was 8,1 g/mL (IQR 6,3- 9,2 g/mL).All the four patients were eligible for therapeutic treatment with PSMA considered the VISION criteria[1]. ***Conclusion:*** Our initial experience showed that PSMA PET/CT has a high diagnostic performance in detecting metastatic ccRCC and that this pathology could benefit from a theragnostic approach for PSMA targeted therapy. Further studies are needed to confirm these findings and to assess the potential use of PSMA theragnostic in other urologic cancers beside prostate cancer. ***References:*** 1. ### Feasibility study about the intra-operative use of a novel PET/CT Specimen Imager in Prostate Cancer and Neuroendocrine Tumors

***L. Muraglia***[1], *F. Mattana*[1], *L. Travaini*[1], *G. Musi*[2], *E. Bertani*[3], *G. Renne*[4], *E. Pisa*[4], *M. Ferrari*[5], *U. Fumagalli Romario*[3], *O. De Cobelli*[2], *N. Fusco*[6], *C. Francesco*[7]; *[1]Nuclear Medicine Division, European Institute of Oncology IRCCS, Milan, ITALY, [2]Urology Division, European Institute of Oncology IRCCS; Oncology and Hemato-Oncology Department, University of Milan, Milan, ITALY, [3]Digestive Surgery Division, European Institute of Oncology IRCCS, Milan, ITALY, [4]Pathology Division, European Institute of Oncology IRCCS, Milan, ITALY, [5]Medical Physics Unit, European Institute of Oncology IRCCS, Milan, ITALY, [6]Pathology Division, European Institute of Oncology IRCCS; Oncology and Hemato-Oncology Department, University of Milan, Milan, ITALY, [7]Nuclear Medicine Division, European Institute of Oncology IRCCS; Oncology and Hemato-Oncology Department, University of Milan, Milan, ITALY.*

***Aim/Introduction:*** The aim of our study was to evaluate feasibility and clinical perspectives of the intra-operative application of a specimen PET/CT imager in Prostate Cancer and Neuroendocrine Tumors. ***Materials and Methods:*** This is a pilot analysis performed in three patients who received an intra-operative administration of 68Ga-PSMA-11 (n=2) and 68Ga-DOTA-TOC (n=1), respectively. Our patients underwent radio-guided surgery with a beta-probe detector during radical prostatectomy for prostate cancer (PCa) and salvage lymphadenectomy for recurrent neuroendocrine tumor (NET) of the ileum, respectively, within two ongoing clinical trials in our Institute (NCT05596851 and NCT05448157). A PET/CT specimen imager was used intra-operatively to scan the specimen after resection. Pathologic assessment with immunohistochemistry (PSMA-staining and SSA immunoreactivity) was considered as standard of truth. Specimen images were compared with baseline PET/CT images and histopathological analysis. ***Results:*** Patients received 1 MBq/Kg of 68Ga-PSMA-11 (PCa) and 1.2 MBq/Kg of 68Ga-DOTA-TOC (NET) prior to surgery. After surgical resection, specimens were positioned in a dedicated specimen container and scanned. In all cases the use of the PET/CT specimen imager did not significantly interfere with any procedures and the radiation exposure of the operating theater staff was lower than 40 µSv per procedure. The PET spatial resolution was sensibly higher for the specimen images compared to the baseline whole-body PET/CT images and a perfect match was observed between the findings detected by the specimen imager and histopathology. ***Conclusion:*** The image acquisition of specimens obtained by patients who received intra-surgery injection of 68Ga-PSMA-11 and 68Ga-DOTA-TOC was feasible

and reliable in a live-experience session. Since the data derived from the specimen PET/CT imager matched perfectly with the histopathological analysis, this pilot-analysis could lead to some newer research perspectives about surgical margins assessment and the evaluation of intra-lesion tumor heterogeneity.

## EP-0390

### Preoperative Radioisotope-guided Localization of Non-palpable Pulmonary Nodules

***M. Olajos***, *K. Park, Á. Ghimessy, K. Csende, M. Csaba, J. Andi, M. Téglás, L. Agócs, F. Rényi-Vámos, I. Sinkovics;*
*National Institute Of Oncology, Budapest, HUNGARY.*

***Aim/Introduction:*** As a result of the development of imaging studies and the screening of high-risk groups, the detection rate of small pulmonary nodules on chest CT scans has improved. The dignity of these small nodules is questionable and therefore removal of these lesions is important both from a diagnostic and therapeutic point of view. Minimally invasive techniques, such as video-assisted thoracic surgery (VATS), are the procedures of choice nowadays. Therefore, accurate preoperative localisation of the lung nodules is essential. Several methods are available for preoperative marking of the lesion; one of them is CT-guided radioisotope marking. ***Materials and Methods:*** 75 patients (mean age 63 years) underwent minimally invasive removal of a nonpalpable lung nodule after isotopic labelling between January 2017 and March 2022 at the Thoracic Surgery Department of the National Institute of Oncology in Hungary. The size of the lung nodules ranged from 0.03 to 2 cm (mean: 0.9 cm) and their distance from the pleura averaged 0.4 cm. Under CT guidance, 10 to 15 MBq of 99mTc-labelled human serum albumin was injected into the nodule in a volume of 0.2ml. Following the administration of the radioisotope, surgery was performed within 1-3 hours. During operation a handheld gamma probe was used to identify the marked nodule, which was removed by wedge excision when possible. ***Results:*** Intraoperative localisation and removal of the nodules was successful in all cases. Primary lung tumour was confirmed in 18 patients and metastasis was found in 49 patients. In 8 patients, histological examination showed a non-malignant process (inflammation, hamartoma, tuberculosis). Isotope administration was completely uncomplicated in 43 patients, and in 32 patients the management of complications (pneumothorax, haemorrhage, bloody sputum or pleural detachment) was easily manageable during surgery. No serious complications requiring immediate intervention developed. ***Conclusion:*** Isotopic labelling of non-palpable lung nodules detected by CT scans helps to localize and remove the nodules safely using minimally invasive techniques. It allows accurate marking and correct removal of deeper lesions. During hookwire marking, breathing movements often result in wire dislodgment, making it difficult to find and remove the nodules. Conversely, with the radio-guided method this problem can be avoided. The procedure is safe, with only mild, easily treatable complications or with no complications at all. ***References:*** Marcello Carlo Ambrogi, Franca Melfi, Carmelina Zirafa, Marco Lucchi, Annalisa De Liperi, Giuliano Mariani, Olivia Fanucchi, Alfredo Mussi. „Radio-guided throracoscopic surgery (RGTS) of small pulmonary nodules." ***Aim/Introduction:*** In localized high-risk prostate cancer (PC) avoidance of positive resection margins improves cancer control. PSMA-PET/CT is currently used for primary staging in high-risk PC due to its higher accuracy. Here we aim to evaluate the feasibility of a novel intraoperative micro-PET/CT in radical prostatectomy (RP). ***Materials and Methods:*** In this prospective two-center feasibility study, we evaluate the diagnostic value of intraoperative ex vivo micro-PET/CT imaging of RP and lymphadenectomy specimens.Ten patients with high-risk PC underwent clinical PSMA-PET/CT preoperatively on the day of surgery. Six patients received $^{68}$Ga-PSMA-11 and four $^{18}$F-PSMA-1007. The resected specimen was measured using a novel micro-PET/CT device (AURA10, XEOS medical, Belgium) developed for ex-vivo intraoperative margin assessment. The resulting PET images were segmented to ascertain the extension of tracer foci, while CT was used with a soft tissue window for organ margin assessment. ***Results:*** Median Age was 66 years with a median BMI of 27. Activity concentrations in the specimens at the time of imaging were 1.0 kBq/ml ($^{68}$Ga) and 7.7 kBq/ml ($^{18}$F). All index lesions of staging multiparametric-MRI could be visualized. Overall, micro-PET/CT correlated well with conventional PET/CT regarding detection of suspicious tracer foci (pearson coefficient 0.935). In addition, micro-PET/CT demonstrated all lymph node metastases detected on conventional PET/CT (n=3), as well as three previously undetected lymph node metastases. Importantly, all positive/close (< 1mm) resection margins could be visualized in agreement with histopathology. ***Conclusion:*** In conclusion, intraoperative micro-PET/CT warrants further investigation to tailor RP, based on a good correlation with final pathology. Future trials will prospectively compare ex-vivo PET/CT to frozen section analysis for the detection of positive resection margins and bio-chemical-recurrence-free survival.

## EP-0393

### Preoperative CT-guided radiolabeling of lung nodules with 99mTc-MAA and Video-Assisted or Robotic-Assisted Thorascopic Surgery: experience in our center since 2017.

***C. Wakfie Corieh***[1,2], *E. Rodríguez Gallo*[1,2], *J. Sánchez Corral*[1,2], *N. Mimica Haasz*[1,2], *F. Moradiellos Díez*[1,2], *S. Amor Alonso*[1,2], *A. Maldonado Suarez*[1,2];
[1]*Hospital Universitario Quirónsalud Madrid, Madrid, SPAIN,* [2]*Universidad Europea, Madrid, SPAIN.*

***Aim/Introduction:*** We evaluated our experience with preoperative CT-guided marking of lung nodules with $^{99m}$Tc-MAA prior to Video-Assisted or Robotic-Assisted Thorascopic Surgery (VATS or

RATS). ***Materials and Methods:*** We retrospectively analyzed 61 patients undergoing radioguided lung nodule surgery between April 24, 2017 and February 06, 2023. Injection of $^{99m}$Tc-MAA (37-296 MBq) in all cases was performed with a 25-gauge catheter, subsequently 3-4 ml of iodinated contrast was administered through the same catheter. SPECT/CT was then acquired to confirm correct nodule radiolabeling and rule out complications. After excluding 8 patients (studies with technical limitations or radiolabelling with 125-I seeds), we analyzed major diameter, attenuation, location and distance of the nodule to the pleura. We also evaluated the presence of post-puncture pneumothorax, radiolabeling, accuracy and correlation of post-radiolabeling contrast localization with that of the radiopharmaceutical. Type of surgical intervention (VATS or RATS) and histology (including surgical margins) were also collected. ***Results:*** Fifty-three patients with CT-guided radiolabeling of pulmonary nodules with $^{99m}$Tc-MAA prior to surgery were included (mean age: 64±10.9 years, 34 males). Mean largest diameter of nodules was 11.7±4.8 mm; nodules were solid in 62.3% (33/53), cavitated in 7.5% (4/53), subsolid in 7.5% (4/53) and ground-glass density in the remaining 22.7% (12/53). 37.7% (20/53) were located in the right upper lobe, 25.5% (13.5/53) in the right lower lobe, 11.3% (6/53) in the left upper lobe, 24.5% (13/53) in the left lower lobe and 1% (0.5/53) in the LM. Mean distance of the nodule to the pleura was 8.5 mm (range 0-50.9). Post-puncture small pneumothorax was identified in 39.6% (21/53). The mean distance between pulmonary nodule and marking was 3.4 mm (range 0-23.4). We found concordance between contrast and radiopharmaceutical in 88.7% of the cases (47/53), discordant in 1.9% (1/53) by vascular puncture and not evaluable in the remaining 9.4% (5/53). Regarding the surgical approach, 88.7% (47/53) of the patients underwent VATS and 11.3% (6/53) underwent RATS. Most of the pulmonary nodules were malignant (84.9%, 45/53), thirty-two were primary lung tumors (60.4%), while thirteen were metastases of extrathoracic tumors (24.5%). The remaining 15.1% (8/53) were benign lesions. Complete resection of lesions was achieved in all patients. ***Conclusion:*** In our experience, preoperative CT-guided $^{99m}$Tc-MAA lung nodule marking is an appropriate and safe technique that allows adequate localization and intraoperative radioguided resection by VATS and RATS approaches.

***E. Gromova***[1], *A. Smirnova*[1], *G. Kataeva*[2], *N. Plakhotina*[1];
[1]*LDC MIBS, Saint-Petersburg, RUSSIAN FEDERATION,*
[2]*RRCRST, Saint-Petersburg, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Brain metastases occur in 20-40% of patients with various solid cancer. The problem of differential diagnosis of recurrent tumor growth and post-radiation changes is relevant. Positron emission tomography with labeled amino acids is an important method in monitoring the treatment of this patients. ***Materials and Methods:*** We performed a PET-CT examination with 18F-FET in 73 patients with brain metastasis, of whom 39.39 % were patients with lung cancer, 36.36% with breast cancer, 9.00% with melanoma, 6.06% kidney cancer and other types of cancers.62 patients were examined after radiosurgical treatment of metastases, single (50 people), double (10 people) or three times (2 people). PET-CT was performed according to the standard static protocol. All patients underwent MRI with standard sequences (T1, T2, FLAIR, T1+C). The conclusion about the progression of the disease was made on the basis of a combination of clinical and tomographic data, including data from a previous PET-CT study with 18F-FET or 11C-MET, available for 24 people ***Results:*** According to the Kaplan-Meier analysis differences of PFS in the groups of patients after single or multiple radiotherapy are significant (Cox-Mantel Test, I = 2.178374 U = 4.592147, Test statistic = 3.111355 p =0,00186). Median, lower and upper quartiles values are (12.9, 10.5;24.4) months after single RT and (7.5, 3.5;10.5) months - after repeated RT. Differences of PFS in groups of patients with a single or multiple metastases are significant (Cox-Mantel Test, I = 7.848240 U = 6.156148, Test statistic = 2.197470 p = .02799). Median, lower and upper quartiles values are (14.6, 9.8;26.7) months in group with single metastasis and (10.9, 7.2;12.8) months - in group with two and more metastases. ***Conclusion:*** 1) Median survival after single radiotherapy is comparable to treatment outcomes for primary glial tumors. This indicates the effectiveness of RT for the treatment of GM metastases.2) The presence of multiple metastases is an additional factor that reduces the value of PFS.3) To interpret PET data with TBR max in the range from 1.7 to 2.8, for a confident judgment about the genesis of increased radiopharmaceutical uptake in tumors, we cannot rely only on the value of TBR max. A search for other biomarkers of progression (beyond the appearance of new pathological foci) is required, and before their verification, a repeat PET study 2-3 months

## EP-0395

**Fast SPECT/CT confirmation of the preoperative location with ROLL: analysis of a 2-year single-centre real life experience**

***I. Lopo***[1], *E. Lima*[2], *A. Bitencourt*[2], *L. Santos*[2], *A. Tavares*[2], *P. Lapa*[1,3], *G. Costa*[1,3];
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,* [2]*A. C. Camargo Cancer Center, São Paulo, BRAZIL,* [3]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

***Aim/Introduction:*** ROLL (Radioguided Occult Lesion Localisation) is a simple method used for preoperative localisation of clinically-occult breast lesions, resulting in small excision volumes and little discomfort for patients. Although this technique is very precise, there can be some difficulties. To identify early and correct errors in the preoperative period, the location of the radioactive material is confirmed with SPECT/CT (single photon emission computed tomography/computed tomography) imaging by using a fast-protocol developed in the Department. When errors are identified, the surgical team is contacted or a new method of localisation is adopted, like wire-localisation. We aim to review the contribution of SPECT/CT, with a particular focus on those cases in which the ROLL method failed. ***Materials and Methods:*** We performed a retrospective study with all patients with breast lesions submitted to ROLL between September-2019 and September-2021. Patients were injected with 0.9-1mCi of 99mTc-phytate, guided either by stereotaxic-mammography or ultrasound, and surgery was performed the day after. The precision of location was analysed based on SPECT/CT findings. To evaluate the influence of incorrect location on surgical outcome, we collected all relevant clinical data available. ***Results:*** A total of 1110 ROLL were selected (mean lesion size 15.5±10.7mm). Patients (100% female) had a mean age of 52.8±12.8 years. ROLL was used for more than 1 lesion in 104 patients. There was a low prevalence of non-precise location on SPECT/CT imaging (6.4%, N=71): 55 cases (5.0%) being only reported to the surgical team and 16 (1.4%) undergoing another method of localisation, either re-injection of radiotracer (N=2) or wire-localisation

(N=14). Among these patients (2.9% invasive carcinoma, 11.4% carcinoma in situ), 11 (15.7%) had no evidence of tumour, mainly because of response to neoadjuvant chemotherapy (81.8%), and 6 lesions (8.6%) were not resected. There were involved resection-margins in 11 patients (15.7%): 3 between patients submitted to wire-localisation (21.4%) and 8 between patients in whose error was reported to the surgical team (14.5%) - 3 of these being re-operated. ***Conclusion:*** Our results show that ROLL is an effective method. Despite not being routinely used in most nuclear medicine departments, fast SPECT/CT imaging allows greater confidence in the preoperative localisation procedure, mainly in departments where the technique is starting to be implemented. Furthermore, this combined method highlights the importance of close collaboration of the different medical specialties (radiology-nuclear medicine-surgery), in the efficiency of patients' flow as well as in the optimization of surgical results.

## EP-0396

### Intraoperative PET/CT Specimen Imaging for the Evaluation of Surgical Margins and Nodal Metastases in Prostate Cancer Patients Undergoing Robot-assisted PSMA-radioguided Surgery

***G. Rovera***[1], *S. Grimaldi*[1], *M. Oderda*[2], *L. Delsedime*[3], *D. D'Agate*[2], *F. Lavagno*[2], *A. Marquis*[2], *G. Marra*[2], *L. Molinaro*[3], *P. Gontero*[2], *D. Deandreis*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Department of Surgical Sciences, Urology Unit, AOU Città della Salute e della Scienza di Torino, Molinette Hospital, University of Turin, Turin, ITALY,* [3]*Department of Pathology, AOU Città della Salute e della Scienza di Torino, Molinette Hospital, University of Turin, Turin, ITALY.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is the most accurate radiopharmaceutical for detecting prostate cancer (PCa) localizations at PET/CT imaging. A high-resolution PET/CT specimen scanner recently became available, showing near five-fold higher spatial resolution compared to standard clinical PET/CTs, thus holding potential for the ex-vivo identification of PCa foci in surgically resected specimens. The aim of this feasibility study was to investigate the use of the PET/CT specimen imager in the intraoperative setting to guide robot-assisted radical prostatectomy (RARP) and pelvic lymph node dissection (PLND). ***Materials and Methods:*** Three high-risk PCa patients underwent RARP and PLND with the use of the PET/CT intraoperative specimen imager. Preoperative staging included MRI and $^{68}$Ga-PSMA-11 PET/CT. In the operating room, an intravenous injection of $^{68}$Ga-PSMA-11 (2 MBq/kg) was performed during trocar placement. Lymph nodes were scanned with the specimen imager after their immediate removal through the assistant trocar. After complete excision, PET/CT images of the prostate were acquired to check for positive surgical margins before performing the urethra-vesical anastomosis. Lymph nodes SUVmax, background SUVmax and nodal/background ratio (TBR) were calculated using the AMIDE(v1.0.6) software. ***Results:*** The intraoperative PET/CT scanner allowed to obtain prostatic and nodal specimen images with a mean time of 12 ± 3 minutes. The median time interval between tracer injection and PET/CT acquisitions was 98 minutes for nodal specimens and 3.8 hours for prostatatic specimens. At histopathology, the per-patient nodal yield was 17.3 ± 5.8 nodes, with only one metastatic node. At PET/CT imaging a higher focal tracer uptake was observed in the metastatic node, corresponding to a target-to-background (TBR) SUVmax ratio of 13.6. On the other hand, no uptake or diffuse, faint uptake was found in negative nodes, with a TBR range of 1-5.3. Besides correctly staging nodal metastases in all three patients, the PET/CT specimen scanner also provided intraoperative data regarding surgical margins and seminal vesicles involvement. Indeed, a significant tracer uptake in the seminal vesicles was found only in the two patients with confirmed seminal vesicles involvement at histopathology. Moreover, the intraoperative PET/CT images correctly detected negative surgical margins in two out of three patients, while only one locally advanced case presented with inconclusive findings. ***Conclusion:*** Intraoperative PSMA-PET/CT specimen imaging proved to be safe and feasible, holding potential for the improved assessment of prostate surgical margins and nodal involvement. A more precise evaluation of prostate cancer spread could allow for hyper-conservative surgical approaches while preserving oncological radicality.

## EP-0397

### DROP-IN robotic SPECT in sentinel lymph node prostate cancer patients

***S. Azargoshasb***[1], *A. Berrens*[2], *L. J. Slof*[1], *E. M. K. Wit*[2], *P. J van Leeuwen*[2], *H. G. van der Poel*[2], *M. N. van Oosterom*[1], *F. W. B. van Leeuwen*[1];
[1]*Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Cent, Leiden, NETHERLANDS,* [2]*Department of Urology, NETHERLANDS Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** By allowing for robotic sentinel lymph node (SLN) resections [1] and tumor-targeted resections (PSMA salvage[2] and primary[3]), the DROP-IN gamma probe has revolutionized minimal-invasive radioguided surgery. Current DROP-IN tracing output is in the form of acoustical and numerical signals. While this output can easily be displayed in the view of the surgical console, its value is lacking a visual demarcation of the target location. The freehandSPECT technology has been poised to provide such visual target demarcations [4]. Unfortunately, this technology only works when a rigid probe is in direct line-of-sight of the tracking system. Following earlier phantom studies [5], we now present the translation of a new robotic SPECT concept that uses video-based tracking. ***Materials and Methods:*** Prostate cancer patients (n = 3) received a robot-assisted SLN procedure at a single European medical center. Following ICG-$^{99m}$Tc-nanoscan injection, SN locations were identified at lymphoscintigraphy and SPECT/CT. SNs were excised with a DROP-IN gamma probe that comprised clinical grade PEEK-ring tracking markers. Custom tracking and reconstruction software supported automatic segmentation of these fiducial markers from the video feeds of the Firefly (fluorescence) laparoscope, data that was used to define intraoperative probe positioning. Relating the probe output (counts/second) to its geographic location in the video feed allowed for the creation of a robotic SPECT scan that could be augmented on the laparoscopic view. ***Results:*** Patients were all clinical cT1c (2) or cT2 (1) without signs of metastases on preoperative PSMA PET/CT. In total 8 SNs were mapped on preoperative SPECT/CT and pursued with a DROP-IN gamma probe intraoperatively. During surgery, the robotic freehand data complemented the traditional DROP-IN probe output by providing a heat-map overlay that indicated which soft-tissue anatomies showed the highest count rate (average SN 600 counts/seconds). Thereby providing the surgeons with a visual que of the tissue-target location. Firefly fluorescence imaging helped confirm the target location. The total number of resected SNs was 10, of which all were detected with the DROP-IN. At pathology 2 positive

SNs were found (2 out of 3 patients). ***Conclusion:*** Integrating intraoperative SPECT imaging in robotic surgical procedures provides a means to visually enhance the surgeon's experience. Augmenting the camera view with robotically acquired nuclear medicine imaging, recorded in vivo, opens a new paradigm in radioguided surgery. ***References:*** [1] Dell'Oglio, et al., European_Urology,_(2021) [2] de Barros et al., European_Urology,_(2022) [3] Gandaglia et al., European_Urology,_(2022) [4] Wendler et al., EJNMMI,_(2010) [5] Fuerst et al., IEEE_TMI,_(2015)

## EP-0398

### IMPLEMENTATION OF IODINE-125 (125I) SEEDS MARKING IN NON-PALPABLE MALIGNANT BREAST LESIONS

***M. Garcia Aragon***, *R. Zambrano Infantino, F. Sebastian Palacid, N. Alvarez Mena, A. Sainz Esteban, M. Alonso Rodríguez, M. Moral Cano, M. Gonzalez Soto, R. Ruano Perez;*
*Hospital Universitario Clínico Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** To asses the usefulness of iodine-125I (125I) seeds in the marking of non-palpable malignant breast lesions, including cases after neoadjuvant chemotherapy (NCT), since the implantation of the technique in February-2022. ***Materials and Methods:*** The 68 patients (mean age 61.49 years) diagnosed with non-palpable breast cancer between February and January 2023 were included. The marking of the tumor was done with 125iodine seeds under ultrasound control, controlling the correct placement by mammography. The need for a second surgery due to insufficient margins was assessed. Other variables were also evaluated: seed placement time, tumor size, and previous NCT. The recovery of the seed was carried out in the Pathological Anatomy service. ***Results:*** Seeds were placed on average 5.26 days (range 1-12) before surgery. Radioguided tumorectomy was possible in all 68 cases, recovering the seed in all of them. Only 2/68 (3.03%) of the women had to undergo reoperation for affected margins. The final tumor size was 10.30mm (3-24mm), and in 4/12 cases after NCT no residual tumor was found. The sentinel node was negative in 55/68, final staging of patients without NCT (pTis: 3, pT1a:4, pT1b:18, pT1c: 29, pT2:3; pN0:48, pNmi:3, pN1:6;). ***Conclusion:*** 125iodine seed labeling of non-palpable breast cancers is a technique that involves multidisciplinary logistics. The possibility of placing the seed days before surgery facilitates the programming of the patients. The low rate of reoperations due to insufficient margins is its main potential for its healthcare implementation in breast units.

## EP-0399

### Minimally invasive radioguided parathyroidectomy: A descriptive report and correlation between variables of interest

***M. Sanchez Torrente***, *R. Nieto Serrano, A. Martin Garcia, M. Gallego Marquez, J. Venero Chaparro, D. Becerra Garcia;*
*Hospital Universitario Clínico San Cecilio, Granada, SPAIN.*

***Aim/Introduction:*** The minimally invasive approach to parathyroid glands represents an important field of application in radioguided surgery. Our Aims were to perform clinical and laboratory data analysis of patients undergoing radioguided parathyroidectomy, calculate surgical success rate depending on whether sestamibi (MIBI) or macro-aggregated-albumin (MAA) is used and the variation of pre/post-surgical PTH levels regarding age and sex. ***Materials and Methods:*** A total of 78 patients who underwent radioguided parathyroidectomy with Tc99m-MIBI or Tc99m-MAA between 2016-2023 were studied. MIBI-Tc99m or MAA-Tc99m was used depending on the time-logistics from the injection to the act of surgery, uptake ratio of MIBI lesion/thyroid tissue in late phase and MIBI washout rate, performing MIBI-guided surgery whenever these parameters allowed it. We collected the variables age, sex, MIBI-Tc99m or MAA-Tc99m as surgical guide, pre/post-surgical PTH values at 5 and 10 minutes, post-surgical PTH values fall >50% compared to pre-surgical values, PTH levels normalization 2 months after surgery, parathyroid adenoma location, anatomopathological results, SPECT-CT-MIBI/Tc99m, cervical ultrasound and, if applicable, 4D-CT and 18F-Choline-PET/CT results. We performed T-Student-test to compare the mean drop in pre/post-surgical PTH values (DMPTH) depending on whether MIBI/MAA is used and the association between DMPTH and sex. We also calculated Pearson's correlation between DMPTH and age. ***Results:*** The average age was 58.9 years, female sex was the most frequent (74.36%). PTH decreased >50% 10 minutes after excision in 87.3% cases, achieving normalization of PTH after two months in 88.46% patients. The most frequent location was lower right (36.5%) followed by lower left (35.14%) and the less frequent was ectopic (5.41%). The diagnostic accuracy(DA) were 97.43% and 71.79% for SPECT-CT-MIBI-Tc99m and cervical ultrasound, respectively. 4D-CT was performed in 7 patients (DA=85.7%) and 18F-Choline-PET/CT in 4 patients (DA=100%). Anatomopathological results were: parathyroid-adenoma (92.31%), parathyroid-hyperplasia (2.56%), parathyroid-carcinoma(1.28%), normal-parathyroid-tissue (3.58%). T-Student test for DMPTH in MIBI and MAA obtained t=-1.81(p=0.037), and DMPTH and sex obtained t=-1.39(p=0.087). Pearson Correlation for DMPTH and age obtained -0.372(p=0.001). ***Conclusion:*** MIBI guided surgery and younger age showed association with DMPTH higher values. Relationship between female sex and DMPTH did not reach statistical significance, although it was very close. This suggests that with larger sample sizes we may obtain a statistically significant result. The greater DA of nuclear medicine studies and the higher success rate in MIBI-Tc99m guided surgeries stand out.

## EP-0400

### Lung nodule radioguided localization results.

***M. Guiote Moreno***[1], *A. Lopez Cano*[1], *S. Castejón Echevarne*[1], *D. Tercero Garrido*[1], *R. Zurera Pareja*[2], *J. Vallejo Casas*[1];
[1]*Hospital Universitario Reina Sofía, Cordoba, SPAIN,* [2]*IMIBIC, Cordoba, SPAIN.*

***Aim/Introduction:*** The aim of the study is to describe our experience in lung nodule radioguided localization. ***Materials and Methods:*** 12 patients have been included in our study since January 2022 to March 2023, (5 women and 7 men) with a mean of 70,5 years old ( 42-80 SD 10,8). In all the cases the patients had one or multiple pulmonary nodules with suspicion of malignancy that were described in a 18F-FDG PET-CT. 6 patients had a primary lung cancer, 4 colorectal cancer, 1 chordoma, and the last one a renal cancer. The mean size of the nodules were 9 mm (21-5 mm SD 5,3 mm) with a mean of SUVmax 5,3 (42,3- 0,5 DS 11,7), which were located in left upper pulmonary lobe in 33% of the cases. Intranodular CT guided injection with 99mTc-MAA were performed in patients with a mean dose of 29.6 Mbq ( 37- 74 MBq SD 22.2 MBq) . A SPECT-CT was done in all patients previous to the surgery. ***Results:*** The uptake of the nodule was intralesional in 10 patients, one patient was perilesional and we found pleural efussion in two patients, (of these two patients one had the nodule radiolabeled). Only in 3 cases was a pneumothorax generated by the puncture. During surgery we found the gamma

probe-guided pulmonary nodule in 11 patients, and only in the patient who had a pleural effusion without a radiolabeled lesion, no guided nodule was found, and a lobectomy was performed. Seven of the 12 nodules were palpable by the surgeon. Finally, the pathology of the lesion was malignant in all but one case; 5 lung ADCs, one lung epidermoid carcinoma, 2 colorectal metastases, one NET tumor, and one metastatic chordoma. ***Conclusion:*** In our experience, pulmonary nodule radioguided localization has very good results, changing the clinical management of 11 of the 12 patients, with a high rate of intraoperative detection of lesions and low complications.

## EP-0401

### Diagnostic Value Of Salivary Gland Scintigraphy In Post-Radiation Xerostomia In Nasopharyngeal Carcinoma Patients: First Tunisian study

***H. Rokbani***[1], *L. Zaabar*[1,2], *S. Zarraa*[3,2], *L. Kechaou*[3], *M. El bessi*[3], *T. Ben Ghachem*[1,2], *C. Nasr*[4,2], *A. Mhiri*[1,2];
[1]*Nuclear Medicine departement, Salah Azaeiz Institute, tunis, TUNISIA,* [2]*Faculté de Médecine de Tunis, Tunis, TUNISIA,* [3]*Radiotherapy departement, Salah Azaeiz Institute, tunis, TUNISIA,* [4]*Radiotherapy departement, Salah Azaeiz Institute, Tunis, TUNISIA.*

***Aim/Introduction:*** Post-radiation xerostomia is the most reported late post-radiation toxicity of nasopharyngeal carcinoma. Aim: Functional assessment of the main salivary glands (SG) by analyzing Technetium-99m (99mTc) clearance in patients irradiated for nasopharyngeal carcinoma. ***Materials and Methods:*** Prospective study in the Nuclear Medicine Department of the Salah Azaeiz Institute in collaboration with the Radiotherapy Department of the Salah Azaeiz Institute, on 21 patients (5 women and 16 men), aged between 30 and 60 years, who received nasopharyngeal carcinomas radiotherapy (therapeutic protocol by induction chemotherapy then concomitant radio-chemotherapy). We recorded the mean and maximum dose values for all SG and then separately. We evaluated our patients over a mean period of 11 months (extremes 6 to 22 months) by salivary scintigraphy (SS). These were dynamic acquisitions centered on the skull in anterior incidence, patient in dorsal decubitus position, immediately after intravenous injection of 148-185 MBq (4-5mCi) of 99mTc followed by Vitamin C ingestion at the 16th minute. We analyzed the images qualitatively and then semi-quantitatively (activity versus time curve). We compared our results with the doses received to the SGs and with specific radiotherapy techniques (prophylactic inclusion of submandibular IB lymph node territories). ***Results:*** N0 in 9%, N1 in 36%, N2 in 18% and N3 in 36% of cases. The mean and maximum dose values for all SG were 39 Gy and 73 Gy respectively. The mean and maximum dose values were 72 Gy and 37 Gy for the parotid glands and 58 and 70 Gy for the submaxillary glands respectively. Only 15.4% of our patients had normal overall SG function. A post-vitamin C ingestion emptying disorder was noted in 84.6% of our patients. SS showed parenchymal hypofunction in 61.5% of patients, with 38.4% involvement of the parotid glands (more important on the right side) and 69.3% of the submandibular glands bilaterally. ***Conclusion:*** The SS is an excellent tool for positive diagnosis of several degrees of radiation-induced salivary deficiency. It is a low-radiation, non-invasive exam, simple to perform, and widely available that allows reproducible quantitative analysis of SG secretory function. Our study showed high rates of hypofunction, particularly in the submandibular glands, which are more exposed in therapeutic dosimetry, which remains to be confirmed by additional studies with bigger number of patients and pre/post treatment SS.

## EP-0402

### Comparison of Radioactive Seed Localization and Radioguided Occult Lesion Localization in Surgical Success of Nonpalpable Breast Cancer

***R. Sahin***[1], *M. Baykara Ulusan*[2], *E. S. Ata*[2], *M. B. Cengiz Gökmen*[3], *N. Ergül*[1], *T. Aksoy*[1], *T. F. Çermik*[1], *E. Arslan*[1];
[1]*University of Health Sciences, Istanbul Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*University of Health Sciences, Istanbul Training and Research Hospital, Department of Radiology, Istanbul, TÜRKIYE,* [3]*University of Health Sciences, Istanbul Training and Research Hospital, Department of Surgery, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** In nonpalpable breast tumor, wire-guided localization or radionuclide-guided occult lesion localization (ROLL) is used for intraoperative tumor localization. It is an alternative method for tumor localization and surgical planning with 125-I SEED, using in many centers around the world. In this study, we aim to show the contribution of Iodine-125 SEED to surgical success compared to ROLL. ***Materials and Methods:*** A total of 24 patients with non-palpable breast tumors, with newly diagnosed or after neoadjuvant chemotherapy, were included in our prospective study. In the ROLL group (12 cases), an average of 1 mCi Tc-99m MAA (half-life: 6 hours) was marked under ultrasound guidance on the day of surgery. In the 125-I SEED group (12 cases), the 125-I SEED capsule (half-life: 59.4 days) was placed in the tumor under ultrasound guidance one day before surgery. The surgical procedure was guided by a gamma probe. The excision time and specimen weight were recorded, and differences between the groups were compared. Intraoperative frozen responses were evaluated to compare positive surgical margin and re-excision rates. ***Results:*** The 24 patients (mean age: 56.3±STD:11.89) were invasive breast cancer. The largest axial diameter of the tumor on ultrasound was 13.2±STD:5.96 mm in the ROLL group and 8.86±STD:5.32 mm in the 125-I SEED group (p=0.08). The mean operation time for excision was 11.02±STD:3.85 min for ROLL, and 9.45±STD:5.41 min for 125-I SEED (p=0.42). The specimen weight was 65±STD:15 grams in the ROLL group and 37±STD:12 grams in the 125-I SEED group (p=0.045). In the ROLL group, the lesion was correctly localized in 8/12 (66%) cases, and re-excision was required in 4 cases. In the 125-I SEED group, the lesion was correctly localized in 10/12 (83%) cases, and re-excision was performed in 2 cases (p=0.36). ***Conclusion:*** According to the preliminary findings of our study, reexcision rate was observed to be lower with 125-I SEED compared to ROLL although statistically insignificant. However, it was shown that a statistically significantly lower weight resection specimen was extracted with the 125-I SEED. The use of the 125-I SEED is an easy-to-learn, safe and effective procedure with a low incidence of positive margin. Better localization of the tumor with 125-I SEED during surgery will increase surgical success, decrease recurrence rates, and increase the psychosocial well-being of patients by preserving healthy breast tissue. In addition, due to the longer half-life of 125-I SEED, more flexible study plan will be possible.

### EP-0403

**SPECT/CT imaging and Sentinel lymphnode biopsy in early breast cancer in 150 patients -KMCH India experience.**

***K. Kamaleshwaran***, *E. Ramkumar;*
*Kovai Medical center and Hospital Limited (KMCH), Coimbatore, INDIA.*

***Aim/Introduction:*** Find out number of sentinel lymphnodes seen in SPECT CT imaging and sentinel probe ,identify false negative rate and recurrence rate in early Breast Cancer(EBC) Patients undergoing Sentinel Lymphnode Biopsy (SLB). ***Materials and Methods:*** Total 150 patients with EBC underwent SLB .Average age 50 -60 yrs .youngest age - 25 yrs,oldest age -83 yr old .Tc99m labelled colloid particles such as Nanocolloid or Human serum Albumin in 3 insulin syringes with each (0.5mci) was injected intra-dermally in peri-areolar region.SPECT CT of chest was done on day of surgery and identified number of nodes in three levels of axilla and informed to surgeons before surgery . Blue dye was also injected during surgery.surgeon removed hot nodes with help of hand-held gamma probe and sent to frozen section biopsy.If the nodes are negative ,no axillary lymphnode dissection (ALND) was done , if positive ,then Surgeon will Proceed with ALND. ***Results:*** Among 150 patients,overall 270 nodes were identified in all three levels of axilla in SPECT CT.In only 13 patients ,nodes were not identified in SPECT CT ,but were identified in gamma probe in surgery . Average 2-3 nodes were identified in level I and II axilla .Total 390 sentinel nodes in all 150 patients were removed . 114 patients were sentinel negative . 36 patients having sentinel positive had undergone ALND ,in those 36 ,only 6 patients showed extra nodes positive in dissection . Average nodes removed as sentinel was 1-3 and maximum 8 nodes were removed in one case.4 patients were false negative(4/150 -2.6%) .all underwent clinical breast examination every 3 months and mammogram at 1 year . There is no axillary recurrence and no arm lymphedema . 1 patient developed distant metastases after 1 year and another patient developed breast recurrence .73 patients were not completed one year followup. ***Conclusion:*** Among patients with EBC treated with breast conservation surgery, SLD provides axillary control which is equal to ALND and less false negative rate .SPECT CT helped in identifying exact location of nodes ,more number of nodes and helps surgeon in removing node confidently during surgery. ***References:*** Luan T, Li Y, Wu Q, Wang Y, Huo Z et al .Value of Quantitative SPECT/CT Lymphoscintigraphy in Improving Sentinel Lymph Node Biopsy in Breast Cancer Breast J. 2022; 28;2022:6483318.

### EP-0404

**Unusual lymphatic drainage pathways detected by intradermal lymphoscintigraphy for sentinel lymph node biopsy in breast cancer.**

***G. Tartaglione***[1], *M. Pagan*[1], *F. P. Ieria*[1], *E. Covello*[2], *L. M. Marino Cosentino*[3], *S. Di Filippo*[2], *S. Ghinassi*[3], *R. Marsico*[3], *L. Leone*[3], *M. R. Limiti*[4], *P. L. Bonatti*[2,3];
[1]*Cristo Re Hospital, Nuclear Medicine, Rome, ITALY,* [2]*Santo Spirito Hospital, Breast Unit ASL Roma 1, Rome, ITALY,* [3]*San Filippo Neri Hospital, Breast Unit ASL Roma 1, Rome, ITALY,* [4]*Santo Spirito Hospital, Pathology, Breast Unit ASL Roma 1, Rome, ITALY.*

***Aim/Introduction:*** Sentinel lymph node biopsy is the standard in staging lymphatic system for primary breast cancer. Usually, lymphoscintigraphy shows sentinel node in ipsilateral axilla. However, sometime the lymphatic drainage may occur to extraaxillary lymph nodes. This was a single centre retrospective study to evaluate the incidence and reasons of an unexpected lymphatic drainage using intradermal lymphoscintigraphy for sentinel node radio guided biopsy in breast cancer. ***Materials and Methods:*** From February 2018 to December 2022, we performed preoperative lymphoscintigraphy for sentinel node identification in 1,649 consecutive patients with breast cancer. We injected intradermally a dose of 50 MBq, 0.3 mL, 99mTc-nanocolloidal HSA in the four quadrants of the breast. Patients underwent radio guided sentinel node biopsy 3-24 hours after tracer injection. We used One Step Nucleic Acid Amplification (OSNA) method for the intraoperative analysis of sentinel lymph nodes. ***Results:*** Lymphoscintigraphy showed a sentinel node in ipsilateral axilla in 1,596 pts (96.8%), and no drainage in 19 pts (1.1%). We observed un unusual lymphatic drainage in 34 pts (2.1%), 33 f, 1 m, median age 72 y (range 51-95) with breast cancer (eighteen right, sixteen left). In thirty-three out of 34 pts the abnormal drainage was associated with recurrent breast cancer previously treated with axillary lymph nodes dissection, while 1 pt previously treated for right breast augmentation. Eighteen patients had an unusual drainage in the contralateral axilla (four of these had also a lymph drainage toward internal mammary chain). Sixteen patients had a lymph drainage toward internal mammary chain. Based on OSNA results, three patients were upstaged to pN1mi(sn) and one patient to pN2a from cN0. ***Conclusion:*** Intradermal lymphoscintigraphy may visualize aberrant lymphatic drainage pathways in recurrent breast cancer patient and ipsilateral axillary clearance, the lymph drainage pathway may across the midline of the thorax. This study shows the need of lymphoscintigraphy to find sentinel node particularly in the group of patients previously treated for breast cancer.

### EP-0405

**Sentinel lymph node biopsy and axillary marking after neoadjuvant treatment in node-positive breast cancer patients**

***P. Guardia Jimena***, *A. Santos Bueno, Á. Rebollo Aguirre, E. Sánchez de Mora, A. Jiménez Heffernan;*
*Hospital Universitario Juan Ramón Jiménez, Huelva, SPAIN.*

***Aim/Introduction:*** To provide our experience in sentinel lymph node biopsy (SLNB) and axillary marking in patients with breast cancer with axillary involvement at diagnosis who received neoadjuvant treatment. ***Materials and Methods:*** Retrospective observational study including 62 women, diagnosed with breast cancer with axillary involvement, confirmed with core needle biopsy, who received neoadjuvant treatment with complete radiological nodal response and subsequent surgical

intervention with SLNB between 2019 -2022. The decision to perform SLNB was made after evaluating each case individually in a multidisciplinary team. Lymphoscintigraphy with SPECT/CT was performed to determine the coincidence between the biopsied-marked node (MN), marked with clip markers (54) or magnetic seed (8), and the sentinel node. In the non-coincident ones, wire-localization marking was performed. ***Results:*** The mean age was 50.11 years (range 32 to 73). Molecular subtype: 15 Luminal-A, 14 Luminal-B, 13 Luminal-B like, 9 HER2-enriched and 11 Triple-negative. Histological type: 60 infiltrating ductal carcinoma and 2 lobular carcinoma. TNM: 8 IIA, 25 IIB, 25 IIIA, 2 IIIB, 2 IIIC. Clinical N stage: 52 N1, 8 N2, 2 N3. There was no migration of the radiotracer in 7 cases (11.3%), there were two cases in which the node was not found, and in only one case there was migration to the internal mammary arteries, in 27 the MN did not coincide with the SN (43%). 24 patients were negative in the final anatomopathological results, and 28 patients were positive (12 micrometastases and 16 macrometastases), a total of 34 lymphadenectomies were performed (14 positive); the mean number of GC identified was 1.62±0.83. Out of the 27 patients with mismatched MN and SN, in 10 patients the anatomopathologic result was different; in 7 the MN was positive and the SN negative, resulting in 4 micrometastases and 3 macrometastases, and in 3 the SN was positive and MN negative, resulting in 3 micrometastases. There was one false negative result (3.2%), in this case lymphadenectomy was performed due to the pathological aspect of the axillary nodes. ***Conclusion:*** The anatomopathologic result of MN and SN in conjunction allows us to determine with greater reliability the axillary status and avoid lymphadenectomy in patients with complete axillary response after neoadjuvant treatment.

## EP-0406

### Local anaesthetic improves patient experience of breast and melanoma lymphoscintigraphy

***K. Jewell****, G. Kong, B. Emmerson, T. Akhurst, K. Moodie;*
*Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** The patient experience of pain with preoperative lymphoscintigraphy is variable; techniques to minimise distress to patients during the procedure are non-standardised across Australian nuclear medicine departments. This study assesses the use of local anaesthetic to reduce pain and improve patient experience, whilst ensuring a non-inferior scintigraphic visualisation rate of target sentinel nodes. ***Materials and Methods:*** Consecutive patients undergoing preoperative lymphoscintigraphy with a single-injector at our centre from 18/08/22 to 07/02/23 were included. Patients received 1-4 injections of ~0.2ml technetium-99m antimony colloid (~10-15MBq) mixed with 0.05ml of 2% lignocaine in each syringe as intradermal injections, followed by 20-30 seconds of light massage at the injection site(s). SPECT/CT +/- dynamic imaging of the region was acquired. A series of peri-procedural audit questions evaluated patient experience:1. Time spent thinking about upcoming procedure (surrogate assessment for preprocedural anxiety).2. A pain score from 0 (none) to 10 (extreme) using the Wong-Baker FACES rating scale as reference.3. A qualitative rating of pain in relation to their diagnostic biopsy: hurt much less (1), a little less (2), same (3), a little more (4), much more (5).A sub-set of head/neck melanoma cases (n=7) did not receive local anaesthetic at the referring surgeon's request, and were used as comparator cases. ***Results:*** 99 patients were included (breast cancer n=50, melanoma n=41, penile cancer n=1), 67 female, median age 63; 92 patients received local anaesthetic. For patients with breast and melanoma, the average pain scores were 1.24 and 2.39 respectively. The solitary penile score was 2/10. The average pain score of melanoma comparator cases was 5.3 (range 0-8).Patients with breast cancer rated lymphoscintigraphy as hurting 'much less' than diagnostic biopsy (average of ratings = 1.36), while in melanoma the procedures rated as 'about the same' (2.98). The visualisation rate was 96.7% (89/92) with local anaesthetic and 85.7% (6/7) without. ***Conclusion:*** Local anaesthetic improves the patient experience of antimony colloid injections without compromising visualisation rates. Radiotracer selection and pH buffering as pain minimisation strategies are other areas of ongoing investigation.

## EP-0407

### Detection rates of sentinel lymph node biopsy (SLNB) in gynecological cancer. Our experience.

***C. Ruiz Corbalán****, A. De Agrela Serrao, A. Leiva Montejo, D. Cáceres Silva, M. Castellón Sanchez, L. Frutos Esteban, J. Navarro Fernadez, T. Rodriguez Locarno, A. Hernandez Martinez, L. Mohamed Salem, J. Contreras Gutierrez;*
*ARRIXACA, Murcia, SPAIN.*

***Aim/Introduction:*** The aim of this study is to show detection rates of SLNB in patients diagnosed with early stages of gynecological cancer who were referred to our department. ***Materials and Methods:*** This is a retrospective, observational and analytic study which included 83 patients diagnosed with endometrial (5), cervical (43) or vulvar (35) cancer who underwent SLNB between 2014 and 2022. The mean age was 60±16.6 years old. The technique performed in all patients lied in administering a perilesional dose of 6mCi of 99mTc-nanocolloid divided in 3 or 4 injections the previous day to surgery and performing a lymphoscintigraphy with early and late planar images with or without SPECT-CT for a more specific localization. Besides SLNB, in 75% of patients a unilateral or bilateral lymphadenectomy was performed. ***Results:*** The presence of lymphatic drainage was observed in 87% of patients. Of the remaining 13% whose drainage was not visualized, just in 4 of the cases the sentinel lymph node (SNL) was found during surgery. On the other hand, from those patients who showed drainage in the images, it was not possible to find the SNL with gamma probe in 3 of them. This means that among the 72 patients who showed lymphatic drainage, in 69 of them it was possible to find SLN during surgery, what gave our department a global detection rate of 95,8% for this technique (91,9% for cervical cancer, 100% for endometrial cancer and 97,1% for vulvar cancer), showing a positive significant correlation between visualization of lymphatic drainage in molecular imaging techniques and SNL detection in surgery (p-value under 0.001). ***Conclusion:*** SLNB is a reliable technique that guarantees a less invasive surgery and a correct lymph node staging in gynecological cancer, with a great correlation between lymphatic drainage visualized in molecular imaging techniques and SLN detection during surgery.

## EP-0408

### Radiation-free bimodal sentinel node procedure combining fluorescence and magnetic guidance and pre-operative resonance imaging in prostate cancer - A first in-human study

***B. Michalik****[1], S. Engels[1], M. C. Otterbach[2], M. N. van Oosterom[3], M. Maurer[2], F. Wawroschek[1], A. Winter[1];*
*[1]University Hospital for Urology, Klinikum Oldenburg, Carl von Ossietzky University Oldenburg, Oldenburg, GERMANY, [2]University Institute for Diagnostic and Interventional Radiology, Klinikum Oldenburg, Carl von Ossietzky University Oldenburg, Oldenburg, GERMANY, [3]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS.*

***Aim/Introduction:*** In prostate cancer (PCa), pelvic sentinel lymph node dissection (sLND) using a bimodal fluorescent-radioactive hybrid tracer significantly improves staging ability due to pre-operative lymphoscintigraphy and intra-operative lymph node (LN) visualisation through fluorescence imaging (FI). Based on our pre-clinical proof of concept [1], here, we introduce the clinical translation of a radiation-free bimodal sentinel node procedure combining pre-operative magnetic resonance imaging (MRI), intra-operative FI and magnetic guidance. ***Materials and Methods:*** In March 2023, six PCa patients at an individual risk for LN involvement of 8-58% (Winter nomogram [2]) received magnetometer- and FI-guided pelvic sLND during radical prostatectomy at our centre. The day before surgery, patients were intraprostatically injected with a mixture of indocyanine green (ICG) and superparamagnetic iron oxide nanoparticles (SPION; 0.5 mg ICG in 2 ml SPION) under transrectal ultrasound guidance. Approximately five hours after injection, pelvic sentinel LNs with SPION uptake were visualised by MRI to define a lymphatic road map for surgical planning. During surgery, all fluorescent LN samples visualised by FI and/or magnetically active LN samples detected by a handheld magnetometer were dissected. Each resected sample was checked for ex situ fluorescence and magnetic activity, respectively, and was analysed for LN as well as for metastatic yield by an experienced uropathologist. ***Results:*** Pre-operative MRI identified 80 (median 12, range 6-21) LNs with SPION uptake in the external and internal iliac and obturator fossa regions. From these regions, we dissected 83 (median 13, range 8-21) LNs, of which 45 (median 6, range 3-13) were magnetically active and 49 (median 7, range 5-13) were fluorescent, respectively. During surgery, fluorescence as well as magnetic signal could be detected in each patient. Ex situ, each magnetically active LN showed also fluorescence signal, which could not be detected during surgery in four samples due to anatomical location. None of the dissected LNs contained metastasis. ***Conclusion:*** These are the first promising in-human results combining MRI and intra-operative FI presenting a radiation-free alternative to the conventional fluorescent-radioactive hybrid tracer for pelvic sLND in PCa patients particularly during robotic surgery. ***References:*** [1] Azargoshasb et al. (2022) IJCARS 17:211-218, doi: 10.1007/s11548-021-02458-2; [2] Winter et al. (2017) J Cancer 8:2692-2698, doi: 10.7150/jca.20409

## EP-0409

### Validation of sentinel node biopsy in head and neck tumors at one single center. Our experience.

***D. Rivas-Navas****, J. Fernández-Fernández, E. Triviño-Ibáñez, C. Ramos-Font, R. Sánchez-Sánchez;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this work is to validate the sentinel lymph node biopsy (SLNB) in head and neck tumors at the Virgen de las Nieves University Hospital (Granada, Spain) and to statistically analyze the collected data. ***Materials and Methods:*** We performed an observational and prospective study that included patients with early-stage (T1 and T2) head and neck tumors who underwent SLNB between February 2021 and October 2022. Statistical, technical, clinical parameters, image and pathological anatomy results were collected. Following SLNB, bilateral cervical lymphadenectomy was performed in all patients to assess the effectiveness of the technique by comparing both techniques. ***Results:*** A total of 31 patients (mean age: 64.39 ± 13.02 years, 54.8% men) were included. The primary tumor was most commonly located on the lateral border of the tongue (61.3%) followed by the floor of the mouth (29%), while the most common affected side was the left (48.4%). 58.1% had well-differentiated squamous cell carcinoma, with cT2 being the most common stage (54.8%). In all cases, tracer migration to the SLN was observed in both early and late images and SPECT/CT (100% identification of the SLN), bilateral in 11/31 (35.5%) cases. The mean number of identified SLN was 3, and the most frequent location was cervical levels II and III (65.4%). 32.3% had a positive result in the anatomopathological study. In 9/10 cases, the SLN was the only node affected in the lymphadenectomy. The mean number of removed nodes in lymphadenectomy was 31.6. The false negative rate was 10%. The only factor associated with a higher probability of a positive result in the SLNB, in the binary logistic regression model, was the female sex (OR: 14.63, p=0.019). ***Conclusion:*** SLNB is a feasible technique in patients with head and neck cancer, being able to avoid unnecessary lymphadenectomies.

## EP-0410

### Nodal staging in patients with penile cancer. Correlation between [18F]FDG-PET/CT and sentinel node biopsy.

***A. Piñeiro Donis****, J. Fernández Fernández, E. Triviño Ibáñez, C. Ramos Font, R. Sánchez Sánchez;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this work is to evaluate and correlate the use of positron tomography with [$^{18}$F]FDG in the staging of patients with penile cancer, with the result of sentinel lymph node biopsy (SLNB). ***Materials and Methods:*** We performed an observational retrospective study. All patients underwent preoperative [$^{18}$F]FDG-PET/CT study and SLNB with [$^{99m}$Tc]-nanocolloid. The histologic result of sentinel lymph node (SLN) is correlated with the findings of imaging techniques. Statistical analysis was performed. ***Results:*** 10 males were included (mean age: 73±11.72 years). The most frequent location of the primary tumor was the glans (40%), followed by the foreskin (30%). Fifty percent presented well-differentiated squamous cell carcinoma. In 6/10 (60%) of the cases the radiopharmaceutical was injected pericicatricially, in 2/10 (20%) perilesionally and in 2/10 (20%) in the balanopreputial sulcus. In all cases tracer migration to the sentinel lymph nodes were observed in both early and late images, being 70% bilateral inguinal and unilateral in the remaining 30%. SPECT-CT was performed in 80% of the patients. The anatomical pathology (AP) of the SLN result was negative in 9/10 (90%) of the patients. The result of the [$^{18}$F]F-FDG PET/CT study was negative at the lymph node level in 90% of the cases, showing 100% concordance with the SLN AP results. Comparative analysis of quantification parameters (SUVmax, SUVpeak, SUVmed, MTV and TLG) between the moderate-undifferentiated and well-differentiated histological subgroups showed higher values for the moderate-undifferentiated group, although statistical significance was not reached. ***Conclusion:*** [$^{18}$F]FDG-PET/CT and SLNB are accurate techniques in the nodal staging of penile cancers, obtaining an excellent correlation of their results with respect to pathological anatomy.

## EP-0411

### Investigation into the frequency of systemic tracer uptake when performing sentinel lymph node examinations

***A. Carradus****[1,2], M. Bradnam[1,3], J. Foster[1,3], A. Bolster[1,2,3];*
*[1]Department of Clinical Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM, [2]Nuclear Medicine, North East Sector Glasgow, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM, [3]College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** In sentinel lymph-node (SLN) procedures, 99mTc-Nanocolloid is injected intradermally to find the first lymph-node in the drainage pathway. A gamma probe is used in theatre to locate the sentinel node for biopsy. While the procedure is thought to be the optimal method for detecting the SLN[1], the false-negative rate is relatively high, with one study reporting a false-negative rate of 5.7% over a 15-year period[2], although this was 29.4% in the first year. However, during routine imaging of breast and melanoma patients at Glasgow Royal Infirmary and Stobhill Ambulatory Care Centre, we have occasionally seen tracer uptake in the liver, suggesting that some 99mTc-Nanocoll has travelled systemically through the bloodstream, which would potentially reduce the amount of tracer travelling to the SLN. The aim of this study was to audit SLN imaging procedures performed at Glasgow Royal Infirmary and Stobhill Ambulatory Care Hospital over the previous six years, to determine the proportion of procedures which had resulted in $^{99m}$Tc-nanocolloid travelling systemically through the circulatory system. ***Materials and Methods:*** 1627 $^{99m}$Tc-nanocolloid SLN patients (2017-2022) were audited through visual inspection. Injection sites were masked automatically and images were automatically windowed and displayed using Python. If the liver was visible on the images, this was determined to be an administration which has moved into the circulatory system. Quantification was performed on a sample of 25 positive scans by comparing the uptake in the liver to the uptake in the injection site. ***Results:*** Systemic tracer uptake could be seen in 85 SLN patients (5.22%). When considering only breast cancer patients, some systemic tracer uptake could be seen in 15 of 1372 patients (1.09%), and for melanoma patients some systemic tracer uptake could be seen in 70 of 255 patients (27.5%). Median liver uptake was 1.7% when comparing to the injection site, and the maximum uptake seen was 16.2%. ***Conclusion:*** It is important to note that systemic uptake does not mean that the procedure has been unsuccessful, rather that the signal from the gamma probe may be reduced compared to other patients. These results may also have wider implications for the use of other tracers where the effects of systemic uptake may be unknown.

## EP-0412

### Single Institution Study of Sentinel Lymph Node Detection in Cervical Cancer: Validating an Alternative to Pelvic Lymphadenectomy

***D. Rombo***[1], *D. Fraga*[1], *M. Bernardino*[2], *I. Vitorino*[1], *E. Sousa*[1], *J. Aço*[1], *I. P. Carvalho*[1], *R. Sousa*[1], *A. F. Jorge*[2], *L. Salgado*[1]; [1]*Serviço de Medicina Nuclear, Instituto Português de Oncologia de Lisboa Francisco Gentil E.P.E., Lisboa, PORTUGAL,* [2]*Serviço de Ginecologia, Instituto Português de Oncologia de Lisboa Francisco Gentil E.P.E., Lisboa, PORTUGAL.*

***Aim/Introduction:*** Cervical cancer (CC) is the fifth most common cancer among women in Portugal with an estimated prevalence of 10.7 per 100,000 women. Lymph node status is a key prognostic factor in CC, with nodal metastasis indicating a poorer prognosis and the need for more aggressive treatment. Sentinel lymph node (SLN) detection has emerged as a promising alternative to traditional lymphadenectomy in CC, allowing for accurate staging with reduced morbidity. This study aims to validate SLN detection in women with early-stage CC, as an alternative to pelvic lymphadenectomy, in our institution. ***Materials and Methods:*** We retrospectively reviewed 46 women with early-stage CC (stages IA to IIA1, FIGO 2018) who underwent SLN detection followed by complete pelvic lymphadenectomy from 05/2021 to 04/2023. Lymphatic mapping was conducted preoperatively with [$^{99m}$Tc] Tc-nanocolloidal albumin (111 MBq) injections in four cardinal points of the cervix, followed by planar and SPECT/CT imaging, as well as intraoperatively with patent blue injections. SLNs were identified as blue and/or radioactive by visual inspection and using a gamma probe, respectively. Pathological evaluation of the SLNs was performed separately from the remaining pelvic lymph nodes. ***Results:*** At least one SLN was identified in 40 patients (87.0%) and bilateral SLNs were identified in 33 patients (71.7%). The median number of SLNs identified per patient was two (range, 1 to 5). The locations of SLNs included external iliac (41.4%), obturator (25.3%), common iliac (21.8%), internal iliac (10.3%) and parametrium (1.15%) regions. There was no difference in detection rates between patients with body mass index <30kg/m$^2$ versus ≥30kg/m$^2$, tumor size ≤2cm versus >2cm or between patients with/without conization. The detection rate was significantly lower in women aged >60 years (OR 9.43, 95% CI 1.70-53.3). Metastatic disease was detected in SLNs of eight patients (20.0%). Two patients had a false-negative result. In both cases, metastatic involvement was detected in the contralateral lymph nodes, where no SLN was identified. The technique yielded a sensitivity of 80.0% (95% CI 49.0%-96.5%) and a negative predictive value of 93.8% (95% CI 79.9%-98.9%). The follow-up median time was 7 months (range, 1 to 23) with only one patient experiencing a local relapse 5 months after surgery. ***Conclusion:*** Our study confirms that SLN procedure is a reliable alternative to pelvic lymphadenectomy, with comparable sensitivity and negative predictive value to those reported in the literature. This supports the adoption, in our institution, of isolated SLN mapping, without lymphadenectomy, in future procedures.

## EP-0413

### Prospective evaluation of SPECT/CT & intra-operative Gamma probe techniques for identification of sentinel lymph node (SLN) in early stage oral cancer

***M. L Narayan***[1], *P. Kaul*[2], *P. Singh*[3], *T. Singhal*[3], *M. Negi*[1], *P. K. Garg*[2]; [1]*All India Institute of Medical Sciences (A.I.I.M.S), Rishikesh,India, INDIA,* [2]*SGRR Institute of Medical Sciences and SMI Hospital, Dehradun, Uttarakhand, India, INDIA,* [3]*All India Institute of Medical Sciences (A.I.I.M.S), Bhubneshwar , Orissa, INDIA.*

***Aim/Introduction:*** The aim of this prospective study was to assess the feasibility of SLNB and compare SPECT-CT, with gamma probe techniques, for identifying SLN in early stage oral cavity cancer (T1/2) at a newly established tertiary care Institute of North India ***Materials and Methods:*** A total of 17 patients could be recruited for this study with a median age of 49 years(41-54 years),including14(82%) male & 3 were females. 15/17(88.2%) Tongue was the most common sub-site involved by the tumor 12(70.6%), followed by buccal mucosa and floor of mouth in four(23.5%) and one(5.9%) patients respectively. On clinical assessment, 47%(n=8) of tumors were staged as T1 while remaining 53%(n=9) were staged as T2.All patients underwent Lymphoscintigraphy (LSG), using either one or two day protocol with 250-500 microCi(in 0.4-0.5ml) of 99mTc-Sulphur colloid (filtered), that was injected superficially (either submucosally or intradermally) in the four cardinal points around the tumor. Planar, SPECT-CT images were acquired upto 90min post injection, followed by methylene blue injection (peritumour) &

intraoperative localization of SLN using Gamma probe. ***Results:*** The sentinel lymph node identification rate was 94.1% with SPECT-CT. Additional draining lymph nodes were identified in 14/17(82.35%) patients. Bilateral drainage was seen in two(11.7%) patients on SPECT-CT. Neck dissection was either a SND I-III (n=11, 64.7%) or SND I-IV (n=3. 17.6%) and MND I-V (n=3. 17.6%). Contralateral neck dissection- SND I-III was done in one(5.9%) patient with primary located in floor of mouth.SLN identification rates for SPECT-CT, gamma probe, blue dye and dual technique localization (gamma probe+blue dye) were 94.1%, 88.2%, 76.4% & 94.1% respectively. The sensitivity, specificity, PPV, NPV and diagnostic accuracy of various techniques namely, SPECT-CT, gamma probe and dual technique (gamma probe + blue dye), against the current standard i.e., END was 100 %All patients were alive and disease free during the last follow up visit, except one patient with oral tongue primary (pT2N1), who developed regional recurrence during 6th month of follow-up, denied any further treatment and died two months later. ***Conclusion:*** The SLNB is feasible technique for neck staging in early stage oral cancer and has a high sensitivity, specificity, positive and negative predictive value. A high concordance was noted between the findings of SPECT-CT and intraoperative gamma probe for identification of SLN. Thus, use of this technique should be encouraged to reduce morbidity associated with extensive surgery and achieve a comparable survival outcome, to elective neck dissection.

## EP-0414

### DROP-INradioguidanceduring robotic sentinel nodeprocedures in bladder cancer

***D. Rietbergen***[1], *M. N. van Oosterom*[1], *E. van Gennep*[1], *B. van Rhijn*[2], *H. G. van der Poel*[2], *F. W. B. van Leeuwen*[1];
[1]*Leids Universitair Medisch Centrum (LUMC), Leiden, NETHERLANDS,* [2]*NKI, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** In the management of bladder cancer, lymph node invasion has proven to be an independent predictor and prognostic factor for recurrence and cancer-specific survival. We recently demonstrated the feasibility of using the hybrid tracer ICG-99mTc-nanocolloid for sentinel node (SN) procedures in bladder cancer, all be it with a high degree of non-visualizations [1]. As bladder surgery is increasingly being conducted robotically, radioguidance modalities must adapt accordingly. Based on initial technological validations during prostate cancer SN procedures [2], we have now studied the use of the DROP-IN gamma probe technology during robot-assistedbladder SN surgery. ***Materials and Methods:*** This study group included a bladder cancer patient population of n= 11, treated at a single European center. All patients had histologically confirmed muscle-invasive bladder cancer (cN0M0), but no suspected nodal disease on diagnostic imaging (i.e., CT and 18F-FDG). Given the investigative nature of this setup, patients not only received a SN biopsy, but also benefitted from an extended pelvic lymph node dissection(ePLND). Following transurethral injection of the hybrid tracer ICG-99mTc-nano-colloid, SN mapping was performed using lymphoscintigraphy and SPECT/CT. Intraoperative localization was guided by both DROP-IN gamma probe and Firefly fluorescence imaging. ***Results:*** After hybrid tracer injection (mean injected activity of 213 MBq), 3 out of 11 patients had non-visualization on preoperative imaging. Excluding these 3, on average 1.4 SNs were mapped per patient. During surgery, the sterilizable DROP-IN could successfully be used repeatedly. After insertion in to the abdominal cavity by the bedside assistant (either through or next to a trocar), the surgeon could autonomously pick up and maneuver the probe with thesteerable Prograsp-forceps instrument. Intraoperative DROP-IN guidance proved effective, directing the surgeon to SNs located in the various anatomies found in this patient cohort (i.e., iliac communis, iliac externa and the obturator area).Once the SNs were localized in situ, fluorescence imaging provided confirmation and helped guide the resection in real-time. On average 1.6 SNs were dissected per patient, and on average a total of 18.6 lymph nodes were harvested per patient. Interestingly, in 1 patient with non-visualization at preoperative imaging, still 2 active SNs were found during surgery. Histopathology showed lymph node metastases in 2/11 patients. ***Conclusion:*** The DROP-IN gamma probe also proves valuable during robotic SN procedures of bladder cancer. Thereby helping to advance this technically challenging SN indication. ***References:*** 1. Rietbergen et al., Clin Nucl Med, 20222. Dell'Oglio et al., Eur Urol, 2021

## EP-0415

### Lymphoscintigraphy patterns in recurrent breast cancer. Can they predict the outcome?

***B. Pereira****, P. Soeiro, A. Fernandes, A. Oliveira;*
*Centro Hospitalar Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** Breast cancer is the most common malignancy in women and is associated with high morbidity and mortality. Identifying the individual lymph node drainage pattern with lymphoscintigraphy allows better staging of each tumour and helps to determine treatment and follow-up plans. This study aims to evaluate lymph node drainage patterns in women with recurrent breast cancer and to assess its association with subsequent lymph node spread of the disease. ***Materials and Methods:*** A retrospective, longitudinal, single-centre observational study was conducted, enlisting patients whose breast cancer recurrence had previously been treated surgically and who had undergone sentinel node lymphoscintigraphy in our department between November 2009 and December 2022. Statistical analyses were performed using SPSS Statistics 28® software. Statistical significance was set at $p \leq 0.05$. ***Results:*** From 677 patients, 108 met our inclusion criteria. All patients were female; 86.5% had invasive tumours, 13.5% had ductal carcinoma in situ. Most patients (62%) had at least one lymphatic drainage pathway identified: 75% had ipsilateral axillary lymph nodes (24% from multiple pathways), 25% had contralateral axillary lymph nodes, 24% had ipsilateral internal mammary lymph nodes and 3% had contralateral internal mammary lymph nodes; 25% had drainage to more than one lymphatic chain. From these patients, 24% had previous axillary lymph node dissection;during follow-up 7% were diagnosed with metastatic axillar lymph node disease. From the patients without identifiable lymphatic drainage (38%), 39% had previous axillary lymph node dissection; during follow-up, 15% were diagnosed with metastatic axillar lymph node disease. We found no statistically significant association was found between a specific drainage pattern and a higher risk of recurrence of lymph node disease during follow-up. ***Conclusion:*** In recurrent breast cancer previously operated on, lymph node drainage patterns are diverse and cannot predict the recurrence of lymph node disease. Nevertheless, secondary metastatic lymph node disease is more common in patients whose lymphoscintigraphy found no drainage. ***References:*** Donohoe KJ, et al. Summary: Appropriate Use Criteria for Lymphoscintigraphy in Sentinel Node Mapping and Lymphedema/Lipedema. J Nucl Med. 2023 Apr;64(4):525-528. doi: 10.2967/jnumed.123.265560.

## EP-0416

### Lymphoscintigraphy in Breast Cancer. Is there a difference in primary versus recurrent disease?

***B. Pereira***, *P. Soeiro, P. Dias, A. Oliveira, A. Fernandes; Centro Hospitalar Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** Breast cancer that spreads through the lymph nodes is relatively common. For accurate staging, it is therefore essential to assess the involvement of the lymph nodes. There are several techniques for this purpose, with lymphoscintigraphy being one of the most common for sentinel lymph node biopsy. Lymphoscintigraphy is an accessible and straightforward technique, which is why it is often used. Nevertheless, there are different scenarios that can alter the sensitivity and accuracy of this technique. Therefore, we aim to evaluate the differences in outcomes obtained with this technique in patients with primary breast cancer compared with patients with cancer recurrence and previous treatments. ***Materials and Methods:*** A retrospective, longitudinal, single-centre observational study was conducted involving patients ≥ 18 years who underwent sentinel node lymphoscintigraphy for breast cancer in our department from January 2014 to December 2021. Clinical and histological data were obtained from medical records. Statistical analysis was performed using SPSS Statistics 28® software. Statistical significance was set at p≤0.05. ***Results:*** 194/209 patients met the inclusion criteria (100% female, mean age: 54.75±13.11 years). The left breast was affected in 49% of patients, the right breast in 48% and 3% of patients had bilateral disease. Most tumours were invasive (82%), only 18% were ductal carcinoma in situ (DCIS). 45% of patients had recurrent previous treated breast cancer. Sensitivity, specificity, accuracy, PPV and NPV were 77.3%, 95.9%, 91.6%, 85.9% and 93.4% for all groups, respectively, 93.1%, 93.6%, 93.5%, 84.4% and 97.3% in the treatment-naïve group, and 46.7%, 98.6%, 89.7%, 87.5% and 89.9% in the group with recurrent previously treated disease. Axillary secondary lymph node disease occurred more frequently during follow-up in the groups with invasive breast cancer (9.4% vs. 5.5%), prior breast surgery (11.4% vs. 6.5%), prior lymph node dissection (15.6% vs. 7.4%) and chemotherapy prior to lymphoscintigraphy (13.2% vs. 7.0%). However, no statistically significant difference was found for any of the variables between the two groups. The prevalence of secondary axillary lymph node disease was similar during follow-up in patients with or without prior sentinel node biopsy, with or without prior radiotherapy to the breast, axilla or both, regardless of the number or location of sentinel lymph nodes identified by lymphoscintigraphy. ***Conclusion:*** Lymphoscintigraphy is a very accurate and specific technique with a very high negative predictive value for identifying sentinel lymph nodes, even in patients with pre-treated and recurrent breast cancer.

## EP-0417

### Concordance between portable SPECT and conventional scintigraphy for detection of sentinel node in breast cancer

***J. Orozco Cortés***[1], *Á. Esteban Hurtado*[2], *C. Siscar Gelo*[2], *M. Navas de la Cruz*[2], *L. Casas Calabuig*[2], *Á. Badenes Romero*[3], *T. Mut Dolera*[2], *D. Reyes Ojeda*[1], *D. Balaguer Muñoz*[2], *P. Abreu Sánchez*[2], *P. Carcamo Ibarra*[1], *C. Plancha Mansanet*[2], *E. Caballero Calabuig*[2]; [1]*Hospital Clínico Universitario de Valencia, Valencia, SPAIN,* [2]*Hospital Universitario Doctor Peset Valencia, Valencia, SPAIN,* [3]*Hospital Universitario Joan XXIII Tarragona, Tarragona, SPAIN.*

***Aim/Introduction:*** Introduction: Portable SPECT can be a useful imaging technique for preoperative planning of selective sentinel lymph node biopsy (SLNB) as it allows localization of the sentinel node (SN) by 3D and real-time tomographic imaging and determines its depth after a few minutes of scanning. ***Materials and Methods:*** 100 patients with a diagnosis of invasive breast cancer and no clinical evidence of lymph node involvement prospectively underwent selective sentinel node biopsy. The preoperative study included portable SPECT imaging at 15 minutes after injection and LG imaging at 25 and 60 minutes (early and late). The observed agreement was analyzed and a concordance study was performed between the number of SNs detected with portable SPECT and LG. ***Results:*** The observed agreement in the detection of CG between portable SPECT and early LG was 72%; between portable SPECT and late LG was 85%; and between early and late LG was 87%. In the concordance study, there was moderate concordance between portable SPECT and early LG (kappa coefficient: 0.42); moderate-high concordance between portable SPECT and late LG (kappa coefficient: 0.60); and moderate-high concordance between early and late LG (kappa coefficient: 0.70), with no significant differences between them (p-value=0.16). ***Conclusion:*** Portable SPECT presented a moderate-high concordance with conventional imaging studies and could be a valid alternative for the pre-surgical study of BSGC in breast cancer. ***References:*** Orozco Cortes, J. ## EP-0418

### Is SPECT/CT useful in selective sentinel lymph node biopsy in melanoma in all primary lesion location?

***P. Zaragoza Ballester***, *X. T. Guarnizo Poma, S. Angiolillo Grau, D. Vega Pérez, P. Sarandeses Fernández, Á. Galiana Morón, A. Saviatto Nardi, E. Martínez Albero, S. Ruiz Solís, M. Marín Ferrer, V. Godino Gulloteu, A. Gómez Grande, M. Tabuenca Mateo; Hospital Universitario 12 De Octubre, Madrid, SPAIN.*

***Aim/Introduction:*** SPECT/CT added to planar imaging can increase sensitivity of melanoma sentinel node (MSN) detection and improve anatomical localisation at the time of surgery. However, increased scanning time may have controversial implications on delays to surgery and scanner availability. In this study, we want to evaluate our experience in selective sentinel lymph node biopsy (SLNB) in melanoma and SPECT/CT contribution. ***Materials and Methods:*** We perform a retrospective study (January 2018 - December 2022) collecting all melanoma sentinel node studies performed at our institution. Cases were stratified by tumour site (head/neck, trunk, upper limbs and lower limbs). Clinical and histological data, number and localisation of nodes detected in planar images and additional nodes and localisation on SPECT/CT were recorded. We analyzed whether SPECT/CT modified the surgical approach (new MSN, location and/or depth) compared to planar images. ***Results:*** 93 patients were collected (15 without SPECT/CT due to technical failure).

54.8% male (n=51), mean age 61.79 years (range: 29-87 years). Initial lesion location: head/neck (n=13), trunk (n=47), upper limbs (UL) (n=15), lower limbs (LL) (n=17) and vulva (n=1). Lesions in head/neck, UL, LL and vulva, always drained to their ipsilateral and most proximal lymphatic region (laterocervical, axillary and inguinal, respectively). 57.5% (27/47) of truncal lesions showed a single lymphatic region. Cases with SPECT/CT: head/neck (n=11), trunk (n=41), UL (n=11), LL (n=13), vulva (n=1). SPECT/CT modified surgical approach in 3/11 patients (27.7%) of head/neck and 3/41 (7.3%) of trunk, locating nodes not observed in the planar images. Also, it modified the surgical approach in all cases of head/neck, 8/41 (19.5%) of trunk and in 2/13 (15.38%) of LL. We observed no differences between planar imaging and SPECT-CT in the UL and vulvar lesion groups. ***Conclusion:*** SPECT/CT improves accuracy in the localisation of sentinel nodes, specially in lesions of the head/neck, trunk and lower limbs. According to the experience in our center, where we have multidisciplinary teams experienced in axillary surgery, we have observed that we could save tomographic studies in melanomas of the upper limbs. However, further studies are needed to assess their optimal indication. ***References:*** 1. Bluemel, C., Herrmann, K., Giammarile, F., Nieweg, O. E., Dubreuil, J., Testori, A., Audisio, R. ## EP-0419

### Selective sentinel lymph node biopsy (SLNB) in early stages oral cavity cancer: a single center study

***A. De Agrela Serrao***, *C. Ruiz Corbalan, A. M. Leiva Montejo, J. L. Navarro Fernández, M. Castellón Sanchez, T. E. Rodríguez Locarno, L. Frutos Esteban, A. C. Hernández Martínez, L. Mohamed Salem, D. R. Cáceres Silva, J. F. Contreras Gutierrez; Hospital Clinico Universitario Virgen de Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** To determine the detection rate of SLNs in the operating room previously visualized on lymphoscintigraphy as well as to determine the impact on final TNM staging after performing selective sentinel node biopsy. ***Materials and Methods:*** Retrospective, descriptive single center study of 25 patients with squamous cell carcinoma of the oral cavity in stages T1-T2N0M0 from January 2019 to December 2022. All of them underwent lymphoscintigraphy after perilesional injection of 3 mCi of $^{99m}$Tc-albumin nanocolloid, performing a dynamic study, delayed images and SPECT/CT. The following day, intraoperative detection of the sentinel node was carried out using an intraoperative gamma probe, with subsequent clinical and/or imaging follow-up (CT or ultrasound). ***Results:*** 25 patients (18 men), with a mean age of 64.04±13.21 years, mean follow-up of 11.3±9.66 months. The lesions were located on the tongue in 80% of the cases, 12% on the oral mucosa, and 8% on the floor of the mouth. 72% of the patients presented unilateral drainage, 28% bilateral. The most frequent histology was squamous cell carcinoma with 88%, followed by verrucous carcinoma with 12%. The number of nodes visualized in the image ranges from 1 to 4 per patient (mean of 2.36±1.03), we detected intraoperative an average of 2.20±0.86 SLN, corresponding to 93.2% of the total visualized, detecting at least 1 SLN in 100% of patients. The reported pathology was non-malignant in 22 of the patients (88%) and nodal metastases or micrometastases were identified in 3 patients (12%) that the clinical and radiological assessment was unable to detect, which allowed early identification for more aggressive treatment. The estimated mean time to relapse/progression was identified is 7.5 months (CI: 95% 2.65-12.3 months). Twenty-one patients were followed up with 1 local recurrence and 3 lymph node recurrences (13.6%). The overall survival was 27.48 months (95% CI: 21.19-33.68 months), without finding significant differences between both sexes. ***Conclusion:*** SLNB is a safe, effective, and well tolerated method for staging cN0 oral cancer, modifying the final TNM staging of patients in 12% of the cases. SLNB shows a high intraoperative detection rate of 93.2%, Patients with negative SLNB have greater overall disease-free survival than those with initially positive biopsies.

## EP-0420

### Sentinel Lymph Node Mapping For Endometrial Cancer: Results of the First Tunisian, Arab and African study.

***L. Zaabar***[1,2], *H. Bouaziz*[3,2], *S. Sghaier*[4], *G. Sahraoui*[5,2], *M. Slimane*[4,2], *M. Hechiche*[4,2], *K. Mrad*[5,2], *K. Rahal*[4,2], *A. Mhiri*[1,2]; [1]*Salah Azaeiz Institute, Nuclear Medicine departement, Tunis, TUNISIA,* [2]*Faculté de Médecine de Tunis, Tunis, TUNISIA,* [3]*Salah Azaeiz Institute,Surgical Department of Oncology, Tunis, TUNISIA,* [4]*Salah Azaeiz Institute, Surgical Department of Oncology, Tunis, TUNISIA,* [5]*Salah Azaeiz Institute, Pathological Anatomy Department, Tunis, TUNISIA.*

***Aim/Introduction:*** Endometrial cancer represents the most common gynecological cancer mostly diagnosed at stage I (90%). Sentinel lymph node (SLN) arised as a valuable option to lymph node dissection.Our aim was to determine negative predictive value, positive predictive value, overall and bilateral detection rates of SLN in endometrial cancer stage I. ***Materials and Methods:*** This was a cross-sectional prospective study including 38 patients with endometrial cancer stage I treated at Salah Azaiz Institute over a period of 34 months from March 2018 to January 2021 with descriptive and analytical parts. ***Results:*** The median age was 59.79. The histologicc type was mostly represented by endometrioid adenocarcinoma in 89% of cases. A pelvic magnetic resonance imaging showed a stage IA in 58% of tumors and IB in 42% of cases. The detection techniques were combined (48%), colorimetric (34%) and radioisotope (18%). Lymphoscintigraphy was conducted in 66% of women demonstrating overall and bilateral detection rates of 92% et 24%, respectively and a detection failure in 8% of cases. The SLNs were mainly localized in the right internal iliac in 36% of cases. The overall and bilateral intra-operative detection rates were of 76% and 37%, respectively. Intra-operative detection failed in 24% of cases. The blue SLNs were mostly in the right internal iliac (46%). The «hot-spot» SLNs were also mainly localized in the right internal iliac (37%). A micrometastasis (1%) was noted in one case among a total of 87 SLNs. False negative rate and negative predictive value were of 0% and 100%. Positive predictive value was 0%. Specificity was of 98.85%. Factors that affected overall detection were initial histologic grade (p=0.01) and tumor size (p=0.04) on magnetic resonance imaging. Final histologic grade 1 (p=0.005), 2 (p=0.002) and myometrial invasion (p=0.04) were also significant factors. A final IA stage (p=0.03) as well as low risk (p=0.03) and high-intermediate risk (p=0.04) groups represented significant contributors. No significant factors affecting bilateral detection were set. ***Conclusion:*** False negative rate and negative predictive value were of 0% and 100% similarly to previous results through literature. We aim to continue this promising protocol toward including more patients that may helps us improve our overall and bilateral detection rates.

## EP-0421

**Performance of99mTc-albumin nanocolloid and indocyanine green as tracers in sentinel lymph node detection in cervical and endometrial cancer.**

***M. Grajeda Gallardo***, *A. Prieto Soriano, P. Meneses Soares, K. Velasquez Díaz, I. Garrido Solesio, L. Santamaria Chico, I. Obedkova, S. Guzmán Ortiz, M. Mitjavila Casanovas;*
*Hospital Universitario Puerta de Hierro, Madrid, SPAIN.*

***Aim/Introduction:*** To evaluate the detection rate (DR) of the sentinel lymph node (SLN) in cervical and endometrial cancer with lymphoscintigraphy (LS) and with indocyanine green (ICG), both combined and separately. ***Materials and Methods:*** Sixty patients (62.4± 13.4 years) were prospectively included in the period between 2020 and 2023, diagnosed with cervical cancer (16) and endometrial cancer (44). LS was performed the day before surgery and ICG, on the day of the surgery. The intraoperative detection and biopsy of SLNs was performed. We compared the findings of both techniques separately and jointly. The level of agreement between both techniques was determined by measuring Cohen's Kappa index. A statistical software was used to perform the data analysis. ***Results:*** In patients with endometrial cancer, the SLN DR with LS was 56.8% (25/44) and with ICG 84.0% (37/44). The DR with both techniques was 86.3% (38/44). In one patient, the SLN was detected exclusively with LS, while with ICG it was detected in 13. No migration was observed in 6 patients. Bilateral migration with LS was detected in 34.1% patients (15/44) and with ICG in 75% (33/44). With the combined technique, bilateral detection of 75% (33/44) was obtained. Lymph node metastasis rate was 9.1% (4/44). Comparing both techniques, statistically significant differences were observed in nodal mapping and concordance was obtained in 68.2% of the patients (30/40), with a Cohen´s Kappa index of 0.298 (fair agreement). In patients with cervical cancer, the DR was 81.3% (13/16) with LS and 75% (12/16) with ICG. The DR with both techniques was 93.7% (15/16). In one patient, no SLN was located with either technique. Bilateral SLN detection was achieved in 50% (8/16) with LS and 56.3% (9/16) with ICG. Bilateral detection with both techniques was achieved in 80% of the patients (12/16). Lymph node metastasis rate was 6.25% (1/16). Comparing both techniques, no statistically significant differences were observed in nodal mapping, and concordance was obtained in 68.8% of the patients (11/16), with a Cohen´s Kappa index of 0.0909 (insignificant agreement). ***Conclusion:*** In patients with endometrial cancer, ICG has a higher SLN detection rate compared to LS. In patients with cervical carcinoma, the detection rate was higher with LS. In both cases, the use of radiotracer and dye techniques is complementary and together they improve the overall detection rate in these patients.

**C-reactive protein and myocardial perfusion imaging**

***C. Sioka***, *A. Kekiopoulou, P. Kekiopoulos, A. Bechlioulis, A. Rammos, A. Papadopoulos, J. Al-Boucharali, S. Tsiouris, X. Xourgia, D. Dristiliaris, C. Katsouras;*
*University Hospital of Ioannina, Ioannina, GREECE.*

***Aim/Introduction:*** Inflammation induced by a cytokine cascade is an important mechanism leading to the formation of an atherosclerotic plaque. C-reactive protein (CRP) is the most widely used biomarker in daily clinical practice to detect inflammation and has also been associated with various structural heart diseases. The present study investigated the correlation of myocardial perfusion scintigraphy (SPECT) findings with the corresponding CRP values, in clinically stable patients. ***Materials and Methods:*** The study included consecutive patients (n=102, mean age 71 years, 68% males) who underwent myocardial perfusion imaging (MPI) SPECT due to clinical indication. Patients were required to have a recent CRP measurement available (within one month). None of the subjects had signs and symptoms of recent infection or acute coronary syndrome, and those with a history of autoimmune disease were clinically stable, to rule out other common causes of elevated CRP. ***Results:*** The increased value of CRP (>6mg/L) was related to a pathological cumulative stress score [summed stress score (SSS) >3] and an increased cumulative score during rest [summed stress score (SRS) (p=0.006 and p=0.001 respectively), however this correlation was applicable only to patients over 70 years old (p=0.027 and p=0.005 respectively. ***Conclusion:*** CRP is a useful biomarker for the evaluation of ischemia in MPI. Further studies are needed to show whether it could be used to the selection of patients referred for MPI, considering clinical indications and other risk factors.

## EP-0423

**Atrial fibrillation is an independent predictor of the extent and severity of myocardial ischemia in myocardial perfusion imaging**

***C. Sioka***, *A. Bechlioulis, P. Zotou, S. Alexiou, A. Kekiopoulou, E. Gkika, P. Kekiopoulos, D. Dristiliaris, A. Rammos, L. Lakkas, K. Naka, L. Michalis, C. Katsouras;*
*University Hospital of Ioannina, Ioannina, GREECE.*

***Aim/Introduction:*** Atrial fibrillation (AF) and coronary artery disease (CAD) are highly prevalent cardiovascular conditions. The importance of AF history in the detection of ischemia in patients undergoing myocardial perfusion imaging (MPI) is unknown. This study investigated the association of extent and severity of perfusion abnormalities in MPI with AF in patients with suspected stable CAD. ***Materials and Methods:*** A total of 251 consecutive patients (mean age 64 years) without a prior history of CAD who had a 99mTc MPI with single photon emission computed tomography (SPECT) due to suspected stable CAD were included in the study retrospectively. Semi-quantitative assessment of the extent and severity of perfusion abnormalities with summed stress score (SSS) and summed difference score (SDS) were evaluated. ***Results:*** Patients with a history of AF (n=85) were older (p<0.001) and had a higher prevalence of male gender, dyslipidemia and smoking (p<0.05 for all) compared to patients without AF history. History of AF was associated with increased SSS ≥4 (OR 5.12, p<0.001) and SDS ≥2 (OR 2.66, p<0.001). After adjustment for other risk factors, history of AF remained an independent predictor of increased SSS ≥4 (OR 4.54, p<0.001) and SDS ≥2 (OR 2.77, p<0.001). ***Conclusion:*** Medical history of AF was shown to be an independent predictor of the extent and severity of perfusion abnormalities in high risk patients with suspected stable CAD. Whether AF constitutes a risk factor or merely a risk marker of perfusion defects in SPECT imaging needs to be clarified in future studies.

## EP-0424

**How did the COVID-19 pandemic affect SPECT myocardial perfusion scans? A single center experience**

***A. Aghaee***, *s. ataei nakhaei, e. askari, h. mohammadzadeh, h. roustaee, f. karamian;*
*nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The aim of this study is to evaluate the effects of the COVID-19 pandemic on characteristics of myocardial perfusion scans (MPS) during the COVID-19 pandemic

period. ***Materials and Methods:*** We respectively reviewed SPECT-myocardial perfusion scans performed between June and September 2020 (n = 423) during the COVID-19 pandemic in our center and compared them with findings of studies acquired in the same months before the pandemic (2019; n = 619) . ***Results:*** The number of patients with non-anginal or typical chest pain significantly decreased during the COVID-19 pandemic, while atypical chest pain cases increased significantly. Cases with high pretest probability decreased significantly and patients with intermediate pretest probability increased non-significantly. No statistically significant difference was observed on the rate of myocardial ischemia for COVID-19 era versus non-COVID-19 era .However, the number of stress SPECT-MPS studies performed during the COVID-19 pandemic (n = 423) was significantly lower (p = 0.014) compared with the number of studies carried out in the dedicated months of the year 2020 (n= 619). ***Conclusion:*** Our survey demonstrated significantly reduction in the number of SPECT-MPS studies during the COVID-19 pandemic and patients in the two ends of anginal chest pain spectrum (i.e., non-anginal & typical chest pain) were referred less frequently for MPS. However, patients in the middle of the spectrum (i.e., the atypical chest pain) underwent MPS more often. No change in the rate of myocardial ischemia or cardiomyopathy was observed in the COVID-19 period.

## EP-0425

### Stress Myocardial Perfusion Imaging (MPI) for Predicting Major Cardiac Events in Diabetic Women and Men

***N. Fatima***[1,2], *S. Zaman*[3], *A. Zaman*[4], *J. Bano*[2], *M. u. Zaman*[5,2];
[1]*Dept of Radiology Aga Khan University, Karachi, PAKISTAN,* [2]*Dept of Nuclear Cardiology, Karachi Institute of Heart Diseases (KIHD), Karachi, PAKISTAN,* [3]*Dr Ruth Pfau (CHK), Karachi, PAKISTAN,* [4]*Dept of Medicine, Sunny Downstate Medical Centre, New York, NY, UNITED STATES OF AMERICA,* [5]*Dept of Radiology Aga Khan University, KARACHI, PAKISTAN.*

***Aim/Introduction:*** The major adverse cardiac events (MACEs) between men and women in diabetic patients stratified by CAD (previous MI and/or coronary revascularization, CR) were analyzed. ***Materials and Methods:*** A cohort of 1135 consecutive diabetic patients (age 61.5±9 years) underwent gated SPECT (single-photon emission computed tomography) myocardial perfusion imaging (MPI). In 281 individuals (40 females, 55 ± 12 Yr and 241 males, 56 ± 10 Yr), MPI was positive for CAD. Risk factor in female and male participants were hypertension (68 Vs 78%), dyslipidemia (43 Vs 27%) and positive family history (25 Vs 30%). Female diabetics were found to have significantly higher body mass index (37.43 ± 4.20 Vs 24.27 ± 2.98). ***Results:*** The cohort was followed for a mean period up of 12-60 month for MACEs (fatal and non-fatal MI). Female diabetics were found to have fixed defect in 12% and reversible defect in 88% on MPI. Male diabetics were found to have fixed defect in 45% and reversible defect in 55% on MPI. During follow-up period, fatal events in female were significantly higher (3 events; survival 92.5%) as compared to males (0 event; 100% survival) [Log Rank = 27.166, p <0.5]. During follow-up period, non-fatal events in female were significantly higher (05 events; survival 87.5%) as compared to males (02 event; 99.2% survival) [Log Rank = 16.419, p <0.5]. ***Conclusion:*** The prognosis of diabetic patients for MACEs is different in men and women stratified by CAD. The worst prognosis for MACEs occurs in women with known CAD.

## EP-0426

### Prognostic Value of Rest SPECT MPI Derived Left Ventricular Shape Indexes in Patients with Prediabetes

***Y. Hu***, *Y. Zhao, R. Wang, L. Yang, Y. Li, Y. Wang, X. Diao, S. Li;*
*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** Prevalence of prediabetes is rising worldwide and prediabetes is associated with increased cardiovascular risk. The prognostic value of left ventricular (LV) remodeling has been well validated in cardiovascular diseases including myocardial infarction (MI). LV shape index (SI) by single photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) has clinical implications in patients with diabetes. However, the prognostic value of LVSI in patients with prediabetes remains unknown. We aimed to elucidate the prognostic value of LVSI in individuals with prediabetes. ***Materials and Methods:*** We retrospectively recruited a total of 171 patients (mean age 61.64 ± 11.64 years, 67 women) with prediabetes(5.6 mmol/L ≤ fasting plasma glucose < 7 mmol/L and/ or 5.7 ≤ HbA1c < 6.5% ) and known or suspected CAD who underwent rest SPECT MPI. The major exclusion criteria were structural heart disease and a history of myocardial infarction. All the patients were followed up and categorized for the occurrence of major adverse cardiac events. The clinical characteristics and MPI findings processed by Quantitative perfusion SPECT (QPS) and Quantitative gated SPECT (QGS) software programs were collected. All variables were first assessed by univariate Cox proportional hazards regression analysis. Receiver operator characteristic (ROC) curve analyses were applied to determine the optimal cutoff value of variables showing univariate relationships with outcome. Multivariate Cox regression and Kaplan-Meier survival analysis were conducted for prognostic prediction and risk stratification. ***Results:*** During a median follow-up of 44.2 ( 3.0 -79.8 ) months, 86 (38.6%) MACE occurred. Patients who occurred MACE had higher SI (0.62 ± 0.09 vs. 0.58 ± 0.07, P = 0.001), end diastolic (ED) SI (0.65 ± 0.08 vs. 0.62 ± 0.07, P = 0.016) and end systolic(ES) SI (0.54 ± 0.10 vs. 0.50 ± 0.08; P = 0.001) compared to those without MACE. Multivariate Cox regression analysis showed an abnormal ESSI ( > 0.5) was the only independent predictor for MACE (HR: 2.580, 95% CI: 1.115-5.970, P < 0.05) after adjustment for clinical and imaging risk predictors as determined by preliminary univariate analysis. MACE-event-free survival in patients with abnormal ESSI was significantly lower than that in patients with normal ESSI ($\chi^2$ = 12.785, log-rank P < 0.001). ***Conclusion:*** LV remodeling conveys prognostic value in individuals with prediabetes. ESSI assessed by rest SPECT MPI is the novel independent predictor of MACE and might improve the risk stratification in prediabetes patients.

## EP-0427

### The Correlation Study between MPI and CAG in Risk Stratification of CAD Patients with Different Uric Acid Levels

***Y. Chen***[1], *X. Liu*[1], *X. Li*[1], *M. Cai*[2], *S. Li*[3];
[1]*Shanxi Medical University, Tai Yuan, CHINA,* [2]*Shanxi provincial People's Hospital & Fifth Clinical College of Shanxi Medical University Medicine, Tai Yuan, CHINA,* [3]*The first hospital of Shanxi Medical University, Tai Yuan, CHINA.*

***Aim/Introduction:*** To study the correlation between myocardial perfusion imaging (MPI) and coronary angiography (CAG) in risk stratification of coronary heart disease (CAD) patients with different uric acid levels. ***Materials and Methods:*** We collected patients with coronary artery disease who were admitted to

our hospital from July 2021 to December 2022, and all patients underwent both stress myocardial perfusion imaging and coronary angiography and completed uric acid, blood lipid and serum creatinine tests after admission. The patients were then divided into a group of CAD patients with hyperuricemia (HUA) and a group of CAD patients with normal uric acid levels based on their uric acid levels. Subsequently, the patients were stratified according to the summed stress score(SSS)of myocardial perfusion imaging and the coronary stenosis score shown by angiography. And the correlation between the two for the stratification results was evaluated. ***Results:*** A total of 106 CAD patients were collected, including 46 patients with hyperuricemia and 60 patients with normal uric acid. There was a moderate correlation between MPI and CAG in the risk stratification of all CAD patients (r=0.527, P<0.001), especially in the medium-risk group and high-risk group showed a strong correlation (r=0.772, P<0.001). The stratification results of patients in the low-risk group were significantly different, showing no correlation (r=0.131, P>0.05).In CAD patients with normal uric acid, MPI was weakly correlated with CAG in the stratification of risk (r=0.277, P<0.05), with moderate correlation in the medium-risk group and high-risk group (r=0.401, P<0.05), and no correlation in the low-risk group (r=0.279, P>0.05).In CAD patients with hyperuricemia, MPI and CAG showed a strong correlation in the stratification of risk (r=0.787, P<0.001), the medium-risk group and high-risk group showed a very strong correlation (r=0.846, P<0.001), and the low-risk group showed a very weak correlation (r=0.144, P<0.05). ***Conclusion:*** For this study, in the risk stratification results of MPI and CAG for CAD patients, the correlation between hyperuricemia patients was strong, which was extremely weak in the low-risk group, and extremely strong in the medium-risk group and high-risk group. The correlation was higher than that of the whole patient group and the normal uric acid level group. For coronary heart disease patients with hyperuricemia, MPI can provide accurate and effective risk assessment information. For such patients, MPI can be given priority as a reliable means to evaluate the severity and progression of the disease.

## EP-0428

### Prognostic Value of Gated SPECT MPI Varied by Atherosclerotic Cardivascular Disease Risk: A Retrospective Study

***Y. Li***, *Y. Zhao, R. Wang, Y. Hu, Y. Wang, X. Diao, J. Zhang, S. Li;*
*First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** Patients with atherosclerotic cardiovascular disease (ASCVD) have a significantly different risk of occurrence of adverse cardiovascular events and clinical management for patients with very-high and extreme risk for ASCVD is still suboptimal. While single photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) parameters are increasingly used to guide management in patients with stable chest pain, information on whether prognostic value of MPI parameters varies across ASCVD risk is missing. This study aimed to validate the incremental prognostic value of MPI parameters beyond ASCVD very-high and extreme risk. ***Materials and Methods:*** We retrospectively recruited a total of 1584 patients with known or suspected coronary artery disease (CAD) who underwent rest SPECT MPI and followed up for major adverse cardiac events (MACE). According to the risk stratification scheme of ASCVD in the Chinese Guidelines for Lipid Management 2023, all patients were assigned into primary and secondary prevention group (G1 and G2) based on whether they had ASCVD or not, and then further divided into very-high and extreme risk with the pooled cohorts equation in G2. The clinical characteristics and MPI parameters were collected. Multivariable Cox regression analyses were used to determine independent predictors. The Youden index was used to select optimal thresholds for predictors. Kaplan-Meier survival analyses were conducted for prognostic prediction and risk stratification. ***Results:*** Among 1,584 patients (61±13 years, 66.5% men, median follow-up of 3.05 years), 167 were in G1 (16.8% MACE), and 1,417 in G2 (42.8% MACE). In multivariate analysis after adjustments for clinical and imaging risk factors, left ventricular shape index obtained by QPS ($SI_{QPS}$) >0.625, end systolic volume (ESV) >67.5ml, and peak filling rate (PFR) <1.415ml/s all emerged as independent predictors of MACE (HR=1.522,1.482, and 0.694 respectively, all $P < 0.001$) in G2; however, they didn't show significant correlation with MACE in G1. MACE-event-free survival analyses displayed significant differences for $SI_{QPS}$, ESV and PFR ($\chi 2 = 20.087$, 29.438 and 21.110 respectively, all log-rank $P < 0.001$). ***Conclusion:*** Prognostic values of MPI parameters differ by ASCVD risk categories. $SI_{QPS}$, ESV and PFR predicted MACE solely in patients with very-high and extreme risk of ASCVD. These findings suggest that SPECT may improve lipid management and treatment goals through further risk stratification.

## EP-0429

### Improving multi-pinhole cadmium zinc telluride myocardial perfusion imaging specificity without changing sensibility by using adapted prefilter parameters

***F. Vauchot***, *A. Bourdon, M. Benkiran, J. Dubois;*
*CHU Gui de Chauliac, Montpellier, FRANCE.*

***Aim/Introduction:*** Meta-analysis show the diagnostic performance of cardiac dedicated multi-pinhole cadmium zinc telluride (CZT) myocardial perfusion imaging (MPI) with a sensibility and a specificity around 0.9 and 0.7 respectively. The aim of the present study is to explore a simple method in order to generate less artefact on MPI using single photon emission computed tomography (SPECT) and to enhance specificity without altering sensibility. ***Materials and Methods:*** From October 2018 to March 2019, 200 patients who underwent single photon-emission tomography (SPECT) with $^{99m}$Tc-tetrofosmin using cardiac dedicated multi-pinhole CZT were prospectively recruited: 100 patients with ischemia or necrosis diagnosis (first arm), and 100 patients with myocardial reversible SPECT artefact (second arm). Each SPECT was explored using two image processes based on a Butterworth prefilter: the original image processing (treatment A) with a cut-off frequency equals to 37% of the Nyquist frequency and order equals to 7, and a second image processing (treatment B) with a cut-off frequency equals to 25% of the Nyquist frequency and order equals to 5. For each patient, sum stress or rest score with and without septum (SSRS and SSRSws respectively) were calculated with the two treatments leading to four absolute parameters (SSRSa, SSRSwsa, SSRSb, SSRSwsb). Absolute variations between the two treatments ($\Delta$ = SSRSa-SSRSb and $\Delta$ws = SSRSwsa-SSRSwsb) and relative variations ($\Delta$r = $\Delta$/SSRSa and $\Delta$rws = $\Delta$ws/SSRSwsa) were calculated. We used a two-tailed Student's t-test to compare different scores for the two treatments. ***Results:*** No significant statistical difference between SSRSa and SSRSb was identified for the first arm (p=0.54) and the relative variation $\Delta$r was -0.5 ± 11.1 % (IC95 -2.6-1.8). We found a significant statistical difference between SSRSa and SSRSb for the second arm ($p < 0.0001$) with a relative variation

Δrws of 86.5 ± 14.6 % (IC95 83.6-89.4). ***Conclusion:*** In conclusion, using a prefilter cut-off frequency equals to 25% of the Nyquist frequency and a five order before iterative reconstruction generates less artefact and improves myocardial SPECT specificity without altering sensibility when compared to the conventional treatment using a prefilter cut-off frequency equals to 37% of the Nyquist frequency and a seven order. ***References:*** Cantoni and al. Diagnostic performance of myocardial perfusion imaging with conventional and CZT single-photon emission computed tomography in detecting coronary artery disease: A meta-analysis. J Nucl Cardiol. 2019.

## EP-0430

### Spherization Indexes by Rest SPECT Improves Risk Stratification in Patients with Non-obstructive Coronary Artery Disease

***Y. Zhao***, *Y. Hu, P. Wu, Y. Li, S. Li;*
*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** The prevalence of non-obstructive coronary artery disease (CAD) is substantial, and its risk-stratification remains suboptimal. The prognostic role of left ventricular remodeling (LVR) has been extensively investigated in various populations, including patients with myocardial infarction. However, there is a paucity of data to inform the prognostic value of spherization indexes assessed by single photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) for non-obstructive CAD. Therefore, we aimed to evaluate the prognostic value of spherization indexes in individuals with non-obstructive CAD. ***Materials and Methods:*** 285 patients (mean age 56.60 ± 12.28 years, 129 women) with non-obstructive CAD who underwent resting SPECT MPI were retrospectively enrolled. The clinical characteristics and MPI findings including spherization indexes (shape index (SI) and eccentricity index (EI)) by Quantitative perfusion SPECT (QPS) and Quantitative gated SPECT (QGS) were collected. Patients were followed up for major adverse cardiovascular events (MACE) and categorized into groups by MACE occurrence. Receiver operating characteristic (ROC) curve analyses were applied to find optimal cutoff value as appropriate. All variables were first assessed by univariate analyses. Multivariate Cox regression and Kaplan-Meier survival analyses were conducted for prognostic prediction. ***Results:*** There were 66 (23.2%) patients occurred MACE during a median follow-up of 47.2 ± 20.8 months, and they had higher $SI_{QPS}$ (0.60 ± 0.07 vs. 0.58 ± 0.06; P = 0.013), lower $EI_{QPS}$ (0.812 ± 0.044 vs. 0.829 ± 0.041; P = 0.004) and $EI_{QGS}$ (0.832 ± 0.044 vs. 0.845 ± 0.046; P = 0.034) compared to those without MACE. The other spherization indexes did not differ between groups (P > 0.05). MACE-event-free survival analysis displayed significant differences for $SI_{QPS,}$ $EI_{QPS}$ and $EI_{QGS}$ in all patients ($\chi^2$= 7.840, 6.598 and 6.706, respectively, all Log-rank P < 0.05). Multivariate analysis showed abnormal $SI_{QPS}$ (HR: 2.141, 95% CI: 1.158-3.958, P = 0.015) and $EI_{QPS}$ (HR: 1.818, 95% CI: 1.064-3.108, P = 0.029) were both independent predictors for MACE when they were put into the same model respectively, after adjustment with age, diabetes and number of vessels diseased. ***Conclusion:*** For patients with non-obstructive CAD, spherization indexes, especially $SI_{QPS}$ and $EI_{QPS}$, were associated with long-term MACE, may be a more preferable indicator for risk stratification and prognostic prediction.

## EP-0431

### Long-term Outcome of Patients after Radionuclide Myocardial Perfusion Imaging

***J. Huang***[1], *K. Chien*[2], *Y. Wu*[3];
[1]*Department of Nuclear Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, TAIWAN,* [2]*Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, TAIWAN,* [3]*Division of Cardiology, Cardiovascular Medical Center, Far Eastern Memorial Hospital, New Taipei City, TAIWAN.*

***Aim/Introduction:*** Prognostic implications of myocardial perfusion imaging (MPI) are imperative to provide proper management of coronary artery disease. Few studies have investigated the impact of computed tomography attenuation correction (CTAC) on the prognostic value of MPI and revealed discordant results. The purpose of this study was to investigate the long-term prognostic value of MPI using a large cohort from a stable agricultural county. ***Materials and Methods:*** From 2008 to 2010, 4,687 patients who underwent CTAC and non-AC (NC) Tl-201 MPI were followed for all-cause mortality, hospitalization of all cardiovascular (CV) reasons including coronary intervention and heart failure (HF) till December 2018. Medical records were reviewed, and missing information was completed by telephone contact. The prognostic significance was evaluated by Kaplan-Meier (KM) analysis, univariable and multivariable Cox proportional hazards models. We also analyzed the effect of coronary interventions on survival with KM analysis and Cox model. Sensitivity analysis was done after excluding patients who received intervention to check the robustness of our result. ***Results:*** A total of 2278 patients (893 women, 64.22 ± 10.37 years of age) were included. After a mean follow-up period of 8.17 ± 2.17 years, 516 (22.7%) patients died, 645 (28.3%) had been hospitalized for CV events, 382 (16.8%) received coronary interventions, and 140 (6.1%) had been admitted for HF. KM curves for all-cause mortality by previously reported cutoffs of summed stress score (SSS) and summed rest score (SRS) showed significant differences between 4 curves in SSS, SRS and both in CTAC and NC MPI (p<0.0001). In the multivariable model, SRS was the independent predictor for all-cause mortality and SSS was the independent predictor for all secondary endpoints. Coronary intervention after MPI was a significant protecting factor for all-cause mortality (HR: 0.42-0.44, p<0.001). Also, the independent predictive effect of scores derived from MPI remained after adding intervention as an explanatory variable. In sensitivity analysis, KM curves for all-cause mortality by conventional cutoffs of SSS and SRS also showed significant differences in patients without coronary intervention. In addition, the prognostic values of MPI persisted in the 2-, 5- and 10-year survival models. ***Conclusion:*** Both CTAC and NC MPI had good long-term prognostic values for risk stratification for future cardiac events. SRS showed superior risk stratification than SSS or SDS for all-cause mortality and SSS was a good predictor for all measured future CV events. Also, coronary intervention seems a strong protective predictor against all-cause mortality.

## EP-0432

### Comparison of Myocardial Perfusion Imaging Studies of Patients with Confirmed Coronary Artery Disease Performed on Traditional SPECT Gamma Camera and Dedicated Semiconductor Cardiac Gamma Camera

***P. Cichocki***[1], *M. Blaszczyk*[1], *A. Aulich*[1], *Z. Adamczewski*[1], *A. Plachcinska*[2];
[1]*Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND,* [2]*Department of Quality Control and Radiological Protection of the Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Discovery 530c (DIS) is a semiconductor gamma camera dedicated for myocardial perfusion imaging (MPI). It uses pinhole collimators and different image reconstruction

than traditional cameras. This is known to affect final reconstructed images (eg. by eliminating breast attenuation artifacts commonly seen on traditional cameras in women). The aim of this study was to assess differences in perfusion defects found in MPI preformed using DIS and traditional SPECT gamma camera in a group of patients with confirmed coronary artery disease (CAD). ***Materials and Methods:*** 90 patients (59 male, 31 female) with a history of CAD were included in the study. Each patient underwent MPI on two cameras - Discovery 530c and Optima 630NM/CT (OPT) in a 2-day stress-rest protocol in supine position using 10MBq/kgbw of $^{99m}$Tc-Sestamibi. Studies were assessed using a semiquantitative scale (0 - normal perfusion, 4 - complete absence of perfusion) in 17 segments, resulting in summed stress, rest and difference scores (SSS, SRS and SDS, respectively) for whole myocardium (TOT) and 3 main vascular territories. ***Results:*** SSS, SRS and SDS>3 for TOT or >1 for vascular territories were considered abnormal. In TOT, in following number of cases assessed scores were normal on DIS vs abnormal on OPT: SSS-17, SRS-10, SDS-21, and abnormal on DIS vs normal on OPT: SSS-7, SRS-11, SDS-10. According to McNemar's test, differences in assessment were statistically insignificant for SRS (p=1,0), while for SSS and SDS they were at the borderline of statistical significance (p=0,07). In vascular territories, statistically significant differences were observed in LAD for SSS (p=0,0001, men p=0,0009, women p=0,08) and SRS (p=0,046, men p=0,75, women p=0,039), and in RCA for SRS (p=0,02, men p=0,02, women p=0,39). In these territories, in the following number of cases assessed scores were normal on DIS vs abnormal on OPT: LAD SSS-24, LAD SRS-18, RCA SRS-4, and abnormal on DIS vs normal on OPT: LAD SSS-3, LAD SRS-7, RCA SRS-15. This did not cause statistically significant differences for SDS. ***Conclusion:*** Our study focused on patients with confirmed CAD, almost all of whom had perfusion defects in MPI. Comparison of MPI results showed a general trend of fewer abnormal results in rest and stress studies acquired using Discovery 530c camera, especially in LAD territory. Opposite trend was observed only for SRS in RCA territory. In our material, these differences were at the borderline of statistical significance in case of whole myocardium SSS and SDS.

## EP-0433

### Coronary Reserve assessement by means of routine standard perfusion SPECT (no first-pass): easy method to evaluate macro-angiopathy and microvascular lesions.

***L. Philippe***, *C. Prunier-Aesch, Y. El Yaagoubi;*
*Medecine Nucleaire Tourangelle, Chambray-les-Tours, FRANCE.*

***Aim/Introduction:*** Coronary Flow Reserve (CFR) assessment is important to understand myocardial perfusion. Analysis of epicardial coronary flow, is not sufficient when a micro-angiopathy dysfunction is present, as for diabetes. However, methods evaluating CFR are not everywhere available. We have developed an easy and reliable method to quantify CFR, by means of a Coronary Reserve Index (CRI), using routine SPECT 99mTc-tetrofosmin (1 day Stress-Rest protocol) with no need of 1$^{st}$ pass acquisition. ***Materials and Methods:*** Myocardial tetrofosmin uptake is related to myocardial perfusion. CFR is defined by the myocardial counts ratio Stress/Rest. To use this ratio, we apply 5 successive corrections allowing to get the CRI and functional images representing CFR. This processing was applied to a series of 60 patients addressed to our institution for routine myocardial Stress/Rest, with suspicion of CAD. CRI was computed for each patients. Previous study indicated a CRI value of 3 for the threshold normal/abnormal. Patients with previous revascularization were not included. Invasive Coronary Angiography (ICA), performed for the 60 patients, was considered as the gold standard for ischemia diagnosis. ***Results:*** Among the 60 patients, we studied the group of 16 patients with normal ICA (no significant Coronary Artery Disease (CAD)) for 16 patients: CRI < 3 for 9/16 patients (mean CRI = 1.62), and CRI >3 for 7/16 patients (mean CRI = 3.86). For the16 normal ICA, according to risk factors, mean CRI was 2.9 for patients with Hypertension, 2.39 for patients with Hypertension + Diabetes, and 3.16 with no risk factor. CRI performances (60 patients) for CAD diagnosis are good for Sensitivity (0.82) and Positive Predictive Value (0.80), but specificity was only 0.40 . This result is the consequence of considering ICA, as "gold standard", since ICA does not analyze micro-circulation. If micro-circulation is impaired, without epicardial coronary lesions, ICA considers CRI <3 as False Positive, decreasing Specificity and Positive Predictive Value. We propose the following global perfusion analysis: Normal perfusion SPECT and CRI> 3 : Normal / Normal perfusion SPECT and CRI< 3 : microvascular lesions / Abnormal perfusion SPECT and CRI> 3 : Epicardial lesions and preserved microcirculation / Abnormal perfusion SPECT and CRI< 3 : Epicardial coronary lesions + microvascular lesions. ***Conclusion:*** Gated SPECT with CRI calculation allows evaluation of macro- and microvascularization. The CRI calculation is fully automatic and can be performed with every routine standard perfusion SPECT, or retroactively.

## EP-0434

### Clinical value of Tc-99m MIBI Myocardial Gated SPECT in children and adolescents presenting with exercise related chest pain

***A. Alakbarli***[1], *M. A. Karacan*[1], *Y. Ozananar Sevinc*[2], *Y. Ceylan*[3], *A. M. Argon*[1], *Z. Ozcan*[1];
[1]*Ege University Hospital Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Bakircay University Cigli Regional Education Hospital, Izmir, TÜRKIYE,* [3]*Usak University Hospital, Usak, TÜRKIYE.*

***Aim/Introduction:*** Chest pain on exertion or syncope attack is a common complaint in paediatric cardiology practice. While it is rarely associated with cardiac ischemia, chest pain due to cardiac reasons may lead to life-threatening situations. Therefore, it is critical to detect or to exclude the presence of ischemia for differential diagnosis and patient management. Although MPS is frequently used in adult population, it is less commonly used in paediatric ages for cardiac evaluation. This study aims to retrospectively examine MPS findings to reveal the presence of ischemia in children presenting with effort-induced chest pain or syncope. The value of MPS in the evaluation of ischemia and also in the clinical management has been reviewed in relation to clinical and other imaging findings. ***Materials and Methods:*** The study group included 10 cases with chest pain or syncope attacks after exertion. They were clinically examined according to paediatric guidelines including detailed physical evaluation and ECG. Transthoracic echocardiography was performed to evaluate common heart diseases in children. Those cases with abnormal ECG findings, T wave inversion, ST changes, and suspected ischemia in the exercise test referred for cardiac perfusion and functional evaluation with Tc-99m MIBI. MPS was performed as SPECT Gated study with a single-day Tc-99m MIBI protocol. Cardiac CT imaging was also performed in all cases except for one. ***Results:*** Cardiological assessment and TTE excluded possible heart diseases that might induce chest pain such as congenital heart disease, cardiomyopathy, myocarditis, and Kawasaki disease. MPS gated SPECT study detected reversible perfusion defects related to anterior wall ischemia in 2 of 10 cases. Left ventricular wall motion and stress EF were normal. Cardiac CT showed myocardial bridging in these cases which was compatible with the ischemic area observed in MPS. No evidence of coronary abnormality was noted in other cases in agreement with MPS. Those cases with ischemia due to MB were followed up closely under medication

and competitive sports were restricted accordingly. ***Conclusion:*** MPS, is a safe and non-invasive method for the evaluation of ischemia in adolescents and children with exercise-related chest pain. Though MB is a rare entity in paediatric practice, the results of this very selected and limited case series indicate that it should be considered in cases with perfusion defects on stress MPS. Also, MPS provides complementary information for patient management and clinical follow-up such as limiting intensive sports activity in these cases due to possible myocardial risks.

## EP-0435

### Long-term prognostic value of semi-quantitative myocardial perfusion imaging in patients with homozygous familial hypercholesterolemia

***J. Jiao***, *W. Dong, T. Mou, H. Mi, Y. Zhang;*
*Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** To evaluate the long-term prognostic value of myocardial perfusion imaging (MPI) in patients with homozygous familial hypercholesterolemia (HoFH). ***Materials and Methods:*** Patients who were confirmed HoFH by clinical diagnosis and chromosome genetic tests and underwent stress/rest MPI were retrospectively enrolled from June 2010 to March 2022. Patients were followed up for 5.9 ± 3.0 years. Major adverse cardiac events (MACE) included all-cause death and unplanned revascularization. MPI images were analyzed using AHA 17-segment 5-point method. The severity of the MPI defect was semi-quantitated using the summed stress score (SSS) and summed difference score (SDS). SDS 0-1 was normal and ≥2 was abnormal. The functional parameters such as stress end-diastolic volume (SEDV), rest end-diastolic volume (REDV), stress end-systolic volume (SESV), rest end-systolic volume (RESV), stress ejection fraction (SEF) and rest ejection fraction (REF) were calculated automatically. Cox univariate and multivariate regression analysis were used to determine the risk factors and independent predictors for MACE. Patients were grouped according to independent predictors. Receiver operating characteristic curve (ROC) analysis was used to identify the best cutoff point. The Kaplan Meier survival curve together with log rank test was used to analyze the incidence of MACE in different groups. ***Results:*** 45 HoFH patients (22 males, mean age: 19.00 ± 10.20 years) were enrolled. During follow-up, 12 patients (12/45, 26.7%) occurred MACE. In the Univariate Cox regression analysis, SSS, SDS, SEDV, REDV, SESV, RESV, SEF and REF were risk factors for MACE (P<0.05). After corrected for age, low density lipoprotein cholesterol (LDLC), SEDV, SESV and SEF, multivariate Cox regression analysis showed SDS and SESV were independent predictors for MACE. The SDS abnormal group (n=21) exhibited higher risk of MACE. The adjusted hazard risk ratio was 8.623 (95% CI: 1.799~41.333, P=0.007). In Kaplan-Meier analysis, the incidence of MACE in SDS abnormal group was significantly higher than that in SDS normal group (47.6% vs. 8.3%, Log Rank $\chi^2$=12.402, P <0.05). In ROC analysis of SESV, the area under the curve was 0.7. The optimal cut-off value was 35.5 mL. In Kaplan-Meier analysis, the incidence of MACE in SESV≥35.5 mL group (n=22) was higher than that in SESV<35.5 mL group (n=23) (40.9% vs. 13.0%, P=0.035). ***Conclusion:*** MPI has important prognostic value in HoFH patients. SDS and SESV of MPI are independent predictors of MACE. Patients with normal SDS and SESV<35.5mL had an excellent prognosis. Abnormal SDS or SESV≥35.5mL increased the risk of MACE.

## EP-0436

### The relationships between apolipoproteins and myocardial blood flow in patients with non-obstructive coronary artery disease

***K. Zavadovsky***, *A. Maltseva, K. Kopeva, A. Mochula, O. Trubacheva, E. Grakova;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Dyslipidemia can be a reason for the development of microvascular dysfunction (MD) in patients with non-obstructive coronary artery disease (NOCAD). Over the past few years, scientific data have demonstrated that NOCAD patients could have high risk for adverse cardiovascular events. From this point of view, new opportunities for the risk stratification in NOCAD population may be considered as a field of future investigations. The aim of the study is to assess the relationships between apolipoproteins and myocardial blood flow and reserve impairment in NOCAD patients. ***Materials and Methods:*** Based on CCTA results, patients with NOCAD (stenosis <50%) were included in the study. All patients underwent dynamic SPECT CZT with the assessment of myocardial perfusion: SSS, SRS, SDS, stress and rest myocardial blood flow (MBF), myocardial flow reserve (MFR), flow difference (FD) [1]. The Net Retention with attenuation correction flow model was used for quantitative analysis. Furthermore, the blood lipid levels were assessed: low-density lipoprotein cholesterol (LDL-C), apolipoprotein B (ApoB), apolipoprotein A1 (ApoA1) and index of apolipoprotein B/apolipoprotein A1 (ApoB/ApoA1). Based on the LDL-C level was divided into two groups: 1. High level of LDL-C, 3.33(3.0;3.95), n=29; 2. Normal level of LDL-C, 1.7(1.4;2.3), n=15. ***Results:*** The study included 44 patients (27 men, age 56.4±9.5 years). Lipid profile was differed significantly in two groups: apoB 3.38(2.91;3.59) vs 2.61(2.27;2.81) mg/ml, apoA1 10.66(8.29;12.71) vs 11.41(8.41;12.04) mg/ml, ApoB/ApoA1 0.33(0.26;0.37) vs 0.24(0.19;0.3), respectively. SPECT CZT parameters did not differ significantly in two groups: SSS 0.0(0.0;2.0) vs 2.0(0.0;2.0), SDS 0.0(0.0;2.0) vs 2.0(0.0;2.0), stress MBF 1.33(1.05;1,63) vs 1.4(1.01;1.71) ml/min/g, MFR 2.51(1.57;3.31) vs 2.53(1.56;2.84), DFR 0.75(0.36;1.3) vs 0.73(0.38;1.27) ml/min/g, respectively. The Spearman correlation showed that ApoB/ApoA1 had negative relationships with MFR (ρ=-0.64, p=0.01) and FD (ρ=-0.63, p=0.03), meanwhile ApoA1 had positive relationships with MFR (ρ=0.63, p=0.02) and FD (ρ=0.58, p=0.01) in normal LDL-C patients. Based on ROC analysis, ApoB/ApoA1 value of 0.27 (AUC=0.85, 95%CI 0.564-0.98, p=0.008) had a sensitivity of 75% and specificity of 90%, in prediction of reduced MFR (<2.0). ApoA1 value of 7.77 (AUC=0.88, 95%CI 0.593-0.988, p=0.004) allowed to predict decreased MFR with sensitivity and specificity of 75% and 100%, respectively. ***Conclusion:*** Myocardial flow reserve and flow difference had strong relationships with ApoA1 and index of ApoB/ApoA1 in NOCAD patients. ***References:*** 1. Mochula AV, et al. The myocardial flow reserve in patients with heart failure with preserved ejection fraction. Heart Vessels. 2023;38(3):348-360. DOI:10.1007/s00380-022-02161-5.

## EP-0437

### Predictive Factors of Myocardial Perfusion SPECT Positivity using a CZT D SPECT Camera in 3594 Patients Referred For Myocardial Perfusion Imaging In one year.

***M. Esnault***[1], *D. Legallois*[2], *P. Richard*[3], *D. Agostini*[2], *M. Alain*[2];
[1]*Caen University, Caen, FRANCE,* [2]*Caen University Hospital, Caen, FRANCE,* [3]*Hospital privé Saint Martin, Caen, FRANCE.*

***Aim/Introduction:*** The number of normal myocardial perfusion SPECT significantly increased over the last decades. Given the widespread use of dedicated cardiac CZT cameras, the aim of this study was to analyze the predictive factors of positive myocardial

SPECT results using a CZT camera. ***Materials and Methods:*** This retrospective study evaluated the results of myocardial SPECT using a D-SPECT camera (Spectrum dynamics, Caesarea, Il) with the use of 99mTc-labeled radiopharmaceutical in our department during 2019 and a one-day stress/rest protocol. A myocardial perfusion SPECT was considered positive in case of (i) a reversible perfusion defect in at least 2 myocardial segments and/or (ii) a nonreversible perfusion defect with a matched segmental wall motion abnormality. ***Results:*** The cohort consisted of consecutive 3594 patients (3028 performed a pharmacological stress, 196 exercise, and 370 a combined pharmacological and exercise stress test). Patients were referred for diagnostic of suspected coronary artery disease (n=2167, 60%), risk assessment of documentedcoronary artery disease (n=1194, 33%), or preoperative assessment before noncardiac surgery (n=233, 7%). There were a total of 594 (16.5%) positive myocardial SPECT. In univariate analysis, among all clinical variables, predictors of positive CZT SPECT were male gender ($p < 0.0001$), age ($p < 0.0001$), BMI ($p < 0.0001$), obesity ($p < 0.005$), hypertension ($p = 0.0015$), diabetes ($p < 0.0001$), smoking ($p = 0.0005$), dilated cardiomyopathy ($p = 0.0004$), peripheral arterial disease ($p < 0.005$), and the clinical indication for SPECT examination ($p < 0.005$). Using multivariate analysis, the independent predictors of myocardial CZT SPECT positivity were male gender (OR: 1.45, $p <0.001$), age (OR: 0.98, $p < 0.0001$), diabetes (OR: 1.43, $p < 0.001$), smoking (OR: 1.33, $p < 0.01$), and preoperative assessment (OR: 1.7, $p < 0.01$). ***Conclusion:*** In this single-center study, the rate of negative perfusion SPECT was high (83.5%). Positive myocardial SPECT was higher in men, older patients, diabetics, smokers and patients referred for preoperative assessment before non-cardiac surgery.

## EP-0438

### Shorten Acquisition of Dynamic 11C-Acetate Cardiac PET/CT in Quantifying Pharmacokinetic Parameters

***T. Gong***[1], *F. Shang*[1], *X. Tang*[1], *L. Huo*[2], *S. Liu*[1];
[1]*School of Life Science, Beijing Institute of Technology, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Shorten acquisition of dynamic 18F-FDG PET/CT could achieve a strongly correlated pharmacokinetic parameters with long-time acquisition[1,2]. This study investigated ($K_1$ and $k_2$). ***Materials and Methods:*** This retrospective study analyzed 55 subjects with dynamic $^{11}$C-acetate cardiac PET/CT imaging. Each subject was injected with about 740MBq $^{11}$C-acetate before a 40 minutes' PET/CT scan. Arterial input function was image-derived from blood pool in left ventricle. All pharmacokinetic parameters were obtained by a one-tissue compartment model. Linear regression was performed on pharmacokinetic parameters between shortened and 40 minutes' acquisitions. Relative differences (RD) between shortened and 40 minutes' acquisitions were obtained, and evaluated at global left ventricle, the left anterior descending (LAD), right coronary artery (RCA), and left circumflex artery (LCX). ***Results:*** The regression coefficient of $K_1$ and $k_2$ between shortened and 40 minutes' acquisitions summarized in Table 1. $K_1$ and $k_2$ from acquisition time over 16 min (≥ 36 frames) exhibited a strong correlation with those obtained from 40 minutes' acquisition (all $R^2 > 0.9$). Meanwhile, the regression coefficients of $K_1$ ranged from 0.962 to 1.000, while $k_2$ ranged from 0.975 to 1.032. When the scan time was set to 16 min (36 frames), the regression coefficients of $K_1$ and $k_2$ were 0.962 and 0.975, respectively, and the relative difference (RD) of pharmacokinetic parameters were [$K_1$: (3.87 ± 2.40) %, $k_2$: (13.14 ± 8.17) %] at global, [$K_1$: (3.87 ± 2.40) %, $k_2$: (13.14 ± 8.17) %] at LAD, [$K_1$: (2.99 ± 2.20) %, $k_2$: (10.20 ± 7.29) %] at RCA, and [$K_1$: 3.71 ± 2.52, $k_2$:12.33 ± 8.32] at LCX. ***Conclusion:*** Shorten acquisition of cardiac $^{11}$C-acetate PET/CT with a time of 16 min (36 frames) were strongly correlated with 40 minutes' acquisition in quantifying the pharmacokinetic parameters. This study demonstrated the feasibility of dynamic cardiac $^{11}$C-acetate PET/CT with shorten acquisition. ***References:*** [1] Liu G, Yu H, Shi D, et al. Short-time total-body dynamic PET imaging performance in quantifying the kinetic metrics of 18F-FDG in healthy volunteers. Eur J Nucl Med Mol Imaging. 2022 Jul; 49(8):2493-2503. ## EP-0439

### Evaluation and related influencing factors of left ventricular systolic dyssynchrony after PCI in patients with acute myocardial infarction by gated myocardial perfusion imaging

***J. Wang***[1,2], *Y. Wang*[1,2];
[1]*The Third Affiliated Hospital of Soochow University, Changzhou, CHINA,* [2]*Institute of Clinical Translation of Nuclear Medicine and Molecular Imaging, Soochow University, Changzhou, CHINA.*

***Aim/Introduction:*** To clarify whether left ventricular systolic dyssynchrony(LVSD) occurs after percutaneous coronary intervention (PCI) in patients with acute myocardial infarction(AMI) and its associated factors by gated myocardial perfusion imaging (GMPI) . ***Materials and Methods:*** The patients with AMI who underwent PCI in the third affiliated Hospital of Soochow University from January 2020 to December 2021 were prospectively enrolled (registration number: ChiCTR2000038729). All patients underwent rest + stress GMPI, electrocardiogram and echocardiography within 1-2 months after PCI. After GMPI image reconstruction, Cedars-Sinai QGS quantitative analysis was used to obtain the LVSD parameters of resting GMPI: phase histogram bandwidth (BW) and phase standard deviation (SD). QPS quantitative analysis was used to obtain the quantitative index of resting GMPI to evaluate myocardial infarction size: myocardial perfusion defect size (Extent, %). The abnormal critical threshold (BW: 60.6°; SD: 22.62°) was taken as the mean ± 2 standard deviations of the BW and SD values of the normal population, and any index greater than the threshold was defined as LVSD. ***Results:*** A total of 175 AMI patients undergoing PCI were included. There was no significant difference in sex, age, body mass index, previous drinking and smoking history, hypertension, diabetes and hyperlipidemia between the Non-LVSD group (n = 91) and the LVSD group (n = 84) (all $P > 0.05$). Compared with the Non-LVSD group, the ECG QTc interval of the LVSD group was significantly prolonged (416.26ms ± 49.74ms vs. 402.37ms ± 25.76ms), and left ventricular ejection fraction (LVEF) is significantly lower (56.89% ± 6.84% vs. 59.71% ± 5.08%) (all $P < 0.05$). The proportion of multi-vessel coronary artery disease, the proportion of MPI residual myocardial ischemia and Extent in the LVSD group were significantly higher than those in the Non-LVSD group (76.19% vs. 59.34%; 52.38% vs. 28.57%; 11% vs. 3%). Multivariate Logistic regression analysis showed that coronary multi-vessel disease (OR=3.526, 95%CI:1.346~9.238, P=0.010) and Extent (OR=1.144, 95%CI:1.070~1.222, P=0.000) were independent risk factors for LVSD after PCI in patients with AMI. ***Conclusion:*** LVSD still exists in about half of the patients with AMI after PCI, and multi-vessel coronary artery disease and myocardial perfusion defect extent (Extent) are independent risk factors for LVSD after PCI in AMI patients, indicating that the higher the probability of LVSD after PCI is in AMI patients with multi-vessel coronary artery disease and / or higher myocardial perfusion defect extent.

## EP-0440

### The Characteristics of Perfusion in Cardiac SPECT/CT of Suspected INOCA and Obstructive Coronary Artery Disease Patients.

***M. Kalnina***[1,2], *B. Vitola*[3,4], *J. Kedrova*[1], *I. Mintale*[3,5], *A. Erglis*[3,2]; [1]*Department of Radiology, Pauls Stradins Clinical University Hospital, Riga, LATVIA,* [2]*Faculty of Medicine, University of Latvia, Riga, LATVIA,* [3]*Latvian Centre of Cardiology, Pauls Stradins Clinical University Hospital, Riga, LATVIA,* [4]*Faculty of Medicine, Riga Stradins University, Riga, LATVIA,* [5]*University of Latvia, Faculty of Medicine, Riga, LATVIA.*

***Aim/Introduction:*** Ischemia with non-obstructive coronary artery disease (INOCA) is highly prevalent in symptomatic patients with a female predominance diagnosed by cardiac SPECT/CT. As the cardiovascular risk is high and quality of life is reduced in INOCA patients, the confirmed functional disorders in patients with no obstruction in coronary arteries is of high importance. The aim of the study was to find out if there is a difference in myocardial perfusion in patients with suspected INOCA and in obstructive (CAD) patients. ***Materials and Methods:*** In total 726 [99mTc] SPECT/CT in women with suspected CAD was performed from 2018 to 2021 at university hospital. True myocardial perfusion defect was detected in 125 patients (17.2%). Further analysis included 121 patients in whom coronary angiography or CT coronorography was performed. The patients were divided into 2 groups: suspected INOCA and obstructive CAD. The perfusion defects were characterized by localization and segments involved. The prevalence of CVD risk factors was assessed. ***Results:*** In the suspected INOCA group were 93 patients, but in the obstructive CAD group - 28 patients. The mean age in both groups was 70,5 years. The prevalence of dyslipidemia and elevated body mass index (BMI) were similar. In the INOCA group previous myocardial infarction (7,5% vs 42,9%), percutaneous coronary intervention (15% vs 64.3%) and arterial hypertension (58.0% vs 96.0%) were less common. Although the established diagnosis of depression was more frequent into the INOCA group (4.3% vs 0%). The localization of perfusion defects differed between both groups. In patients with obstructive CAD, defects were more present in one coronary artery region. In patients with suspected INOCA the defect was more diffuse (36.0% vs 18.0%). In both groups perfusion defects were found mostly in apex and apical segments - 47% in obstructive CAD and 44% in suspected INOCA group. ***Conclusion:*** The localization and severity of myocardial perfusion defects in suspected INOCA patients did not differ from the obstructive CAD group. Suspected INOCA group had more diffuse pattern of the disease. Further analysis performing intracoronary physiological measurements is necessary to detect INOCA and its endotype to start early treatment of the disease.

## EP-0441

### Comparison of Ejection Fraction Measurements with Novel Multi-pinhole Collimator on Triple-NaI-Detector SPECT and Conventional Dual-NaI-Detector Parallel-hole Collimator Technique

***Á. Krizsán***[1], *K. Kukuts*[1], *L. Balazs*[2], *J. Kiss*[3], *M. Alamin*[1], *V. Linczerne Bencze*[1], *S. Barna*[1], *I. Garai*[1], *J. Mester*[4], *A. Forgacs*[1]; [1]*ScanoMed Nuclear Medicine Centers, Debrecen, HUNGARY,* [2]*Mediso Ltd., Budapest, HUNGARY,* [3]*Medical Imaging Clinic Radiology, Clinical Center, University of Debrecen, Debrecen, HUNGARY,* [4]Universitäsklinikum *Hamburg-Eppendorf, Hamburg, GERMANY.*

***Aim/Introduction:*** In this study we evaluated the Left Ventricle Ejection Fraction (LVEF) measurement accuracy of a novel Multi-pinhole collimator (MPH-Cardiac) on a Triple-NaI-Detector SPECT/CT system with patient scans and 3D printed phantom scans evaluated with three commercially available cardiac software suites. ***Materials and Methods:*** Resin based 3D printing of three LV models (20 ml, 60 ml and 140 ml with 10 mm fillable wall thickness) were performed on an Elegoo Mars II Pro 3D printer. The phantom set was filled from a stock solution of 41.71 ± 6.42 kBq/ml $^{99m}$Tc-sestamibi at the start of the SPECT acquisitions. Image acquisitions were performed with LEHR collimators on a dual head SPECT system AnyScan SC in 90° detector configuration, 64 views covering 180° scan arc, and the MPH-Cardiac collimators on a triple head SPECT system AnyScan TRIO in 75° detector configuration, 125° scan arc. Ecg-triggered gated SPECT acquisitions were performed with scan duration of 16 minutes. Image reconstructions were performed with Tera-Tomo 3D SPECT using 5 iterations 8 subsets 3.6 mm voxel size for the MPH-Cardiac, and OSEM with Butterworth pre-filter 6.5 mm voxel size in case of the LEHR. End Diastole Volume (EDV) was determined from the image sets using Cedars-Sinai QGS, Invia 4DM and Emory Toolbox. Gated SPECT scans of 42 patients with suspected coronary artery disease (CAD) were performed on both the LEHR and MPH-Cardiac systems. EDV, End Systole Volume (ESV) and LVEF were determined for both techniques with all three cardiac software suites. ***Results:*** In case of dual-head LEHR measurements EDV values were found to be 12 ml, 54 ml, 123 ml with QGS, 11 ml, 49 ml, 125 ml with Corridor 4DM and 11 ml, 47 ml, 117 ml with Emory Toolbox. In case of triple-head MPH-Cardiac measurements EDV values were found to be 19 ml, 59 ml, 139 ml with QGS, 19 ml, 58 ml, 138 ml with Invia 4DM and 18 ml, 55 ml, 133 ml with Emory Toolbox. Median values of the distribution of LVEF values for all patients were found to be lower due to significantly higher ESV values in case of MPH-Cardiac compared to the LEHR technique. ***Conclusion:*** The MPH-Cardiac collimator on a Triple-NaI-Detector SPECT/CT system provides more precise volume measurements and consequently more reliable LVEF results compared to dual head LEHR SPECT.

## EP-0442

### Prognostic Value of Myocardial Blood Flow and Coronary Flow Reserve on Dynamic Myocardial SPECT

***M. Havel****, M. Kaminek, A. Klegova, L. Quinn, L. Henzlova, P. Koranda, V. Icova, G. Havlova; Department of Nuclear Medicine, University Hospital and Faculty of Medicine and Dentistry Palacký University, Olomouc, CZECH REPUBLIC.*

***Aim/Introduction:*** Dynamic SPECT on a CZT dedicated camera enables absolute quantification of myocardial blood flow (MBF) and coronary flow reserve (CFR). The aim of the work is to assess the prognostic significance of CFR detected using dynamic SPECT on a CZT camera. ***Materials and Methods:*** Retrospective analysis of 44 patients examined with dynamic myocardial SPECT. The adverse cardiac events (CE) defined as sudden cardiac death, myocardial infarction, situations requiring coronary revascularization, and hospitalization for heart failure with reduced ejection fraction, were recorded. ***Results:*** Patients with CE (n = 11) had comparable rest MBF (1.24 vs 1.23 ml/min/g) but significantly lower stress MBF (1.82 vs 2.73 ml/min/g ; a cut-off value for the prediction of CE was 2.35 ml/min/g with a sensitivity of 91% and a specificity of 67%) and a lower CFR (1.48 vs 2.40). In the group with a reduced CFR <2 (n = 18), a significantly higher incidence of CE (50% vs. 7.7%, p = 0.003) and a significantly shorter time to CE were observed (p = 0.001). ***Conclusion:*** Lower stress MBF and lower CFR detected by dynamic myocardial SPECT on a CZT camera represents an increased risk for the occurrence of adverse cardiac events. ***References:*** Crea F, Camici PG, Bairey

### Role of Myocardial Scintigraphy in Evaluating Patients in the Emergency Department

***I. Gotuzzo***[1], *P. Ferro*[1], *R. Boni*[1], *P. Vai*[1], *R. H. J. A. Slart*[2], *P. A. Erba*[3]; *[1]Nuclear Medicine Department ASST Ospedale Papa Giovanni XXIII, Bergamo, ITALY, [2]Medical Imaging Center, University Medical Center Groningen, Groningen, NETHERLANDS, [3]Department of Medicine and Surgery, University of Milan Bicocca and Nuclear Medicine Department ASST Ospedale Papa Giovanni XXIII Bergamo, Bergamo, ITALY.*

***Aim/Introduction:*** Chest pain (CP) accounts for a significant number of attendances at emergency departments (ED). Although history, physical examination, electrocardiogram (ECG), echocardiography, and serial troponins can rule out acute coronary syndrome (ACS) and aid prompt discharge of patients, additional testing might still be warranted to decide whether to safely discharge or hospitalize patients. Myocardial scintigraphy (MS) has emerged as an important diagnostic modality for evaluation of CP in the ED for patients at low to intermediate risk for ACS. Several clinical trials have shown it has an excellent negative predictive value in the detection of coronary artery disease. We examined the utility of performing stress myocardial perfusion imaging for stratification of low-risk patients presenting with CP in the emergency department for safe and rapid discharge. ***Materials and Methods:*** From July 2017 to September 2022, 100 low-intermediate risk non-critical patients accessing the ED with CP underwent MS; 51 were included. Data on risk factors, ECG, echocardiography, troponin values and previous cardiac events were collected. One-day protocol stress (pharmacological or physical according to the patients 'needs) and rest MS with 99mTc-tetrofosmin or 99mTc-sestamibi on a CZT tomograph was performed according to EANM guidelines. MS results, the decision of ED physicians and follow-up data were also analyzed. ***Results:*** 5.8% of patients presented with troponin elevation, 1.9% with ECG suggestive for STEMI and 37.2% with either akinesia or hypokinesia at echocardiography. 63.8% of MS were negative, 21.3% showed ischemia, 4.2% myocardial necrosis and 10.7% both ischemia and necrosis. No complications after MS ensued. 23.9% were hospitalized and 10.9% underwent coronography, which only in 4 patients was not concordant with MS results. 73.9% of patients, including all those with negative MS, were discharged: 41.3% without undergoing further invasive examinations, and 19.6% with medical therapy adjustments. None of those patients experienced further cardiac events during the time of follow-up. Only 2.2% of MS were inconclusive. ***Conclusion:*** Our study demonstrated that positive MS and coronography showed concordance in identifying the myocardial territory affected by CAD in most cases. Conversely, negative MS guided ED clinicians towards discharging patients without further examinations. Follow-up proved the decision to be safe, as no other cardiac events were observed, and avoided unnecessary hospitalization. Studies on a larger cohort with longer follow-ups are needed to assess the actual clinical impact of MS performed in the emergency setting and the benefits of early discharge rather than unnecessary hospitalization in terms of cost-effectiveness.

## EP-0444

### myocardial injury Assessment of SPECT MPI in fulminant and suspected myocarditis compared with CMR

***J. Cui***, *S. Wang, Y. Ge;*
*Henan Provincial People's Hospital Heart Center, Zhengzhou, CHINA.*

***Aim/Introduction:*** The aim of our study was to access the SPECT Myocardial perfusion imaging (MPI) findings in fulminant myocarditis (FM) and clinically suspected myocarditis (CSM) of left ventricle compared with cardiac magnetic resonance (CMR). ***Materials and Methods:*** 30 FM patients and 21 CSM patients with both MPI and CMR examinations were included in this retrospective study, with interval time less than 5 days. CMR were performed in 1 week after weaned from Mechanical Circulatory Support (including IABP, Impella & ECMO) for FM patients. Additionally to the routine CMR protocol, T2-mapping and late gadolinium enhancement (LGE) data were acquired and segmented according to the 16-segments AHA-model, as well as the segmental pixel-standard deviation (SD) were analyzed, MPI applies a 17-segment model and the total summed rest score (SRS) of the left ventricle. Compared the abnormal findings of MPI toT2-mapping and LGE. ***Results:*** There were 5 diffuse lesions, 18 multiple focal lesions, 6 single focal lesions and 1 normal in FM. There were 2 diffuse lesions, 9 multiple focal lesions, 7 single focal lesions and 3 normal in CSM. The total SRS has high co-relation with total T2-mapping and LGE, with an AUC of 0.82 and 0.79 in ROC-analysis. The location of lesions from visual and 16-segments has high co-relation too. There has significant difference between FM and GSM on SRS, T2-mapping value and LGE±5SD. ***Conclusion:*** MPI was in good agreement with CMR in evaluating the location and degree of myocarditis, and its radioactivity distribution was high correlated with edema on T2 mapping and injury on LGE.

## EP-0445

### Psychology of attendants/caregivers during the myocardial perfusion imaging of patients

***C. Sioka***, *A. Bechlioulis, P. Giantsouli, Z. Panagiotou, S. Alexiou, P. Kekiopoulos, A. Kekiopoulou, A. Papadopoulos, L. Astrakas, P. Zotou, J. Zika, A. Arseniou, K. Pappas, C. Katsouras, P. Petrikis; University Hospital of Ioannina, Ioannina, GREECE.*

***Aim/Introduction:*** Examinations performed in a Nuclear Medicine Department may provoke or exacerbate the appearance of anxiety of the patient and his or her companion for the course and the outcome of the disease. Usually, family is the one who takes the burden of care, and the caregiver develops negative emotions, depression, stress, chronic fatigue, health problems and doubt about the care. The aim of this study was the assessment of anxiety and depression of companions (relatives/caregivers) of patients, who came to the Nuclear Medicine department for a myocardial perfusion scintigram (MPI). ***Materials and Methods:*** The existence of anxiety and depression was assessed in 98 companions of patients who underwent MPI in the context of suspected coronary artery disease. Demographic data questionnaires, the Hamilton Anxiety Rating Scale (HAM-A) and the Zung Self-Rating Depression Scale (SDS) were used to collect

the data. ***Results:*** Of the 98 attendants who completed the questionnaires, 27 were men (28%, mean age 54 years) and 72 were women (72%, mean age 51 years). Seventy-two attendants (74%) reported a feeling of anxiety, while based on the questionnaires 78 attendants indicated mild anxiety (HAM-A <17) and 20 people more than mild anxiety (HAM-A ≥18). Based on the SDS scale, 4 people were diagnosed with depression, while 10 people were already on treatment with antidepressants. The results of the two scales HAM-A and SDS presented a positive correlation (r 0.615, p<0.001). Women presented higher values in the HAM-A scale (r 0.352, p<0.001) and SDS (r 0.414, p<0.001). Companions who reported anxiety also had higher values on the HAM-A scale (r 0.222, p=0.028). ***Conclusion:*** About 3 in 10 caregivers experience stress during a Nuclear Medicine examination of a patient. Anxiety is mainly experienced by female attendants regardless of the patient's history. These feelings are probably related to the examination and its findings as well as the course of the patients' disease.

## EP-0446

### The effect of Attenuation correction on myocardial blood flow and reserve measured by dynamic SPECT

***A. Mochula****, A. Maltseva, A. Cygikalo, O. Mochula, K. Zavadovsky;*
*Cardiology Research Institute, Tomsk NRMC,*
*Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Myocardial blood flow (MBF) and reserve (MFR) are the most informative indices for myocardial perfusion evaluation, at this moment. Currently, the dynamic SPECT by on CZT-detectors gamma-camera allows obtaining the MBF and MFR values. Nevertheless, the influence of attenuation correction [1] on a value quantitative dynamic SPECT data has been studied not enough.Aim of the study to assess, the Influence of attenuation correction on a value quantitative dynamic SPECT data ***Materials and Methods:*** In the study was enrolled 245 stable patients with various cardiac pathologies. The comprehensive clinical and instrumental examination for all patients was performed. Additionally, dynamic SPECT on the two days rest-stress protocol was provided. Dynamic SPECT protocol with evaluating MBF and MFR described in previously study. ATF in 160 mcg/kg/min as a stress-agent was used [2]. Net retention and one-compartment tissue with and without attenuation (NRAC, NRNC, 1CAC, 1CNC) were used for post-processing. Stress and rest MBF, difference flow and MFR were assessed. ***Results:*** Pairwise comparison (Durbin-Conover test) showed significant difference between four models in all indices, except stress and rest MBF for NRAC vs NRNC pair - 1.17 (0.73; 1.59) vs 1.33 (0.75; 1.82) for stress MBF and (0.55 (0.41; 0.81) vs 0.56 (0.37; 0.83) for rest MBF, respectively . Moreover, the use of attenuation correction increased of values MFR: for one-compartment 1.74 (1.21; 2.61) vs 1.82 (1.40; 2.51) and for net retention 1.93 (1.31; 2.61) vs 2.13 (1.56; 2.76) - for AC and NC measurement, respectively. Bland-Altman analysis showed that models were not agreement for stress and rest MBF, except NRAC and NRNC pair for rest MBF. However, MFR values showed were agreement (-0.09 (-0.19/0.02), p=0.11) for AC models - 1.74 (1.21; 2.61) vs 1.93 (1.31; 2.61); that does not apply to NC models (-0.24 (-0.34/-0.2), p<0.0001), 1.82 (1.40; 2.51) vs 2.13 (1.56; 2.76) - for 1-compartment and Net Retention models respectively. ***Conclusion:*** The use of attenuation correction for evaluating quantitative perfusion indices by dynamic SPECT increases of agreement for the most used models. ***References:*** 1. ## EP-0447

### Transient ischemic dilatation and heart rate at stress and rest: Searching for a threshold of significance in patients with normal perfusion.

***A. Alomar****, A. Camarero, I. Blanco, N. Rudic, I. Saura, J. Cruz, A. Barrera, M. Ribelles, E. Goñi;*
*Hospital Universitario de Navarra (HUN), Pamplona, SPAIN.*

***Aim/Introduction:*** The existence of Transient Ischemic Dilatation (TID) during the stress is a scintigraphic sign that has been associated with worse prognosis in patients with positive findings for myocardial ischemia. However, it has also been detected in patients without scintigraphic evidence of myocardial ischemia, and the possible cause is considered to be heart rate variability. The aim of this study is to assess the influence of heart rate (HR) variability on TID in patients who have undergone myocardial perfusion imaging at stress and rest, with an additional objective of searching for a possible threshold from which HR variability will result in the appearance of transient dilatation in non-ischemic patients. ***Materials and Methods:*** A total of 296 consecutive patients who underwent two-day protocol gated myocardial perfusion imaging with 99mTc-Sestamibi (Siemens Symbia Intevo T6/IQ-SPECT) were analyzed. Heart rate was recorded during the acquisition of both studies, and the difference in heartbeats was calculated as a percentage, along with the TID in studies without attenuation correction. ***Results:*** Patients (mean age of 63.8 between 37 and 87 y.o being men 62.3%) were classified into three groups according to the test results: negative for ischemia (n=181; ΔHR=12.0%±1.0; TID=1.00 [1.19-0.81]), positive (n=103; ΔHR=13.5%±1.5; TID=1.03[1.25-0.82]), and non-conclusive (n=12; ΔHR=12.0%±2.2; TID=0.99±0.05). A strong correlation (r=-0.615, p=0.00) was observed between the percentage difference in HR and TID. This correlation was maintained in non-ischemic patients (r=-0.667, p=0.000), but was lower in patients with ischemia (r=-0.547, p=0.000), and not significantly correlated in the non-conclusive group (p=0.084). In non-ischemic patients, the threshold from which HR variability was significantly associated with alteration of TID was 15.97%. ***Conclusion:*** Heart rate variability between stress and rest may result in an alteration of TID due to the strong correlation between these variables, which is stronger in the group with normal perfusion than in the ischemic group. In patients with ischemia, who have lower HR variability, the alteration of TID could be due to the influence of ischemia itself, which needs to be evaluated in future studies. No correlation was found in non-conclusive group possibly due to a low number of patients.

## EP-0448

### The prognostic value of complex CMR and dynamic SPECT assessment in patient with acute myocardial infarction

***A. Mochula****, O. Mochula, E. Nalesnik, A. Maltseva, A. Sulejmanova, V. Ryabov, K. Zavadovsky;*
*Cardiology Research Institute, Tomsk NRMC,*
*Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Acute myocardial infraction (AMI) is one of the major cause of mortality and morbidity in the developed world. If a diagnostic algorithms of detection and treatment of this acute condition is clear and developed enough, predictors of adverse course of the disease have not been sufficiently identified. Aim of this study to reveal of a complex diagnostic accuracy of dynamic SPECT and cardiac MRI in predicting of adverse course of the disease. ***Materials and Methods:*** Ninety patient with first identified AMI average age 62.5±10.5 years (61% male ) were included. Complete clinical and instrumental examination according to ESC guide-lines was provided. Additionally, CMR with gadolinium enhancement due to 2-7 days and dynamic rest-stress SPECT within 7-10 day after admission were provided. Rates of incident MACE following 12 months after acute coronary event was assessed. ***Results:*** MACE were identified in 11 patients: nonfatal stroke in 5 patients, 5 cases of cardiovascular death and nonfatal MI in one patient. MACE group of patients characterized significant increase of myocardial mass, end systolic and diastolic volumes of LV; end systolic volume of RV compare to group without MACE: 285 (198;450.6)g vs 182 (157.9;225.5)g, 98 (65; 317) ml vs 41.3 (32.7;55.5) ml; 160 (152;385.6)ml vs 120 (102;137.4)ml, 54 (47;85)ml vs 41 (32;56)ml, respectively. Ejection fraction of LV and RV as well as myocardial salvage index were lower in patients with MACE: 39.2 (16;55)ml vs 63.5 (54.9;70)ml and 35 (28;43) ml vs 51 (46;56)ml; 11.62 (0.51;13.5) vs 30.95 (10.5;44.4) - against non-MACE patients, respectively. Other CMR indices were not significant difference. Compare of dynamic SPECT indices showed that MACE group of patient against non-MACE characterized increase of summed stress score and summed rest score 6.5 (6;30) vs 5 (3;12) and 6 (4.5;26) vs 3 (0;7), respectively. Moreover, stress and rest myocardial blood flow decreased in MACE patients: 0.86 (0.44;1.12)ml/min/g vs 1.09 (0.81;1.67) ml/min/g and 0.48 (0.28;0.48) ml/min/g vs 0.67 (0.40;1.04) ml/min/g. However myocardial flow reserve did not differ between enrolled groups of patients. Multivariate logistic regression analysis revealed that ESV LV (1,04 [1,02-1,06]), EF RV (0,84 [0,76-0,98]) and rest MBF (0,85 [0,77-0,94]) were independed predictors of MACE in patients with AMI (sensitivity 0.85, specificity 0.67, accuracy 0.79 and AUC 0.91). ***Conclusion:*** The complex evaluation of cardiac MRI and dynamic SPECT performed in subacute period of AMI is an informative approach and can be used in the prognosis of MACE. These results require further investigation.

## EP-0449

### Attenuation correction in SPECT-Myocardial perfusion imaging:It can be corrected, but is it really useful?

***S. Abhilash****, S. Jeevan, P. Pradeep, S. Sarath, L. N. Manishi;*
*All India Institute of Medical Sciences, Rishikesh, INDIA.*

***Aim/Introduction:*** SPECT myocardial perfusion imaging (MPI) is a non-invasive diagnostic method for assessing myocardial perfusion in patients with coronary artery disease (CAD). Soft tissue attenuation can affect its accuracy, but attenuation correction (AC) compensates for this by correcting for photon absorption. With the advent of hybrid SPECT/CT cameras, CT-based AC is now widely used. This study evaluated the benefits of AC in three major vascular territories and compared it to coronary angiography (CAG) and echocardiography (ECHO). ***Materials and Methods:*** We retrospectively analysed 42 patients who were referred by the cardiologist for assessment of myocardial perfusion (SPECT-MPI). CAG done within 5 months of MPI along with recent ECHO findings were taken as the reference standard. A coronary artery stenosis >75% and wall motion abnormality on ECHO were considered the reference standards. For all patients, cardiac SPECT with low-dose CT was acquired 1 hour after i.v. injection of 10-15 mCi of 99mTc Sestamibi at rest. Images were reconstructed and CT-based attenuation correction was applied. Images were processed using Emory Cardiac Toolbox software V:3.2 (ECT box; Emory University, Atlanta, GA) on a Xeleris 4.0 Nuclear Medicine workstation. Both AC and NAC images were compared. ***Results:*** 42 patients (39 males and 3 females) with a mean age of 57 years were studied. Using a standard 17-segment polar map, a total of 126 major coronary artery territories (42 LAD, 42 RCA, and 42 LCX) were analysed.On visual and semiquantitative analysis, 23/126 (RCA = 9, LCX = 1) vascular territories showed normalisation of perfusion defects after AC. 1/126 new perfusion defects were observed after AC in apparently normal territories (LAD = 1). On comparing MPI findings with reference standards, LAD territory defects that were observed (34/126) on MPI remained unchanged after AC and correlated well with reference standards. 13/21 RCA and 11/17 LCX territory defects had significant stenosis and RWMA, which were persistent even after AC, were considered true positives. However, 8/21 RCA and 2/17 LCX defects normalised after AC, thus being considered false negatives. ***Conclusion:*** In our study, though fallacious inferior wall defects involving RCA in non-AC MPI images resolved with AC, few apparent perfusion defects were underestimated with AC. It is important to understand that CT-based AC can overcorrect perfusion defects and introduce new artefacts. It should be used with caution; both non-corrected and corrected image datasets should be reviewed before integrating them into the final report.

### Automated absolute quantitation of cardiac sympathetic activity using convolutional neural network and 123I-MIBG SPECT/CT

***S. Saito***[1]*, K. Nakajima*[2]*, L. Edenbrandt*[3,4]*, M. Larsson*[5]*, O. Enqvist*[5]*, J. Ulén*[5]*, S. Kinuya*[1]*;*
*[1]Department of Nuclear Medicine, Kanazawa University, Kanazawa, JAPAN, [2]Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa, JAPAN, [3]Sahlgrenska University Hospital, Gothenburg, SWEDEN, [4]University of Gothenburg, Gothenburg, SWEDEN, [5]Eigenvision, Malmö, SWEDEN.*

***Aim/Introduction:*** We have already created algorithm for segmentation of cardiac region in $^{123}$I-MIBG SPECT images without X-ray CT using convolutional neural networks (CNN). We have also attempted to use $^{123}$I-MIBG SPECT/CT images and successfully conducted automatic heart segmentation based on CNN. Since CNN-based automatic absolute quantitation in $^{123}$I-MIBG SPECT/CT has not been evaluated, the purpose of this study was to quantify CNN-based absolute heart counts and standardized uptake value (SUV) using $^{123}$I-MIBG SPECT combined with low-dose CT for attenuation correction purposes and compare these values with conventional planar image-based quantitation. ***Materials and Methods:*** A total of 70 patients (46% men, mean

age 66.7 years) with cardiac and neurological diseases, including Parkinson's disease, Lewy body disease, and chronic heart failure, were assessed by $^{123}$I-MIBG early and delayed planar and SPECT/CT images. The heart was automatically segmented on SPECT/CT images by using a CNN with 3D U-Net architecture, in which analysis and synthesis paths have multiple resolution stages. The CNN was trained to segment the heart on 50 manually annotated images (40 for training and 10 for validation) using cross entropy loss and the Adam optimizer with the CT image as input. The CNN-based heart segmentation in 20 cases of early and delayed $^{123}$I-MIBG SPECT/CT images was tested. The standardized uptake value (SUV) was then determined by dividing the $^{123}$I-MIBG activity in the heart (Bq/cm$^3$) by the injected dose (Bq)/body weight (g). Further, we calculated CNN-based SPECT/CT washout rates (WR) based on early and delayed SUV values. Ultimately, we examined correlations between CNN-based SPECT/CT SUV and planar HMR, as well as CNN-based SPECT/CT WR and planar WR. We also classified WR into normal and abnormal categories based on linear regression lines derived from the relationship between CNN-based SPECT/CT WR and planar WR, and then analyzed their agreement. ***Results:*** CNN-based early and delayed SUV, which were calculated using $^{123}$I-MIBG SPECT/CT, correlated significantly with the planar HMR ($R^2 = 0.51$ and 0.69, $p < 0.0001$, respectively). There were also statistically significant correlations between CNN-based SPECT/CT WR and planar WR ($R^2 = 0.87$, $p<0.0001$). The contingency table results for high and low WR (cutoffs: 33% and 34% for SPECT/CT and planar studies, respectively) demonstrated 90.0% agreement between CNN-based and planar methodologies. ***Conclusion:*** The CNN-based method can effectively quantify cardiac counts and calculate SUV using $^{123}$I-MIBG SPECT/CT images. Automatic three-dimensional absolute quantification of sympathetic innervation was significantly correlated with conventional planar image quantification.

## EP-0451

### Long-term cardiac risk in recovered Covid-19 patients evaluated by 123I-mIBG

***A. Liebich***[1], *G. Sheikh*[2], *B. Nittbaur*[1], *R. A. Bundschuh*[1], *M. Kircher*[1], *A. Dierks*[1], *P. Raake*[3], *M. Rieger*[3], *T. Higuchi*[4], *C. Lapa*[1], *C. H. Pfob*[1]; [1]*Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY,* [2]*Department of Nuclear Medicine, LMU Munich, Munich, GERMANY,* [3]*Cardiology, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Wuerzburg, Wuerzburg, GERMANY.*

***Aim/Introduction:*** COVID-19 patients without underlying heart disease can develop heart failure, myocarditis or cardiac arrhythmias. Significant cardiac involvement seems to occur independent from the severity of the initial disease pattern and may persist during the long-term recovery period. To evaluate the presence of cardiac sympathetic nervous dysfunction in such patients, non-invasive imaging using the radiotracer $^{123}$I-metaiodobenzylguanidine (mIBG), a norepinephrine analogue, was performed in COVID-19 patients without pre-existing cardiac conditions. ***Materials and Methods:*** 33 recovered COVID-19 patients (14 men and 19 women; aged 21 - 66 years) without any known severe cardiac, renal, neurological or metabolic diseases underwent $^{123}$I-mIBG -SPECT/CT and echocardiography as well as serum measurement of cardiac enzymes, renal retention parameters and electrolytes 0 to 3 months after recovery. In 82% of these patients (27/33), follow-up was performed 6 to 8 months after diagnosis, nine patients (27%) underwent additional imaging after 12 to 15 months. SPECT/CT scans were acquired 15 minutes and 4 hours post-injection of 370 MBq $^{123}$I-mIBG. For quantification of results, a circular region of interest (ROI) was placed over the heart and mediastinum to calculate late (4-hour) heart-to-mediastinum ratios (HMR), a method commonly employed in clinical settings. ***Results:*** Increased cardiac sympathetic activity as indicated by decreased late HMR (mean HMR 1.8±0.22), was observed in 67.7% of the patients (23/33, 95% CI 0.54 - 0.854). At 6-8 months follow-up, cardiac sympathetic innervation abnormalities were still present in 70.4% of the patients (19/27, 95% CI 0.532 - 0.876), with a mean late HMR of 1.74±0.27. Additionally, 9 of the patients showing an initial abnormal sympathetic innervation underwent follow up 12 - 15 months post-diagnosis. All were found to have persistently abnormal HMRs. Left ventricular ejection fraction (LVEF) and cardiac enzyme levels remained normal in all cases during both the initial diagnosis and follow-up periods, with no significant correlation identified between LVEF, nt-pro-BNP or troponin levels and HMR. ***Conclusion:*** Persistent increased cardiac sympathetic activity is observed in COVID-19 patients without any prior cardiac disease. Further follow-up is necessary to investigate potential long-term consequences, such as COVID-induced heart failure.

## EP-0452

### The characteristic myocardial accumulation pattern in oncologic FDGPET/CT under long-term fasting is likely indicative of ischemic lesions

***Y. Yashima***[1], *K. Takanami*[2], *K. Kiso*[2], *A. Masuda*[2], *M. Saito*[2], *Y. Toyama*[2], *Y. Maekawa*[2], *K. Takase*[2], *Y. Taniyama*[1], *T. Kamei*[1]; [1]*Department of Surgery,Tohoku University Hospital, 1-1, Seiryo-cho, Aoba-Ku,Sendai, Miyagi, JAPAN,* [2]*Department of Diagnostic Radiology,Tohoku University Hospital, 1-1, Seiryo-cho, Aoba-Ku,Sendai, Miyagi, JAPAN.*

***Aim/Introduction:*** The purpose of this study was to retrospectively examine the association between myocardial accumulation patterns and ischemic heart disease in the oncologic FDGPET under prolonged fasting. ***Materials and Methods:*** Forty-six patients who underwent FDGPET performed for tumor diagnostic purposes and stress myocardial perfusion imaging performed for ischemic lesion scrutiny within 3 months between March 2019 and July 2022 were selected through chart review. Then, 36 cases with blood glucose <150 mg/dl before FDGPET and a fasting duration of at least 12 hours were included in the study. FDG accumulation patterns in the left ventricular myocardium on tumor FDG PET were classified as "none" "basal ring" "diffuse high" "focal high" and "focal defect on diffuse high" with the latter two patterns defined as positive, suggesting ischemia. Fasting duration and blood glucose level at the time of examination were also investigated. Stress MPI was scored using a 17-segment model, and Summed Stress Score (SSS) of 4 to 8 was defined as low risk and 9 or more points as moderate or high risk. ***Results:*** The mean duration of fasting during FDG PET was 17.3±1.6 hours (range,14-21). There was no difference in fasting duration between the diabetic and insulin-using groups. 14 of the 36 patients had "focal high" or "focal defect on diffuse high," and 12 (85.7%) of the 14 patients also had abnormal findings on stress MPI. Six patients had an SSS score of 9 or higher, indicating moderate risk or higher for cardiac events, and five patients had a "focal high" myocardial accumulation pattern on FDG PET, while the rest had "none".The sensitivity, specificity, and accuracy of ischemia findings on FDG PET were 66.7 %, 88.9 %, and 77.8 %, respectively, when patients with abnormal findings of 9 or more SSS points on stress MPI were defined as sick. There was no difference in HbA1c and blood

glucose at the examination between the positive and negative groups of stress MPI and myocardial FDG accumulation patterns. ***Conclusion:*** The characteristic myocardial accumulation pattern on oncologic FDG PET under sufficiently prolonged fasting duration and at appropriate blood glucose levels is likely to suggest ischemic heart disease.

### Combined Assessment of PET and CMR for Decision Making in patients with Coronary Artery Disease

***X. Han***, *L. Wang, S. Song, W. Fang;*
*Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

***Aim/Introduction:*** The aim of this study is to explored whether combined application of myocardial viability and scar could provide potential incremental value. ***Materials and Methods:*** All patients with CAD and LVEF<50% underwent myocardial viability assessment with 18F-FDG PET metabolic imaging, as well as CMR examinations. The total extent of mismatch on FDG PET and the transmural extent on LGE CMR were calculated for each patient. Primary endpoint of the study was all-cause mortality and secondary endpoint was a composite clinical outcome. Event rates over time in groups across mismatch and LGE categories were estimated. The HRs with 95% CIs were compared using univariate and multivariable Cox proportional hazards regression models. ***Results:*** The patients were divided into four groups: group-A: mismatch>10% and LGE≤26% (n=168, 33.14%); group-B: mismatch≤10% and LGE≤26% (n=108, 21.30%); group-C: mismatch>10% and LGE>26% (n=133, 26.23%); and group-D: mismatch≤10% and LGE>26% (n=98, 19.33%).Patients who underwent CABG had lower overall rates of death than those who received medical therapy in group-A, group-B and group-C. When individually adjustment for significant baseline prognostic variables in multivariate model, the risk for primary endpoint remained higher among patients without CABG in group-A (HR=10.595, 95%CI 3.407-32.952, P<0.001). Patients who received medical therapy were also associated with an increased rates of secondary endpoint compared with those who underwent CAB in group-A and group-B. The composite endpoint rates in patients received medical therapy were remain significantly higher compared with those underwent CABG in group-A and group-B (group-A: HR=4.938, 95%CI 2.284-10.679, P<0.001; group-B: HR=3.059, 95%CI 1.294-7.229, P=0.011). ***Conclusion:*** CABG plus medical therapy is associated with significantly lower events rates compared with medical therapy alone in patients with large mismatch and small LGE. The combined assessment of mismatch and LGE has independent and incremental value in predicting whether patients likely to benefit from CABG.

## EP-0454

### Comparing the heart-to-mediastinum ratio of 123I-mIBG myocardial scintigraphy between a 2D image and a pseudo planar image converted from a 3D image acquired with a conventional and a ring CZT gamma camera

***J. Hagerman***[1], *D. Minarik*[2], *R. Smith*[3,4], *E. Stormrud*[3,4], *S. Hall*[3,4], *A. Nahimi*[3,4], *O. Hansson*[3,4], *F. Hedeer*[1,5];
[1]*Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund/Malmö, SWEDEN,* [2]*Radiation Physics, Skåne University Hospital, Lund/Malmö, SWEDEN,* [3]*Clinical Memory Research Unit, Lund University, Malmö, SWEDEN,* [4]*Memory Clinic, Skåne University Hospital, Malmö, SWEDEN,* [5]*Clinical Physiology and Nuclear Medicine, Department of Clinical Sciences, Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** Myocardial sympathetic innervation can be visualized and quantified (heart-to-mediastinum ratio, H/M) with $^{123}$I-mIBG myocardial scintigraphy. The calculation of H/M traditionally requires a static planar scintigraphic (2D) image of the thorax. Recently, a new generation of gamma cameras (ring CZT) has been introduced utilizing multiple digital solid-state detectors (CZT) in a ring design, featuring SPECT (3D) imaging only and the possibility to convert a SPECT image to a pseudo-planar image. We aimed to explore $^{123}$I-mIBG myocardial scintigraphy H/M quantification of 2D imaging on a conventional gamma camera compared to a pseudo-planar image converted from 3D SPECT imaging on a ring CZT gamma camera. ***Materials and Methods:*** $^{123}$I-mIBG scintigraphy images from 37 subjects (controls n=7, suspected Parkinson´s Disease n=5, suspected idiopathic rapid eye movement sleep behavior disorder n=25) participating in an ongoing research study (The Swedish Sleep Study) were analyzed. A static planar image was acquired 226 (220-229) minutes (mean (range)) post injection of 116 (108-130) MBq $^{123}$I-mIBG with a conventional gamma camera, followed by a SPECT/CT acquired with a ring CZT gamma camera 20 (16-29) minutes after the static image. A regularized expectation maximization reconstruction using a relative difference prior, with attenuation and resolution correction but no scatter correction, was used for the SPECT images. SPECT images were converted to pseudo-planar images using software from the manufacturer. Region-of-interest was drawn over the heart and mediastinum, and the H/M was calculated for the static planar and the pseudo-planar image, respectively. Data were analyzed with a paired two-sample t-test (significance level p<0.05). ***Results:*** A significant difference in the H/M was observed comparing the two imaging methods (conventional 1.59 (1.01-2.74), ring CZT 1.52 (0.98-2.46), p=0.02). Stratifying by a H/M cutoff value of 1.8, there was a significant difference among subjects with a H/M >1.8 (conventional 2.25 (1.95-2.74), ring CZT 2.09 (1.75-2.46), n=13, p=0.02), but not among subjects with a H/M <1.8 (conventional 1.23 (1.01-1.76), ring CZT 1.21 (0.98-1.68), n=24, p=0.56). H/M was <1.8 for 24 subjects and >1.8 for 12 subjects on both gamma cameras. In one subject, H/M was >1.8 for the conventional (1.95) and <1.8 for the ring CZT gamma camera (1.75). ***Conclusion:*** $^{123}$I-miBG myocardial scintigraphy H/M quantification on a pseudo-planar image (ring CZT gamma camera) is feasible and identified subjects with impaired sympathetic innervation of the heart at a similar rate as conventional 2D planar imaging.

## EP-0455

### Prognostic Role of 123i-Mibg Cardiac Scintigraphy in Patients With Cardiac Transthyretin Amyloidosis (Attr)

***F. Sebastián Palacid***, *B. Pérez López, R. Zambrano Infantino, M. García Aragón, N. Álvarez Mena, M. Alonso Rodríguez, J. Gómez Hidalgo, C. Gamazo Laherrán, R. Ruano Pérez;*
*Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** To determine the prognostic role of $^{123}$I-MIBG cardiac scintigraphy in patients diagnosed with cardiac transthyretin amyloidosis (ATTR). ***Materials and Methods:*** Comparative study of 26 patients (18 men and 8 women) with a suspected diagnosis of ATTR due to heart failure and ventricular hypertrophy, who were previously evaluated with cardiac scintigraphy with $^{99m}$Tc-DPD. All underwent cardiac scintigraphy with $^{123}$I-MIBG, using a chest-centred planar imaging protocol at 15 minutes and 4 hours post-administration. The heart-to-mediastinum ratios (HMR) and washout index (WI) were evaluated

in both groups and the results were correlated with the clinical evolution of these patients in the 6 months after the scan. ***Results:*** 13 patients (50%) had a positive $^{99m}$Tc-DPD scan (84.6% male; 84.6% Perugini grade 3). In all patients with a negative $^{99m}$Tc-DPD scan, ATTR or other types of amyloidosis were ruled out. The mean WI in both patient groups were above the normal range, being slightly higher in the ATTR group (WI 39.8% vs. 37%; p=ns).There were no significant differences in both groups in terms of early or late HMR: Early HMR 1.52 ± 0.17 (ATTR) vs. 1.57 ± 0.32 (non ATTR); late HMR 1.4 ± 0.12 (ATTR) vs, 1.46 ± 0.27 (non ATTR). 4 patients in the ATTR group had fatal cardiac events within 6 months of the scan, while no patient in the non-ATTR group suffered serious cardiac events (p=0.0081). When looking for differences within the group with TTR amyloidosis, it was shown that deceased patients had an average higher WI than the rest (WI 52.75 vs 39.95; p=0.0224). ***Conclusion:*** $^{123}$I-MIBG cardiac scintigraphy could be an useful tool in patients with TTR cardiac amyloidosis.The increment of the washout index might be a parameter to be considered in the prognosis of these patients.

### The proportion of hibernating myocardium in total perfusion defect predicts the reversal of ventricular remodeling and clinical outcomes in patients with HFrEF after CABG

***Y. Lu****, X. Zhang;*
*Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** To evaluate the predictive value of the proportion of hibernating myocardium (HM) in total perfusion defect (TPD) on reversing ventricular remodeling (RR) and outcomes after coronary artery bypass graft (CABG) in patients with heart failure with reduced ejection fraction (HFrEF) by myocardial perfusion imaging (MPI) and $^{18}$F-FDG gated PET(GPET). ***Materials and Methods:*** Patients diagnosed with HFrEF at Beijing Anzhen Hospital of Capital Medical University were prospectively recruited. MPI combined with GPET was performed before surgery and the patients received follow-up MPI and GPET at different stages (3~12m) after surgery. Δ indicated changes (post-pre). ESV reduced at least 10% was defined as RR, patients were divided into reverse remodeling (RR+) group and the non-reverse group (RR-). Binary logistic regression analysis was used to identify predictors of RR. ROC curve analysis was performed to assess the cut-off value for predicting RR. Additionally, we retrospectively enrolled patients with HFrEF as the validation group, who underwent MPI and GPET before surgery. Echocardiography was performed before and after CABG. In the validation group, the reliability of obtaining the cut-off value for the ROC curve was verified. The endpoints included heart failure, coronary revascularization and cardiac death. The survival curves were obtained by the Kaplan-Meier (K-M) method. ***Results:*** A total of 28 patients with HFrEF (26 males; 56.9±8.7 years) were included in the prospective cohort. HM/TPD was significantly higher in the RR + group than in the RR – group (P = 0.016). Binary logistic regression analysis revealed that HM/TPD was an independent predictor of RR [Odds ratio=1.073, 95% Confidence interval: 1.005-1.145, P=0.035]. ROC curve analysis revealed that HM/TPD=38.3% yielded the highest sensitivity, specificity, and accuracy (all 75%) for predicting RR and the AUC was 0.786 (P=0.011). Meanwhile, a total of 100 patients with HFrEF (90 males; 59.7±9.6 years) were included in the validation group. In the validation group, HM/TPD=38.3% predicted RR in HFrEF patients with the highest sensitivity, specificity and accuracy (82%, 60% and 73% respectively). Compared with the HFrEF patients in the HM/TPD<38.3% group (n=36), RR and cardiac function improved significantly in the HM/TPD≥38.3% group (n=64) (P < 0.05).K-M analysis showed that the cumulative cardiovascular event-free survival rate of patients in the HM/TPD≥38.3% group was significantly higher than that in the HM/TPD<38.3% group (P=0.024). ***Conclusion:*** HM/TPD is an independent factor for predicting RR in patients with HFrEF after CABG, and HM/TPD ≥ 38.3% can accurately predict RR and outcome after CABG.

## EP-0457

### Dynamic SPECT in heart failure with preserved ejection fraction: tips and tricks

***K. Kopeva****, A. Maltseva, A. Mochula, V. Shipulin, A. Gusakova, E. Grakova, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** To evaluate the prognostic role of dynamic SPECT parameters in adverse events (AEs) in patients with heart failure with preserved ejection fraction (HFpEF) during 12-month follow-up period and to assess their relationship with biomarkers and echocardiographic parameter. ***Materials and Methods:*** Totals of 58 patients (age of 64 [54; 65] years) with non-obstructive CAD and HFpEF of NYHA class I-III (LVEF of 63 [59; 64]%) were enrolled. Dynamic CZT SPECT and echocardiography were performed baseline. Serum levels of NT-proBNP, fibroblast growth factor-23, tissue inhibitor of metalloproteinase-1 (TIMP-1), soluble ST2, matrix metalloproteinase-9 and tetranectin, hsC-reactive protein, interleukin-1β, 6 and 10 were measured using ELISA. ***Results:*** After 12 months of observation, the patients were divided into 2 groups: group 1 (n=11) included patients with AEs, group 2 (n=47) comprised those withou it. MFR and rest-MBF significantly correlated with NT-proBNP levels (r=-0.763 and r=0.401, respectively). MFR correlated with sST2 (r=-0.337), global longitudinal strain (GLS, r=0.721), left atrial volume index (r=-0.464) and septal e' (r=0.375), and rest-MFR with E/e' (r=0.424). Interleukin 10 levels correlated with MFR (r=0.511, p=0.005), rest-MBF (r=-0.432, p=0.045), and stress-MBF (r=0.317; p=0.012) values, while interleukin 1β levels significantly only correlated with MFR values (r=-0.371; p=0.046). In group 1, the level of NT-proBNP was 3,8-hold higher than in group 2 (284.5 [183.42; 716.73] and 1071.4 [272.4; 2168.1] pg/ml, respectively). In group 1, soluble ST2 levels were higher by 17.1% (p<0.001), TIMP-1 by 31.1% (p=0.012), MMP-9 by 23.4% (p=0.049), hsC-reactive protein by 1.9 times (p=0.004), and interleukin-1β by 2 times p=0.048) compared to group 2. MFR values were lower in group 1 by 45.4% (p<0.001) than in group 2 (1.19 [0.86; 1.55] vs. 2.18 [1.7; 2.55], respectively). Rest-MBF levels were higher by 23.6% (p=0.046) and stress-MBF lower by 28.2% (p=0.046) in group 1 than in group 2. In multivariate regression analysis, NT-proBNP levels (OR 3.23; p=0.008), GLS (OR 2.27; p=0.012), and MFR (OR 8.09; 95% CI p<0.001) were independent predictors of AEs. Based on ROC-analysis, MFR levels ≤1.62 (AUC=0.827; p<0.001), GLS ≤-18 (AUC=0.756; p=0.002) and NT-proBNP ≥760.5 pg/ml (AUC=0.708; p=0.040) may be considered as markers of AEs. However, the combined determination of NT-proBNP with MFR had a greater significance (AUC 0.935; p<0.001) in risk stratification. ***Conclusion:*** Dynamic SPECT parameters were associated with biomarkers

of fibrosis and inflammation, and LV remodeling. Levels of NT-proBNP, GLS and MFR may be used as non-invasive markers of AEs in HFpEF patients with non-obstructive CAD. ***References:*** Funding: MK-4257.2022.3

## EP-0458

### Left ventricle myocardial remodeling and coronary flow reserve in heart failure patients with non-obstructive coronary artery disease

***K. Kopeva***, *A. Maltseva, A. Smogon, A. Mochula, V. Shipulin, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** To evaluate the relationships between the miocardial (MFR) flow reserve and myocardial blood flow (MBF) indicators, obtained by dynamic SPECT, and the left ventricle (LV) myocardial remodeling parameters and cardiac biomarkers in heart failure patients with preserved ejection fraction (HFpEF) and non-obstructive coronary artery disease (CAD). ***Materials and Methods:*** A total of 27 patients (44.4% men, median age of 64 [54; 65] years) with HFpEF of NYHA class I-III and baseline LVEF of 63% [59; 64]% were enrolled. Dynamic CZT SPECT, echocardiography and coronary computed tomography angiography studies were performed baseline. Serum levels of NT-proBNP were measured using ELISA. ***Results:*** Depending on MFR value, all patients were divided into 2 groups: group 1 included patients with MFR >2 (n=13), group 2 included those with MFR ≤2 (n=14). The median values of NT-proBNP (p<0.0001) were 743.75 (261.1; 1987.2) pg/mL in group 1 and 125.81 (87.2; 531.4) ng/mL in group 2. The values of myocardial systolic and diastolic stresses parameters were higher by 6.9% (p=0.043) and by 7.8% (p = 0.043), respectively, in group 1 than in group 2. Myocardial-arterial stiffness was significantly higher among group 1 patients in comparison to group 2 patients (0.65 [0.57, 0.95] and 0.54 [0.52, 0.64], respectively). The global longitudinal strain of LV were lower by 25.1% (p<0.001) in group 1 than in group 2 (-14.9 [-13.7; -18.6] vs. -19.9 [-17.8; -20.9]%, respectively). The lateral e' values were lower in group 1 (p=0.006) by 32% than in group 2. The peak rate of tricuspid regurgitation was higher by 11.7% (p=0.043), the E/e' ratio by 21.4% (p=0.041) and indexed left atrial volume by 22.1% (p=0.036) in group 1 than group 2. The values of MFR significantly correlated with global longitudinal strain (r =0.508; p=0.007), end-systolic elasticity (r=0.347; p=0.008), integral systolic remodeling index (r=0.532; p=0.004), E/e'(r =0.769; p<0.001), lateral e' (r=-0.680; p=0.001), and E/A (r=0.416; p=0.038). MFR and rest-MBF significantly correlated with NT-proBNP levels (r=-0.763 and r=0.401, respectively). MFR also correlated with sST2 (r=-0.565), interleukin-10 (r=0.645; p=0,008), interleukin 1β (r=-0.371; p=0.042). ***Conclusion:*** Our data suggest that MFR is associated with LV remodeling and fibrosis and inflamation biomarkers in patients with HFpEF and non-obstructive CAD. HFpEF patients with CMD had more severe LV remodeling then those without it. ***References:*** Funding: MK-4257.2022.3

## EP-0459

### Diagnostic Value of Semi-Quantitative Parameters Obtained from [99mTc]Tc-PYP Bone Scintigraphy and SPECT/CT in Cardiac Amyloidosis

***K. Kucuker***, *A. Aksu, B. Turgut;*
*Izmir Katip Celebi University, Ataturk Training and Research Hospital, Nuclear Medicine Department, Izmir, TÜRKIYE.*

***Aim/Introduction:*** Scintigraphy with bone-seeking agents has a diagnostic role in cardiac amyloidosis. It is aimed to evaluate [$^{99m}$Tc]Tc-pyrophosphate(PYP) bone scintigraphy in the diagnosis of cardiac transthyretin amyloidosis using semi-quantitative data obtained from both planar and Single Photon Emission Computerized Tomography/Computerized Tomography (SPECT/CT) images. ***Materials and Methods:*** Patients referred to our department with the suspicion of cardiac transthyretin amyloidosis were included. Anterior-posterior chest and whole-body images were taken 90 minutes after [$^{99m}$Tc]Tc-PYP administration. Afterwards, SPECT/CT was performed on the thoracic region of all patients. Myocardial involvement of [$^{99m}$Tc]Tc-PYP was assessed visually on planar images according to the Perugini Grading Scale (Grade 0:negative, 1:equivocal, 2-3:positive). $H/Cl_{Ant}$ was calculated by dividing the counts from Region of Interests (ROI) plotted over the heart(H) and contralateral hemithorax(CL) region in anterior planar images only. The $H/Cl_{GeoMean}$ was calculated as the ratio of the geometric mean of the heart and contralateral hemithorax obtained from ROIs of both anterior and posterior images. In addition, Voxel of Interests (VOI) were drawn on the areas compatible with the heart and corpus sterni(S) on axial SPECT images with CT correlation. $H/S_{SPECT}$ was obtained by dividing the mean voxel counts of VOI areas. The semi-quantitative data were compared statistically between positive and equivocal/negative patients. Patients with sternotomy or trauma to thorax history were excluded from study group. ***Results:*** Thirty-two patients (18 male, 56.2%) with a mean age of 59±12 (37-80) were included in the study. Sixteen patients were Grade 0 (50%), 11 were Grade 1 (34.4%), two were Grade 2 (6.3%) and three were Grade 3 (9.4%). A total of five patients were evaluated positive for cardiac transthyretin amyloidosis. Median $H/S_{SPECT}$ was 1.43 (1.13-1.9) and 0.8 (0.35-1.18), median $H/Cl_{GeoMean}$ was 1.26 (1.07-1.46) and 1.05 (0.89-1.79) and median $H/Cl_{Ant}$ 1.37 (1.11-1.48) and 1.08 (0.85-1.99) in positive and equivocal/negative groups respectively. Statistically significant differences were found in $H/S_{SPECT}$, $H/Cl_{GeoMean}$ and $H/Cl_{Ant}$ between groups. Best cutoffs according to Youden index were found 1.11 (AUC: 0.993, 0.969-1.000, 95% CI, 100% sensitivity, 96.3% specificity) for $H/S_{SPECT}$, 1.165 (AUC: 0.900, 0.763-1.000, 95% CI, 80% sensitivity, 96.3% specificity) for $H/Cl_{GeoMean}$ and 1.105 (AUC: 0.878, 0.745-1.000, 95% CI, 100% sensitivity, 66.7% specificity) for $H/Cl_{Ant}$. ***Conclusion:*** Our results show that semi-quantitative data obtained from SPECT images are more successful in detecting cardiac transthyretin amyloidosis than those obtained from planar scintigraphic imaging. Analyzing SPECT images may enable us to detect patients with cardiac transthyretin amyloidosis with higher sensitivity and specificity.

## EP-0460

### Prognostic value of right ventricular involvement in Transthyretin Cardiac amyloidosis: a quantitative 99mTc-DPD SPECT/CT study

***M. Zhao***[1], *R. Calabretta*[2], *P. Binder*[2], *J. Yu*[2], *Z. Jiang*[2], *M. Hacker*[2], *X. Li*[2];
[1]*The Thrid Xiangya Hospital of Central South University, Changsha, CHINA,* [2]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** To evaluate the prognostic value of right ventricular (RV) bone tracer uptake in patients with transthyretin cardiac amyloidosis (TTR-CA) by using quantitative (SPECT/CT. ***Materials and Methods:*** We enrolled 53 patients with scintigraphy-confirmed TTR-CA based on Perugini's uptake(grade 2-3) and exclusion of monoclonal gammopathy. All patients underwent $^{99m}$Tc-DPD scintigraphy with both planar and SPECT/CT acquisitions. Left ventricle (LV), RV free wall, adjacent vertebra, and ascending aorta SUVmax were calculated. Myocardial SUVmax was also normalized to bone activity (nSUVmax) or blood pool (wSUVmax), respectively. The primary outcome was the occurrence of major adverse cardiac events (MACEs), defined as

all-cause deaths, hospitalization due to heart failure, complete atrioventricular block, recurrence or onset of sustained ventricular tachycardia, atrial fibrillation/flutter, mitral regurgitation, and coronary revascularization. ***Results:*** Thirty-five (66%) patients had RV uptake visible on planar scintigraphy. Patients with RV uptake had significantly greater serum NT-proBNP($p<0.05$), troponin T($p<0.05$), and interventricular septum(IVS) thickness($p<0.01$) than those without. During a median follow-up of 16.1 months, 19 events were recorded. On univariate Cox regression analysis, NT-proBNP, TnT, 6-MWT, NYHA class, amyloid type, LV wSUVmax , and RV wSUVmax were associated with MACEs ($P<0.10$ for all). RV wSUVmax were the independent predictors associated with MACEs at univariable Cox analysis ( HR:1.12, 95%CI:1.02-1.22; $p<0.05$). ***Conclusion:*** RV uptake appears to represent a more advanced stage of disease burden in TTR-CA and could serve as a new prognostic marker in TTR-CA patients with worse outcomes.

## EP-0461

### Evaluation of left ventricular contractile function in patients with large perfusion defects: is gated MPI applicable?

***V. Shipulin***, *S. Andreev, T. Shelkovnikova, V. M. Shipulin, A. Maslova, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Gated myocardial perfusion imaging (gMPI) is a widely used technique to evaluate left ventricular (LV) function along with perfusion. However, in patients with extent perfusion defects relevance of such approach is controversial. The aim of the present study was to assess the applicability of gMPI in evaluation of LV contractile function in presence of large perfusion defects. ***Materials and Methods:*** Sixty-four patients with ischemic cardiomyopathy were included in the study. All of them underwent gMPI and gated blood pool SPECT (gBPS), as well as cardiac magnetic resonance (CMR). All investigations were performed at rest. Then patients were divided into two groups according to gMPI data (summed rest score, SRS): with large (≥20% of LV, LPD) and medium (<20% of LV, MPD) perfusion defect. The following parameters of LV contractile function were estimated by nuclear modalities: ejection fraction (EF, %), end-systolic (ESV, ml) and end diastolic (EDV, ml) volumes, as well as mechanical dyssynchrony (MD) parameters (phase histogram standard deviation (PSD, degree) and bandwidth (HBW, degree)). With cardiac magnetic resonance LVEF, EDV and ESV were evaluated. ***Results:*** MPD group comprised 21 patients (SRS 11.7 (IQR 5.8; 16.1) %), LPD group - 43 (SRS 30.8 (25; 41.1) %). In the MPD, no intermodal differences in evaluated parameters were found. In the LPD group all evaluated parameters differed between gMPI and gBPS (EF: 25 (23; 29)% and 30 (22; 35)%, p=.03; EDV: 348 (300; 405) ml and 292 (248; 343) ml, p=.005; ESV: 294 (221; 322) ml and 208 (176; 254) ml, p=.005; PSD: 61 (59; 73) deg. and 52 (43; 66) deg., p=.04; HBW: 288 (237; 309) deg. and 205 (170; 260) deg., p=.0001, respectively). According to Bland-Altman analysis, all parameters were comparable in the MPD group, whereas in the LPD group volumes and MD were significantly overestimated by gMPI (mean differences: EDV 52.5 ml, ESV 35.9 ml, PSD 7.9°, HBW 67.2°) and EF was underestimated (-3.4%). According to Friedman ANOVA in the LPD group significant differences were found between gMPI and both gBPS and CMR, while no difference was found between gBPS and CMR. ***Conclusion:*** In patients with extend perfusion defect the use of gMPI may lead to errors in evaluation of LV volumes and contractile function, including mechanical dyssynchrony parameters.

## EP-0462

### Prediction value of left ventricular mechanical dyssynchrony indicators associated with super response to cardiac resynchronization therapy

***T. Atabekov***, *A. Mishkina, R. Batalov, S. Sazonova, S. Krivolapov, V. Saushkin, M. Khlynin, Y. Varlamova, K. Zavadovsky, S. Popov;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution "Tomsk National Research Medical Center of the Russian Academy of Sciences", Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The cardiac resynchronization therapy (CRT) has been shown to improve heart failure (HF) morbidity, quality of life, and survival in those with the reduced left ventricular ejection fraction (LVEF). Patients (pts) with CRT who exhibit above the expected improvement are known as super responders. The left bundle branch block (LBBB) with wide QRS duration, nonischemic HF, and female gender are most powerful predictors for CRT super response (SR). We aimed to evaluate the value of left ventricular (LV) mechanical dyssynchrony parameters detected by the cardiac scintigraphy in CRT SR predicting in chronic HF (CHF) pts. ***Materials and Methods:*** 49 sinus rhythm pts (male - 34 [69.4%], age 58.3 ± 11.4 years) with QRS duration ≥ 150 ms, permanent LBBB and New York Heart Association (NYHA) II-III functional class (FC) of CHF were included to the study. In all cases CRT devices with the defibrillation function (CRT-D) were implanted. Before and 6 month after CRT-D implantation myocardial perfusion scintigraphy (MPS) and gated blood pool single-photon emission computed tomography (gBPS) were performed. Pts were considered as super responders to CRT if they fulfilled after 6 month follow-up the following combined criteria: NYHA FC improvement ≥ 1 class + LV end systolic volume (LVESV) decrease > 30% or NYHA FC improvement ≥ 1 class + LVEF improvement > 15%. ***Results:*** The 1st group included 28 (57.1%) pts with SR to CRT, the 2nd group - 21 (42.9%) pts without it. Groups were comparable in terms of pre CRT-D implantation clinical and instrumental parameters, with the exception of MPS and gBPS parameters. The multivariate logistic regression with the inclusion factors such as baseline QRS duration, ΔQRS, female gender, non-ischemic CHF, baseline LVEF and right ventricular systolic pressure, LV lead lateral position, quadripolar LV lead, biventricular pacing percentage, MPS and gBPS indicators had shown that only Δphase standard deviation (PSD) (adjusted odds ratio [OR] 1.0508; 95% confidence interval [CI] 1.0021-1.1018; p=0.04), LV septal PSD (OR 1.0837; 95% CI 1.0235-1.1475; p=0.005) and interventricular dyssynchrony (IVD) (OR 1.0374; 95% CI 1.0114-1.0640; p=0.004) were CRT SR independent predictors. The univariate ROC-analysis showed that ΔPSD increase > 6.22° (AUC=0.758; p=0.0002), LV septal PSD increase > 23° (AUC=0.704; p=0.007) and IVD increase > 71.8 ms (AUC=0.770; p=0.0001) were predictors of the SR. ***Conclusion:*** LV mechanical dyssynchrony indicators (ΔPSD, IVD and LV septal PSD) assessed by MPS and gBPS were independently associated with CRT SR.

## EP-0463

### Potential utility of SPECT/CT with 99mTc-Tektrotyd for imaging of post myocardial infarction inflammation

***J. Ilyushenkova***, *S. Sazonova, A. Syrkina, A. Trusov, O. Mochula, A. Mishkina, V. Ryabov;*
*RI Cardiology, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** There is a need to develop methods for post myocardial infarction (MI) inflammation monitoring. Scintigraphy with somatostatin receptor targeted radiotracers has prospects in this regard [1]. The purpose was to study the association of $^{99m}$Tc-Tektrotyd uptake intensity in myocardial infarction MI area with heart contractility indices in 6 months period. ***Materials and Methods:*** Fourteen patients with acute ST-segment elevation

anterior MI (STEMI) were examined with $^{99m}$Tc-Tektrotyd SPECT/CT, myocardial perfusion scintigraphy (MPS) at rest, cardiac magnetic resonance imaging (cMRI) and transthoracic echocardiography (TTE). Initial scintigraphic results were compared with 6-month TTE indices ***Results:*** On the 7$^{th}$ day after MI onset cardiac $^{99m}$Tc-Tektrotyd uptake was found in 7 of 14 patients. Median of $^{99m}$Tc-Tektrotyd SUVmax was 1.59 (1.38; 2.83), summed rest score (SRS) - 11 (5; 18), infarct size (by cMRI) - 13.15 (3.3; 32.2) %. $^{99m}$Tc-Tektrotyd SUVmax strongly correlated with 6-month heart contractility indices (r=0.81, p<0.05 for end diastolic volume; r=0.61 p<0.05 for Δ end diastolic volume), with SRS (r=0.85, p<0.05) and infarct size (by cMRI) (r=0.79, p<0.05). ***Conclusion:*** The intensity (SUVmax) of $^{99m}$Tc-Tektrotyd uptake in the area of recent MI directly depends on a size of ischemic myocardial injury and correlates with changes of heart contractility indexes within 6 months follow-up.This work is supported by Russian Science Foundation, grant № 22-25-00234 ***References:*** 1. Sazonova SI, Syrkina AG, Mochula OV, Anashbaev ZZ, Popov EV, Ryabov VV. Subacute myocardial infarction detected by technetium-99m-labeled somatostatin analog scintigraphy. ### 99mTc-PYP Quantification Through SPECT/CT-Based Parameters in the Assessment of Cardiac Transthyretin Amyloidosis: Feasibility and Correlation with Semiquantitative Planar Indices

***A. Lazar***[1], *M. Mutuleanu*[1,2], *A. Jercan*[3], *S. Badelita*[3], *D. Coriu*[3,2], *M. Gherghe*[1,2];
[1]*Institute of Oncology "Professor Doctor Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA,*
[3]*Fundeni Clinical Institute, Bucharest, ROMANIA.*

***Aim/Introduction:*** Bone scintigraphy using $^{99m}$Tc-labelled bone-seeking radiopharmaceuticals is currently used in standard practice for the imaging assessment of patients suspected for transthyretin-related cardiac amyloidosis (ATTR). Currently diagnosis is primarily based on visual scoring and semiquantitative indices, but the introduction of new, potential life-prolonging medication for ATTR has underlined the necessity for a better evaluation of the cardiac amyloid burden, thus raising the opportunity for its estimation through single photon emission computed tomography/computed tomography (SPECT/CT) quantification. The present study assesses if quantitative SPECT/CT measurements of absolute $^{99m}$Tc-pyrophosphate ($^{99m}$Tc-PYP) uptake can accurately diagnose patients suspected for ATTR. ***Materials and Methods:*** This study prospectively evaluated 18 patients, mean age 47.44±8.15 years old, suspected for cardiac ATTR, who underwent $^{99m}$Tc-PYP scintigraphy in our department between June 2022 to February 2023, both planar acquisition 1 hour post $^{99m}$Tc-PYP administration and SPECT/CT imaging of the thoracic region 3 hours post-injection. All patients had also either serum or urine immunofixation performed. Obtained images were independently analysed by two physicians and semiquantitative planar indices and body-weight adjusted standardized uptake values (SUV), $SUV_{max}$ and $SUV_{peak}$, were measured. A cardiac SUV retention index (CRI) was also calculated by normalizing the $SUV_{max}$ value of the myocardium to the $SUV_{mean}$ of bone tissue and paraspinal muscle. Obtained results were statistically correlated. ***Results:*** Out of the 18 patients we evaluated, 14 had myocardial uptake positive for ATTR on the planar scans, presenting a visual Perugini score over grade 2, which was then confirmed on the SPECT/CT examination. All three measured SPECT-based parameters, $SUV_{max}$, $SUV_{peak}$ and CRI, correlated with the Perugini score and heart-to-contralateral lung ratio (p<0.05 for all). A receiver operating curve analysis was performed for all the measured quantitative parameters and it revealed that CRI had the best area under curve (AUC=0.964), obtaining a diagnostic CRI threshold of 0.681. Both $SUV_{max}$ and $SUV_{peak}$ exhibited good diagnostic performances as well, presenting AUC of 0.857, respectively, of 0.847. The patients with positive myocardial uptake underwent genetic testing, all of them having the Glu54Gln mutation. ***Conclusion:*** Quantitative SPECT/CT parameters can be used to assess patients suspected for cardiac ATTR, for a more accurate evaluation of myocardial uptake, this method offering good prospects in the appraisal of cardiac amyloid burden and treatment monitoring. CRI is the most feasible parameter for evaluating the cardiac amyloid burden, but both $SUV_{max}$ and $SUV_{peak}$ can be used with good diagnostic accuracy.

## EP-0465

### Utility of SPECT/CT in 99mTc-PYP scan in patients with suspected ATTR cardiac amyloidosis

***B. Bardessi***, *P. Canales, J. Quintana, I. Díaz, C. Waeger, F. Aguila, A. Hiplan, D. Jordan, N. Covarrubias, R. Jaimovich, K. Colorado; Pontificia Universidad Catolica de Chile, Santiago de Chile, CHILE.*

***Aim/Introduction:*** Myocardial scintigraphy labeled with Tc99m-pyrophosphate (PYP) has a high sensitivity and specificity in the diagnosis of ATTR-type cardiac amyloidosis. In static images qualitative - Perugini score (PS)- and semiquantitative -heart/contralateral thorax index- measurements are made . The main limitation in the interpretation of these images is the differentiation between the uptake of the radiopharmaceutical in the vascular pool vs myocardium. The objective of our study was to compare the values assigned in static images PS with visual interpretation in SPECT/CT images in order to see the correlation between PS assigned to each patient and the outcome of the visual analysis in SPECT/CT images. ***Materials and Methods:*** We reviewed all pyrophosphate myocardial scintigrams performed in our center (50 exams). Static images and SPECT/CT were evaluated after an hour of injection of the radiotracer.The PS in the static image of all the patients was compared with the result of SPECT/CT image (positive qualitative evaluation for uptake of the radiotracer in myocardium that exceeds rib uptake or negative for uptake in myocardium) ***Results:*** Of 50 patients evaluated, 8 were reported with Perugini Score 0 and 33 with PS 1, all of them presented vascular pool uptake on SPECT/CT images (true negatives). 6 patients had PS 3, of which 5 presented uptake in myocardium in SPECT/CT images (true positives) and 1 presented uptake in vascular pool. When evaluating with Perugini 2 (3 patients), only 1 of them presented myocardial uptake in the SPECT/CT, the other 2 presented activity in the vascular pool, this coincides with what has been reported in the literature (up to 2/3 of exams with grade 2 PS are false positive or equivocal findings when performing SPECT/CT). ***Conclusion:*** The utility of SPECT/CT in patients with suspected ATTR amyloidosis is greater in PS grade 2, since the tomographic image improves diagnostic accuracy by allowing a more precise visualization of the distribution of the radiotracer. For this reason, routine SPECT/CT is recommended for all PYP myocardial scintigrams. ***References:*** Avalon JC, Fuqua J, Deskins S, Miller T, Conte J, Martin D, Marano G, Yanamala N, Mills J, Bianco C, Patel B, Seetharam K, Raylman R, Sengupta PP, Hamirani YS. ### Potential of glucose metabolic rate obtained from dynamic18F-FDG PET/CT scan in differentiating cardiac sarcoidosis from physiological accumulation

***M. Nagao***[1], *Y. Shirai*[1], *A. Yamamoto*[1], *K. Kaneko*[1], *A. Sakai*[1], *N. Komura*[2], *S. Sakai*[1];
[1]*Tokyo Women's Medical University, Tokyo, JAPAN,*
[2]*Siemens Health Care, Tokyo, JAPAN.*

***Aim/Introduction:*** $^{18}$F-Fludeoxyglucose PET (FDG-PET) is a useful tool in the diagnosis and therapeutic monitoring of cardiac sarcoidosis (CS). In order to suppress physiological glucose metabolism in the myocardium, patients are forced to prolonged fasting and restriction of glucose intake. Nevertheless, physiological accumulation is often difficult to distinguish from active CS. The glucose metabolic rate (MRglu mg/min/100ml) is a new quantification of glucose metabolic kinetics derived from dynamic FDG-PET scan with a silicon photomultiplier. We investigate the potential of MRglu in differentiating active CS from physiological accumulation. ***Materials and Methods:*** One hundred CS patients and sixty-three cancer-bearing patients who underwent four sets of dynamic FDG-PET scan with a silicon photomultiplier from 30 minutes after FDG administration were enrolled. Preparation included 18 hours of fasting and restricted glucose intake for the former and 6 hours of fasting for the latter. Myocardial uptake of SUVmax 2.7 or greater was defined as active CS in the former (Ref. 1) and physiological accumulation in the latter. Parametric analysis of dynamic FDG-PET data was performed on these lesions, and SUV and MRglu were calculated. ***Results:*** Thirty-four of 100 CS patients (34%) had active CS, with SUV and MRglu of 4.1±1.5 and 1.9±1.1 mg/min/100ml. Twenty-eight of 63 cancer-bearing patients (44%) had physiological accumulation, with SUV and MRglu of 4.9±2.1 and 2.9±1.6 mg/min/100ml. Both SUV and MRglu were significantly greater for physiological accumulation than active CS ($p<0.005$). MRglu and SUV showed a significant positive correlation in both groups [CS: Pearson r, 0.841 (95%CI 0.775-0.889), $p<0.0001$; Physiological accumulation: Pearson r, 0.916 (95%CI 0.881-0.942), $p<0.0001$]. The correlation coefficient was significantly greater for physiological accumulation than active CS ($p=0.0072$). Receiver-operating-characteristic analysis revealed that the area under the curve for active CS diagnosis was 0.626 for SUV, 0.721 for MRglu, and 0.741 for the ratio of MRglu to SUV, respectively. ***Conclusion:*** For both active CS and physiological accumulation, MRglu was significantly positively correlated with SUV. However, the correlation coefficient was greater for physiological accumulation than active CS. The use of MRglu improved the discrimination between active CS and physiological accumulation compared to SUV alone. ***References:*** 1. Kaneko K, Nagao M, Yamamoto Y, et al. FDG uptake patterns in isolated and systemic sarcoidosis. J Nucl Cardil 2022. DOI: 10.1007/s12350-022-03106-1.

### Relationship between the distribution of diphosphonate uptake and changes in cardiac MRI in patients with transthyretin cardiac amyloidosis

***L. Santamaría-Chico****, K. Velásquez-Díaz, M. Mitjavila-Casanovas, P. Soares-Meneses, I. Obedkova, M. Grajeda-Gallardo, I. Garrido-Solesio, M. Pastrana-Ledesma, F. de Haro-del Moral;*
*Hospital Universitario Puerta de Hierro, Madrid, SPAIN.*

***Aim/Introduction:*** Transthyretin cardiac amyloidosis (ATTR) is a myocardial disease caused by the deposition of altered transthyretin fibrils, either naturally or hereditary. In recent decades, it has been seen that 99mTc-diphosphonates bind to these protein deposits in such a way that scintigraphy allows us to diagnose them. However, we do not yet know the role of diphosphonate uptake in the quantification of myocardial amyloid burden. This study aims to assess the distribution of the deposit in the different segments and its relationship with changes in cardiac MRI. ***Materials and Methods:*** We studied 24 patients (22 men and 2 women) aged between 60 and 92 years (mean 77.58), diagnosed with ATTR, who presented a grade 3 of Perugini in cardiac scintigraphy. Taking advantage of the intense myocardial uptake, a G-SPECT was performed to obtain a polar map of the distribution of uptake in the 17 segments in which the myocardium is divided, and were compared with the phenomenon of altered kinetics in the delayed enhancement sequences of cardiac MRI. ***Results:*** The maximum uptake in the G-SPECT was observed in segments 3 (basal inferoseptal) (92-100%) and 9 (medial inferoseptal) (79-100%). Intense uptake was also observed in segments 2 (basal anteroseptal) and 8 (medial anteroseptal). The segment with the lowest uptake was 12 (medial anterolateral) (0 -75%) and in some patients segments 1, 5, 6, 7, 10, 11 and 12 did not show uptake. Regarding the phenomenon of altered kinetics in the late enhancement sequences of the cardiac MRI, the least affected segments were the apical ones, being very variable in the rest of them. On the contrary, the deposit in the apex was very variable (between 6 and 87%). After gadolinium administration, global myocardial enhancement, typical of cardiac amyloidosis, was observed in all patients. ***Conclusion:*** Most patients had greater uptake of diphosphonate on the septal side, and the degree of uptake does not correlate with the phenomenon of altered kinetics in late enhancement sequences of cardiac MRI. ***References:*** 1. ## EP-0468

### Using reprojected planar images from 99mTc-labelled diphosphonate scintigraphy for visual scoring of transthyretin amyloidosis: validating a novel ring-configured cadmium zinc telluride gamma camera

***I. Ceric Andelius***[1,2], *D. Minarik*[1,2], *R. Fridriksdóttir*[3], *F. Hedeer*[3,4], *A. Stenvall*[1,4], *E. Trägårdh*[2,3], *J. Oddstig*[1,2];
[1]*Radiation Physics, Skånes University Hospital, Lund/Malmö, SWEDEN,* [2]*Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN,* [3]*Department of Clinical Physiology and Nuclear Medicine, Lund/Malmö, SWEDEN,* [4]*Department of Clinical Sciences, Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** Myocardial uptake due to cardiac amyloidosis in planar $^{99m}$Tc-labelled diphosphonate ($^{99m}$Tc-DPD) scintigraphy is widely accepted as a diagnostic tool for detecting transthyretin amyloidosis (ATTR-amyloidosis) with high sensitivity and specificity. Recently ring-configurated cadmium zinc telluride (CZT) single-photon emission computed tomography-computed tomography (SPECT/CT) systems have been introduced. These systems only enable reprojected anterior and posterior planar images generated from reconstructed SPECT-data. When scoring amyloidosis planar imaging and SPECT/CT are recommended by American Society of Nuclear Medicine and European Association of Nuclear Medicine. We aimed to compare planar versus reprojected planar images to validate the reprojected images into

clinical practice. ***Materials and Methods:*** 30 patients referred to clinically indicated amyloidosis scintigraphy were scanned on both a conventional gamma camera and a ring-configurated CZT gamma camera. Planar imaging from the conventional gamma camera was compared to reprojected planar images (reconstructed using block-sequential regularized expectation maximization (BSREM) with 10 iterations, 10 subsets, RDP regularisation with beta 0.2, 0.3, 0.4, 0.6 and 0.8 and gamma 4). SPECT/CT from the ring-configurated CZT system (reconstructed with BSREM 10 iteration 10 subsets beta 0.4 and gamma 2) was used for anatomical correlation when planar scintigraphy was positive. The images were evaluated regarding image quality and Perugini score in a blinded fashion by three nuclear medicine physicians. The contrast to noise ratio ($CNR=ROI_{rib,mean}-ROI_{background,mean}/sqrt(SD_{ROI,rib,mean}^{2}+SD_{ROI,background,mean}^{2})$) was analysed quantitatively by placing a ROI in the rib and the background. ***Results:*** There was no significant difference between the planar and reprojected images regarding image quality and inter observer variability (p= 0.6 and 0.4) and Perugini score and inter observer variability (p= 1 and 0.7) which enables a clinical reconstruction within the beta range 0.2-0.8. The highest image quality scores were given for beta 0.2 and 0.4. Higher CNR was observed for reprojected planar images compared to planar scintigraphy. Reprojected images reconstructed using beta 0.4 yielded slightly higher CNR compared to other beta factors. ***Conclusion:*** Reprojected planar images reconstructed with BSREM can be used to score ATTR-amyloidosis. The 3D data generated from the ring configurated CZT system is sufficient for the assessment of ATTR-amyloidosis.

## EP-0469

### Different extracardiac uptake, evidenced on 99mTc-HDP scintigraphy, in various types of cardiac amyloidosis

***M. Starace***[1], *F. Cappelli*[2], *F. Perfetto*[3], *E. Costanzo*[4], *R. Sciagrà*[5], *V. Berti*[1];
[1]*Nuclear Medicine Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, 50134 Florence, Italy., florence, ITALY,* [2]*Tuscan Regional Amyloid Centre, Careggi University Hospital, Florence, Italy, florence, ITALY,* [3]*Tuscan Regional Amyloidosis Centre, Careggi University Hospital, Florence, Italy., florence, ITALY,* [4]*Department of Nuclear Medicine, Azienda Ospedaliero-Universitaria Careggi, Largo Brambilla 3, 50134, Florence, Italy., florence, ITALY,* [5]*Nuclear Medicine Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, 50134 Florence, Italy, florence, ITALY.*

***Aim/Introduction:*** Cardiac amyloidosis is a rare form of restrictive cardiomyopathy caused by the deposition of amyloid fibrils at the cardiac level. The causative amyloid fibril deposits are of monoclonal light chain (AL) or transthyretin (ATTR) types. ATTR amyloidosis may be wild-type or associated with variants in the transthyretin gene. Increased cardiac uptake on $^{99m}$Tc-HDP scintigraphy has showed diagnostic values in cardiac amyloidosis but extracardiac uptake has been poorly studied. We evaluated if extracardiac uptake was observed in $^{99m}$Tc-HDP scintigraphy in different amyloidosis types. ***Materials and Methods:*** Results of bone scintigraphy were analyzed from 115 patients with cardiac amyloidosis. Of these, 90 patients had cardiac amyloidosis ATTR wild-type (wt), 13 had cardiac amyloidosis ATTR mutated (m) and 12 had amyloidosis AL. In these three groups, we considered the Perugini score and then we observed if $^{99m}$Tc-HDP uptake was present at the level of the soft tissues (particularly the limbs), lungs, liver, abdominal wall, and right ventricle. For each parameter we created continhgency tables and applied a chi-square test. Statistical significance was set at p<0,05. ***Results:*** Extracardiac uptake in $^{99m}$Tc-HDP scintigraphy was differently distributed in the 3 groups. In particular, soft tissues and liver uptake is more evident in amyloidosis AL (41,7% and 16,7% respectively), compared with ATTRwt (soft tissue uptake 36,7%, hepatic 0%) and ATTRm (soft tissue uptake 38,5%, hepatic 7,7%). Accumulation in the abdominal wall and right ventricle is more represented in amyloidosis ATTRm (69,2% and 61,5% respectively) compared with amyloidosis ATTRwt (adbominal wall uptake 64,4%, right ventricle 51,1%) and amyloidosis AL (abdominal wall uptake 25%, right ventricle 16,7%). Finally, pulmonary uptake is more pronounced in amyloidosis ATTRwt (67,8%) than in amyloidosis ATTRm (61,5%) and amyloidosis AL (25%). ***Conclusion:*** $^{99m}$Tc-HDP scintigraphy can be used for visualization of extracardiac uptake in the various types of amyloidosis and could help direct the diagnosis toward a specific type of the disease.

### The Relationship of Tc-99m Pyp Scıntıgraphy Parameters wıth Prognosis and Life Expectation ın Cardiac Amiloidosis

***Ü. Aksu***[1], *E. Akgün*[1], *S. G. Yaran*[1], *M. Ayer*[2], *A. Güler*[3], *G. B. Güler*[3], *A. Türkvatan*[4], *M. Kaya*[1], *B. E. Akkas*[1];
[1]*Başakşehir Çam and Sakura Hospital Clinic of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Başakşehir Çam and Sakura Hospital Clinic of Hematology, Istanbul, TÜRKIYE,* [3]*Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Hospital Clinic of Cardiology, Istanbul, TÜRKIYE,* [4]*Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Hospital Clinic of Radiology, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The aim of the study is to determine cardiac amyloidosis involvement with 99mTc-PYP scintigraphy and to investigate the relationship between scintigraphic parameters and survivals in patients investigated for transtiretin cardiac amyloidosis (TTR CA). ***Materials and Methods:*** A total of 127 patients (64 M, 63 F mean age: 60.5) who were referred to our clinic for 99mTc-PYP scintigraphy with suspected CA were included in the study. Clinical and laboratory data, ECG, ECHO, MR findings were noted. Serum Kappa/Lambda ratio, immunofixation test results, and biopsy results were noted for light chain (AL) amyloidosis. Counts were taken from the heart (H) and from the contralateral side of the heart (CL) with the same size ROI(Region of interest) on planar images. Patients were categorized in 3 groups according to H/CL ratio (≤1: Group 1, n=18; 1-1.5: Group 2, n=104; >1.5: Group 3, n=5). Those with heart/CL ratio > 1.5 and/or Perugini score GRADE 2-3 and negative hematological tests for AL amyloidosis were accepted as TTR CA. The PYP scintigraphy results of the patients were compared with clinical data, and survivals. ***Results:*** Group 1 patients were considered negative for CA either ATTR and AL, In group 2, 13 patients (17%) were diagnosed with AL CA. There was no TTR CA. The diagnosis was confirmed with biopsy in 4 of them. During follow-up 4 of these patients dead because of AL CA. In Group 3, all of 5 patients were accepted as TTR CA. One of them dead because of TTR cardiac involvement. Other six patients dead from cardiac causes other than CA (Group 1 n= 0 Group 2 n=6). When H/CL ratio cut-off was chosen as 1.3, mortality rates increased significantly along with H/CL ratios (21% 7/33 vs 4.2% 4/94; p=<0,05). Mortality rates were 30.7% in AL CA cases, 20% in TTR CA cases, and 5.5% in cases without cardiac amyloidosis involvement. ***Conclusion:*** Our findings support that AL CA has a worse prognosis than TTR-CA. It shows that mortality rate increases significantly myocardial radiopharmaceutical uptake on PYP scintigraphy. Scintigraphy findings are prognostic as well as diagnostic in CA. ***References:*** Poterucha TJ et al. Diagnosing Transthyretin Cardiac

***Aim/Introduction:*** To identify the number and location of extracardiac uptake in patients undergoing bone scintigraphy for suspected cardiac amyloidosis (CA). In addition, we will study possible statistical associations between the "Red Flags" for cardiac amyloidosis and the different types of extracardiac uptake. ***Materials and Methods:*** Bone scans for suspected cardiac amyloidosis with extracardiac uptake (regardless of the final diagnosis made by noninvasive diagnosis by clinicians -table 1-) between 2014 and 2022 were included. Clinical "Red Flags" (carpal tunnel syndrome, atraumatic rupture of the biceps brachii tendon and lumbar canal stenosis) have been collected from the electronic medical history. A descriptive and an analytical study will be carried out, in which the possible association between the type of uptake and the "Red Flag" type will be determined by calculating the Habermann's corrected typed residuals. ***Results:*** A total of 280 patients were reviewed, 31 of whom met the inclusion criteria. According to the descriptive study, the prevalence of extracardiac uptake was 11.1% (31); 9 patients had pulmonary, 6 hepatic and 21 soft tissue uptake. In respect of the 9 pulmonary uptakes (3 unknown-origin CA, 4 ATTR and 2 non-CA), 2 presented carpal tunnel syndrome and were classified as unknown-origin CA and ATTR. None of the 6 hepatic uptakes presented "Red Flag" and all patients were classified as non-CA. Regarding to the 21 soft-tissue uptakes (8 unknown-origin CA, 10 ATTR, 1 AL and 2 non-AC), 7 presented carpal tunnel syndrome (2 unknown-origin CA and 5 ATTR) and 1 atraumatic rupture of the biceps brachii tendon that was diagnosed as ATTR. In the analytical study, there was statistical association between the presence of carpal tunnel syndrome and unknown-origin CA, the presence of carpal tunnel syndrome and ATTR, the absence of carpal tunnel syndrome and no CA. We also found a statistical association between the presence of pulmonary uptake in bone scintigraphy and ATTR and its absence with non-CA. Finally, we detected a statistical association between the presence of soft tissue uptake in bone scintigraphy and unknown-origin CA or ATTR, and the absence with non-CA. ***Conclusion:*** The association between the different clinical Red Flags and the type of extracardiac uptake cannot be concluded. However, in our study the presence of carpal tunnel syndrome, soft tissue and pulmonary uptake pointed to CA (ATTR or unknown CA), whereas hepatic uptake was not related to CA and might be caused by other etiologies.

## EP-0472

### Is T-DM1 cardiotoxicity close monitoring relevant in palliative breast cancer patients? A single center experience using equilibrium radionuclide ventriculography (ERNV)

***D. Silva****, H. Duarte, P. Leite-Silva, J. F. Ferro, I. Próspero, D. Barbosa, S. F. Castro, G. Ferreira, J. P. Teixeira, I. L. Sampaio;*
*Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.*

***Aim/Introduction:*** Ado-trastuzumab emtansine (T-DM1) is a standard of care option for patients with advanced breast cancer with positive human epidermal growth factor receptor 2 (HER2). Due to its association with cardiotoxicity, left ventricle ejection fraction (LVEF) is evaluated before and during the treatment period using either equilibrium radionuclide ventriculography (ERNV) or echocardiogram (ECHO). Besides this recommendation, published "real life studies" with palliative patients showed low levels of cardiac toxicity with none/very few cases of treatment interruption for that reason, and disease progression being the number one cause of T-DM1 discontinuation. The aim of this study was to evaluate systolic and diastolic dysfunction (which is thought to be an earlier predictor of cardiac malfunction) over T-DM1 treatment time in our center. ***Materials and Methods:*** We included all patients (n= 40) who started palliative treatment with T-DM1 from 1/1/2018 to 31/12/2022 whose cardiotoxicity was assessed by ERNV during the treatment period. Patients' sequential ERNV tests (from baseline until 12 months of treatment or discontinuation) were re-analysed using Xeleris™-4-DR GE workstation and LVEF, peak filling rate (PFR) and time to peak filling rate (TPFR) values were collected. Patients' demographic and clinical data were recorded and analysed. Wilcoxon signed-rank test was performed in R version 4.0.5 to access any statistically significant variation over time. ***Results:*** Patients group presented a median age of 55 years old (20-80), ECOG PS 0-1, and a median treatment period of 10 months (3-43). Median baseline LVEF value was 61% (50-72%) and none of the patients presented a decrease of LVEF value equal/superior to 10 percentage points plus LVEF<50%. Four patients (10%) discontinued T-DM1 due to other toxic side effects (hematologic, hepatic, and cutaneous), and the other 90% thanks to disease progression (namely progression of bone, brain, and liver disease). Regarding diastolic parameters there weren't significant differences over time, all patients demonstrated normal PFR and TPFR values during the treatment period. ***Conclusion:*** The present study has some limitations due to small sample size. Nevertheless, our results endorse T-DM1's satisfactory safety profile of published studies. The vast majority of patients discontinued treatment due to disease progression before evidence of drug-induced cardiotoxicity. Pertinence of close cardiotoxicity monitoring must be questioned in the setting of breast cancer palliative treatment with T-DM1.

## EP-0473

### Diagnostic Performance of Cardiac Magnetic Resonance and Cardiac Scintigraphy in patients with clinical suspicion of Transthyretin Cardiac Amyloidosis

***M. Pudis***[1], *P. C. Notta*[1], *L. Gràcia-Sánchez*[1], *I. E. Sánchez-Rodríguez*[1], *E. Claver-Garrido*[2], *C. Diez-López*[2], *J. González-Costello*[2], *V. Carrero-Vasquez*[1], *C. Martínez-Ramos*[1], *S. Bondia-Bescós*[1], *B. Hervás-Sanz*[1], *J. Diaz-Moreno*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [2]*Cardiology Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** The aim of this study was to evaluate and compare the diagnostic efficacy of two imaging techniques - Cardiac Scintigraphy (CS) with $^{99m}$Tc-HMDP and Cardiac MRI (CMRI) - in the diagnosis of cardiac amyloidosis due to transthyretin (CA-ATTR) using statistical parameters. ***Materials and Methods:*** This study retrospectively analyzed patients (p) who were clinically suspected of having cardiac amyloidosis caused by transthyretin (CA-ATTR) and underwent both cardiac scintigraphy (CS) and cardiac magnetic resonance imaging (CMRI) as part of their diagnostic workup between 2016 and 2022. Patients with a final clinical diagnosis of CA-ATTR were included in the analysis. The study calculated the sensitivity (S), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV) of both diagnostic techniques. These metrics were used to evaluate the diagnostic performance of CS and CMRI in identifying CA-ATTR in this patient population. ***Results:*** A total of 103p with suspected CA-ATTR underwent both imaging techniques. Among them, 17p were found to be positive for CA-ATTR by either one or both imaging techniques. However, five of the 17p who were diagnosed with CA-ATTR by MRI were later found to have other types of CA-AL (n=3) or CA-AA (n=2) upon further evaluation and were excluded from the analysis. Out of the remaining 12p who had a final clinical diagnosis of CA-ATTR, 6p were diagnosed concordantly by both imaging techniques. 3p were diagnosed with CA-ATTR only by cardiac scintigraphy, while MRI revealed alternative diagnoses of hypertrophic cardiomyopathy or Fabry disease. The remaining 3p were diagnosed only by MRI, all of whom were recipients of domino liver transplant DLT from patients with familial amyloid polyneuropathy (FAP) and in the early stage of the disease. There were no differences between the S=75% and Sp=100% or PPV=100% and NPV=96.8% of both imaging techniques when considering the same number of false negatives (n=3) and false positives (n=0). ***Conclusion:*** CS and CMRI have proven to be useful techniques in the diagnostic workup of CA-ATTR. Both techniques have high sensitivity and high positive predictive value. CS seems to be more reliable in most of the patients with an exception of receivers of DLT from FAP patients, where CMRI was able to detect depositions in an early stage.

## EP-0474

### Usefulness of semi-quantitative analysis in cardiac amyloidosis.

***J. Venero Chaparro****, M. Gallego Márquez, M. Sánchez Torrente, F. Garí Martínez, D. Guirado Llorente, M. Martínez-Valle Torres; Hospital Clínico San Cecilio, Granada, SPAIN.*

***Aim/Introduction:*** This study was designed to evaluate the quantification of myocardial uptake of 99mTc-HDP in patients with suspected amyloidosis and to establish an optimal threshold to differentiate between transthyretin (ATTR) and light chain (AL) deposition. ***Materials and Methods:*** An observational, descriptive, cross-sectional analysis was performed in which, retrospectively, 75 patients with suspected cardiac amyloidosis were selected between 2022 and 2023, with an anteroposterior planar scintigraphic study 2 hours after radiopharmaceutical injection. Patients were classified according to the Perugini scale into 3 uptake grades. The quantification test result, R, is defined as the ratio between the number of counts obtained in the ROI corresponding to the heart (H) and the number of counts in the ROI corresponding to the contralateral thorax (CL). The test is considered positive for ATTR if R=H/CL > TH. The paper analyses the effect of the choice of TH on the diagnostic ability of the test, determining the values of sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy using Monte Carlo methods. Furthermore, in order to characterise the uncertainties, a study of the dependence of the results on the observer is carried out in the semi-quantitative analysis. For this purpose, 5 patients are randomly taken from the sample and analysed by 4 different nuclear medicine physicians, who follow the process of defining the ROIs and determining R from them. An average uncertainty for the R value is established from the standard deviations calculated from the four R values for each patient. ***Results:*** For the determination of ATTR of grade ≥1, the optimal threshold, obtained from the point where sensitivity and specificity are equal, is found to be TH=1.3. For this threshold value, a sensitivity and specificity of 0.875 ± 0.003 are obtained; whereas, for the commonly used threshold, TH=1.5, a sensitivity of 0.657 ± 0.006 and a specificity of 0.973 ± 0.001 are obtained. All uncertainties correspond to a coverage factor k=2. The average inter-observer variability (standard deviation) in the calculation of R is 6.9%, with a range between 1.5% and 16%. ***Conclusion:*** The semi-quantitative planar imaging analysis used in the study is a reliable method with high sensitivity and specificity to differentiate transthyretin (ATTR) from light chain (AL) deposition, with an optimal threshold of 1.3 in the H/CL ratio for the sample studied.

## EP-0475

### Ventricular Function Patterns In Ttr Cardiac Amyloidosis: Can We Select Patients For Resynchronization Therapies Using $^{99m}$TC-DPD Gspect?

***F. Sebastián Palacid****, B. Pérez López, M. García Aragón, R. Zambrano Infantino, N. Álvarez Mena, M. Alonso Rodríguez, J. Gómez Hidalgo, C. Gamazo Laherrán, R. Ruano Pérez; Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** To evaluate amyloid deposition and ventricular function patterns in ATTR using $^{99m}$Tc-DPD gated-SPECT-CT. ***Materials and Methods:*** Analysis of 34 patients with a gammagraphic diagnosis of TTR amyloidosis (24 males and 10 females; mean age: 83.5 ± 6.28 years; 85.3% Perugini grade 3) who underwent a GATED SPECT-CT study focused on the thoracic region. Images were processed and quantified with Myovation Evolution GE® and Emory Cardiac Tool Box GE® softwares. Demographic variables, left ventricular function variables and myocardial uptake of 99mTcDPD were analyzed by SPSS.We use normal phase values (peak, bandwidth and kurtosis) established by Chen et al in perfusion studies[1]. ***Results:*** GATED SPECT-CT study was performed in all patients. 85.3% were classified as Grade 3 according to Perugini grade. Mean $SUV_{max}$ was 9,65±2,87, being grade 3 Perugini the group with higher $SUV_{max}$ (p=0.004).Left ventricular ejection fraction (EF) and volumes were obtained, being mean EF of 51.3±15.5%. 16 patients (47%) had an EF <50%.13 patients (38.2%; 6 females and 7 males) presented abnormal phase peak, kurtosis and bandwidth values (mean phase peaks were 122.1 ± 24º in men and 151.4 ± 26.8º in women), indicating dyssynchrony.When looking for differences within sex, women showed worse peak phase values than men (p=0.004). In addition, in this group a negative correlation was found between EF and bandwidth (p=0.002).In the male group, a negative correlation between phase peak and kurtosis (p=0.004) and a positive correlation between the degree of Perugini and age (p=0.001) were demonstrated. Indeed, males with pathological peak phase (7/24) showed a positive correlation between the degree of Perugini and age (p=0.001) ***Conclusion:*** According to our data, using $^{99m}$Tc-DPD GATED SPECT-CT is a feasible technique that allows us a quantitative assessment of amyloid deposition as

well as left ventricular function in the same study. This technique might allow the identification of patients with impaired EF and ventricular synchrony susceptible to cardiac resynchronization therapy, 38.2% of patients in our study. However, further studies are needed to confirm the results. ***References:*** (1) Chen J, García EV, Bax JJ, Iskandrian AE, Borges-Novo S, Soman P. ### The Utility of Right Ventricular Myocardial Strain Ratio Estimated by Ammonia Positron Emission Tomography to Stratify the Risk for Coronary Artery Disease

***A. Yamamoto***[1], *M. Nagao*[1], *M. Kawakubo*[2], *R. Nakao*[1], *Y. Matsuo*[1], *A. Sakai*[1], *M. Momose*[1], *K. Kaneko*[1], *K. Fukushima*[3], *J. Yamaguchi*[1], *S. Sakai*[1];
[1]*Tokyo Women's Medical University Hospital, Tokyo, JAPAN,* [2]*Kyushu University, Fukuoka, JAPAN,* [3]*Fukushima Medical University, Fukushima, JAPAN.*

***Aim/Introduction:*** We have made it possible to measure right ventricular myocardial strain (RVMS), adapting a feature–tracking technique to electrocardiography–gated high–resolution $^{13}$N–ammonia positron emission tomography ($NH_3$–PET). We indicated that RVMS identified right coronary artery territory ischemia in patients with ischemic heart disease (IHD). Previous studies showed that RV function was a prognostic factor of cardiovascular events. The aim of this study was to investigate the potential of RVMS estimated by $NH_3$–PET as a prognostic factor in patients with IHD. ***Materials and Methods:*** Between January 2017 to January 2021, 577 consecutive patients performed resting and stressed myocardial $NH_3$–PET because of known or suspected IHD were enrolled. Patients with congenital heart disease, a transplanted heart, adenosine ineffectiveness, or poor imaging that could not be analyzed were excluded.RVMS in the free wall was measured by a feature–tracking technique on the $NH_3$–PET images of horizontal long–axis slices, and the RVMS ratio (RVMSR) was defined as RVMS at stress divided by that at rest. The endpoint was major adverse cardiac events (MACEs) comprising cardiac death or hospitalization due to heart failure. The patients were divided into two groups using the RVMSR cutoff value obtained by receiver–operating characteristic (ROC) analysis, and event–free survival was analyzed by Kaplan–Meier and log–rank test. For imaging parameters, hazard ratios (HR) and 95% confidence intervals (CI) were calculated using the Cox proportional hazards regression model. ***Results:*** 480 patients were retrospectively analyzed. The ROC analysis demonstrated a cutoff of 1.006 for MACE with RVMSR, and showed that area under the curve, sensitivity, and specificity were 0.84, 84% and 82%. Patients with RVMSR <1.006 had a significantly higher MACE rate than those with RVMSR ≥1.006 (p<0.0001). Multivariate analysis indicated that RVMSR was an independent marker that could predict MACE in imaging parameters (HR: 454, 95% CI: 40–6727, p <0.0001). ***Conclusion:*** RVMSR is a prognostic factor for MACE in patients with IHD.It is possible to predict cardiovascular events from the RV function assessed by routine $NH_3$–PET without additional imaging or radiation exposure.

## EP-0477

### The relationships between quantitative CCTA and dynamic CZT SPECT in patients with non-obstructive coronary artery disease

***K. Zavadovsky***[1], *A. Maltseva*[1], *R. Dorzhieva*[2], *A. Mochula*[1], *K. Kopeva*[1], *E. Grakova*[1];
[1]*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION,* [2]*Siberian State Medical University of the Ministry of Health of the Russian Federation, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Nowadays, CCTA is a well-established method for identification of coronary artery disease in patients with low pre-test probability. Most of these patients have non-obstructive coronary artery disease (NOCAD) and microvascular dysfunction. However, the data about the relationships between coronary plaque composition and the values of myocardial blood flow and reserve is lacking. The aim of the study is to assess the relationships between quantitative CCTA variables and dynamic CZT SPECT in NOCAD patients. ***Materials and Methods:*** Based on CCTA results, patients with NOCAD (stenosis <50%) were included in the study. In addition to stenosis severity, quantitative analysis of coronary atherosclerosis was performed by estimation of the following variables (in mm3 and in %): general plaque volume (GPV), soft tissue plaque volume (STPV), fibrous plaque volume (FPV), calcified plaque volume (CPV). All patients underwent dynamic SPECT CZT with the assessment of stress and rest myocardial blood flow (MBF), myocardial flow reserve (MFR) [1]. The 1-tissue-compartment model with attenuation correction was used for quantitative analysis. ***Results:*** The study included 55 patients (31 men, age 57.0±8.8 years). Quantitative CCTA parameters were the following: GPV 42.4 (0.0;138.1) mm3, 2.5 (0.0;7.2)%; STPV 0.1 (0.0;9.5) mm3, 0.006 (0.0;0.4)%; FPV 34.0 (0.0;113.5) mm3, 1.9 (0.0;5.2)%; CPV 3.5 (0.0;20.5) mm3, 0.2 (0.0;0.98)%. Based on SPECT CZT results, stress MBF was 1.59 (1.27;1.93) ml/min/g, rest MBF - 0.7 (0.5;0.94) ml/min/g and MFR - 2.26 (1.61;3.01). The Spearman correlation showed that stress MBF had negative relationships with GPVmm3 (ρ=-0.38, p=0.008), GPV% (ρ=-0.35, p=0.01), STPVmm3 (ρ=-0.33, p=0.02), STPV% (ρ=-0.32, p=0.03), FPVmm3 (ρ=-0.35, p=0.02), FPV% (ρ=-0.34, p=0.02). Meanwhile, rest MBF had negative relationships with GPVmm3 (ρ=-0.48, p=0.0005), GPV% (ρ=-0.41, p=0.003), STPVmm3(ρ=-0.5, p=0.0002), STPV% (ρ=-0.52, p=0.0002), FPVmm3 (ρ=-0.47, p=0.0007), FPV% (ρ=-0.41, p=0.003), CPVmm3 (ρ=-0.33, p=0.02), CPV% (ρ=-0.31, p=0.03). Myocardial flow reserve did not have significant association with quantitative CCTA parameters. ***Conclusion:*** Based on dynamic quantitative CCTA data, the structure of atherosclerosis plaques has strong relationships with stress and rest myocardial blood flow in NOCAD patients. ***References:*** 1. Mochula AV, et al. The myocardial flow reserve in patients with heart failure with preserved ejection fraction. Heart Vessels. 2023;38(3):348-360. DOI:10.1007/s00380-022-02161-5.

## EP-0478

### Prognostic value of coronary artery calcifications (CAC) applying a dedicated ECG-gated CT protocol using a hybrid gamma camera in combination with cardiac SPECT performed with a CZT scanner in patients during primary diagnosis of ischemic heart disease.

***M. Chojnowska***, *A. Giżewska, A. Mazurek, M. Dziuk;*
*Military Institute of Medicine - National Research Institute, Warsaw, POLAND.*

***Aim/Introduction:*** In diagnosis of primary coronary artery disease (CAD) both ECG-gated CT with evaluation of coronary artery calcifications (CAC) and cardiac single-photon emission computed tomography (SPECT) are used. However diagnostic value of correlating these two methods is yet to be established. In this study we aim to perform a head-to-head comparison and examine the relationship between those two methods in diagnosis of primary coronary artery disease. ***Materials and Methods:*** We included 50 subjects without previous cardiovascular disease diagnosis who had been referred to our Nuclear Medicine Department for primary CAD diagnostics using cardiac SPECT performed with a CZT scanner. During the day of admission an additional ECG-gated CT with CAC score evaluation was performed. The acquired results were then analyzed based on a number of criteria, including, but not limited to comorbidities, symptoms and demographical data. ***Results:*** During statistical analysis. ***Conclusion:*** According to the current state of knowledge the CAC score and cardiac SPECT results have positive combined diagnostic value, increasing the interpretative certainty. However in our study we focus specifically on the CZT scanner, which combined diagnostic value with the CAC score is yet to be well established. During statistical analysis we also hope to find additional factors (or lack thereof) influencing the correlation. In the future we are planning to rise the number of subjects to 100.

## EP-0479

### Myocardial Extracellular Volume Fraction from Late Iodine Enhancement for Risk Stratification in Non-ischemic Heart Failure

***J. Deng***, *D. Li*;*
*Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, CHINA.*

***Aim/Introduction:*** Our previous study demonstrated that CT-ECV derived from LIE can serve as an excellent alternative to CMR-ECV in noninvasively quantifying diffused myocardial fibrosis. We will further explore the potential of CT-ECV derived from late iodine enhancement (LIE) via using dual-layer spectral detector computed tomography (SDCT) for disease risk stratification in patients with non-ischemic heart failure(NIHF). ***Materials and Methods:*** Eighty-two NIHF patients (52±13 years, 21 female) underwent SDCT. CT-ECV was calculated based on LIE images according to AHA's 16-segmentation. Clinical data of NIHF patients were reviewed and patients were followed up for primary clinical endpoints, the primary clinical endpoint was the first occurrence of a major adverse cardiovascular event (MACE), which included hospital admission for heart failure and all-cause mortality. Receiver operating curve (ROC curve) and area under curve (AUC) were used to evaluate the prediction model. ROC curve and Yoden index determine the optimal cut-off value of CT-ECV. Kaplan-Meier curve and log-rank test were used to analyze the relationship between MACE and CT-ECV of patients with NIHF. ***Results:*** Clinical outcome data were collected from 82 patients with NIHF after a median follow up of 10 months. Final status check was performed during March 2023, and 7 patients lost follow-up. 31 (41.3%) of the 75 patients with MACE, including 28 (37.3%) patients were hospitalized for heart failure, and all-cause mortality occurred in 3 (4%) patients. The ROC curves demonstrated CT-ECV ≥ 31.28 % to be the optimal cut-off point for MACE with 83.9% sensitivity, 75% specificity and the area under the ROC curve = 0.863 (95% CI 0.782 to 0.944). Kaplan-Meier survival curves and Log-rank test demonstrate that NIHF patients with CT-ECV ≥ 31.28% had higher probability of MACE than NIHF patients with CT-ECV < 31.28%. ***Conclusion:*** CT-ECV derived from Late Iodine enhancement can assist in risk stratification in patients with non-ischemic heart failure.

## EP-0480

### First-pass determination of thoracic aortic blood flow rate

***V. Saushkin***, *Y. Varlamova, N. Ryumshina, A. Vrublevsky, D. Panfilov, B. Kozlov, S. Sazonova;*
*Cardiology Research Institute, Tomsk NRMC, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Aneurysm is a common pathology of the aorta and is the 13th leading cause of death in developed countries. The pathological enlargement is located in the ascending aorta (AA) and the aortic arch in more than 60% of cases. Until now, the only criterion for surgical treatment has been the diameter of the ascending aorta (55 mm). Recent studies have shown that an aortic diameter of less than 45 mm is associated with life-threatening complications such as aortic dissection and rupture. The search for new criteria for the assessment of the adverse effects of aortic dilatation is an urgent task. The aim of this work was to calculate the blood flow (BF) rate in the thoracic aorta and compare with the AA diameter, wall elasticity in patients with AA dilatation. ***Materials and Methods:*** We studied 16 patients with AA dilatation. All patients underwent ECG-gated CT angiography and first pass (FP). Experimental evaluation of the mechanical strength of the aortic wall was carried out on a testing machine. The AA wall specimens were stretched to failure. Circular strain (CS), longitudinal deformation (LS), compliance, distensibility aortic wall were calculated by CT. Thoracic aortic BF rate was calculated by FP. Tensile strength index, strain and area under the curve were determined by experimental evaluation. ***Results:*** Decrease of an AA deformation was noted in patients with AA dilatation (CS: 2.78[1.81;6.17] %; LS: 1.23[-2.99;8.30] %). Compensatory increased compliance (2.88[1.45;5.12] $mm^2$/mmHg) and decreased distensibility (0.12[0.03;0.22] %/mmHg) of the AA were also noted in patients with AA dilatation. We revealed a negative correlation (r=-0.59) between tensile strength of the aneurysm wall and patient's age. A moderate positive correlation was found between the mechanical strength of the aorta and its diameter (r=0,65). In addition, there was a moderate decrease in BF rate in the thoracic aorta (455 [445; 618] mm/sec. Strong correlations between BF rate and tensile strength index (r=-0.84) as well as BF rate and AA LS (r=-0.83) were found. Diameter AA and BF rate were not correlated. ***Conclusion:*** The BF rate of the thoracic aorta calculated using the first pass can be used as an additional criterion to assess the negative effects of AA dilatation. Increasing the length and mechanical stiffness of the AA results in a decrease in aortic BF rate. To establish detailed relationships, further research is needed. ## EP-0481

### Unusual discovery of a lipomatous hypertrophy of interatrial septum causing hot spot on 18 fluorodeoxyglucose positron emission tomography: a case report

***T. Ben Ghachem***, *M. Somai, I. Yeddes, I. Slim, A. Mhiri; Salah Azaiez Institute, Tunis, TUNISIA.*

***Aim/Introduction:*** Lipomatous hypertrophy of the interatrial septum (LHIS) is a benign but less recognized pathology of the heart. It is caused by benign fatty infiltration of the interatrial septum which most often spares the fossa ovalis. The importance of this pathology is that there is increased incidence of atrial arrhythmias and sudden cardiac death. ***Materials and Methods:*** We share a case report of A 70-year-old men with no significant past medical history who originally presented with left thigh melanoma with lymph node metastasis. He was treated with surgery: extended excision with inguinal lymph node dissection and immunotherapy. In a short-term follow-up computed tomography (CT) scan showed 3 suspicious pulmonary micronodules. A reassessment whole-body PET-CT was then performed 60 minutes after the injection of 210.9 Megabecquerel (MBq) of 18F-FDG. ***Results:*** 18F-FDG PET/CT revealed intense 18F-FDG uptake, maximum standardized uptake value (SUVmax): 13.3,of the interatrial septum with no suspicious hypermetabolic focus on the rest of the explored volume and in particular within the pulmonary micronodules.Magnetic resonance imaging (MRI) and transoesophageal echocardiography confirmed typical LHIS. ***Conclusion:*** Recognizing LHIS is important to avoid misdiagnosis of cardiac metastases which may lead to unnecessary cardiac surgery or given suboptimal treatment.

### Neuroimagen. Enfoque multimodal para la evaluación de pacientes con enfermedad de Alzheimer leve y terapia neuroprotectora.

***Y. Peña Quián***[1], *L. Pérez*[2], *J. Batista*[1], *L. Torres*[1], *L. Rodríguez*[3], *T. Rodríguez*[2];
[1]*Centro de Isotopos, La Habana, CUBA,* [2]*Center for Molecular Immunology., La Habana, CUBA,* [3]*Hermanos Ameijeiras Hospital, La Habana, CUBA.*

***Aim/Introduction:*** Introduction: Alzheimer's disease (AD) represents a growing health problem. In clinical practice, it is difficult to obtain an early diagnosis and determine the therapeutic stages of this disease.Objective: To evaluate the integration of neuroimaging in a multimodal approach for the early diagnosis and follow-up of patients with AD who received neuroprotective therapy. ***Materials and Methods:*** Multicenter, controlled and randomized clinical trial. 200 patients with possible AD (NIA-AA 2018) were evaluated before and one year after treatment neuroprotective (recombinant human erythropoietin with low sialic acid content) versus placebo. Clinical evaluation, electroencephalogram (EEG), single photon emission computed tomography (SPECT) and magnetic resonance imaging (MRI) were performed. Bilateral posterior temporal-parietal hypoperfusion and the volume of the hippocampus was determined. SPECT/MRI co-registrations were performed. Changes in cerebral perfusion, clinical response, and the results of the techniques were compared. ***Results:*** Early and differential diagnosis: SPECT: Sensitivity 78,2%; specificity 82.8%. Established the differential diagnosis with other neurodegenerative entities. MRI: Sensitivity 71%; specificity 65%. The intensity of cortical atrophy was more precisely determined. SPECT/MRI: Sensitivity 80.8%; specificity of 85.7%. Treatment evaluation: Clinical Evaluation:54% of patients showed significant clinical improvement (FDA criteria). There was a significant difference between treated patients versus placebo(p=0.001).EEG:56,2% of the treated patients stabilized or decreased the EEG alterations versus placebo(p=0.003). SPECT:Neuroprotective group: 61.3% of patients showed increased brain perfusion in previously affected regions. 31.2% presented no perfusion changes and 7.5% had a slight decrease in perfusion. Control group: 0.8% of the patients showed increased brain perfusion in the frontal regions. 33% showed no perfusion changes and the rest had decreased perfusion. Increased brain perfusion was associated with clinical improvement(r=0.98). MRI:42% of the treated patients showed volume increase in the hippocampus. 6% had a decrease in volume. 52% showed no changes. ***Conclusion:*** The integration of neuroimaging in a multimodal approach was useful for early diagnosis and follow-up of patients with AD who received neuroprotective therapy. The increase in cerebral perfusion in the treated patients was associated with clinical improvement. SPECT/MRI improved diagnostic accuracy. The multimodal approach is an important instrument for the identification of AD and its treatments.

### Screening of risk factors influencing the responsiveness of lung metastatic forci of differentiated thyroid cancer under 131I radiotherapies

***W. Muyu***[1], *X. Liu*[2], *C. Liu*[3], *S. Qin*[4], *X. Lin*[1], *W. Shi*[5], *Q. Ding*[3], *X. Zhang*[3], *P. Li*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA,* [2]*Department of General Surgery, Xinqiao Hospital, Army Medical University, Chongqing, CHINA,* [3]*School of Mathematical Sciences, Shanghai Jiao Tong University, Shanghai, CHINA,* [4]*Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of MedicineUniversity, Shanghai, CHINA,* [5]*Department of Nuclear Medicine, Tianjin Medical University General Hospital, Shanghai, CHINA.*

***Aim/Introduction:*** Clinically, patients diagnosed with metastatic differentiated thyroid cancer (mDTC), especially with diffuse metastatic pulmonary forci, are commonly suggested for iodine-131 ($^{131}$I) radiotherapy. However, the therapeutic efficacies

are always challenging to predict due to individual distinctions of different patients. Thereafter, seeking factors influencing the $^{131}$I radiotherapeutic responsiveness of mDTC has always been a pivotal but ambiguous issue in clinical practice. ***Materials and Methods:*** In order to screen the possible key factors influencing the responsiveness of metastatic pulmonary forci of mDTC under iodine-131 radiotherapies, 66 patients with at least 3 continuous $^{131}$I radiotherapies were enrolled from two centers, and 24 features of whom were considered. The feature_importances function in Scikit-Learn Library of Decision Tree and Random Forest (RF) algorithms was employed to achieve the pivotal features with significant influences in responsiveness. Furthermore, receiver operating curves (ROC) and their corresponding area under the curve (AUC values) were illustrated to evaluate the classification efficacies of these two models. Finally, the predict_proba function in Scikit-Learn was utilized to give some detailed predictions and reclassifications of our patients. ***Results:*** We firstly screened 6 and secondly screened 8 crucial factors which mainly dertermine the therapeutic responsiveness of metastatic pulmonary forci of mDTC and their corresponding weighting factors were obtained. The AUC values of RF and Decision Tree algorithms could reach 0.9 and 0.7, respectively and the accuracy, sensitivity and specificity of RF algorithm in testing set was 0.833, 0.800 and 0.833 (with first screened 6 factors); 0.802, 0.963 and 0.483 (with second screened 8 factors). Furthermore, the decision surface verified the accuracy of our models as well. Finally, the programs and softwares were fabricated to give some responsive probability predictions as well as detailed reclassifications of the responsiveness to $^{131}$I radiotherapies. ***Conclusion:*** Our present study results indicate that the screened pivotal features were capable of classifying the responders and nonresponders under $^{131}$I radiotherapies with Decision Tree & RF algorithms and feature_importances function. Meanwhile, further responsive probabilities and reclassification details could be presented via predict_proba function as well. ***References:*** [1] J. Maciel, D. Cavaco, C. Silvestre, J. ### An exploratory study on pathologic molecular characteristics of sestamibi single positron emission computed tomography/computed tomography in predicting primary hyperparathyroidism

***J. Yang***, *X. Su, J. Zhang, W. Weng, P. Zhou;*
*the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

***Aim/Introduction:*** Dual-phase $^{99}$Tc$^{m}$-MIBI SPECT/CT imaging has become a commonly used preoperative diagnostic imaging method for PHPT patients. However, there are many clinicopathological factors that affect the accurate localization of $^{99}$Tc$^{m}$-MIBI SPECT/CT, and the mechanism of $^{99}$Tc$^{m}$-MIBI uptake in lesions is not completely clear at the histopathological and immunohistochemical levels. ***Materials and Methods:*** Single parathyroid pathological specimens of PHPT patients who underwent $^{99}$Tc$^{m}$-MIBI SPECT/CT imaging and surgery in our institution from August 2017 to December 2020 were retrospectively analyzed. Correlation analysis and multivariate regression analysis were performed for the length and diameter of the lesion, the ratio of eosinophils, the expression of proliferating cell nuclear antigen (PCAN) and P-glycoprotein (P-gp) in the nucleus and cell membrane of the lesion and the $ROI_{T/NT}$ value of the lesion in dual-phase $^{99}$Tc$^{m}$-MIBI SPECT/CT imaging. ***Results:*** A total of 146 PHPT patients with complete clinicopathological data and a single lesion were included in this study, with an average age of 55±12 years, 69.2% of whom were female. The average length of the lesions was 20.5±10.4 mm. Oxyphil cells were scattered, localized and diffused in the lesions, accounting for different proportions of oxyphil cells, ranging from 0 to 99.6%, among which no oxyphil cells were found in 27.4%. PCNA and P-gp were expressed in the nucleus and cell membrane of parathyroid tissues to different degrees. The average IOD/area value (IOD, Intergrated Optical Density) of PCNA was 0.25 (range: 0.04-0.48), and the median IOD/area value of P-gp was 111.12 (range: 0.82-2362.67). 129 lesions of 146 patients in $^{99}$Tc$^{m}$-MIBI SPECT/CT, which was consistent with the intraoperative results, the average $ROI_{T/NT}$ was 6.99 (range: 1.32-26.15). The length diameter of the parathyroid gland (r=0.041, p=0.014) and the proportion of eosinophils (r=0.119, p=0.0) were positively correlated with the $ROI_{T/NT}$ value, and there was no correlation between PCNA (p=0.233) and P-gp (p=0.979) expression and the $ROI_{T/NT}$ value. Multivariate regression analysis showed that IOD/area values of the long diameter (p=0.047, OR=3.93) and P-gp expression levels (p=0.0, OR= 9.50) were independent factors to predict negative imaging. ***Conclusion:*** This study was found that the size of the parathyroid gland and eosinophil ratio of lesions were positively correlated with the $ROI_{T/NT}$ value of $^{99}$Tc$^{m}$-MIBI SPECT/CT, while the size of lesions and P-gp expression were risk factors for negative $^{99}$Tc$^{m}$-MIBI SPECT/CT imaging. $^{99}$Tc$^{m}$-MIBI SPECT/CT can provide an important basis for clinicians to predict the pathological molecular features of lesions.

## EP-0485

### Graves' disease: do TRAb measurement help predicting thyroid radioiodine uptake?

***I. Casimiro***, *G. Costa, R. Silva;*
*Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.*

***Aim/Introduction:*** Graves' disease (GD) is an autoimmune disorder clinically characterized by thyrotoxicosis due to the production of autoantibodies against thyrotropin-receptor (TRAb), which continuously activate the TSH receptor (TSH-R). This condition can be successfully treated with radioactive iodine-131 (RAI), administered as Na[$^{131}$I]I. A theranostic approach can help to personalize this treatment modality, being the 24-hour thyroid RAI uptake (24h%RAIU) a valuable functional parameter for therapeutic activity estimation (easily obtained from a diagnostic test with Na[$^{131}$I]I). Knowing that the RAI thyroid follicular cell uptake depends on the activation of the TSH-R, is reasonable to expect a positive correlation between TRAb and 24h%RAIU. This study aims to verify, in our population of GD patients submitted to RAI thyroid test in the last decade in our department, if there is a relationship between TRAb titer and 24h%RAIU. The relationship between TRAb titer and the TSH levels and the thyroid mass was also evaluated. ***Materials and Methods:*** We retrospectively reviewed the clinical file of all GD patients referred to our department for treatment with Na[$^{131}$I]I, between January-2012 and December-2021. We selected the 250 patients who had blood measurements of TSH and TRAb within 6 months before RAI therapy was planned with a diagnostic test using Na[$^{131}$I]I. The 24h%RAIU and the thyroid mass estimation based on scintigraphic imaging were recorded. Conducting a non-parametric test, we calculated the Spearman's

Rank correlation coefficient between TRAb values and 24h%RAIU, TSH levels and gland mass of the corresponding patients. ***Results:*** We found a statistically significative (p<0.001) moderate negative correlation between TRAb and TSH values (ρ=-0,454). Also, there was a statistically significative (p<0.001) weak positive correlation between TRAbs levels and thyroid gland mass (ρ=0,240). Concerning the RAI thyroid uptake, we observed that 82% of patients had a 24h%RAIU>50%. Besides that, we found a very weak positive correlation between TRAbs levels and 24h%RAIU (ρ=0,144) that was statistically significative (p=0,023). ***Conclusion:*** Our study showed that even though elevated TRAbs are frequently used to diagnose GD, the elevation of these antibodies is a poor predictor of the gland mass or its iodine uptake at 24h, as the correlation with these variables is weak and very weak, respectively. Concerning TSH levels, we found a moderate negative correlation with TRABs, confirming the commonly observed low TSH level in hyperthyroidism patients.

## EP-0486

### Does the hypothalamus-pituitary-adrenal axis play a role in the difference in treatment response to GLP-1 receptor agonists in type 2 diabetes?

***S. Tokgöz***[1], *T. J. P. Jansen*[1], *R. Meijer*[2], *C. Frielink*[1], *C. J. Tack*[2], *B. E. de Galan*[2,3], *M. Gotthardt*[1], *M. Boss*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of Internal Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [3]*Department of Internal Medicine, Maastricht University Medical Center, CARIM School for cardiovascular diseases, Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Glucagon-like peptide-1 receptor agonists (GLP-1RA) are potent antidiabetic drugs for treatment of type 2 diabetes (T2D), but up to 20% of all individuals with T2D are partly or completely unresponsive to treatment with GLP-1RAs. Besides the insulinotropic effects on pancreatic beta cells, GLP-1RAs can stimulate the hypothalamic-pituitary-adrenal (HPA) axis, inducing cortisol secretion. Cortisol is pro-diabetogenic, which is associated with weight gain and insulin resistance. We thus hypothesized that this effect could be at the root of unresponsiveness to GLP-1RA treatment. To investigate this, we used PET/CT imaging with a radiolabeled stable GLP-1 analogue ([$^{68}$Ga]Ga-NODAGA-exendin-4) to quantify GLP-1R expression in the pituitary of individuals with T2D with (responders) and without (non-responders) an adequate response to GLP-1RA treatment and assessed the downstream effects on the HPA axis. ***Materials and Methods:*** The responder and non-responder groups were defined based on the level of HbA1c and weight loss after a maximum of one year of GLP-1RA treatment. Both responders (n=10) and non-responders (n=8) underwent an oral glucose tolerance test, HPA axis stimulation test, 24h urine collection to assess baseline cortisol levels and a 60 min dynamic PET/CT scan of the brain after infusion with 100±5 MBq of [$^{68}$Ga]Ga-NODAGA-exendin-4. The maximum standardised uptake value ($SUV_{max}$) between 45 and 60 min was used to quantify GLP-1R expression. ***Results:*** Our data showed tracer uptake in the pituitary in all individuals with T2D, which did not significantly differ between responders and non-responders ($SUV_{max}$ 2.7±1.0 vs 3.2±1.3, p=0.41). However, when analysing the entire study population (n=18), we found significant interindividual differences in pituitary GLP-1R expression (25$^{th}$ vs 75$^{th}$ percentile of $SUV_{max}$: 1.8±0.19 vs 4.5±0.75, p<0.001). No significant differences were observed in beta cell function ($AUC_{C\text{-}peptide}$ p=0.44; $AUC_{C\text{-}peptide}$:$AUC_{glucose}$ ratio p=0.26) and hormones related to HPA axis stimulation ($AUC_{ACTH}$ p=0.47; $AUC_{cortisol}$ p=0.18) between responders and non-responders. Pituitary tracer uptake did not correlate to BMI ($R^2$=0.00053, p=0.93), beta cell function ($AUC_{C\text{-}peptide}$ $R^2$=0.074, p=0.32; $AUC_{C\text{-}peptide}$:$AUC_{glucose}$ ratio $R^2$=0.051, p=0.42) and hormones related to the HPA axis ($AUC_{ACTH}$ $R^2$=0.10, p=0.23; $AUC_{cortisol}$ $R^2$=0.010, p=0.71). ***Conclusion:*** Our data do not indicate a role of pituitary GLP-1R expression and HPA axis stimulation in the difference in treatment response to GLP-1RA among individuals with T2D. The origin of these differences in treatment response thus remains unclear. The substantial tracer uptake with significant interindividual differences that we observe does point to a potential role of GLP-1R in the pituitary, which requires further elucidation.

## EP-0487

### 68Ga-NODAGA-exendin4 PET-CT Imaging of Pancreatic Beta Cells: Preliminary Data in Type 1 Diabetic Patients and in Obese People

***L. Ruffini***[1], *M. Scarlattei*[1], *G. Ladisa*[1], *S. Migliari*[1], *G. Baldari*[1], *V. Spigoni*[2], *R. Aldigeri*[2], *G. Cinquegrani*[2], *A. Dei Cas*[2], *R. Bonadonna*[2];
[1]*Nuclear Medicine Division, University Hospital of Parma, Parma, ITALY,* [2]*Dept of Medicine & Surgery, University of Parma, Parma, ITALY.*

***Aim/Introduction:*** PET scans of radioactive exendin-4, a ligand of the GLP-1 receptor (GLP1R) expressed on the β-cell surface, have been proposed to provide a tentative quantitative in vivo biomarker of pancreatic β-cell mass. Throughout 2020-2022 we developed and validated a fully automated radiosynthesis of 68Ga-NODAGA-exendin4 (68Ga-Ex4) with high specific activity, and subsequently, we optimized a PET-CT scan method to assess 68Ga-Ex4 uptake by pancreatic endocrine cells. Aim of this work was to assess the performance of 68Ga-Ex4 PET-CT in a clinical study of patients with long standing type 1 diabetes (T1DM) and of obese people (OB). ***Materials and Methods:*** The synthesis of 68Ga-Ex4 was performed using an automated synthesis module (Scintomics GRP®) connected to a GMP-certified 68Ge/68Ga generator (GalliaPharm®) as previously described [Migliari et al. Molecules 2022].The radiopharmaceutical was administered i.v. over 5 minutes after an overnight fast. Blood pressure, heart rate, blood glucose were measured before tracer injection and at each image time point. Soon after tracer injection dynamic images were acquired over 20 minutes (one bed on pancreatic/cardiac region). Whole body PET/CT was performed 60' post injection. Semiquantitative analysis of tracer uptake was performed using spherical volumes of interest (VOIs) semi-automatically drawn on the pancreatic head, body and tail to measure SUVmax and SUVmean at each time point. ***Results:*** Eight patients (age 50±4 yrs; BMI 26.6±1.9 kg/m2) with long standing (34±3 yrs) T1DM (HbA1c: 58±4 mmol/mol) and 8 OB subjects (age 49±2 yrs; BMI 37.4±2.1 kg/m2) were injected with 68Ga-Ex4 (mean dose 117.44 MBq). Mean RCP%, RCY% and Am of the produced radiopharmaceutical were 97.50%, 49.29%, and 259.05 GBq/umol respectively; mean peptide amount was 2.66 ug. Average SUVmean of the whole pancreas at 20' (grouped dynamic images) was 3.4±0.8 in T1DM and 5.0±0.5 in OB (p=0.0115); 1.9±0.8 in T1DM and 3.7±1.1 in OB at 60' (p=0.0025). Average SUVmax was 4.7±1.3 in T1DM and 7.5±1.0 in OB at 20' (p=0.0008); 3.1±1.1 in T1DM and 5.8+1.4 in OB at 60' (p=0.0011). Renal uptake was intense at both time points (average SUVmax and SUVmean 88.5±20, 55.2±13.8). No side effects were registered. ***Conclusion:*** 68Ga-Ex4 allows to visualize pancreatic GLP1R expression capturing quantitatively different pattern of receptor engagement. The fully automated production of high specific activity 68Ga-Ex4 remains reproducibile and accurate for routine use. Next steps to improve 68Ga-Ex4 imaging

will be correction of quantitative measures for renal excretion. ***References:*** Migliari S. Molecules 2022 PMID:35056858; Migliari S. Curr Radiopharm. 2022 PMID:33687908

## EP-0488

### Role of 68Ga DOTANOC PET/CT In Localisation of Culprit Ectopic ACTH Secreting Tumors

***R. Kumar***, *S. Sagar, D. Khan, R. Khadgawat;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Ectopic Cushing's syndrome (ECS) or ectopic ACTH syndrome, accounts for 10-15% of the cases of Cushing's syndrome. We aim to evaluate the role of $^{68}$Ga DOTANOC PET/CT in localisation of culprit ectopic ACTH secreting tumors. ***Materials and Methods:*** All consecutive patients with clinical evaluation suggestive of EAS, referred to our department for $^{68}$Ga DOTANOC PET/CT from 2017 to 2022, were evaluated retrospectively. All patients were injected 3-4mCi of $^{68}$Ga DOTANOC intravenously and underwent whole body PET/CT 40-60 minutes post-injection, on either Biograph mCT PET/CT, Siemens or Discovery 710 PET/CT, GE. Scanned images were interpreted by two nuclear physicians independently with an experience of 3-20 years. $^{68}$Ga DOTANOC PET/CT findings were corroborated with clinical details. ***Results:*** Over the study period, 50 (29 females (58%) and 21 males (42%) patients having mean age of 32.41(range-13 to 69 years) with ECS underwent $^{68}$GaDOTANOC PET/CT .$^{68}$GaDOTANOC identified the suspected primary ECS in 14 out of 50 patients (28%). Of these, six patients had increased SSTR expression in lungs with another four patients having increased SSTR expression in different lymph nodes. Other two patients had adrenal lesion causing ECS. Out of the remaining two out of 14, one had increased SSTR expression at fourth inter costal space and other had at third part of duodenum. These fourteen patients had a mean SUVmax of 10.97(95%CI= 5.30-16.64) compared to background mean SUVmax of 0.80 (95%CI= 0.35-1.25). ***Conclusion:*** Our study reinforces the role of $^{68}$Ga-DONANOC PET/CT to localise ectopic ACTH secreting tumors in appropriate clinical settings. In the future, advances in imaging techniques will improve the identification of small occult NETs and thus allow their removal, thereby further limiting the time bound complications of hypercortisolism.

## EP-0489

### Short 4D 18F-Fluorocholine PET/CT for hyperparathyroidism: A new tool for hyper-functional parathyroid finding ?

***A. CALLAUD***[1], *M. Bailly*[2], *G. Metrard*[2];
[1]*CHR, Orléans, FRANCE,* [2]*CHRU Orléans, Orléans, FRANCE.*

***Aim/Introduction:*** In primary hyperparathyroidism, preoperative imaging is essential for diagnosing hyper-functional parathyroid(s), and 18F-Fluorocholine (FCH) PET can be used in addition to ultrasound and scintigraphy. However, 18F-FCH PET protocol lacks standardization. An alternative modality is 4D-CT, but it appears to be less sensitive. Combining the two modalities has succinctly been tried, with discordant result and seems to be irradiating and complex. In this preliminary work we propose a simplified approach using a "short 18F-FCH 4D PET/CT" with 2 CT acquisitions and an early 18F-FCH PET acquisition only (at 5 minutes) for detection of hyper-functional parathyroid, and evaluate its performance compared to full dual time point 18F-FCH PET/CT. ***Materials and Methods:*** Dual time point 18F-FCH PET exams with 2 low-dose CT (non-enhanced and contrast-enhanced) were retrospectively collected and blindly analyzed. For each patient, operative and histopathological analysis reports were fully available and used as a reference. Exams were read separately by two nuclear medicine physicians. Patients were classified into four diagnosis categories: adenoma, multi-glandular disease, negative, or non-conclusive. Each exam was read twice, first with the early PET acquisition and non-enhanced CT (and immediately after with the late PET acquisition) and 2 weeks after with the early PET acquisition alone and contrast enhanced CT ("4D-CT"). ***Results:*** Between May and October 2022, 25 patients were included, 18 women, 7 men, mean age 68.2 Y (41-81), mean BMI 27.4 kg/m2 (18-69). 18F-FCH PET accuracy rates for diagnosis were respectively: 78%, 80% and 88% for early acquisition only, dual-time PET, and short 4D-PET/CT. Adding contrast-enhanced CT seemed to reduce false positive foci detection, without reducing the excellent sensibility of 18F-FCH PET for foci detection that were almost identical for the 3 readings. ***Conclusion:*** Thus, short 4D 18F-FCH PET/CT not only saved time for the patient and the system, but also appears to have better global performance than dual time point FCH PET. Our preliminary results indicate that short 4D PET/CT might be a relevant "all-in-one" pre-surgical imaging modality, fitting perfectly in the hybrid imaging era. Further analysis (such as reproducibility and more patients) are needed. It should also be compared directly to other imaging modalities to compare its performances.

## EP-0490

### Detection of hyperfunctioning parathyroid glands using 18F-choline PET/CT in patients with negative or equivocal results of the complex 99mTcO4/99mTc-MIBI scintigraphy (including SPECT/CT)

***P. Koranda***[1], *L. Quinn*[1], *M. Jenčo*[1], *J. Klacanek*[1], *M. Halenka*[2], *M. Mocňáková*[3], *M. Kamínek*[1];
[1]*Dept. of Nuclear Medicine, Univ. Hospital and Palacký University, Olomouc, Olomouc, CZECH REPUBLIC,* [2]*Dept. of Internal Medicine III, Univ. Hospital and Palacký University, Olomouc, Olomouc, CZECH REPUBLIC,* [3]*Dept. of Surgery II, Univ. Hospital and Palacký University, Olomouc, Olomouc, CZECH REPUBLIC.*

***Aim/Introduction:*** To assess the diagnostic value of $^{18}$F-choline PET/CT in cases where complex scintigraphy (combining $^{99m}$TcO4/$^{99m}$Tc-MIBI subtraction including $^{99m}$TcO4 washout using perchlorate - to eliminate patient´s displacement between scans, $^{99m}$Tc-MIBI SPECT/CT, and two-phase evaluation of $^{99m}$Tc-MIBI scintigraphy) yields negative or equivocal results. ***Materials and Methods:*** A retrospective analysis was performed on a cohort of 35 patients (pts.) who underwent $^{18}$F-choline PET/CT. Previous complex scintigraphy results were negative in 18 cases, equivocal in 9 cases. Scintigraphic findings were highly suspicious and required verification in 6 cases, and 2 cases were not evaluated with $^{99m}$Tc-MIBI due to claustrophobia. The $^{18}$F-choline PET/CT findings were classified as positive (21 pts.), negative (7 pts.), or equivocal (7 pts.), ***Results:*** $^{18}$F-choline PET/CT detected enlarged parathyroid tissue in 8 out of 18 scintigraphically negative patients (44%), 5 out of 9 cases with equivocal scintigraphy findings, and in both claustrophobic patients. Among the subset of patients from these three groups who could not be indicated for targeted surgical intervention based on scintigraphy, 15 out of 29 cases (52%) had successful localization of parathyroid tissue using $^{18}$F-choline PET/CT. All 6 cases referred for verification of highly suspicious scintigraphy findings were confirmed by $^{18}$F-choline PET/CT. In 7 cases, $^{18}$F-choline PET/CT findings were classified as equivocal, and 3 surgeries were performed (2 false positives, 1 true positive). Seven times the PET/CT finding was interpreted as negative. ***Conclusion:*** Although the detection rate in our cohort of patients is lower than in published studies [1], it is evident that

$^{18}$F-choline PET/CT is beneficial in cases of suspected primary or tertiary hyperparathyroidism when $^{99m}$TcO4/$^{99m}$Tc-MIBI SPECT/CT findings are negative or equivocal. The reason for relatively lower $^{18}$F-choline PET/CT yield in our group of patients may be related to the very complex performance of previous $^{99m}$TcO4/$^{99m}$Tc-MIBI scintigraphy (including CT as a part of SPECT/CT). This complexity could be a prerequisite for efficient detection of enlarged parathyroid tissue using scintigraphies (in accordance with the article [2]). In cases of equivocal $^{18}$F-choline PET/CT findings, there is an increased risk of false positive results. ***References:*** [1], Quak E, et al. Detection, resection and cure: a systematic review and meta-analysis od 18F-choline PET in primary hyperparathyroidism. ## EP-0491

### [$^{18}$F]Fluorocholine PET-CT in Preoperative Localization of Hyperfunctioning Parathyroid Glands: Continuing to Strengthen the Evidence

***S. Casanueva Eliceiry***[1,2], *N. Sánchez Izquierdo*[2,1], *A. Niñerola-Baizán*[2,1], *M. Manyalich-Blasi*[1,3], *P. Domínguez-Garijo*[1,3], *M. Mora-Porta*[1,3], *F. Hanzu*[1,3], *M. Rodrigo-Calvo*[1,4], *S. Vidal-Sicart*[2,1], *O. Vidal-Pérez*[1,3], *D. Fuster-Pelfort*[2,1];
[1]*Hospital Clínic Barcelona, Barcelona, SPAIN,* [2]*Instituto de diagnótico por la imagen CDI, Barcelona, SPAIN,* [3]*Instituto Clínic de Enfermedades Digestivas y Metabólicas (ICMDM), Barcelona, SPAIN,* [4]*Centro de Diagnóstico Biomédico (CDB), Barcelona, SPAIN.*

***Aim/Introduction:*** Primary hyperparathyroidism (pHPT) is a relatively common endocrine disorder in which one or more parathyroid glands (PTG) secrete excess amounts of parathyroid hormone (PTH), with surgery being the only curative treatment. Minimally invasive parathyroidectomy (MIP) is the preferred approach, wherein preoperative localization of hyperfunctioning parathyroid tissue (HFPT) is crucial. In this regard, $^{99m}$Tc-MIBI parathyroid scintigraphy has already proven to be useful and is currently established as the standard preoperative imaging modality in many centers worldwide. However, there has been a steadily increasing interest in using [$^{18}$F]Fluorocholine, a positron emission tomography (PET) radiotracer, for preoperative localization of HFPT, particularly in situations where conventional techniques had failed. The aim of this study was to determine the efficacy of [$^{18}$F]Fluorcholine PET-CT (FCH) in locating HFPT and to compare it with that of $^{99m}$Tc-MIBI SPECT-CT (MIBI). ***Materials and Methods:*** Retrospective observational study. A total of 90 consecutive pHPT patients who underwent MIP were included. Both MIBI and FCH imaging modalities were used for preoperative evaluation. MIBI images were acquired 90 minutes post-injection of 24 mCi (888 MBq) $^{99m}$Tc-MIBI. FCH images were obtained 60 minutes after the injection of 5.4-10 mCi (200-370 MBq) [$^{18}$F]-Fluorocholine. Regional focal uptake not associated with thyroid disease was considered positive for HFPT. Images were analyzed by a Nuclear Medicine specialist and a resident in training. Pathology reports from resected PTG were compared to findings from both imaging modalities and served as the gold-standard. The diagnostic performance of both imaging modalities was calculated and compared using McNemar's test, with statistical significance set at P<0.05. The cure of pHPT was defined as a reduction of 50% or greater in postoperative serum PTH. ***Results:*** A total of 92 PTG were resected, comprising 86 adenomas, 5 hyperplasias and 1 lipo-adenoma. On a gland-based analysis, FCH presented higher diagnostic performance compared to MIBI; with sensitivity, positive predictive value and accuracy rate of 96.7%, 100% and 95.7% vs. 69.5%, 100% and 70.2%, respectively (P<0.001). 84 patients had follow-up data on PTH. Biochemical criteria for cure was met in 76.1%(64/84) and was correctly located by FCH and MIBI in 100%(64/64) and 71.8%(46/64), respectively. ***Conclusion:*** FCH demonstrated superior diagnostic performance compared to MIBI, and was able to accurately characterize all patients that met the cure criteria. These findings support the promising role of FCH in the preoperative setting of pHPT.

## EP-0493

### Diagnostic and Prognostic Value of [18F]F-DOPA PET/CT for Medullary Thyroid Cancer

***S. Li***, *E. Rainer, S. Rasul, L. Hargitai, P. Riss, C. Scheuba, M. Hacker; Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Correct diagnosis and prognostic evaluation of medullary thyroid cancer (MTC) are crucial for the therapy of MTC. The purpose of this study was to evaluate the diagnostic and prognostic value of [$^{18}$F]F-DOPA PET/CT in patients with MTC. ***Materials and Methods:*** [$^{18}$F]F-DOPA PET/CT examinations of 60 patients with histologically verified MTC were analysed. Serum basal calcitonin (bCt) and stimulated calcitonin (sCt) as well as CEA were determined. The diagnostic value of PET/CT for detection of tumour lesions were calculated. Overall survival (OS) was estimated using the Kaplan-Meier method. ***Results:*** 53 of 60 patients had positive [$^{18}$F]F-DOPA PET scans with a sensitivity of 88 % and specificity of 100 %. The lesion-related sensitivity of [$^{18}$F]-F-DOPA PET was 96 % (308 of 320 lesions). Significant correlations were found between bCt, sCt and CEA with [$^{18}$F]F-DOPA-uptake (SUVmax, $p < 0.01$). Patients with negative [$^{18}$F]F-DOPA PET had longer survival than patients with positive [$^{18}$F]-F-DOPA-PET results. ***Conclusion:*** High sensitivity and specificity of [$^{18}$F]F-DOPA PET were shown for evaluation of MTC. The uptake of [$^{18}$F]-F-DOPA in tumour lesions correlates significantly with bCt, sCt and CEA. [$^{18}$F]F-DOPA PET/CT may be of great value for diagnosis and prognostic assessment in patients with MTC.

## EP-0494

### Correlation between SUVmax and analytical values in patients with primary hyperparathyroidism undergoing 18F-choline PET/CT

***E. Rodriguez Gallo***[1,2], *C. Wakfie Corieh*[1,2], *A. Fernandez Alfonso*[1,2], *A. Álvarez Vázquez*[1,2], *E. Jodar Gimeno*[1,2], *B. Pérez-Arroyo*[1,2], *J. Martín Gil*[3], *A. Maldonado*[1,2];
[1]*Hospital Universitario QuironSalud Madrid, Madrid, SPAIN,* [2]*Universidad Europea, Madrid, SPAIN,* [3]*Hospital Quirónsalud San José, Madrid, SPAIN.*

***Aim/Introduction:*** To establish the correlation between the standard uptake value (SUV) and the parathyroid hormone (PTH), serum calcium and ionic calcium in patients diagnosed with primary hyperparathyroidism undergoing $^{18}$F-choline PET/CT as an adenoma localisation test. ***Materials and Methods:*** A retrospective analysis of 111 patients with primary hyperparathyroidism undergoing 18F-choline PET/CT between October 2015 and March 2023 was performed; PTH, serum calcium and ionic values were obtained for the month prior to PET/CT. Patients with no blood tests and in absence of parathyroid adenoma were excluded. On the day of the scan, 150 µCi/kg of $^{18}$F-choline was injected, images were acquired at 20 (with intravenous contrast administration) and 60 minutes; a visual and semi-quantitative analysis with SUVmax measurement was

performed once the adenoma was located on both images. The Statistical Package for the Social Sciences (SPSS) 25.0 was used for the statistical analysis. Not all variables showed a normal distribution, so non-parametric statistics were used. Statistical significance was defined as $p < 0,05$. It was decided to use the SUVmax of the late image as the reference value. Non-parametric bivariate analysis was performed to detect influential factors on SUVmax. Spearman's correlation coefficient and scatterplot were used as graphical representation. A linear regression was carried out to analyse the relationships between variables, using the r-squared coefficient and the equation of the model. ***Results:*** Assessing the results of the Spearman's correlation between SUVmax and PTH values, it is observed that there is a direct correlation between both variables, statistically significant ($p< 0.05$). With respect to serum calcium and ionic calcium values, these correlations are also direct, but not statistically significant. An indirect correlation was observed between SUVmax and age, which, although not statistically significant, may be a variable to consider in future studies. ***Conclusion:*** There is a positive correlation between the SUV value of parathyroid adenoma on $^{18}$F-choline PET/CT and the analytical value of PTH. These data may be useful in further studies to evaluate their relationship with pathological anatomy in patients undergoing parathyroidectomy.

## EP-0495

### Impact of digital [18F] Fluorocholine (FCH) PET/CT reconstruction technique on detection rate, reader confidence and agreement in localisation of parathyroid adenomas in persistent/ recurrent primary hyperparathyroidism

***M. Naik****, C. Ferguson, S. Lazic, A. Eccles, S. Khan, S. Khan, F. Palazzo, K. Houghton, T. D. Barwick;*
*Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** In persistent or recurrent primary hyperparathyroidism, (PHPT) parathyroidectomy remains the only cure. However, redo-surgery is has higher complication and failure rates; thus accurate localisation is essential. Reported detection rates of [18F] Fluorocholine (FCH) PET/CT for persistent and recurrent pHPT are 58-65% using previous-generation PET/CT scanners. Digital silicon-photomultiplier (SiPM) PET/CT scanners offer higher spatial resolution and coincidence time resolution. Post-reconstruction smoothing filters reduce noise and improve image quality, but may decrease lesion contrast and reduce conspicuity of small lesions. (1,2)We aimed to assess differences in detection rates, diagnostic confidence and level of lesion uptake using three reconstructions (Gaussian 6.0, Gaussian 4.5 and unfiltered All Pass) on a digital PET/CT scanner. We also assessed inter-observer agreement. ***Materials and Methods:*** Single-centre retrospective observational study of consecutive persistent/recurrent pHPT (n=29) patients undergoing FCH PET/CT on a digital scanner.Two expert, two moderately experienced, and two inexperienced readers independently reviewed randomised anonymised reconstructions with at least one week washout between each set of reads.Three expert reviewers agreed a consensus for detection rates for each reconstruction. ***Results:*** Detection rates were 51%, 72%, and 86% for Gaussian 6.0, Gaussian 4.5, and All Pass reconstructions respectively. Diagnostic confidence for positive lesion detection was highest with the All Pass reconstruction. Median SUVmax for detected lesions was 3.5, 4.1, and 6.1 for Gaussian 6.0, Gaussian 4.5, and All Pass reconstructions respectively. Inter-observer agreement was high between expert ($\kappa \geq 0.65$) and moderate readers ($\kappa \geq 0.67$) across all reconstructions. For inexperienced readers, highest agreement was observed when using the unfiltered All Pass reconstruction ($\kappa=0.93$) compared to traditional Gaussian filtering. ***Conclusion:*** Digital smoothing reconstructions impact detection rate, diagnostic confidence and SUVmax in localisation of parathyroid adenomas using FCH PET/CT. Detection rates and diagnostic confidence are highest with the All Pass reconstruction, outperforming previously reported rates utilising previous-generation PET/CT scanners. ***References:*** (1) Performance Characteristics of the Digital Biograph Vision PET/CT System. van Sluis J, de Jong J, Schaar J, Noordzij W, van Snick P, Dierckx R, Borra R, Willemsen A, Boellaard R. ## EP-0496

### Utility of 18F-fluorocholine PET/CT in the management of primary hyperparathyroidism: our experience.

***M. Sicilia Pozo****[1], V. Poblete García[1], A. Padilla Bermejo[1], C. Lucas Lucas[1], M. Contreras Ameduri[1], L. García Zoghby[2], M. Cruz Montijano[2], F. J. Pena Pardo[1], M. P. Talavera Rubio[1], E. Noriega Álvarez[1], A. M. García Vicente[2], Á. Soriano Castrejón[2];*
*[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department, University General Hospital of Toledo, Toledo, SPAIN.*

***Aim/Introduction:*** To assess the utility of 18F-fluorocholine PET/CT in the management of primary hyperparathyroidism with negative parathyroid scintigraphy and its association with parathyroid hormone (PTH) level. ***Materials and Methods:*** Retrospective study including successively patients who underwent a 18F-fluorocholine (FCH) PET/CT scan, from June 2019 to November 2022, for diagnostic suspicion of primary hyperparathyroidism, with prior negative localization imaging techniques, including at least a negative parathyroid scintigraphy. We collected clinical variables and PTH level, to evaluate their association with the result of FCH PET/CT scans using Pearson's chi-square test and Spearman's rank correlation coefficient. Additionally, we evaluated the association between FCH PET/CT and surgery results by Fisher's exact test, in those patients that underwent parathyroid surgical intervention in the follow-up. ***Results:*** The cohort included 122 patients (86 women), with a mean age of 60 ± 13.7 years. FCH PET/CT scans were positive for hyperfunctioning parathyroid tissue in 53/122 patients. The median PTH level was 119 pg/ml (41-1899). In the follow up, 28 patients went under surgery, 22 of them with positive result in the FHC PET/TC scan. In 2/6 patients operated with negative FHC PET/CT, no parathyroid adenoma was found. PTH level and FCH PET/CT positivity showed a statistically significant correlation ($0.385$, $p < 0.001$), with stronger association in the patients that underwent surgery, with a Spearman's coefficient of $0.507$ ($p = 0.006$). We found better results in patients with FCH PET-guided surgery, with a statistically significant association between histopathological confirmation and FCH PET/CT positivity ($p = 0.04$). No other significant association was found. ***Conclusion:*** FCH PET-guided surgery shows utility in patients with suspected primary hyperparathyroidism and previous negative imaging techniques, with better results in those patients with higher PTH level.

## EP-0497

### Role of 18F-DOPA PET/CT imaging in patients with Hyperinsulinemic Hypoglycemia(HI)

***S. Sagar***, *N. A. Damle, D. Khan, P. Kumar, C. Bal, M. Tripathi, R. Sharma, V. Jain, M. Jana, N. Tandon;*
*AIIMS, Delhi, INDIA.*

***Aim/Introduction:*** Hyperinsulinemic hypoglycaemia(HI) is a rare but life threatening disease. $^{18}$F-DOPA, is known to be useful modality in the localization of focal pancreatic lesions in these patients. We aimed to assess the role of $^{18}$F-DOPA in this disease at our institution. ***Materials and Methods:*** $^{18}$F-DOPA scans and clinical details of 10 adults and 22 children with clinical diagnosis of HI were reviewed. Scans were acquired 30-45 min post-injection of 2-3 mCi of $^{18}$F-DOPA (without carbidopa premedication). The scans were acquired on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE). Only abdominal spot images over 1-2 bed positions were acquired for $^{18}$F-DOPA. Additional early images were acquired for adult patients at 5min post injection. ***Results:*** A total of 10 adults and 22 children were included in the study. Out of 22 children (9 female and 13 male), 14 were infants. The age of the children ranged from 1 month to 8 years. Sixteen children had undergone genetic analysis, 13 were positive for ABCC8, 1 for GLUD-1, 1 for GCK mutations and 1 had not showed any mutation. $^{18}$F-DOPA PET/CT scan showed 5 focal pancreatic lesions in 5 children (1 in each), two focal lesions in 1 child and diffuse pancreatic uptake in 16 children. Of the 13 ABCC8 mutation positive children, $^{18}$F-DOPA PET scan showed focal pancreatic lesion in 5 (38.4%) and diffuse uptake in 8. Of the 7 children who inherited ABCC8 paternal monoallelic recessive mutation, 5 (71.4%) were having focal pancreatic lesions on $^{18}$F-DOPA PET scan. One child with GLUD-1 mutation showed multifocal pancreatic uptake, 1 with GCK mutation showed diffuse pancreatic uptake and one child with no mutation on gene analysis showed mild diffuse uptake on PET scan. However, in 6 children with unknown mutation status, $^{18}$F-DOPA scan showed diffuse uptake. Out of 10 adults underwent $^{18}$F-DOPA PET/CT scan between 2017 to 2023 at our institution. Our results showed diffuse uptake in all 10 patients. Of these 10 patients only one underwent surgery with HPE corroboration of scan findings, other 9 patients on follow up were undergoing medical management. ***Conclusion:*** In children with persistent hyperinsulinemic hypoglycemia, 18F-DOPA PET/CT is an effective method for identifying focal pancreatic lesions but in adults without Carbidopa premedication it doesn't appear useful, and early imaging doesn't substitute for this deficiency. The detection rate is particularly high in paediatric patients with a paternal monoallelic recessive gene mutation in ABCC8.

## EP-0498

### Efficacy of F-18 Fluorocholine PET/CT in detection of culprit lesions in normocalcemic & hypercalcemic primary hyperparathyroidism: Does it differ?

***R. Wakankar***, *N. A. Damle, Y. Dharmashaktu, A. Khurana, P. Kumar, C. Bal, M. Tripathi, S. Agarwal, N. Tandon, R. Khadgawat;*
*AIIMS, New Delhi, INDIA.*

***Aim/Introduction:*** Some patients with primary hyperparathyroidism (pHPT) remain normocalcemic, however, they are susceptible to the adverse effects of pHPT. There is paucity of literature in assessing the role of F-18 Fluorocholine (FCH) PET/CT in this subgroup of patients. We aim to compare the efficacy of FCH PET/CT in localization of culprit lesions in patients of normocalcemic pHPT as compared to hypercalcemic pHPT. ***Materials and Methods:*** Data of 101 patients with clinical and biochemical evidence of pHPT, who underwent an FCH PET/CT in our department from November 2017 to February 2020 were retrospectively analyzed. The scans were acquired 45-60 minutes post-injection of 3-5mCi of FCH from the floor of the orbit to the diaphragm on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and 710 Discovery PET/CT, GE) and the images were reconstructed using OSEM algorithm (iterations=3; subsets=21). FCH PET/CT scan findings were reviewed by two experienced nuclear medicine physicians and the findings were correlated with the biochemical and clinical details of said patients. Histopathology results were considered as the gold standard. ***Results:*** In total 101 patients (61 females; 40 males) were recruited for the study. Surgery was performed in 34 patients (22 with hypercalcemic pHPT; 12 with normocalcemic pHPT), 33 of which were reported positive on FCH scan. FCH scan had a sensitivity and positive predictive value (PPV) of 100% and 95.4%, respectively for hypercalcemic pHPT and a sensitivity and PPV of 91.7% and 100%, respectively for normocalcemic pHPT. ***Conclusion:*** Within the limited subgroup of patients who underwent surgery, these were the findings. The sensitivity of FCH PET/CT was higher in the hypercalcemic pHPT, with a higher PPV being present in the normocalcemic pHPT. The two groups did not differ significantly from each other in terms of their biochemical parameters with the singular exception of their serum Calcium levels.

## EP-0499

### Does myocardium and liver fractional uptake of circulating fatty acids change after consuming a meal in people with prediabetes?

***J. Fernández Fernández***[1], *G. Sánchez-Delgado*[2,3,4], *S. Hogan-Lamarre*[4,5], *G. Richard*[4], *F. Frisch*[4], *S. Phoenix*[4,6], *M. Fortin*[3,4], *L. Bouffard*[4], *C. Noll*[4], *W. Mampuya*[4], *B. Guérin*[4,6], *É. E. Turcotte*[4,6], *J. Hoeks*[7], *P. Schrauwen*[7], *A. C. Carpentier*[3,4], *D. P. Blondin*[4,8];
[1]*Department of Nuclear Medicine, Virgen de las Nieves University Hospital, Granada, SPAIN,* [2]*Institute of Nutrition and Food Technology "Jose Mataix" and University Institute of Sports and Health, University of Granada, Granada, SPAIN,* [3]*Department of Medicine, Division of Endocrinology, Université de Sherbrooke, Sherbrooke, QC, CANADA,* [4]*Centre de recherche du Centre hospitalier universitaire de Sherbrooke, Sherbrooke, QC, CANADA,* [5]*Department of Pharmacology-Physiology, Université de Sherbrooke, Sherbrooke, QC, CANADA,* [6]*Department of Nuclear Medicine and Radiobiology, Université de Sherbrooke, Sherbrooke, QC, CANADA,* [7]*Department of Nutrition and Movement Sciences, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht University Medical Center, Maastricht, NETHERLANDS,* [8]*Department of Medicine, Division of Neurology, Université de Sherbrooke, Sherbrooke, QC, CANADA.*

***Aim/Introduction:*** The increased uptake and accumulation of fatty acids in lean tissues is a causal factor in the development of insulin resistance and type 2 diabetes mellitus. The uptake rate of non-esterified fatty acids (NEFA) by lean tissues depends on NEFA plasma concentrations and the fractional extraction by the tissue. Because NEFA concentration is regulated by insulin action, it is largely modified during the postprandial period. However, whether the fractional uptake of NEFA in key organs such as the liver and the heart vary between fasted and postprandial periods has never been assessed. Here, we aim to compare the heart and liver fractional NEFA uptake of individuals with prediabetes between the fasting and postprandial states. ***Materials and Methods:*** Twelve people with prediabetes have already participated in this ongoing study. Of them, four have available

data at the time of submitting this abstract (2 men / 2 women; 53-70 years old; Body mass index: 28.6-30.9 kg/m$^2$). Participants arrived at the research center early in the morning after an overnight fast, and consumed a standardized liquid meal (400 mL, 854 Kcal, 33.1% fat, 17.2% protein and 49.8% carbohydrates) after a ~3-hour resting period. Before and after consuming the meal, a 30-minute dynamic [$^{11}$C]-palmitate positron emission tomography scan, combined with a computerized tomography of the thoraco-abdominal area, was performed. The liver NEFA fractional uptake was calculated following the model proposed by Iozzo et al.(1), whereas the calculation of the heart´s fractional uptake rate was performed following de Jong et al.'s model(2). ***Results:*** The study is ongoing, but we observed a trend towards an increase in both the liver (0.35±0.06 vs 0.40±0.11 min$^{-1}$, increased in 3 out of 4 participants) and heart (0.24±0.02 vs 0.30±0.05 min$^{-1}$, increased in all 4 participants) NEFA fractional uptake rate in the first 4 participants. ***Conclusion:*** This study will unravel whether the fractional NEFA uptake of key lean organs varies along the fasting and feeding cycle. These findings will contribute to a better understanding of the pathophysiology of type 2 diabetes and will be very informative for the design of future studies investigating fatty acid metabolism in humans. ***References:*** 1. Iozzo, P. et al. Fatty acid metabolism in the liver, measured by positron emission tomography, is increased in obese individuals. Gastroenterology 139, 846-56, 856.e1-6(2010). 2. de Jong, H. W. A. M. et al. Kinetic models for analysing myocardial [(11)C]palmitate data. Eur. J. Nucl. Med. Mol. Imaging 36, 966-78(2009).

## EP-0500

### Incremental value of Tc-99m-sestamibi SPECT/CT in patients with positive planar scintigraphy in the detection of additional lesions in patients with Secondary/Tertiary hyperparathyroidism

***R. Goel***, *N. A. Damle, Y. Dharmashaktu, C. Bal, P. Kumar, A. Kumar, Y. Gupta, R. Aphale, G. Puri, S. Chumber;*
*All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.*

***Aim/Introduction:*** Tc-99m-sestamibi scintigraphy is of value in non-invasively localizing abnormal parathyroid glands before surgical exploration as well as for ruling out ectopic glands in patients with secondary/tertiary hyperparathyroidism. However, most centres in India restrict to planar scintigraphy rather than SPECT/CT. In this retrospective analysis, we aim to demonstrate the incremental value of Tc-99m-sestamibi SPECT/CT over planar scintigraphy in detecting additional culprit lesions in patients with secondary/tertiary hyperparathyroidism. ***Materials and Methods:*** We retrospectively reviewed data of 313 patients (205 female, 108 males; age 2.5-80 years) with biochemical evidence of hyperparathyroidism referred from Endocrinologists(mainly from our institute) between January 2021 to December 2022. All patients were injected with 20mCi of Tc-99m-sestamibi intravenously. Planar images were acquired at 15-minute, 50-minute, and 2-hour intervals. SPECT/CT images were acquired at 50 minutes. The imaging findings were correlated with histopathology. ***Results:*** Out of the total 313 patients, 94(61-female, 33-male; age 2.5-72years) had secondary/tertiary hyperparathyroidism with a mean iPTH of 1351.2 pg/mL. In patients with tertiary hyperparathyroidism, planar scintigraphy was positive for presence of hyperfunctioning parathyroid in 30/94 patients(31.9%), while SPECT/CT detected lesions over and above planar imaging in 21/30 patients(70%). In these 21 patients, planar imaging detected a total of 33 lesions, of which 3 were in right superior location, 14 in right inferior, 5 in left superior and 11 in left inferior.SPECT/CT of these 21 patients revealed 27 additional lesions of which 8 were in right superior location, 6 in right inferior, 9 in left superior and 4 in left inferior location. Of the 27 additional lesions on SPECT/CT, 5 were considered positive, 16 suspicious and 6 indeterminate for a parathyroid adenoma. 16/27 of these lesions were less than 1cm in longest axis dimension and therefore likely to be missed on planar imaging.4/21 patients underwent surgery and 14 supposed lesions were excised in total. On a per patient analysis, SPECT/CT correctly identified lesions over and above planar imaging in 4/4 patients. On a lesion-based analysis, 14/14 lesions resected during surgery were positive on histopathology for adenoma/hyperplasia. 7/14 lesions were described in planar and SPECT/CT imaging. 5/14 were described only in SPECT/CT images. 1/5 lesions were given as positive and 4/5 as suspicious for a parathyroid adenoma/hyperplasia. 2/14 lesions were not described on either. ***Conclusion:*** Tc-99m-sestamibi SPECT/CT provides incremental value over planar scintigraphy in the detection of additional lesions thus reducing the possibility of failed parathyroidectomy in patients with secondary/tertiary hyperparathyroidism.

## EP-0501

### Predictive value of preoperative 18F-Flurocholine PET/CT in bone mineral density improvement after parathyroidectomy in primary hyperparathyroidism.

***S. Seyedinia***[1], *S. Mirshahvalad*[2,1], *T. Kiener*[1], *H. Kässmann*[1], *M. Beheshti*[1], *C. Pirich*[1];
[1]*Division of Molecular Imaging & Theranostics, Department of Nuclear Medicine, University Hospital Salzburg, Paracelsus Medical University, Salzburg, AUSTRIA,* [2]*Joint Department of Medical Imaging, University Health Network, University of Toronto, Toronto, ON, CANADA.*

***Aim/Introduction:*** To evaluate the predictive value of semi-quantitative metabolic parameters derived by 18F-Flurocholine PET/CT (FCH PET/CT) in bone mineral density (BMD) changes after parathyroidectomy in patients with clinical diagnosis of primary hyperparathyroidism (PHP). ***Materials and Methods:*** Imaging and clinical findings of 71 Patients (62 female, 9 male, mean age: 65.80± 13.3) with clinical diagnosis of PHP and histopathologically proven parathyroid adenoma were analysed in this retrospective study. Inclusion criteria were FCH PET/CT imaging prior to the parathyroidectomy as well as pre-and postoperative follow-up dual energy X-ray absorptiometry (DXA). Semi-quantitative FCH-PET parameters (SUVmax, SUVmean, SULpeak, and SULmean) and metabolic short-axis diameter (mSAD) of the detected parathyroid lesions were extracted. Successful surgery was assessed by histopathological and follow-up laboratory data. The patients were divide into two groups of responder and non-responder according to the BMD changes between pre and postoperative follow-up DXA scans. Main outcome measure was percentage of BMD-change on lumbar spine (LS). Predictors were dichotomised via the receiver operating characteristics curve to find the best coordinate point. ***Results:*** On the post-operative follow-up BMD examinations, the distal radius region showed the lowest improvement (p-value = 0.01), while the lumbar spine and neck of femur had a comparable significant improvement (p-value>0.05).On univariate analysis, SULmean and mSAD were significantly associated with improvement of bone mineral density on follow-up LS-BMD (p<0.05). On multivariate analysis, SULmean was the most sensitive (72%) and specific (70%) predictor of BMD-response to surgery. Moreover, a cutoff SULmean value of >2.95 of the resected lesions were highly predictive of LS-BMD improvement

showing responder in 92% of cases. ***Conclusion:*** FCH PET/CT not only appears to be a promising functional imaging modality for accurate detection and localization of parathyroid adenomas (1), but also may independently predict BMD improvement after surgery. SULmean of parathyroid adenomas detected by FCH PET/CT was the most sensitive and specific semi-quantitative metabolic parameter for predicting treatment response. Quantitative metabolic FCH-PET imaging parameters could potentially be incorporated into clinical prediction models to identify PHP patients, who could benefit from active surveillance and prophylactic treatment approaches after parathyroidectomy. ***References:*** 1.Beheshti et al. 18F-Fluorocholine PET/CT in the assessment of primary hyperparathyroidism compared with 99mTc-MIBI or 99mTc-tetrofosmin SPECT/CT: a prospective dual-centre study in 100 patients. Eur J Nucl Med Mol Imaging. 2018 Sep;45(10):1762-1771.

## EP-0502

### 18F-Choline PET/CT in the detection of parathyroid adenomas hidden from conventional imaging techniques

***E. López Llobet****, C. Lancha Hernandez, L. Domínguez Gadea, J. Cordero García, S. Rizkallal Monzon, D. Monachello Araujo, Y. Abadi Sedraoui, L. Giraldo Gonzalez, P. Portilla Merino; Hospital Universitario La Paz, Madrid, SPAIN.*

***Aim/Introduction:*** Preoperative detection of pathological parathyroid glands in primary hyperparathyroidism(PPH) currently plays an essential role in surgical planning, increasing success rates, simplifying surgical approach and associated comorbidities. However, a small percentage of patients (around 20-30%) present false negatives in conventional imaging techniques (neck ultrasonogrohpy, 99mTc-sestamibi SPECT-CT). The objective of our study was to analyze the usefulness of 18F-CholinePET-CT in the detection of parathyroid adenomas in patients with previous negative localization techniques. ***Materials and Methods:*** Sixty-five patients diagnosed of PPH, with surgical criteria and negative conventional tests, were retrospectively reviewed.In all of them a PET/CT was performed in a Siemens Biograph system, 30 min after the intravenous injection of 4MBq/Kg of 18F-Fluorocholine. PET/CT acquisitions were performed from the skull base to the diaphragm.All focal 18F-fluorocholine uptakes more intense than the background tissue with correlation in the CT (nodular lesion located in the cervical o mediastinal area), were considered positive.When a low intensity focal uptake with no clear morphological correlation was detected, the PET/CT was considered doubtful.Every finding location was described according to its position regarding the thyroid gland (left/right, superior/inferior or ectopic)All patients underwent surgery.Sensitivity and positive predictive value (PPV) of PET/CT were calculated. Demographic variables, clinical and biochemical parameters, as well as surgical procedure were analyzed. ***Results:*** A total of 65 patients were included, mean age of 61 years and female predominance (92%). The mean levels of preoperative biochemical parameters were: PTH 134pg/mL, Ca 10.67mg/dL, VitD 38.76ng/mL, and a mean post-operative PTH level of 29.95pg/mL. 62 patients had single adenomas and the remaining 3 had double adenomas, a total of 68 adenomas were analyzed.PET/CT detected 62/68(91%) parathyroid adenomas, 60 of them were single adenomas and in one patient 1 double adenoma was detected.There were 5/68(7%) false negatives. Three of them were single adenomas and the remaining two had a second contralateral adenoma not detected by the PET/CT.In 1/68(2%) PET/CT was considered doubtful and was subsequently confirmed histologically as a single parathyroid adenoma. Sensitivity was 92% and PPV 98%. Minimally invasive techniques were used in 55(85%) patients, and in the remaining 10(15%) bilateral cervical exploration was performed: 3 patients without preoperative localization, 3 with double adenoma and 4 by surgeon's decision. ***Conclusion:*** PET/CT with 18F-Fluorocholine is a technique with high sensitivity and PPV for the detection of parathyroid adenomas in patients with negative conventional imaging.This could reduce the frecuency of extensive surgeries and therefore their associated comorbidities.

## EP-0503

### PET/CT with 18F-choline in the study of primary hyperparathyroidism: evaluation of the technique, and correlation with histopathological and biochemical findings

***E. Campaña Díaz****, P. García-Talavera San Miguel, J. Alvarez Pérez, F. Gómez-Caminero López, C. Montes Fuentes, A. Peñaherrera Cepeda, J. Badell Martinez, S. Rama Alonso, M. Tamayo Alonso; Hospital Universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** Assess the efficacy of 18F-Choline in the localization of primary hyperparathyroidism (pHPT) with negative or doubtful imaging techniques, analyzing the dual point imaging protocol. To correlate fluorocholine uptake with biochemical parameters and glandular weight. ***Materials and Methods:*** We included 20 patients (14 females; 56.3 ± 14.4 years) in whom 18F-Choline PET/CT was performed for pre-surgical localization of pHPT in cases with negative or doubtful imaging techniques. Standard 18F-Choline images were acquired 5 and 60 minutes after 185 MBq intravenous administration. PET/CT results were correlated with intraoperative histopathological findings and biochemical parameters. Calcium and iPTH were collected after surgery to ensure success. Initial and delayed images were assessed visually and semiquantitatively with pathological parathyroid SUVmax (P-SUVmax), thyroid gland SUVpeak (T-SUVpeak) and mediastinum SUVpeak (M-SUVpeak). Pearson's chi-squared test was used to calculate the correlation between P-SUVmax with calcium, PTH and adenoma size. Mann-Whitney U test was used to evaluate the differences between initial vs delayed P-SUVmax, T-SUVpeak, P-SUVmax/T-SUVpeak index and P-SUVmax/M-SUVpeak index. ***Results:*** In surgery the pathological gland was located in 19 cases (18 solitary adenomas, 1 double adenoma). PET/CT was positive in 17/19, one of them with multiglandular disease was not detected by PET/CT. 2/19 had negative PET/CT (one with multiglandular disease, not localized in any imaging technique).The patient in whom parathyroid adenoma was not found during surgery was a false positive because of papillary thyroid carcinoma on PET/CT.The detection rate per patient is 89.5%, and per lesion 81%. In the visual analysis of the 17 positive cases: in 7 delayed images offer relevant information, in 4 initial images, in 6 cases both images provide the same information.In the semiquantitative analysis the initial P-SUVmax (5.0 ±2.26) did not increase in the delayed images (4.65 ± 2.71). The initial (3.19± 1.5) vs delayed (2.64 ± 1.2) T-SUVpeak showed statistical significance (p=0.03); P-SUVmax/T-SUVpeak index did not show significant differences initial vs delayed (1.61±0.57 vs 1.83±0.82); P-SUVmax/M-SUVpeak index initial vs delayed (3.43±2.14 vs 5.17±2.45) had statistical significance (p=0.014).There was correlation between P-SUVmax and adenoma weight (initial: p=0.93; delayed: p=0.94), and with pre-surgical PTH (initial: p=0.67; delayed: p=0.79). No correlation was observed

with pre-surgical calcium. ***Conclusion:*** 18F-Choline PET/CT is a recommended preoperative localization technique in patients with hyperparathyroidism with negative or doubtful imaging techniques, showing good correlation with histopathological and biochemical findings. Dual time point imaging is necessary for localization of pathological parathyroid gland in more than half of the cases (65%).

## EP-0504

### Role of [18F]F-choline PET/TC for presurgical identification of hyperfunctioning parathyroid glands in patients with primary hyperparathyroidism and inconclusive conventional imaging

***P. Azpeitia Hernández****, O. Ajuria Illarramendi, A. Martínez Lorca, P. Paredes Rodríguez, T. Navarro Martínez, U. Vera Schmülling, M. Gutiérrez Guerrero, M. Orduña Díez;*
*Hospital Universitario Ramón Y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** Primary hyperparathyroidism (HPT) is an endocrine disorder caused by hyperfunctioning parathyroid, and for those patients with surgical criteria, localization is essential. Therefore, when ultrasound and/or [99Tc]Tc-MIBI parathyroid scintigraphy (conventional imaging) are negative or inconclusive, more accurate images are required. We evaluate [18F]F-choline PET/TC role in the presurgical identification of hyperfunctioning parathyroid glands in patients with primary hyperparathyroidism and inconclusive conventional imaging. Check if there is a correlation between preoperative PTH versus [18F]F-choline PET/TC findings. ***Materials and Methods:*** A retrospective study between September 2020 and December 2022 of patients with primary HPT presenting previous negative or inconclusive ultrasound and/or parathyroid scintigraphy, performing [18F]F-Choline-PET/CT (two phases), assessed visually and semiquantitatively. Histopathological correlation was the standard reference technique. In addition, laboratory values (PTH and calcemia) prior to diagnostic tests and their correlation with [18F]F-Choline-PET/CT results were analyzed. ***Results:*** Fifty-six patients (mean age 61.5 (±10.7) years; 73.2% women) with primary HPT and surgical criteria (51.8% osteoporosis) were included. In addition, 83.9% had cervical ultrasound (83.9% negative, 16.1% doubtful) and all [99mTc]Tc-MIBI scintigraphy-SPECT/CT (78.6% negative, 21.4% doubtful). [18F]F-Choline-PET/CT (Dose 191.41±19.9MBq) detected 64.3% positive, 32.1% negative, and 3.6% doubtful. Positive parathyroid lesions: mean size 7.4mm(r3-17), early SUVmax 3.8±1, and late SUVmax 3.7±1. Location rate: posterior lower right (31.6%) and left (26.3%), posterior upper right (7.9%) and left (7.9%), and right tracheoesophageal groove (7.9%).25% (14/56) underwent surgery with [18F]F-Choline-PET/CT positive, surgically removed with pathological confirmation of adenomas (sensitivity 100%). PTH: pre-surgical 103.5pg/ml(71.4-218, 7pg/ml) with post-surgical normalization: 42.9pg/ml (10.4-70pg/ml). The remaining 73.2% (41/56): 13 who did not undergo surgery (3 rejected surgery with positive [18F]F-Choline-PET/CT and 10 due to negative [18F]F-Choline-PET/CT), .28 pending reassessment (75%[18F]F-Choline-PET/CT positive).Laboratory data prior to ultrasound PTH 119.6pg/ml(70.9-196pg/ml), Ca 10.1mg/dL(±0.6mg/dL); scintigraphy PTH 122pg/ml(70.9-214.4pg/ml), Ca 10.2mg/dL(±0.7mg/dL); [18F]F-Choline-PET/CT PTH 117.4pg/ml (64.6-233.7pg/ml), Ca 10.2mg/dL(±0.7mg/dL).Despite the small sample size, statistical significance ($p<0.05$) was observed between PTH prior to [18F]F-Choline-PET/CT with size (Spearman=0.4; p=0.016), early SUVmax (Spearman=0 .45;p=0.005) and result [18F]F-Choline-PET/CT (Spearman=0.3;p=0.039). ***Conclusion:*** [18F]F-Choline PET/CT is a very sensitive hybrid technique for localizing parathyroid adenomas in primary HPT with inconclusive ultrasound and/or [99mTc]Tc-MIBI scintigraphy-SPECT/CT, facilitating surgical treatment and therefore PTH normalization. In addition, there is a significant correlation between PTH with size, early SUVmax, and [18F]F-Choline PET/CT positivity.

## EP-0505

### Role of 99mTechnetium Sestamibi SPECT/CT in patients with negative planar scintigraphy in lesion localization in patients with hyperparathyroidism

***Y. Dharmashaktu****, N. A. Damle, R. Goel, C. Bal, P. Kumar, S. Chumber, G. Puri, R. Aphale;*
*All India Institute of Medical Sciences, Delhi, INDIA.*

***Aim/Introduction:*** $^{99m}$Tc-SestaMIBI scintigraphy is a widely used first line non-invasive imaging modality for detection of culprit lesions in patients with hyperparathyroidism. Although SPECT/CT has higher sensitivity and specificity over planar imaging, many facilities only perform planar scintigraphy. Here we demonstrate the role of SEPCT/CT in lesion detection in patients with hyperparathyroidism. ***Materials and Methods:*** 318 patients with hyperparathyroidism (HPT) were retrospectively evaluated who underwent $^{99m}$Tc Sestamibi scintigraphy from January 2021 to January 2023. Patients were injected with 20 mCi of $^{99m}$Tc Sestamibi intravenously and planar images were taken at 15 mins, 50 mins and 2 hours post injection along with early SPECT/CT at 50 min interval. Lesions were graded as positive, suspicious and indeterminate by a Nuclear Medicine physician. ***Results:*** 136/318 patients were negative on planar scintigraphy. Of those 136 patients (84 were females and 52 were males), 75 patients (46 primary HPT and 29 secondary/ tertiary HPT patients) were negative on both planar scintigraphy and SPECT/CT and rest 61 patients had atleast one lesion on SPECT/CT (27 primary HPT and 34 secondary/tertiary HPT patients). In 27 primary HPT patients, mean iPTH was 197.8 pg/ml and mean age was 45.6 years. SPECT/CT detected 38 lesions (3 ectopic, 10 in right superior, 11 in right inferior, 7 in left superior and 7 in left inferior location). 2 lesions were graded as positive, 24 were suspicious and 12 were indeterminate. 3 ectopic lesions were located in superior mediastinum and right cervical level III & IV (1 in each location). In 34 secondary/ tertiary HPT patients, mean iPTH was 1160 pg/ml and mean age was 37.5 years. SPECT/CT showed 62 lesions (19 in right superior, 17 in right inferior, 16 in left superior and 10 in left inferior location). 5 lesions were graded as positive, 22 were suspicious and 35 were indeterminate. 7/61 patients underwent surgery and 11 supposed lesions were excised. Histopathology of excised glands revealed, 8 adenomas, 2 hyperplasia, and 1 normal gland.On a lesion-based analysis, of these 11 lesions, 1 was given as positive, 6 as suspicious, and 3 as indeterminate on SPECT/CT for a parathyroid adenoma. 1 lesion was not described in SPECT/CT images. ***Conclusion:*** Combined interpretation of $^{99m}$Tc Sestamibi planar scintigraphy and SPECT/CT helps in better localization and identification of additional suspicious lesions needing correlation with other modalities so as to define the exact kind of surgery required potentially reducing chances of persistent/recurrent HPT.

## EP-0506

### [18F]fluorocholine positron emission tomography/computed tomography characterization of benign thyroid nodules

***K. Bajuk Studen****[1,2], S. Rep[1], S. Gaberscek[1,2], K. Zaletel[1,2], E. Skorjanec Armic[1], L. Lezaic[1,2];*
*[1]University Medical Centre Ljubljana, Ljubljana, SLOVENIA,*
*[2]Medical Faculty, University of Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** [$^{18}$F]fluorocholine (FCH) positron emission tomography/computed tomography (PET/CT) has gained an important role in the preoperative diagnosis of patients with primary hyperparathyroidism (pPHP). In these patients, thyroid nodules are frequently found on preoperative ultrasound. FCH PET/CT provides a high negative predictive value to reliably

exclude cancer in thyroid nodules with low uptake[1]. However, more than half of benign thyroid nodules have been reported to have high uptake of FCH. The aim of our study was to evaluate the characteristics of FCH PET/CT uptake in benign thyroid nodules. ***Materials and Methods:*** A retrospective study was performed in patients with pPHP who were investigated by FCH PET/CT and concomitantly diagnosed with thyroid nodules larger than 1 cm on neck ultrasound. [$^{99m}$Tc]pertechnetate scan was performed in all patients, and benign nature of the nodules was confirmed by either high uptake or by fine-needle aspiration biopsy in patients with low uptake. Neck PET/CT acquisitions were performed 10 (early) and 60 (late) minutes after injection of 1.3 MBq/kg FCH, and maximum standardized uptake value (SUV max) of the nodules was measured. ***Results:*** Thirty-four patients (30/88.2% female, mean age 66.9±9.3 years) with 34 (15/44% hypofunctioning, 19/56% hyperfunctioning) thyroid nodules were included. A trend towards positive but non-significant correlation (r=0.3, p=0.09) of thyroglobulin level (mean 37.5±38.3 µg/L) with early SUVmax was observed, but no further statistically significant correlation of early or late SUVmax with TSH (mean 1.3±0.8 mIU/L), free $T_4$ (mean 15.3±2.0 pmol/L), free $T_3$ (mean 4.9±0.7 pmol/L), thyroid peroxidase antibodies level (median 30.0±253.5 kU/L) or nodule volume (mean 4.5±4.9 mL) was observed. Mean early SUVmax was 5.2±1.8; no difference in SUVmax was detected between hyperfunctioning and hypofunctioning thyroid nodules (mean, 4.9±1.8 and 5.6±1.7, respectively, p=0.28). The mean late SUVmax was 4.3±1.8; no difference in SUVmax was found between hyperfunctioning and hypofunctioning thyroid nodules (mean, 4.3±2.1 and 4.4±1.3, respectively, p=0.42). ***Conclusion:*** Biochemical parameters of thyroid function and autoimmunity do not correlate with FCH uptake in benign thyroid nodules. Hypofunctioning and hyperfunctioning thyroid nodules do not differ significantly in FCH uptake. Further studies should identify those characteristics of benign thyroid nodules that contribute to high uptake on FCH PET/CT scans to increase the specificity of FCH PET/CT in detecting malignant thyroid nodules. ***References:*** 1. Ciappuccini R, et al. [18]F-flurocholine positron emission tomography/computed tomograhy is a highly sensitive but poorly specific tool for identifying malignancy in thyroid nodules with indeterminate cytology: The Chocolate Study. Thyroid 2021; 31 (5): 800-809.

## EP-0507

### Diagnostic Performance of C-X-C Motif Chemokine Receptor 4-directed PET/CT in Patients with Advanced Adrenocortical Carcinoma

***W. Schlötelburg***[1], *A. Kosmala*[1], *P. E. Hartrampf*[1], *S. E. Serfling*[1], *A. Schirbel*[1], *M. Fassnacht*[2], *A. K. Buck*[1], *S. Hahner*[2], *R. A. Werner*[1,3]; *[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Division of Endocrinology and Diabetes, Department of Medicine I, University Hospital Würzburg, Würzburg, GERMANY, [3]The Russel H Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** C-X-C motif chemokine receptor 4 (CXCR4) is highly expressed in adrenocortical cancer (ACC) tumor lesions and thus, may emerge as a theranostic target in those difficult-to-treat patient population (1). Therefore, we aimed to determine the diagnostic performance of CXCR4-directed [$^{68}$Ga]Ga-PentixaFor relative to [$^{18}$F]FDG PET/CT in patients with metastatic ACC and to identify individuals eligible for CXCR4-directed radioligand therapy (RLT) in a theranostic approach. ***Materials and Methods:*** 33 patients with advanced ACC which had exhausted previous treatment options underwent [$^{68}$Ga]Ga-PentixaFor PET/CT to determine eligibility for RLT. In all subjects, concurrent [$^{18}$F]FDG PET/CT were also available. We then compared staging results and tumor-to-background ratios (TBR, to evaluate image contrast) between [$^{68}$Ga]Ga-PentixaFor and [$^{18}$F]FDG PET. For TBR assessment, the entire tumor burden was investigated. Moreover, patients eligible for CXCR4-RLT were also determined based on molecular imaging. ***Results:*** When compared with [$^{18}$F]FDG PET/CT, staging changes were recorded in 12/33 (36.4%) instances based on [$^{68}$Ga]Ga-PentixaFor PET/CT. Among those subjects, upstaging was seen in 5/33 (15.2%), and downstaging in 7/33 (21.2%). In those five patients with upstaging, the following additional lesions were observed on CXCR-directed imaging: multiple liver metastases in 3/5 (60.0%), cerebral metastasis in 1/5 (20.0%) and vascular infiltration in the remaining subject (20.0%). In the 7 downstaged patients, [$^{68}$Ga]Ga-PentixaFor missed lesions in the following organ compartments: lung in 4/7 (57.1%), soft tissue in 2/7 (28.6%) and lymph nodes and liver in 3/7 (42.9%), respectively. TBR were higher on [$^{68}$Ga]Ga-PentixaFor PET (8.43 ± 4.88) when compared to [$^{18}$F]FDG (4.39 ± 2.94, P<0.001), indicative for better contrast in sites of disease accumulating [$^{68}$Ga]Ga-PentixaFor. In addition, 18/33 (54.5%) patients were considered eligible for CXCR4-targeted RLT based on molecular imaging. ***Conclusion:*** Despite improved image contrast with intense radiotracer accumulation in sites of disease, CXCR4-directed PET/CT led to inappropriate downstaging due to missed lesions in a substantial number of subjects when compared to [$^{18}$F]FDG. Nonetheless, over half of patients were considered eligible for RLT using ß-emitting therapeutic equivalents in a theranostic setting. Funding: IZKF Z-2/91 ***References:*** (1) ClinNuclMed. 2017 Jan;42(1):e29-e34. doi: 10.1097/RLU.0000000000001435. ### Minimally Invasive Radio-Guided Parathyroidectomy in Patients with Hyperparathyroidism: Experience at Our Center

***N. Calviño***, *D. Villasboas-Rosciolesi, M. De Bonilla-Candau, A. Ciscar, A. Martin del Rey, J. Echeverri-Díaz, S. Asadurova, F. Velazquez, R. Bellviure-Meiro, A. García-Burillo; Hospital Universitario Vall de Hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** This study aimed to retrospectively analyze the results of the ROLL technique in our center, including the injection site, intraoperative detection rate of parathyroid glands, postoperative complications, and re-operation. ***Materials and Methods:*** Between January 2021 and August 2022, 89 patients (66 female) with hyperparathyroidism were included in the study. All patients underwent preoperative detection tests (neck ultrasound, [99mTc]Tc-MIBI scintigraphy, [18F]fluorocholine PET/CT) to detect affected glands. Of the 89 patients, 47 (52.8%) underwent the ROLL technique. Patients were administered between 14-185 MBq of [99mTc]Tc-MAA intralesional or perilesional, guided by ultrasound, and subsequently SPECT/CT (GE Discovery 670) was performed to confirm the location. On the day of surgery, a gamma probe (EuroProbe3.2) was used to detect the marked lesion, and intraoperative PTH monitoring was performed to assess the success of the extraction. The final diagnosis was confirmed by histopathological analysis, and clinical and analytical follow-up

of the patients was conducted. ***Results:*** Forty-seven patients (35 women, mean age 59.8 years [range 22-80]) underwent ROLL. Conventional ultrasound and, [99mTc]Tc-MIBI scintigraphy detected the affected gland in 15 (32%) patients, while ultrasound and [18F]fluorocholine PET/CT detected it in 7 (15%) patients. [18F]fluorocholine PET/CT alone detected the affected gland in 7 (15%) patients (6 of whom had negative ultrasound and [99mTc]Tc-MIBI scintigraphy, and 1 of whom had negative ultrasound). [99mTc]Tc-MIBI and [18F]fluorocholine detected the affected gland in 6 (13%) patients, [99mTc]Tc-MIBI alone in 6 (13%) patients, all three methods in 5 (10%) patients, and ultrasound alone in 1 patient. Based on SPECT-CT images, the radiopharmaceutical was administered intralesionally in 28 patients (59%) and perilesionally in 9 patients (19%). A total of 52 glands were surgically removed, with a 100% detection rate. Histopathological analysis identified 36 adenomas, 13 hyperplasias, and 3 non-pathological parathyroid tissues. Only 3 patients (6%) experienced surgical complications, all of which were dysphonia. Only one patient required surgical reintervention. ***Conclusion:*** Our results showed a high rate of lesion detection using the ROLL technique, allowing for a minimally invasive procedure with a low percentage of complications and need for reintervention.

## EP-0509

### Diagnostic performance of 18FCH-PET/CT in Primary Hyperparathyroidism: semiquantitative analysis and correlation with biochemical data

***C. Ferrari***, *F. Iuele, M. Frugis, P. Mammucci, C. Palumbo, A. Di Palo, G. Rubini;*
*Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, Italy, Bari, ITALY.*

***Aim/Introduction:*** The detection of hyperfunctioning parathyroid gland(s) (HPTG) in patients with primary hyperparathyroidism (PHPT) with negative/inconclusive first-line imaging is a significant challenge. In this setting, $^{18}$FCH-PET/CT has shown promising results, suggesting superiority over $^{99m}$Tc-MIBI parathyroid scintigraphy (MIBI-scintigraphy). We aim to assess the diagnostic performance of $^{18}$FCH-PET/CT in the detection of HPTG in patients with PHPT, considering both visual and semiquantitative analysis, and its comparison with MIBI-scintigraphy. ***Materials and Methods:*** We prospectively enrolled 42 PHPT patients (6 men, 45 women; mean age 62y) who performed $^{18}$FCH-PET/CT preoperatively. Thirty/42 patients had a previous negative/inconclusive MIBI-scintigraphy. SUVmax and MTV were recorded for positive $^{18}$FCH-PET/CT findings. PTH and serum calcium levels were also collected together with histopathology, if available. Correlation between $^{18}$FCH-PET/CT detection rate and PTH was assessed using Mann-Whitney U test. PET semiquantitative parameters and laboratory values were correlated using the Spearman coefficient. ROC curve analysis was used to find: 1)a PTH cut-off predictive of a positive scan and 2)semiquantitative parameters predictive of positive histopathology. The agreement between $^{18}$FCH-PET/CT and MIBI-scintigraphy results as well as between $^{18}$FCH-PET/CT and histological findings was assessed using Cohen's K test. A p>0.05 was considered statistically significant. ***Results:*** $^{18}$FCH-PET/CT was positive in 34/42 (81%) PHPT patients. SUVmax and MTV mean values were 7.13 (±4.33; range:2.4-18.8) and 1.78 cm$^3$ (±2.41; range:0.1-13.4) respectively. PTH and serum calcium mean values were 169.59 pg/ml (±16.97; range:26.9-958.9) and 10.78 mg/dl (±1.31; range:7.7-13.4) respectively. A strong positive correlation between $^{18}$FCH-PET/CT detection rate and preoperative PTH (p<0.00001) was observed. A significant correlation was found between preoperative calcium levels and both SUVmax (p=0.00005) and MTV (p=0.00084). Applying ROC curves, a PTH of 90.15 pg/ml was predictive of a positive PET (AUC 0.78, 95%CI 0.57-0.99, sensitivity 73.5%, specificity 75%), while a SUVmax of 4.5 (AUC 0.88, 95% CI 0.70-1, sensitivity 75%, specificity 100%) and MTV of 1.5 cm$^3$ (AUC 0.63, 95%CI 0.29-0.96, sensitivity 42%, specificity 100%) significantly predicted a positive histopathology. MIBI-scintigraphy was positive in 12/30 (40%). Compared with $^{18}$FCH-PET/CT results, 12/30 were positive-concordant, 4/30 negative concordant, 14/30 discordant, with a slight agreement (k=0.18). Histopathology was available in 26/34 patients: 24/26 positive-concordant and 2/26 discordant. A strong agreement was observed between $^{18}$FCH-PET/CT and histological findings (k=0.85) ***Conclusion:*** Our preliminary results supported the use of $^{18}$FCH-PET/CT for the diagnosis of HPTG, showing better performance over MIBI-scintigraphy. Choline metabolism correlated with both PTH and calcium level. Semiquantitative analysis could help in imaging interpretation and histopathology prediction.

## EP-0510

### Usefulness of 18F-Choline PET/CT in localizing hyperfunctioning parathyroid glands with negative 99mTc-MIBI scintigraphy and its correlation with pathological findings

***I. Garrido Solesio***, *K. Velásquez Díaz, P. Meneses Soares, A. Grajeda Gallardo, I. Obedkova, L. Santamaría Chico, M. Mitjavila Casanovas, A. Prieto Soriano;*
*Hospital Universitario Puerta de Hierro, Madrid, SPAIN.*

***Aim/Introduction:*** Primary hyperparathyroidism (HPT) is an endocrine disorder with an alteration of the parathyroid hormone (PTH) secretion that affects the regulation of calcium and phosphorus metabolism. It is usually caused by single adenomas (80%), hyperplasia (10-15%), multiple adenomas (5%), or parathyroid cancer (<1%).The only curative treatment is surgery, therefore, pre-surgical detection of hyperfunctioning glands is a crucial step. The objective of this study is to correlate the $^{18}$F-Choline PET/CT findings with the pathological findings after surgery in patients with negative MIBI scan. ***Materials and Methods:*** Retrospective analysis of patients with primary hyperparathyroidism diagnosis who had surgical criteria, a negative $^{99m}$Tc-MIBI scintigraphy and $^{18}$F-Choline PET/CT study at our center from January 2018 to December 2021.Healing criteria were established by the normalization of calcium levels 2-3 months after surgery according to the latest consensus. ***Results:*** Of the 64 patients with HPT and $^{18}$F-Choline PET/CT study, 42 patients who underwent surgery were included. Of which 29 (69%) were considered PET positive, 9 (21%) PET negative and 4 (10%) uncertain.All patients with a positive result underwent directed resection and had pathology of adenoma/hyperplasia.Of the negative results, 1 (11.1%) had an ultrasound scan that was considered sufficient to perform a directed resection (pathology: adenoma/hyperplasia). The other 8 (88.8%) underwent bilateral cervical exploration and parathyroidectomy +/- hemithyroidectomy depending on intraoperative findings (pathology: 6 adenomas/ hyperplasia and 2 negatives).All 4 (100%) patients with uncertain results underwent bilateral cervical exploration presenting pathology of adenoma/hyperplasia.From all 42 MIBI negative patients that would have gone to invasive surgery only 12 did go after PET results (those considered uncertain and 8/9 negative).Calcemia evaluation showed that 38 (90%) patients presented normal values. The other 4 (10%) persisted with elevated values after

surgery. To sum up, from a total of 30 patients with minamally invasive surgery, 27 (90%) were considered cured (the 3 patients with persistent HPT had a positive PET scan). On the other hand, 12 patients that underwent bilateral cervical exploration and 11 ended with calcium within healthy levels (the odd one out had an uncertain PET result). ***Conclusion:*** $^{18}$F-Choline PET/CT is a sensitive and specific technique for locating hyperfunctioning parathyroid glands. As a result, it allows to perform minimally invasive surgeries with the advantages for the patient that this entails and a decent curative rate.

## B: Imaging Clinical Studies -> B7 Infection and Inflammation -> B71 Bone Infection and Inflammation

### EP-0511

**The study of non-infectious inflammatory diseases in paediatric patients: morpho-functional methods compared (18FDG-PET and 99mTc-WB Bone Scintigraphy vs STIR-MRI).**

***A. Monaci***[1], *A. Perrone*[2], *A. Tondo*[2], *F. Carra*[2], *T. Giani*[2], *C. Olianti*[1];
[1]*University of Florence, Firenze, ITALY,* [2]*University Hospital Meyer, Firenze, ITALY.*

***Aim/Introduction:*** There is not much literature on the use of nuclear medicine imaging for the study of paediatric patients with inflammatory disease of a non-infectious nature, as in most cases its usefulness is not established and the use of radiation-free techniques such as MRI is favoured. The aim of this study is to compare the different morpho-functional methods ($^{18}$FDG-PET and $^{99m}$Tc-WB Bone Scintigraphy vs STIR-MRI) in the therapeutic diagnostic procedure of these patients. ***Materials and Methods:*** 9 patients (5 males and 4 females) scheduled between 2014 and 2021, who were between 18 months and 18 years old at the time of the investigations, were selected ($\mu = 9.27 \pm 5.47$ age). The time interval between the performance of the MRI and the $^{18}$FDG-PET/$^{99m}$Tc-WB Bone Scintigraphy ranged between 1 and 20 days, except in the case of two patients, for whom approximately 3 and approximately 18 months elapsed, respectively ($\mu = 8 \pm 5.96$ days). Most of the patients came to the physicians' attention with signs and symptoms such as bone and/or joint pain, fever, difficulty in walking (lameness) and elevation of inflammatory indices (Erythrocyte Sedimentation Rate - ESR); although bone biopsy was not always available, patients with a definite diagnosis in the majority of cases were suffering from Chronic Recurrent Multifocal Osteomyelitis (CRMO) (33%), followed by 1 patient with scurvy, 1 with osteomyelitis, while the remainder appeared without a clear diagnosis (44%). ***Results:*** When comparing radiological and nuclear medical imaging, in most cases the changes visible on MRI images coincided with areas of radiopharmaceutical ($^{18}$FDG or $^{99m}$Tc MDP) uptake. In some cases, especially among patients investigated with $^{18}$FDG-PET, the latter appeared to show additional localisations of metabolically active tissue compared to the findings on MRI. Accuracy, PPV, NPV, sensitivity and specificity are summarized for the two metabolic tools in the tables. Comparison MRI as gold standard vs 18FDG-PET considering 12 bone segments: ***Conclusion***: This result appears to confirm the high sensitivity of medical-nuclear imaging and semiquantitative parameters (Maximum Standardised Uptake Value - SUVmax) are still being evaluated, to obtain a cut-off value between positive and negative and thus to define positive and negative predictive values to better assess the role that these methods could have in the diagnosis and management of patients with non-infectious inflammatory pathology.

**Role of 18 Fluorodeoxyglucose positron emission tomography - computed tomography in the diagnosis of infective endocarditis : A report of 19 cases**

***O. Ben Elkilani***, *S. Mensi, G. Baazoug, Z. Missaoui, A. Ezzine, T. Dardouri, R. Sfar, K. Chatti;*
*University Hospital Sahloul, Sousse, TUNISIA.*

***Aim/Introduction:*** Infective endocarditis is a relatively rare infectious disease, but with a significant morbidity and mortality, the diagnosis is often difficult and is based on clinical, biological and radiological features (Duke's Criteria), nevertheless, in a significant number of patients, the results are inconclusive leading to a sort of therapeutic problem. The goal of this study is to clarify the utility of 18FDG PET CT in diagnosing IE. ***Materials and Methods:*** We have studied 19 cases of suspected IE that benefited from a 18FDG PET CT, these cases spanned between January 2020 and March 2023. All patients were studied on local level (the cardiac region) and on a global level (whole body PET-CT). ***Results:*** In the 19 cases studied, the mean age was 45 (6-78), 12 (63%) were males and 7 (37%) were females, 6 had valvular prothesis, 3 had endoaortic prothesis, 1 had RV-PA conduit and 4 had implanted pacemakers. 2 had a history of anterior episodes of IE, 4 had persistent fever, 6 had a biological inflammatory syndrome, 3 had positive blood cultures, 7 patients had cardiac ultrasound suggestive of IE. Overall, 7 exams were positive (36.8%) and 2 exams were excluded because of inadequate regimen, the rest were inconsistent with endocarditis. In patients with valvular prothesis, PET-CT revealed valvular hypermetabolism that was diffuse in 3 cases, heterogenous in 1 case and focal in 2 cases that were consistent with IE (mean SUV=6.6 : 2-11). Of the patients with endoaortic prothesis, 2 revealed diffuse hypermetabolism, Of the 4 patients with pacemaker, 1 was positive and revealed a focal hypermetabolism regarding pacemaker probe. On the global level, the exams revealed septic emboli in splenic (1case), internal iliac (1 case) and in the femoral (2cases) arteries, the results were highly suggestive of suspected secondary localizations in the spine (2cases), in the hip bone (2cases) and in the sternum (2cases). Moreover, one revealed pneumopathy, one acute cholecystitis and one revealed lytic lesions of the hip bone. ***Conclusion:*** 18FDG PET-CT may play an important role in diagnosing IE when traditional tools are inconclusive. The suggestive findings are especially focal hypermetabolism regarding valves/prothesis. It's also a powerful tool in diagnosing distant complications.

## EP-0513

### Takayasu's Disease - A Pathway To Diagnosis: Clinical Case Solved Using 18F-FDG PET/CT

***P. Ilieva-Gabarska***[1,2,3], *Z. Dancheva*[3], *R. Pencheva*[4], *M. Slavova*[1], *L. Petrakiev*[1], *A. Antonov*[5], *M. Dyankova*[6,3], *I. Vasilev*[7], *T. Baltova*[7], *Y. Todorova-Doneva*[8];

***Aim/Introduction:*** Takayasu's disease is a type of autoimmune vasculitis causing inflammation of the arterial walls of medium and large vessels, including the aorta. Its pathogenesis is based on systemic granulomatous inflammation chain reaction. Our aim was to describe a case of Takayasu's arteritis (TAK) with unusual presentation and delayed diagnosis -extravascular manifestation with infection of the middle ear and TAK-associated polychondritis (of nose and ear) and polyserositis. ***Materials and Methods:*** To present a case of a 44 y.o. caucasian woman with acute inflammation in right middle ear with swelling and redness in right auricle dating 2 weeks without any effect to antibiotic treatment. Additional symptoms were present - dizziness, fatigue, subfebrile temperature, arthralgia in small hand and feet joints, night sweats and weight reduction. After otolaryngology consultation and treatment, according to rheumatologist's recommendations a panel of laboratory tests, including antibody tests, was conducted, which showed high levels of leukocytes, C-reactive protein, thrombocytes, rheumatoid factor, erythrocyte sedimentation rate, and iron deficiency anaemia. Based on these results, the diagnosis of relapsing polychondritis was accepted. After haematology consultation there was a haematological disorder still suspected. A CT study of the head was performed with imaging findings suspecting tumor involvement of left piriform sinus and carcinosis in left carotid space. The patient was referred for a 18F-FDG PET/CT study and a total body protocol with low-dose CT for attenuation correction was conducted. ***Results:*** The PET/CT findings included: diffusely increased uptake of the radiopharmaceutical into the vessels' walls of the thoracic and abdominal aorta, bilateral carotid and femoral arteries including perivascular reaction with moderate wall thickening and inflammatory changes (endarteritis); area with high uptake in the nose cartilage and diffusely activated bone marrow. A focal area of pathological FDG accumulation was found in the area of right carotid artery, which was further examined with MRT and was proven to be kinking of the right internal carotid artery with endarteritis. A bone marrow trephine biopsy and genetic molecular testing excluded myeloproliferative disorder. The diagnosis of TAK was accepted and a treatment with cyclophosphamide, methylprednisolone and methotrexate was initiated. ***Conclusion:*** 18F-FDG PET/CT acted as a valuable method in detecting an active inflammatory process of the arterial blood vessels' walls and carotid abnormality leading to the diagnosis of Takayasu's arteritis. This case adds to the literature, expands knowledge of the spectrum of changes in TAK and addresses the need of multidisciplinary approach to difficult diagnostic cases.

## EP-0514

### Role of FDG PET-CT in Takayasu arteritis

***Z. Missaoui***, *M. Nouira, G. Baazoug, O. Ben Elkilani, K. Ayed, S. Raja, K. Chatti;*
*University Hospital Center Sahloul, Sousse, TUNISIA.*

***Aim/Introduction:*** Takayasu's vasculitis is an inflammatory arteritis of large and medium-sized vessels . It is characterised by clinical polymorphism , the absence of biological or histological markers. The aim of this study is to determine the indications and to assess the impact of FDG PET-CT in the exploration of Takayasu arteritis . ***Materials and Methods:*** We identified all patients who underwent FDG PET-CT in our department for the investigation of Takayasu's vasculitis from September 2020 to February 2023. In total nine patients were included. The protocol for FDG PET-CT examinations was standard. Exames were interpreted with visual analysis comparing the degree of an arterial FDG uptake to that of the liver. 3 grades are distinguished . PET-CT was considered positive for grades 2 or 3. ***Results:*** In our study, we identified two indications for FDG PET-CT in the investigation of Takayasu arteritis: Firstly, two patients were referred to our departmentfor suspicion of Takayasu's vasculitis. The two corresponding PET scans were negative andthe subsequent evolution of the patients' state of health was good with no need for treatment with corticosteroids. Suspicion of relapse was the second indication. The PET scan results were positive in two cases showing a vascular hypermetabolismconfirming therelapse of the disease and negative in the other five cases. The rapid attenuation of vascular fixation under treatment of Takayasu disease is known. Four of our patients were on corticosteroids. Two of them had a negative PET-CT scan. The risk of false-negative results on steroids cannot be assessed in our study due to the small number of patients included. ***Conclusion:*** FDG PET-CT is a useful imaging modality for the diagnosis of Takayasu Arteritis because of the early detection of inflammatory activity. It contributes also todiagnose relapsesand to obtain a therapeutic assessment. A study of a larger number of patients is needed to determine the sensitivity and specificity of the examination and to establish a correlation between the intensity of vascular uptake and disease activity. ***References:*** -Lillian Barra and al : imaging modalities for the diagnosis and desease activity assessment of takayasu's arteritis .-Berit Nielsen et al : Three days of high-dose glucocorticoid treatment attenuates large-vessel 18F-FDG uptake in large-vessel giant cell arteritis but with a limited impact on diagnostic accuracy .-Martin a walter and al : The value of [18F]FDG-PET in the diagnosis of large-vessel vasculitis and the assessment of activity and extent of disease.

### FDG PET/CT response criteria in assessment of post Anti Koch's Treatment evaluation.

***H. Rathore***, *N. R. Thaker, Bombay Hospital, Mumbai;*
*Bombay Hospital And Medical Research Centre, Mumbai, INDIA.*

***Aim/Introduction:*** Tuberculosis(TB) is a highly infectious disease with a record global incidence of high morbidity and mortality. Monitoring disease activity and evaluating treatment response with conventional methods such as culture or chest x-ray is time-consuming and non-specific. Active TB-lesions are typically highly FDG-avid and may be assessed on whole-body

18-fuorine-fuorodeoxyglucose positron emission tomography/computed tomography scan(FDG-PET/CTscan). We hypothesized that FDG-PET/CTscan is highly efficacious for evaluation of disease extent, treatment response and outcome in TB-infected patients undergoing anti-koch's therapy(ATT). ***Materials and Methods:*** Pre and post-ATT FDG-PET/CT scan done for various sign symptoms like pyrexia of unknown origin, weight loss, lymphadenopathy etc which were diagnosed as TB included in the study, to look for the extent of disease before initiation of Anti-Tubercular or Anti-Koch's therapy(ATT or AKT), for the identification of other sites, completely cured patients, non-responders, recurrence of disease, and drug-resistance. FDG-PET/CTscan is also very helpful tool in identification of right biopsy site, to rule out the possibilities of other mimicking granulomatous-infection, lymphoproliferative-disorder or malignancy, and to avoid empirical use of AKT. ***Results:*** A total of 60 biopsy proven patients were included with pulmonary and extrapulmonary-involvement, out of them 35% patients had multiorgan-disease. 23.33% have only nodal-disease, 18.33% have isolated pulmonary-disease with or without mediastinal-nodes, 10% have osseous involvement, 5% have ovarian and 1.6 % of each has testes, prostate, uterus, transplanted kidney, and diffuse peritoneal involvement respectively. 16.66% patients were studied with follow up FDG-PET/CTscan out of them 5 has shown the complete morphological and anatomical response with AKT, 3 were having residual morphological disease with complete metabolic-response and 2 patients were identified as non responders with metabolically active disease which on re-biopsy confirms the drug resistance. ***Conclusion:*** Despite high heterogeneity there was a trend towards the usefulness of FDG-PET/CTscan for evaluation of disease extent prior to treatment and ATT response. Impending research with large-number of patients is needed to further clarify the predictive value of FDG-PET/CTscan with formulation of new guidelines in tuberculosis. ***References:*** 1. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN,* [4]*Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander (España), SPAIN.*

***Aim/Introduction:*** To evaluate if a semiquantitative analysis would improve the ability of the visual analysis of [18F]FDG-PET/CT in the assessment of the osteoarticular inflammatory activity response to tocilizumab (TCZ) therapy in patients with refractory polymyalgia rheumatica (PMR). ***Materials and Methods:*** A deep study of 12 consecutive patients with symptomatic PMR and giant cell arteritis (10 women, 67.0±8.6 years-old) refractory to corticosteroids/methotrexate and treated with TCZ was performed. A baseline and follow-up PET/CT after TCZ were performed (interval: 15.1±6.0 months). Eleven patients were on therapy at the time of baseline PET/CT. PET/CT were obtained 180' after [18F]FDG administration. A semiquantitative analysis of images, based on the SUVmax target-to-liver ratio (TLR), was performed. The results were compared with a previous visual evaluation (score 0-3 compared to liver uptake). Fourteen osteoarticular regions were evaluated per patient: shoulders, sternoclavicular joints, ischial tuberosities, hips, greater trochanters, knees, cervical and lumbar interspinous bursae. ***Results:*** Previous visual analysis had shown uptake >0 in 72/168 (42.9%) regions evaluated at the baseline PET/CT (grade 1=28, grade 2=16, grade 3=28) and in 65 regions (38.7%) after TCZ therapy (grade 1=32, grade 2=18, grade 3=15). TLR decreased from 0.88±0.57 at the baseline PET/CT to 0.78±0.36 at the follow-up (non-significant, p=0.5169). In the 86 regions showing visual score >0 at the baseline and/or follow-up PET/CT, TLR decreased from 1.10±0.70 to 0.93±0.42 (non-significant, p=0.3424). After TCZ therapy, 7/12 patients showed complete clinical response (CR). In the 51 regions with visual score >0 TLR decreased from 0.83±0.31 to 0.79±0.30 (non-significant, p=0.3219). Five patients showed partial response (PR). TLR in the 35 regions with visual score >0 decreased from 1.48±0.93 to 1.13±0.46 (non-significant, p=0.4278). Patients with PR showed higher baseline and follow-up TLR compared to those with CP (baseline: 1.48±0.93 vs. 0.83±0.31, follow-up: 1.13±0.46 vs. 0.79±0.30, p<0.005). TLR decreased in 54.1% and 48.6% of regions in patients with CR and PR, respectively. Discrepancies in individual behaviour of TLR and the visual score were more frequent in patients with PR (18/35 (51.4%) vs. 19/51 (37.3%) regions). ***Conclusion:*** The semiquantitative analysis of [18F]FDG-PET/CT showed a decrease in the TLR after TCZ therapy, globally and in patients with CR and PR, although the differences were not significant. A higher TLR, both at baseline and at the follow-up, was associated with a lower clinical response to TCZ. Discrepancies in individual behaviour of the visual score and TLR were more frequent in patients with PR.

## EP-0517

### Comparative study of body fat distribution in naive people living with HIV (PLHIV) and after 48 weeks of antiretroviral therapies (ART) with Dolutegravir/lamivudine vs TAF/FTC/Bictegravir.

***A. Piñeiro****, C. Hidalgo Tenorio, E. Triviño Ibáñez, C. Ramos Font, R. Sánchez Sánchez;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this work is to analyze after 48 weeks of treatment with these antiretroviral therapies (ARTs) whether changes in body fat distribution occur, and whether these predominate in any regimen. ***Materials and Methods:*** This work is a substudy of two clinical trials (DOLAVI ClinicalTrials.gov Identifier: NCT04002323 and BIC-NOW The EudraCT number: 2019-003251-11) of a single arm, in naive patients, performing dual energy X-ray absorptiometry (DEXA) of body fat before and after 48 weeks of ART. ***Results:*** 13 PLHIV were included. 46.2% with T/F/BIC and 53.8% DTG/LMV, comparable in variables: mean age 31.5 vs 31 (p=0.91); gender 83.3% vs 100%, (p=0.46), AIDS stage 33.3 vs 28.6% (p=1), immediate ART initiation 100% vs 100%, CD4 285.7 vs 411.7 cells/uL (p=0.32), CD4/CD8 ratio 0.34 vs 0.22 (p=0.62) and viral load 5.86 vs 4.94 (log10) (p=0.25); median weight 75 vs 69 kg

(p=0.27), waist 81 vs 77 cm (p=0.48) and Body Mass Index (BMI) 24 vs 23 (p=0.28) and distribution of lean mass and total fat mass and in percentage of upper limbs, lower limbs, and trunk, and the type of distribution gynecoid or android. After 48 weeks we found no differences between both ART (T/F/BIC vs DTG/LMV) in weight 76 vs 68.5 kg (p=0.47); waist 83.5 vs 80 cm (p=0.7) or BMI 25.1 vs 24.6 (p=0.57); nor comparing each patient with each other according to ART (T/F/BIC weight 0.59; waist p=0.34; BMI 0.4 vs DTG/LMV, weight p=0.15; waist p=0.14; BMI p=0.11). Regarding body fat at DEXA we found that DTG/LMV treated patients experienced a post-treatment increase in upper limb fat mass (Left: 1225 basal vs 1576; Right 1221 vs 1443, p=0.018) and lean mass (Left 2550 vs 2927; p=0.018) and total fat percentage (Left 32.3% vs 38.4% p=0.018; Right 32.3% vs 34.4% p=0.018). ***Conclusion:*** DTG/LMV produces an increase in total fat in arms after 48 weeks. This effect needs to be analyzed in larger cohorts to see the possible impact on the occurrence of future cardiovascular events.

## EP-0518

### 18F-FDG PET/CT Imaging in Infectious Mononucleosis: Mimicking Lymphoma and Clinical Implications

***N. Damle***, *J. Jaleel, S. Jain, A. Rasheed, V. Goenka, K. Gyanraj Sa, A. Khurana;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Infectious mononucleosis caused by the Epstein-Barr virus is a common infectious disease in young adults that presents with fever, lymphadenopathy and hepatosplenomegaly and usually follows a self-limiting course. Persistence of symptoms, significant atypical lymphocytosis and disproportionate weight loss can sometimes cause IMN to closely mimic a lymphoreticular malignancy. We present 18F-FDG PET/CT findings in a case of a young adult male who presented with findings closely resembling a lymphoma but was finally diagnosed to have infectious mononucleosis after a detailed diagnostic evaluation. ***Materials and Methods:*** A 31-year-old male presented to the ER with a 6-day history of high-grade fever. His investigations showed mild thrombocytopenia, deranged liver function and probable myocarditis. He was empirically started on antibiotics for a suspected tropical fever (?severe scrub typhus). CT chest-abdomen was unremarkable except for mild hepatosplenomegaly. The microbiological workup returned negative, and despite the antibiotics, the patient continued to have persistent symptoms into the third week of illness. Patient was referred for 18F-FDG PET/CT with a clinical diagnosis of undifferentiated pyrexia under evaluation. Serological workup for EBV and other viral infections were sent and reports were awaited at the time of the PET/CT. ***Results:*** 18F-FDG PET/CT revealed intense bilaterally symmetrical FDG uptake in nasopharynx and bulky bilateral tonsils. FDG avid bilateral preauricular, right intraparotid, bilateral parapharyngeal, bilateral cervical level IB, bilateral level II, III, IV and V lymph nodes were noted. Hepatosplenomegaly was noted with diffusely increased FDG uptake but no focal lesions. A few FDG avid peripancreatic, portocaval, paraaortic, aortocaval, mesenteric, bilateral common iliac, bilateral external iliac and inguinal lymph nodes were noted. There was a diffusely increased FDG uptake in bone marrow with no focal lesions. Based on the above findings, we gave differentials of lymphoma, infectious mononucleosis and post viral lymphoid activation, The diagnosis of EBV-associated infectious mononucleosis was clinched after a positive EBV VCA IgM. Antibiotics were stopped. The patient became afebrile after three weeks of illness and was discharged in a hemodynamically stable state with no subsequent recurrence of symptoms on follow-up. ***Conclusion:*** Infectious mononucleosis can be a close mimicker of lymphoma both clinically and on imaging. This case highlights the importance of considering infectious mononucleosis as a possible differential in young patients with prolonged fever, B-symptoms, lymphadenopathy and hepatosplenomegaly, even when the imaging findings are similar to lymphoma. An accurate diagnosis in such a setting is crucial to avoid unnecessary invasive procedures and patient panic.

## EP-0519

### Real world comparison of radiopharmaceutical parameters and clinical utility in kit based and in house labelled 99m Tc Ubiquicidin as a infection imaging agent

***D. Khan***, *S. Katala, N. A. Damle, C. Bal, S. Sagar, G. Arora, P. Kumar, M. Ansari, R. Kumar, H. Verma;*
*AIIMS Delhi, Delhi, INDIA.*

***Aim/Introduction:*** $^{99m}$Tc Ubiquicidin (UBI) 29-41 is used as an infection imaging agent. Ubiquicidin is a cationic synthetic antimicrobial peptide fragment that binds specifically to the anionic microbial cell membrane at the infection site. Though commercial kits are available, in house synthesis is also possible. The aim of this study was to compare the radiopharmaceutical and clinical aspects of the in house labelling technique with the kit based method of tracer synthesis. ***Materials and Methods:*** We retrospectively analysed forty $^{99m}$Tc-Ubiquicidin patient scans done using radiopharmaceutical synthesised by both in-house (n=20) and commercially available kits (n=20) performed during a period of two years. After intravenous injection of 10 mCi (555-740MBq) of 99mTc-UBI, dynamic images were taken for 15 minutes (with a 15-second frame per frame), followed by serial static (spot) images at 15, 30, 45, 60, and 120 minutes (atleast three sets of images per patient). A dual head SPECT/CT gamma camera with low energy higher resolution (LEHR) collimator was used to acquire the scans. At 45- 60 minutes after injection, whole-body anterior and posterior images were taken to confirm the biodistribution. A SPECT/CT scan was taken at the time of peak uptake in the suspected pathological lesion. ***Results:*** Both methods were evaluated for radiochemical purity through paper chromatography, and in-house labelling was found to be comparable with the kit-based labelling technique with a mean radiochemical purity of >90%. Biodistribution to liver, kidney and bladder was comparable in most of the scans by both techniques. However splenic uptake was noted more frequently in the kit based technique. Kit based method was approximately 10 times costlier than in house labelling method. Kits were available at periodic intervals while in house technique could be used daily thus serving to the patient requirements on time basis. ***Conclusion:*** Based on its cost effectiveness and easy, immediate availability, the in-house prepared 99mTc-UBI appears to be a more practically useful option than the kit-based preparation with comparable lesion uptake and biodistribution. Thus, the in-house method may be practised for labelling of UBI 29-41 with $^{99m}$Tc, especially in resource constrained settings.

**Heterogeneity of PSMA Expression Assessed by 68Ga-PSMA-11 PET/CT in Patients with clear-cell renal cell carcinoma**

***M. Zhang***;
*Department of Nuclear Medicine, Xijing Hospital, Xi'an, CHINA.*

***Aim/Introduction:*** Used 68Ga-PSMA-11 PET/CT to observe intra-tumoral and extra-tumoral heterogeneity of PSMA uptake in primary lesion and metastatic of clear-cell renal cell carcinoma (ccRCC). And analyzed the impact of primary lesions on metastatic lesions. ***Materials and Methods:*** Seventy-five ccRCC patients with preoperative 68Ga-PSMA-11 PET/CT scans and complete surgical specimens were retrospectively enrolled in this study. Radiographic parameters were obtained from PET/CT images, including SUVmax and VP (volume proportion of lesion in VOI: SUV higher than 50% SUVmax). Immunohistochemistry was used to measure the expression of PSMA. The Mann-Whitney U test analyzed continuous variables, and Chi-square test analyzed categorical variables respectively. Used ANOVA and t-test to compare the subtype groups, and used correlation analysis to assess the impact of primary lesions on metastatic lesions. Using Correlation Analysis to Analyze the Relationship between primary and metastatic. ***Results:*** Of the 75 primary lesions, 100% (75/75) PSMA uptake were positive. The average of SUVmax was 14.8±8.2 (CV=72.0%), TBR was 3.14±1.84 (CV=58.6%), and VP was 0.31±0.23 (CV=74.2%). Four patients with 21 bone metastases, 100% (21/21), PSMA uptake were positive. The average of SUVmax was 18.4±10.5 (CV=57.1%), TBR was 3.14±1.51 (CV=48.1%), and VP was 0.48±0.18 (CV=37.5%). Five patients detected tumor thrombus, 60% (3/5) was positive. The average of SUVmax was 7.1±6.0 (CV=84.5%), TBR was 2.14±2.11 (CV=98.6%), and VP was 0.79±0.15 (CV=19.0%). There were significant differences in PSMA SUVmax uptake (P=0.027) and high uptake area volume proportion (VP) (P=0.000) among the primary and metastatic lesions of ccRCC. There was no significant difference in PSMA SUVmax and VP of the primary lesion between local and advanced/metastatic ccRCC. However, the PSMA uptake avid and intra-tumoral heterogeneity of the primary lesion affected the attributes of metastatic lesions, especially the tumor thrombus (SUVmax: r=0.892; P=0.042; VP: r=0.954; P=0.193). ***Conclusion:*** The uptake of PSMA in the primary lesion and metastases of ccRCC had intra-tumoral and extra-tumoral heterogeneity. Heterogeneity of primary tumor, bone metastasis and tumor thrombus were different. The uptake characteristics of the primary lesion may impact on the metastatic lesion.

### EP-0521

**Dynamic characteristics of ureteral cancer with [11C]-choline total-body PET/CT**

***C. Liu***[1], *S. Wang*[2], *R. Wu*[3], *Q. Xie*[1], *Y. Yang*[2], *Z. Yang*[1];
[1]*Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Department of Urology, Peking University Cancer Hospital & Institute, Beijing, CHINA,* [3]*Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.*

***Aim/Introduction:*** The aim of this preliminary study was to investigate the value of dynamic [11C]-choline PET scans on the ureteral cancer. ***Materials and Methods:*** Nine patients with ureteral cancer were enrolled who were referred to [11C]-choline PET/CT before starting treatment. The patients underwent PET/CT scans with a United Imaging uEXPLORER PET/CT immediately after received an injection of [11C]-choline. The PET data were acquired using a list-mode for 30 minutes and dynamic image series in 1 minute per frame were reconstructed, resulting total 30 frames per patient. Volume-of-interests (VOIs) were placed on the primary tumor, descending aorta, posas major muscle and bladder by an experienced nuclear radiologist. The VOIs were carefully placed and adjusted on all dynamic image frames to keep the target tissue in the VOIs. The maximal standard uptake value (SUVmax) in the VOI was measured on each frame and time-activity-curve (TAC) of SUVmax was plotted. The tumor-to-muscle ratio (TMR) was calculated. ***Results:*** The patient cohort included 5 women and 4 men with an average age of 61±16 years, a height of 163±11 cm, a weight of 60±11 kg, and an injection dose of 250±25 MBq. All patients underwent the dynamic scans successfully without significant motions and the image quality of 1-minute frame was satisfactory for tumor delineation. The TMR reached 90% of the maximal level in 1 to 5 minutes after the injection. Normalized TAC of the tumors showed 3 dynamic patterns: plateau, ascent, and descent after a quick upward phase at the beginning frame. The activity in the aorta returned to the background level after 2 minutes post injection. We also found high bladder activity in 3 patients. ***Conclusion:*** Our result suggested static PET imaging between 2nd to 5th minute post injection provide optimal tumor-to-background contrast for ureteral cancer and minimize the interference of the blood pool or bladder. The TAC analysis demonstrated ureteral tumors have 3 dynamic patterns, although the physiological meaning of these patterns requires further study.

### EP-0522

**Role of Tc99m SestaMIBI SPECT/CT in characterization of renal lesions - A prospective study**

***K. Agrawal***, *R. Emerson P, P. Nayak, S. Purkait, P. S. Patro, G. K. Parida;*
*All India Institute of Medical Sciences (AIIMS), Bhubaneswar, INDIA.*

***Aim/Introduction:*** Many benign renal masses are overtreated as a result of conventional imaging overlap between benign and malignant imaging features. Even with biopsy, 10-20% of biopsy results are ambiguous, and biopsy of smaller lesions is difficult. Tc-99m SestaMIBI is a lipophilic cationic molecule taken up by cells that are rich in mitochondria. Clear cell and papillary renal cell carcinoma (RCC) have microvilli but no mitochondria. Therefore, we evaluated role of Tc-99m SestaMIBI in differentiation of malignant and benign renal masses. ***Materials and Methods:*** We prospectively included patients with the solid renal mass, who have not undergone biopsy or surgery, age >18 years and patients who will be willing to give a written informed consent form. The exclusion criteria were patients who have undergone previous biopsy or treatment for RCC, critically ill or hemodynamically unstable patients and pregnant and lactating mothers. The study was approved by institute ethics committee. 15 mCi of Tc-99m sestaMIBI was administered intravenously. SPECT-CT images of the abdomen was acquired at 1 hr. The image counts in 1 cm2 ROI was calculated in the renal mass and liver. ***Results:*** We included 16 patients in the study (male 11, female 5) with mean age 50.9

years (age range: 32 -77 years). Of 16 renal masses, 9 were clear cell RCC, 2 were papillary RCC, 1 undifferentiated malignant spindle cell tumour, 1 poorly differentiated malignancy, 1 granulomatous pyelonephritis and 1 angiomyolipoma. Renal mass to liver (R/L) count ratio was less than 1 in 13/16 patients (all 13 were malignant histopathology). R/L ratio was more than 1 in 3 patients (one clear cell RCC, one granulomatous pyelonephritis and one angiomyolipoma). Sensitivity of R/L ratio in diagnosis of malignant pathology is 92.8% and specificity is 100%. ***Conclusion:*** Although the number of patients studied in the study is less, early result shows that renal count to liver count ratio in the Tc-99m SestaMIBI SPECT-CT is highly sensitive and specific method to distinguish malignant and benign renal lesion.

## EP-0523

### Are non-sampling methods useful for assessing GFR in a potential living kidney donor? A comparative study with the 3-sample method

***M. A. Hernández Fructuoso***, *C. G. Franco Monterroso, B. Santos Montero, L. Garcia Lama, L. Rey Sánchez, V. Pascual Pascual, A. Garcia Burillo;*
*Hospital Universitari Vall d'Hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** The glomerular filtration rate (GFR) is the best overall indicator for the evaluation of renal function and its accurate determination is required in donor candidates for renal transplantation. Estimated GFR (eGFR) calculations can be performed using different methods. We have previously validated a three-blood sample method with [$^{99m}$Tc]Tc-DTPA (SM) that was used as a reference in this study (1). Our aim was to assess the agreement between in vitro blood sampling method (SM) with other commonly used method in clinical practice: in vivo GFR measurement using [$^{99m}$Tc]Tc-DTPA scintigraphy (Gate's method), and two different GFR estimation equations based in creatinine clearance (Chronic Kidney Disease Epidemiology Collaboration, CKD-EPI, and Modification of Diet in Renal Disease, MDRD-4). ***Materials and Methods:*** GFR was measured in 57 potential kidney donors (aged 55; range 71-26 years, female 35) by bolus i.v. injection of 18.5MBq of [$^{99m}$Tc]Tc-DTPA and plasma clearance analysis using 3 extractions at 120', 180' and 240' and Chandler's correction was applied. After, 185MBq were administered i.v. and immediately dynamic study was performed in gammacamera for twenty minutes, and GFR was estimated by Gate's method. GFR was also calculated according to the CKD-EPI and MDRD-4 equations based on creatinine clearance. The correlation and agreement of SM, Gate's method, CKD-EPI and MDRD- 4 were assessed by linear regression and the absolute errors (Ea= SM GFR- non-sampling methods GFR) were calculated. ***Results:*** Mean measured GFR by MS method was 105.39±20.55 ml/min/1.73m$^2$ and median was 106.66 ml/min/1.73m$^2$. Means estimated by Gate's methods, by CKD-EPI and by MDRD-4 were 72.08±16.79 ml/min/1.73m$^2$, 93.45 ±12.35 ml/min/1.73m$^2$, and 92.08± 14.71 ml/min/1.73m$^2$ respectively. The Pearson's correlations between MS and Gate's method, MS and CKD-EPI and MS and MDRD were r=0.51, r=0.61 and r=0.59 p< 0.01, respectively. All methods underestimated GFR, and the mean absolute error was 32.82, 12.72 and 15.06 ml/min/1.73m$^2$ for Gate's, CKD-EPI and MDRD-4 methods. ***Conclusion:*** Gate's GFR estimation showed a weak positive correlation with MS and equations based on creatinine clearance showed a moderate correlation with MS, but all methods systematically underestimated the GFR obtained by the three-sample method. Furthermore, the Gate's method seems to be unacceptable to estimate GFR in potential kidney donors due to their wide range of error. ***References:*** 1) Eur J Nucl Med Mol Imaging (2020) 47 (Suppl 1): S1-S753

## EP-0524

### Assessing the Reliability of GFR Estimation with Lateral Kidney Centroid Depth of 99mTc-DTPA and 99mTc-MAG3 Renography

***K. Thawinprawat***;
*Siriraj Hospital, Bangkok, THAILAND.*

***Aim/Introduction:*** Camera-based Glomerular filtration rate (cGFR) from $^{99m}$Tc-diethylene triamine pentaacetic acid ($^{99m}$Tc-DTPA) and mercaptoacetyltriglycine (MAG3) clearance methods from $^{99m}$Tc-MAG3 are commonly used in clinical practice due to their non-invasiveness and simplicity. However, cGFR and derived GFR (dGFR) from MAG3 clearance can be affected by the depth of the kidney. Hence, we proposed the lateral kidney centroid depth (L-depth) method to improve the estimated GFR (eGFR) and evaluated its performance with commercially available methods. ***Materials and Methods:*** The study population comprised 69 patients (6 $^{99m}$Tc-DTPA, 63 $^{99m}$Tc-MAG3). Scintigraphy was performed after injecting 370 MBq of two radiopharmaceuticals ($^{99m}$Tc-DTPA and $^{99m}$Tc-MAG3), followed by dynamic acquisition for 30 minutes and bilateral static scans for 1 minute. Kidney depth was measured using commercially available methods (Taylor's method and Tonnensen's method) and L-depth. Subsequently, cGFR and dGFR were compared with eGFR. ***Results:*** Based on the type of radiopharmaceutical administered, the data were sorted into two groups. In the $^{99m}$Tc-DTPA group, cGFR from Tonnensen's method and L-depth show weak correlation with eGFR ($r^2$ = 0.193 and $r^2$ = 0.199, respectively). In contrast, in the $^{99m}$Tc-MAG3 group, dGFR from Taylor's method and L-depth show moderate correlation with eGFR ($r^2$ = 0.412 and $r^2$ = 0.452, respectively). The weighted r-square of commercially available methods and L-depth to eGFR are 0.346 and 0.364, respectively. ***Conclusion:*** Lateral scanning is a more reliable approach in determining GFR for both radiopharmaceuticals.

## EP-0525

### Reproducibility of normal Gallbladder Ejection Fraction at 30 min by Biliary Scintigraphy for Diagnosis of Biliary Dyskinesia

***M. A. Olarte***, *D. Cardosa-Cisneros, I. Soldevilla-Gallardo;*
*American British Cowdray Medical Center, Mexico City, MEXICO.*

***Aim/Introduction:*** The diagnosis of gallbladder dyskinesia is usually made by calculating the gallbladder ejection fraction via cholescintigraphy. Ziessman et al. evaluated the use of a commercially available lactose-free fatty-meal food supplement, as an alternative to CCK analog cholescintigraphy, to develop a standard methodology, and to determine normal gallbladder ejection fractions (GBEFs) for this supplement at 1 h later. Being a dynamic and time-consuming scan, it is necessary to determine the gallbladder ejection fraction at 30 minutes in order to reduce the image acquisition time, improve patient comfort, and increase the availability of the gamma camera to be able to carry out other

scans. ***Materials and Methods:*** Thirty-four patients (19 women, 15 men) were studied. They ranged in age from 40.4 to 43.4y. Conventional cholescintigraphy was performed. After voiding, the patient ingested 240-mL (8 oz) can of the supplement while sitting. Patients again lay supine, and images were acquired for 60 min (60 s/frame, 128 x 128). Image processing was performed at the Infinia Hawkeye 4.0 equipment workstation, obtaining the gallbladder ejection fraction at 30 and 60 min after oral stimulation with standardized food, following the recommendations proposed in the guide: Guideline for Hepatobiliary Scintigraphy 4.0 (SNMMI) published in 2010. ***Results:*** Gallbladder ejection fractions (GBEFs) ranged from 1% to 95% at 30 min. The activity-time curves were variable for each patient. Most of the patients presented a time-activity curve with a linear pattern and only one subject showed delayed phase to contractile stimulus at 30 minutes (1% emptying at 30 minutes). The lowest GBEF of the other 33 subjects was 21%. However, the results obtained at 30 min depend on the contractile response of the gallbladder of each patient. ***Conclusion:*** In special situations in which it is not possible to perform a conventional cholescintigraphy, either due to the prolonged inability of the patient to remain lying down or due to insufficient time, we recommend a 30 min phase of vesicular contraction instead of 60 min using a commercially available lactose-free fatty flour food supplement standardized. Normal GBEF values with this short protocol is established with a lower limit of normality of 21% at 30 min. If GBEF is above that value, the patient can be considered not to have a functional disorder of the gallbladder. ***References:*** Ziessman Harvey A. et al. Cholecystokinin Cholescintigraphy: Methodology and normal values using a lactose-free fatty-meal food supplement. J Nucl Med. 2003;44:1263-1266.

## EP-0526

### 75Se- Taurocholic acid in the study of Chronic Diarrhea. Our Experience

***C. Paniagua Correa****, L. Castillejos Rodríguez, A. Herrero Muñoz, D. Rodriguez Oviedo, C. Galindo Fernández, B. Manzarbeitia Arroba, M. Alvarez Moreno, A. Ortega Valle, C. Sandoval Moreno, M. De la Rubia Marcos, M. Tagliatori Nogueira, P. García Alonso; Hospital De Getafe, Getafe, SPAIN.*

***Aim/Introduction:*** To assess our experience with $^{75}$SeHCAT scintigraphy in the diagnosis of bile acid malabsorption (BAM) as a cause of chronic diarrhea. ***Materials and Methods:*** We studied 168 patients with diarrhea (119 women and 49 men, mean age 53.9 years), from April/2015 to December/2022. After oral administration of 0.01 mCi (0.37 MBq) capsule of $^{75}$Se-taurocholic acid, abdominal scintigraphic images were acquired (at 3 h and on the 7th day), and pre/post-acquisition fundus measurements, to calculate its percentage retention (positive study due to retention of the tracer on the 7th day < 10%). ***Results:*** • Of the 168 patients, the test was positive in 74 (43.45%). • According to the reason for the request: o 40/168 (23.8%) had undergone cholecystectomy: 25 (62.5%) were positive; o 20/168 (11.9%) had a history of ileal and/or colonic surgery: 14 cases (70%) positive; o 2/168 (1.19%) had Crohn's disease, both positive (100%); o 80/168 (47.6%) had mainly diarrhea: 31 cases were positive (38.75%); o 26/168 (15.47%) were associated with other clinical-analytical data: 2 positive (7.69%) had vitamin B12 deficiency. • We observed a notable increase in requests for the test in the last 2 years, as it was included in the diagnostic algorithm for chronic diarrhea (because it is a simple, objective and cost-effective method), representing 57.14% of the studies performed (96/168), and 47.3% of the positives (35/74). In the previous 6 years (72 studies/168 = 42.86%), the percentage of positives (39/74 = 52.7%) corresponded mainly to patients with a surgical history, including 42 of the 60 operated patients in the sample (70%), with 64.28% (27/ 42) being positive. ***Conclusion:*** The $^{75}$SeHCAT test is a non-invasive, objective, easy-to-perform and relatively inexpensive test of high diagnostic value in chronic diarrhea, being considered a gold standard method for BAM. Especially useful in patients with digestive surgery.

## EP-0527

### 99米Tc-DTPA肾脏动态成像评估成人患者双功肾功能

***X. Yan***[1]*, Y. Ning*[1]*, Y. Chen*[1]*, M. Cai*[2]*, S. Li*[3]*;*
*[1]Shanxi Medical University, Tai Yuan, CHINA, [2]Shanxi provincial People's Hospital & Fifth Clinical College of Shanxi Medical University, Tai Yuan, CHINA, [3]The first hospital of Shanxi Medical University, Tai Yuan, CHINA.*

***Aim/Introduction:*** To explore technetium-99m-diethylene-triaminepentaacetic acid ($^{99m}$Tc-DTPA) renal dynamic imaging in evaluating the function of duplex kidneys in adult patients. ***Materials and Methods:*** A retrospective study was conducted on 19 patients with duplex kidney who were subjected to $^{99m}$Tc-DTPA renal dynamic imaging. Patients were divided into normal and abnormal group according to the imaging data. Additionally, 19 normal patients were selected as the control group. After imaging, the region of interest (ROI) of the kidneys were delineated, and the renography were obtained, which could provide renal function parameters, including glomerular filtration rate (GFR), $T_{max}$, $T_{1/2}$, renal clearance, and the uptake rate of duplex renal segment (upper renal moiety). ***Results:*** Compared to the control group, the serum creatinine in the duplex kidney group was higher (P=0.026), and the GFR was lower (P=0.008); the patients with impaired renal function were mainly in the abnormal renography group (P=0.008). In the duplex kidney group, the renal clearance of the affected kidney was lower than contralateral kidney (P=0.009), but no significant differences in other indicators. There were no differences in renal function indicators between different uptake rate in upper renal moiety; however, there was a trend that when the uptake rate was higher than 50%, the renal function was worse. ***Conclusion:*** This study showed that $^{99m}$Tc-DTPA renal dynamic imaging could be used to evaluate total and split renal function, and even upper urinary tract patency in patients with duplex kidney. The patients with abnormal renography had worse renal function, and the patients with poor renal clearance in affected renal moiety should receive surgical treatment.

## EP-0528

### V/P-SPECT detection of pulmonary thromboembolism in patients with respiratory infections: a diagnostic challenge?

***I. C. Ferreira****, R. T. Ferreira, J. G. Santos, A. I. Santos; Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL.*

***Aim/Introduction:*** Infectious conditions, particularly viral infections, have been associated with increased risk of venous thromboembolism. The association between respiratory infections (RI) and pulmonary thromboembolism (PTE) has not been well established, however, pneumonia is a common cause of hospitalisation that can be complicated by PTE, especially in patients with risk factors such as immobility. PTE diagnosis in these patients can be challenging because of overlapping features. Clinical suspicion, D-Dimer values (DD) and CT pulmonary angiogram are often first line diagnostic measures for PTE, but ventilation/perfusion single photon emission

computed tomography (V/P-SPECT) may also be used. We aimed to evaluate the prevalence of PTE in hospitalised patients with RI in whom V/P-SPECT was performed due to either persistent respiratory symptoms despite adequate treatment or appearance of other signs or symptoms. ***Materials and Methods:*** We retrospectively analysed hospitalised patients with a diagnosis of RI who underwent V/P-SPECT in our department, referred for suspicion of PTE, and classified them according to V/P-SPECT results (positive or negative for PTE). DD (µg/mL), age, gender, RI aetiology, reason for referral, and hospitalisation time in days (HT) were also recorded. Descriptive statistics and nonparametric tests were applied using IBM SPSS Statistics for Macintosh, Version 26.0. ***Results:*** Between January and December 2022, 35 patients (60% female) were selected, 27(77%) with negative and 8(23%) with positive V/P-SPECT, median ages being, respectively, 73[P25:65;P75:83] and 56[P25:39;P75:72] years; and median DD being 0,99[P25:0,48;P75:2,58] and 3,65[P25:1,96;P75:14,52] µg/mL, respectively. Mann-Whitney Test (MWT) showed a statistically significant difference in age and DD, between the two groups (p=0.017 and p=0.027, respectively). However, no statistically significant difference was found for hospitalisation time between the two groups (p=0.923; MWT). Of those with positive V/P-SPECT, 6(75%) had viral RI (3 with SARS-CoV-2 infection), with the remaining having bacterial RI. Within the negative V/P-SPECT sample, 11% had viral RI and 89% had bacterial RI. Pulmonary hypertension was present in 1 positive V/P-SPECT and in 3 of the negative group. ***Conclusion:*** Our results suggest an increased possibility of PTE in the presence of viral RI, younger age, and higher D-Dimer levels, as expected. Surprisingly, hospitalisation time (often linked to immobilisation and higher PTE risk) was not longer in our PTE group. However, small sample size limited our study. Further research is needed to validate these findings and establish the optimal clinical and analytical standards for requesting V/P-SPECT.

## EP-0529

### Diagnostic Contribution of Volumetric Analysis of Lung Perfusion SPECT/CT in Location of Pulmonary Thromboembolism

***N. Alvarez Mena***, *F. Sebastián Palacid, M. García Aragón, R. Zambrano Infantino, B. Pérez López, R. Ruano Pérez;*
*Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.*

***Aim/Introduction:*** To assess the diagnostic accuracy of volumetric analysis of pulmonary perfusion SPECT/CT for the localisation of pulmonary thromboembolism and to compare these results with those observed with visual analysis. ***Materials and Methods:*** Retrospective series of 100 consecutive patients diagnosed with pulmonary thromboembolism (PTE) after a positive result in lung perfusion SPECT/CT (> 50% segment involvement and visualised in all three planes). Variables such as age, sex, acute or chronic PTE, laterality (uni- or bilateral), location and extent of perfusion defects were analysed. To evaluate the location and extent of perfusion defects, quantification analysis was performed using SPECT/CT segmentation (Q.Volumetrix software, GE). Subsequently, these results were compared with those observed in the visual analysis and the concordance between the two methods was assessed ($\chi 2$ test). ***Results:*** Mean age 73 ± 16 years (26-98 years). 59% female. When comparing the results obtained in the volumetric analysis with the visual analysis, a discordance of up to 41% of the patients evaluated was observed ($p < 0.05$). In this group, up to 68% (28/41) had chronic PTE. Regarding laterality, no significant differences were noted (23 bilateral and 18 unilateral). In the assessment of perfusion defect, overestimation of perfusion defects with visual analysis was more frequent (23 patients actually with less extension: 15 patients with involvement of fewer lobes and 8 patients with involvement of fewer segments). In addition, discordance in the location of the perfusion defect was observed in up to 9 patients (involvement of a different lobe in 4 patients and of a different segment in 5 patients). Of the 41 patients with discordance between the two analyses, 80% (33/41) had involvement in 2 or more lobes (55% of these were associated with involvement of 2 or more segments). Of the 59 patients with concordance between volumetric and visual analysis, up to 60% with single lobe involvement (97% of these with single segment involvement). ***Conclusion:*** Volumetric analysis of lung perfusion SPECT/CT is superior to visual analysis for more accurate localisation of perfusion defects in the clinical setting of pulmonary thromboembolism. Furthermore, it has a special interest in patients with chronic pulmonary thromboembolism or with multilobar or multisegmental involvement, where perfusion defects can often be difficult to evaluate. Finally, since volumetric analysis shows a better estimation of perfusion defects compared with visual analysis, its clinical application could modify the therapeutic approach.

## EP-0530

### The prevalence of pulmonary thrombo-embolism in pregnancy guided clinically by maternal tachycardia

***A. Alnabulsi***[1], *A. Ayeni*[2], *S. More*[1];
[1]*Division of Nuclear Medicine, Department of Radiation Medicine, University of cape Town, Cape Town, SOUTH AFRICA,*
[2]*Division of Nuclear Medicine, Department of Radiation Medicine, University of cape Town, Capetown, SOUTH AFRICA.*

***Aim/Introduction:*** Pulmonary embolism (PE) is a life-threatening complication in pregnant and postnatal patients. Clinical suspicion of PE on the basis of clinical presentation varies particularly in pregnant patients. The challenge is still growing, especially in the absence of sensitive pretest clinical probability for PE in pregnancy utilizing VQ studies. The purpose of this retrospective study was to evaluate the accuracy of the clinical index in predicting PE in pregnant and postnatal patients and to determine the rate of false suspicion based on maternal tachycardia as a presenting symptom. ***Materials and Methods:*** A retrospective study of SPECT VQ scans of all female patients with clinical suspicion of PE was undertaken in the Department of NM. Studies were performed between 2016 and 2023. The study included all pregnant patients and those 6 weeks postpartum. Patients also had to have tachycardia that was defined by >100 beats/minutes with sign and symptoms of possible PE. The EANM criteria was used to define positive PE as a Ventilation/Perfusion mismatch of at least one segment or two sub-segments in keeping with the pulmonary vascular anatomy. ***Results:*** A total of 73 patients were included as part of the study. Thirteen (13) patients out of 73 were positive for PE (18%) with only one patient during pregnancy, in the age range of 16 to 39 years old, with a median age of 26 years old. The positive PE cases (10 patients) representing 14% of total positive PE cases presented from two days post caesarean section. While there were only 2 positive cases after the 2$^{nd}$ week of normal vaginal delivery. In total there were 58 (82%) negative scans for PEs. On the other hand, there were two positive scans for PEs during pregnancy with normal heart rate and known comorbidity. There was no significant association with clinical symptoms and maternal tachycardia in the patients who had negative scans for PE. ***Conclusion:*** The study suggests that the clinical index with

guidance of maternal tachycardia was of limited value during pregnancy and could not be accurate enough to predict PE during pregnancy. While during postnatal period, especially after C-section the prevalence of positive PE was the highest out of all, representing roughly 77% of all positive PE cases. The unnecessary exposure to radiation during pregnancy is highly concerning. This study is intended to encourage further development of the clinical suspicion criteria and algorithm during pregnancy for PE.

## EP-0531

### Are Planar Images In Pulmonary Perfusion Scintigraphy Sufficient For Positive Diagnosis Of Pulmonary Embolism In Pregnant Women?

***L. Zaabar***[1,2], *K. Ben Amara*[3], *T. Ben Ghachem*[1,2], *D. Ben Sellem*[1,2], *B. Letaief*[1,2], *A. Mhiri*[1,2];
[1]*Salah Azaeiz Institute, Tunis, TUNISIA,* [2]*Faculté de Médecine de Tunis, Tunis, TUNISIA,* [3]*Health Ministery, Tunis, TUNISIA.*

***Aim/Introduction:*** Pulmonary embolism (PE) in pregnant women (PW) remains a major cause of maternal morbidity and mortality. Its positive diagnosis is difficult due to non-specificity of clinical and para-clinical signs (excluding imaging). Our study's aim was to describe the contribution of pulmonary perfusion scintigraphy (PPS) with basic scanning protocol in PW with suspected PE, and thus the risks of irradiation incurred for the fetus. ***Materials and Methods:*** Descriptive retrospective study conducted from January 2019 to December 2021, including 184 PW with suspicion of PE, referred to nuclear medicine department at Salah Azaiez Institute in Tunis for PPS. PPS were performed in planar mode (4 views at least). We did not perform ventilation imaging (not available) neither tomography . Patient results were classified into three groups according to PIOPED criteria (G1:High probability of PE. G2: Normal PPS, no PE. G3: inconclusive result: Low probability and intermediate probability of PE). ***Results:*** Median age to patients was 30.3 years. Mean age of pregnancy was 30 week of amenorrhea with a median of 31. Diagnostic yield of PPS was 84% (contribution in 155 PW): G1 with 18 PW (10%) and G2 with 137 PW (74%). It was inconclusive in 29 PW (16%): intermediate probability of PE (16 patients, 9%) and low probability of PE (13 patients, 7%). The statistically significant correlation between clinical symptoms and a positive PPS result was found for the triple association "palpitation, chest pain and dyspnea" noted in three patients (p=0.03), with a sensitivity of 16.67%, a specificity of 96.84%, positive predictive value (PPV) of 37.5% and negative predictive value (NPV) of 91.07%. PPS performances were as comparable as PPS associated to ventilation scanning reported in the litterature.Fetal radiation exposure from chest CT angiography and PPS was poor, lower than natural radiation exposure. ***Conclusion:*** Diagnostic approach orientation in PE depends crucially on clinical probability, but the different clinical scores are not validated in PW and need to be reviewed and adapted as well as the safety and PPV and NPV of imaging means. Technically, the indication of PPS in hybrid mode (SPECT/CT) remains to be enlarged more and more routinely, even in the situation of high clinical probability in PW.

## EP-0532

### Hepatic [18F]FDG uptake in patients with obesity: a study on the effect of NAFLD

***U. Ustsinau****, O. Kulterer, M. Krssak, I. Rausch, F. Kiefer, C. Philippe; Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Excessive hepatic fat accumulation characterizes Non-alcoholic Fatty Liver Disease (NAFLD), which is prevalent in more than 80% of people with obesity. The potential limitations of hepatic [$^{18}$F]FDG-PET imaging for patients with NAFLD are being investigated. The study aimed to determine the reliability of standardized uptake values (SUVs) obtained from [$^{18}$F]FDG-PET in obese subjects, focusing on correction for liver fat content and the effects of whole-body normalizations. ***Materials and Methods:*** Twenty-one lean (M: 10, F: 11, BMI: 19-26kg/m$^2$) and eleven volunteers with obesity (M: 8, F: 3, BMI: 30-39kg/m$^2$) underwent [$^{18}$F]FDG-PET/MR scanning. Dixon images were used to estimate liver fat content and to correct $SUV_{aver}$ for fat[1]. The liver SUVs (aver and max) were normalized to body weight (BW), lean body mass (LBM) and body surface area (BSA) for comparison. Blood samples were analyzed for glucose, GPT, GOT, gGT, insulin, triglycerides, cholesterol, HDL and LDL levels. ***Results:*** Under all normalizations, the median hepatic [$^{18}$F]FDG uptake ($SUV_{aver}$) of the obese group was insignificantly lower compared to the lean group having similar glucose levels. Dixon images confirmed the presence of NAFLD (>5.6% fat[2]) in nine out of eleven volunteers with obesity. Correction of $SUV_{aver}$ for liver fat resulted in increased uptake values in all subjects, with a significant increase in $SUV_{aver}$(BW) in the obese group, likewise observed in $SUV_{max}$(BW). Looking at the individual values using BW and LBM normalizations, with a rise of BMI, SUVs of lean volunteers decreased ($SUV_{aver}$) or remained steady ($SUV_{max}$), whereas the obese group always increased. With BSA normalization, slope of both groups is high, and the extreme minimum lies in BMI of 23-32kg/m$^2$. Additionally, SUVs were independent of levels of GPT, GOT, gGT, insulin, triglycerides, cholesterol and LDL, but low HDL levels (<35 mg/dL) could be associated with an increased hepatic [$^{18}$F]FDG uptake in the obese group. ***Conclusion:*** Hepatic [$^{18}$F]FDG uptake is a result of a combination of hepatocyte function, effects of fat dilution and whole-body metabolic state, including blood glucose and insulin resistance. Therefore, to achieve accurate results for patients with obesity, raw SUV should be combined with correction for the liver fat, corresponding normalization (LBM) and careful consideration of blood glucose and HDL levels. The findings provide insights for clinicians and researchers working in the field of obesity and NAFLD and may help to improve the reliability of hepatic [$^{18}$F]FDG-PET imaging. ***References:*** [1] Keramida G et al. doi:10.2214/AJR.13.12147 [2] Sheka AC et al. doi:10.1001/jama.2020.2298

## EP-0533

### Pre-treatment pituitary gland [18F]FDG uptake in oncological patients

***C. A. Ruiz-Bedoya***[1,2], *S. F. Barrington*[1,3], *M. Yakubu*[1], *A. Hammers*[1], *G. J. R. Cook*[1,3], *M. Subesinghe*[1,3];
[1]*King's College London & Guy's and St. Thomas' PET Centre, London, UNITED KINGDOM,* [2]*Department of Imaging Chemistry & Biology, School of Biomedical Engineering and Imaging Sciences, King's College London, London, UNITED KINGDOM,* [3]*Department of Cancer Imaging, School of Biomedical Engineering and Imaging Sciences, London, UNITED KINGDOM.*

***Aim/Introduction:*** Research exploring the variability of physiological pituitary uptake on [$^{18}$F]FDG PET-CT is scarce although sex and age-related differences in pituitary size on MRI have been described. Knowledge of the range of physiological pituitary uptake will help identify pituitary abnormalities, which is of importance in the era of immunotherapy and immune-related adverse events, which include hypophysitis. The aim of this study was to quantify normal ranges for pre-treatment pituitary [$^{18}$F]FDG uptake and explore any sex and age-related variation in oncological patients. ***Materials and Methods:*** Retrospective analysis on pre-treatment [$^{18}$F]FDG PET-CT scans obtained between April and December 2022 in adult patients (≥ 18 years) with either myeloma

or head and neck cancer (HNC), where scan coverage included the pituitary. Patient demographics and scan acquisition parameters were collated. $SUV_{max}/SUV_{mean}$ for the pituitary and mediastinal blood pool (MBP) were obtained using a $1cm^3$ volume of interest centred on the sella turcica and aortic arch, respectively; this enabled calculation of pituitary-to-mediastinal blood pool ratios, i.e. target-to-background ratios (TBRs). ***Results:*** 256 FDG PET-CTs were reviewed with a higher proportion of males (171 patients = 66.8%), particularly in patients with HNC. There were no significant differences between the sexes with respect to age 64.7 ± 12.7 years; BMI 25.4 ± 5.4 $kg/m^2$; injected [$^{18}$F]FDG dose 337.0 ± 24.5 MBq; uptake period 64.2 ± 5.9 min and capillary blood glucose level 5.9 ± 1.2 mmol/l (Table 1). The median pituitary $SUV_{max}$ in our cohort was 2.9 (interquartile range (IQR): 2.6-3.4), $SUV_{mean}$ 2.5 (IQR:2.1-2.8), $TBR_{max}$ 1.6 (IQR: 1.3-1.8) and $TBR_{mean}$ 1.5 (IQR: 1.3-1.7). There was no correlation between age and $SUV_{max/mean}$ and $TBR_{max/mean}$ parameters ($r< 0.001$, $p > 0.1$). The median pituitary $SUV_{max}$ in females (3.2; IQR: 2.6-3.6), was significantly higher ($p = 0.001$) than in males (2.9; IQR: 2.5-3.2); the median pituitary $SUV_{mean}$ was also significantly higher in females (2.7 vs. 2.2, $p = 0.0002$). There was no significant difference in $TBR_{max}$ between females (1.6; IQR 1.4-1.9) and males (1.6; IQR: 1.3-1.8) nor $TBR_{mean}$ (1.6 vs. 1.5, $p > 0.5$). ***Conclusion:*** Our study quantifies the variation in normal physiological pituitary uptake on [$^{18}$F]FDG PET-CT in oncological patients, prior to treatment, and is the first to highlight differences in pituitary uptake between males and females. Although further research is required to understand the reasons underpinning this, these data will assist PET-CT reporters to differentiate normal from abnormal pituitary uptake.

## EP-0534

### Relationship between the severity of vesicoureteral reflux and renal scarring in children. About 162 patients.

***M. Habbache***, *Q. Naili, M. Abdi;*
*Nuclear medicine Center or Blida, Algier, ALGERIA.*

***Aim/Introduction:*** Vesicoureteral reflux (VUR) is associated with an increased risk of renal scarring, which can lead to long-term complications such as hypertension and renal failure. The aim of this retrospective study was to evaluate the relationship between the severity of VUR and renal scarring in children. ***Materials and Methods:*** We retrospectively studied 162 children under 14 years old with VUR who presented to our department between 2013 and March 2023. Children who were more than 6 months after their last urinary tract infection episode were included. Static renal scintigraphy with Tc-99m dimercaptosuccinic acid (DMSA) was used to evaluate renal scarring. The severity of VUR was graded according to the International Reflux Study, and Pearson correlation coefficient was used for statistical analysis ***Results:*** Of the 240 kidneys with reflux evaluated, 58.7% had renal scars on DMSA scans. The percentage of scarring kidneys increased with the severity of VUR: 13% in grade I , 27% in grade II , 45% in grade III , 81% in grade IV , and 92% in grade V . There was a strong correlation between the severity of VUR and the formation of renal scarring ($r = 0.985$, $p < 0.01$). High-grade VUR (grades 3-5) was responsible for 95 (39%) of scarring, while low-grade VUR (grades 1-2) was only responsible for 13 (5%) of scarring. Five patients with high-grade bilateral reflux were at the stage of renal failure ***Conclusion:*** The severity of VUR is strongly associated with renal parenchymal damage and the formation of renal scarring. High-grade VUR is particularly associated with a higher risk of renal scarring and potential long-term complications. Early detection and management of VUR in children is crucial in preventing the development of renal scarring and long-term sequelae

### Actinium225 -DOTATATE peptide receptor radionuclidetherapy(PRRT) as first line treatment in two cases of bowel Neuroendocrine tumors

***K. Kamaleshwaran***, *E. Ramkumar;*
*Kovai Medical center and Hospital limited (KMCH), Coimbatore, INDIA.*

***Aim/Introduction:*** we report first clinical experience of two cases of rectal and ileal NET treated with Actinium225(Ac225)-DOTATATE as first line treatment . ***Materials and Methods:*** First patient is 65 year old male presented with rectal pain ,on evaluation found to have rectal lesion and biospy showed grade 1 NET(Ki67-4%).Ga68 DOTANOC PET CT showed intense avid pararectal lesion, retroperiotneal lymphnodes ,liver lesions and right rib metastases.He underwent Ac225 DOTATATE . Posttherapy images were acquired at 24 hours. High energy general purpose collimators were used for both whole body and SPECT/CT using 218.keV and 440keV photon energies with 20% window width. Repeat PET CT at 2 months showed partial response in all lesions and CgA showed decreasing trend. He underwent 2nd cycle and on followup with no side effects and complete pain relief. ***Results:*** Second patient is 70 year old male on diagnostic laparascopy showed multiple small bowel lesions ,on biopsy showed grade 1 NET .Ga68 DOTANOC PET CT images showed atleast 5 lesions in ileum with mesentric nodes .Patient prefered for Ac225 DOTATATE as first line treatment .After 2 months ,Interim PET CT showed partial response and without any side effects . ***Conclusion:*** We present here our first clinical experience on Ac225- DOTATATE therapy in 2 NET patients, a promising first line treatment option extending new dimension to treatment of NET.Post therapy Ac225 DOTATATE SPECT CT and whole body images were acquired at 218 and 440 Kev .Both patients showed partial response with no side effects and is on followup . ***References:*** Ian Selçuk N, Demirci E, Ocak M, Toklu T, Ergen S, Kabasakal L.Almost Complete Response with a Single Administration $^{225}$Ac-DOTATATE in a Patient with a Metastatic Neuroendocrine Tumor of Unknown Primary.Mol Imaging Radionucl Ther. 2022 27;31(2):139-141

### Discovery of blood transcriptomic markers for response to [177Lu]Lu-DOTATATE in locally advanced or metastatic neuroendocrine neoplasms

***S. Bae***[1], *H. Sung*[2], *H. Choi*[2], *H. Im*[3], *M. Suh*[2], *J. Paeng*[2], *G. Cheon*[2], *K. Kang*[2];
[1]*Institute of Radiation Medicine, Medical Research Center, Seoul National University, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Applied Bioengineering, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-DOTATATE is a treatment of choice for advanced or metastatic well-differentiated neuroendocrine neoplasms (NENs) that highly express the somatostatin receptor (SSTR). Imaging modalities including CT and SSRT PET have limitation in predicting response to radioligand therapy (RLT).

A few blood biomarkers such as NETest and PPQ have been suggested for assessing and predicting response, but might not completely explain dynamic changes during RLT. The study aims to identify early transcriptomic alterations in blood during RLT in relation to treatment responses. ***Materials and Methods:*** Locally advanced or metastatic NEN patients receiving [$^{177}$Lu]Lu-DOTATATE and with no prior RLT were prospectively enrolled from June 2021 to May 2022. Response to RLT was evaluated after the fourth cycle using contrast-enhanced CT and RECIST 1.1. Blood samples were collected before the first cycle and within one day of the second cycle for bulk RNA sequencing and differential gene expression analysis. Genes exhibiting larger absolute time differences in PD compared to PR or SD, with increased or decreased expression relative to baseline, were classified as 'PD:pos' or 'PD:neg'. Similarly, for comparison between PR and SD or PD, genes were grouped as 'PR:pos' or 'PR:neg'. The expression of the selected genes in primary or metastatic NEN tissues and in normal tissues was compared using publicly available datasets. The proportion and alteration of immune cells in blood across time were examined. ***Results:*** In the study, 16 patients were enrolled, consisting of 10 men and 6 women ranging in age from 26 to 78 years old. The tumor volume measured by SSTR PET was not significantly different between the response groups. Among PD:pos, PD:neg, PR:pos, and PR:neg gene groups, PR:pos group was significantly associated with Gene Ontology (GO) such as the G protein-coupled receptor signaling pathway and regulation of calcium ion. Additionally, 10 out of 15 genes in the PR:pos group showed lower average expression in NENs compared to normal tissues. PR:pos genes did not overlap with the NETest genes, and the NETest genes did not show significant transcriptomic alteration during the first cycle of PRRT. Finally, among the cell types, proportion of CD4+ T cells demonstrated a decreasing pattern over time in the PD group, whereas changes were irregular in other response groups. ***Conclusion:*** The response to RLT was associated with early upregulation of GPCR-related calcium pathways after the first treatment. The proposed dynamic blood biomarkers are expected to represent early biological events after RLT.

## EP-0537

### Long-term effects of peptide receptor radionuclide therapy (PRRT) used as a first-line treatment of GEP-NET - a single centre experience

***M. Opalinska***, *K. Morawiec-Slawek, A. Kurzynska, A. Sowa-Staszczak, A. Hubalewska-Dydejczyk;*
*Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland, Krakow, POLAND.*

***Aim/Introduction:*** Peptide receptor radionuclide therapy (PRRT) is a well-recognized treatment option for inoperable/metastatic somatostatin receptor-positive neuroendocrine tumours (NET). According to the current guidelines it is recommended as a second or a third line of the treatment. Aim: Retrospective analysis of the outcomes and adverse effects of PRRT in patients treated with ([90Y]Y-DOTA-TATE or [90Y]Y/[177Lu]Lu-DOTA-TATE or [177Lu]Lu-DOTA-TATE) as a first line treatment due to metastatic GEP-NET in comparison to PRRT used as a standard 2. line treatment after progression on long-acting somatostatin analogues. ***Materials and Methods:*** Thirteen patients (7 men and 6 women) treated with PRRT as a first line treatment due to metastatic well differentiated GEP-NET (G1 or G2) in 2007-2013 were eligible to analysis. There were 6 patients with pancreatic, 5 with small intestine, 2 with large intestine NET and 1 subject with unknown primary site. As a comparison the group of 13 patients (primary site and WHO grade matched to first group, 6 men, 7 women) treated with PRRT as a second line treatment were analysed. In the first group all patients had liver, 9 lymph node, and 5 bone metastases, while in the second group metastases to the liver were present in all cases, in 11 cases were seen in the lymph nodes, and in 5 cases in bones. ***Results:*** Group in which PRRT was used as first-line therapy: -Median time of follow-up 125 months (range 84-204) -Median progression-free survival (PFS) 66 months (range 18 - 132 months) -Worsening of renal function during follow-up time in 10 of 13 patients (grade IV renal toxicity, required haemodialysis in 3 cases) -No significant long-term hematologic toxicity Group in which PRRT was used as second-line therapy: -Median time of follow-up 37 months (range 5-66) -Median progression-free survival (PFS) 24 months (range 2 - 53 months) -Worsening of renal function during follow-up time in 3 of 15 patients (grade IV renal toxicity, required haemodialysis in 0 cases) ***Conclusion:*** The long-term results of PRRT used as first-line treatment are very encouraging and appear to be much better than in case of PRRT used as a second line therapy. The risk of renal function impairment associated with PRRT increases over time, especially after a period of 5 years after the end of PRRT. Prospective studies are warranted to confirm this observation.

## EP-0538

### Visual and Whole-Body Quantitative Analysis of 68-Ga-DOTATATE PET/CT to Predict Outcomes after 177Lu-DOTATATE

***I. Sonni***[1,2], *M. Hotta*[1,3], *P. Thin*[1], *K. Nguyen*[1], *L. Gardner*[1], *L. Ciuca*[1], *A. Hayrapetian*[1,4], *M. P. Lewis*[1,5], *D. J. Lubin*[1,6], *M. Allen-Auerbach*[1];
[1]*University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Università Magna Graecia, Catanzaro, ITALY,* [3]*National Center for Global Health and Medicine, Tokyo, JAPAN,* [4]*University of South Alabama, Mobile, AL, UNITED STATES OF AMERICA,* [5]*Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA, UNITED STATES OF AMERICA,* [6]*SUNY Upstate, Syracuse, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Somatostatin receptors (SSTR) represent an ideal target for nuclear theranostics applications in neuroendocrine tumors (NET). Studies suggest that a high uptake on SSTR PET is associated with response to SSTR peptide receptor radionuclide therapy (PRRT). However, the prognostic value of whole-body SSTR PET in patients undergoing PRRT is unknown. The purpose of this study was to evaluate the role of baseline whole-body (WB) $^{68}$Ga-DOTATATE PET/CT (DOTA-PET) quantitative parameters, and the presence of NET lesions without DOTA uptake on DOTA-PET, as predictors of outcome in patients with NET treated with $^{177}$Lu-DOTATATE PRRT. ***Materials and Methods:*** All patients with NET who underwent at least 4 cycles of 177Lu-DOTATATE PRRT in our institution between 07/2016 and 03/2021 were included in this retrospective analysis if they fulfilled the following inclusion criteria: available DOTA-PET within 6 months of 1st PRRT cycle, available follow-up CT and/or MRI performed >6 months after the 4th cycle of PRRT. The DOTA-PET analysis consisted in a visual analysis, conducted by one physician with dual board certification (nuclear medicine and radiology), and a quantitative analysis done by a nuclear medicine physician. The visual analysis assessed the presence of NET lesions visible on the DOTA-PET co-registered CT showing DOTA uptake ≤ liver uptake. The quantitative analysis consisted in contouring all DOTA-avid lesions on DOTA-PET and extracting WB quantitative parameters: SUVmean (WB-SUVmean), SUVmax of the lesion with highest uptake (H-SUVmax), and tumor volume (WB-TV). Quantitative DOTA-PET parameters and the presence of DOTA-negative lesions

were correlated to overall survival (OS), progression-free survival (PFS) and radiologic response (assessed by RECIST 1.1 criteria). Fisher's exact test, Mann-Whitney's U-test and Kaplan-Meier curves with Cox-regression analysis were used for the statistical analysis. ***Results:*** Forty patients (F/M: 21/19; 34/40 with GEP NET, 6/40 with non-GEP NET) were included in the analysis. The median follow-up period after the 4th PRRT cycle was 25.7 months (range: 15.2 - 59.1). Fourteen/40 (35%) patients showed radiologic response (RECIST PR). PFS and OS events were 17/40 (42.5%) and 6/40 (15%), respectively. Thirteen/40 (32.5%) patients had DOTA-PET negative lesions at baseline. Higher WB-SUVmean and H-SUVmax were associated with better response (p= 0.015 and 0.005, respectively). The presence of DOTA-PET negative lesions and higher WB-SUVmean were associated with shorter PFS (p=0.026 and 0.008, respectively). Higher WB-TV was associated with poorer OS (p=0.006). ***Conclusion:*** Visual and quantitative analysis of baseline DOTA-PET can be valuable measures to predict outcome after 177Lu-DOTATATE PRRT.

## EP-0539

### Therapy in Advanced Small Cell Lung Carcinoma - Investigating Outcome, Toxicity Profile and Prognostic Determinants

***P. Hartrampf***[1], *A. Weich*[2], *F. Lutz*[1], *A. K. Buck*[1], *T. Higuchi*[1], *S. E. Serfling*[1], *Y. Zhi*[3], *R. A. Werner*[1];
[1]*Klinik und Poliklinik für Nuklearmedizin, Würzburg, GERMANY,*
[2]*Medizinische Klinik und Poliklinik II, Würzburg, GERMANY,*
[3]*Klinik und Poliklinik für Hals-, Nasen- und Ohrenkrankheiten, plastische und ästhetische Operationen, Würzburg, GERMANY.*

***Aim/Introduction:*** In advanced small cell lung carcinoma (SCLC), treatment options are limited. We aimed to evaluate the therapeutic efficacy and toxicity profile of SSTR-directed PRRT in advanced disease, along with determinants of outcome. ***Materials and Methods:*** 24 patients with advanced SCLC, which had exhausted previous treatment options, were scheduled for PRRT. Disease control (DC, partial response [PR] or stable disease [SD]), was evaluated investigating follow-up CTs. Progression-free (PFS) and overall survival (OS) were also recorded. Prior to PRRT and upon last available follow-up (n=15), we also investigated hematotoxicity (including leukocytes, thrombocytes, and hemoglobin), nephrotoxicity (glomerular filtration rate [GFR], serum creatinine) and serum chemistry (lactate dehydrogenase [LDH], aspartate aminotransferase [AST], alkaline phosphatase [AP] and C-reactive protein). For assessing factors associated with survival, univariable cox regression was applied. ***Results:*** 1/24 (4%) patient died due to infection independent from treatment, leaving 23/24 (96%) for outcome analysis. The majority received one cycle 15/24 (63%; two cycles in 5/24 [21%], three cycles in 2/24 [8%], five and six cycles in 1/24 [4%], respectively). DC was observed in 3/24 (13%; with PR in 1/3 [33%] and SD in 2/3 [67%]). Median PFS was 56 days and median OS was 89 days. Directly after administration of the radiotherapeutic agent, no acute toxicity was recorded in any of the subjects. During follow-up, we observed the following grade III/IV toxicities: anemia grade III in 5/15 (33%), and thrombopenia grade III in 1/15 (7%; grade IV in 2/15 [13%]). No leukopenia or nephrotoxicity higher than grade II occurred. Pretherapeutic elevated LDH (HR 1.001 [95%CI, 1.000-1.002], p<0.02), AST (HR 1.013 [95%CI, 1.003-1.022], p<0.01) and AP (HR 1.007 [95% CI, 1.000-1.013], p<0.03) were associated with shorter OS in univariable analysis. ***Conclusion:*** In the present cohort of end-stage disease patients affected with advanced SCLC, PRRT is feasible, along with grade III/IV toxicities in selected cases. As such, PRRT may be incorporated earlier in the disease course, preferably in patients with improved general conditions or by applying dosimetry-based individualized activity concepts.

## EP-0540

### Impact of kidneys absorbed dose assessment during177Lu-PRRT (peptide receptor radionuclide therapy) on patient management: examples from clinical experience

*M. Ferrari, F. Botta,* ***C. Grana****, D. Alio, A. Barone, G. Castiglione Minischetti, S. Papi, I. Clerici, F. Ceci;*
*Istituto Europeo di Oncologia, Milano, ITALY.*

***Aim/Introduction:*** $^{177}$Lu-PRRT is an established treatment for patients affected by neuroendocrine tumours. Kidneys are the major organ at risk, with late toxicity absorbed dose thresholds around 28Gy. In this study dosimetry results are reported, and examples from clinical experience are presented to support the contribution of dosimetry in patient management during $^{177}$Lu-PRRT. ***Materials and Methods:*** Simplified dosimetry based on 24h post-injection SPECT-CT analysis was performed for all patients at each cycle. Whenever possible, multiple points dosimetry was performed during at least one cycle for each patient. Dosimetry results were discussed on patient basis to tailor the subsequent cycles or to implement dose modifying strategies. ***Results:*** Thirty-eight patients were treated for a total of 111 cycles (14 patients 4 cycles, 11 patients 3 cycles, 9 patients 2 cycles, 4 patients 1 cycle). The mean (range) kidneys absorbed dose/activity was 0.7 (0.3-1.5) Gy/GBq. Intra-patient variability (mean ± standard deviation) among different cycles was 13%±12%. The average (range) ratio of absorbed dose obtained with simplified versus multi-points dosimetry, for a same cycle, was 1.01 (0.8-1.2); the variability range reduced to (0.9-1.1) when considering only cases for which the last image was acquired later than 100 hours post-injection. During 31/111 cycles (28%), the kidneys absorbed dose was higher than 0.8 Gy/GBq, a value that projected over 4 cycles with full activity potentially lead to cumulative dose higher than the 28Gy threshold, assuming 20% uncertainty associated to absorbed dose evaluation. The management of these cases was discussed on case-by-case basis, considering different tailoring strategies (including treatment completion or reduction of activity/cycle or number of cycles) to balance treatment outcome and risk of complications. Two patients, affected by urinary infection during two cycles each, exhibited significantly higher doses than the average population, ranging from 0.9 to 1.3Gy/GBq; during subsequent cycles, they both underwent an additional amino acids infusion the day after activity administration. ***Conclusion:*** Kidneys dosimetry during $^{177}$Lu-PRRT is an important tool for treatment optimization. If performed at each cycle, it allows to monitor the therapy effect on kidneys, and to undertake adjustment strategies if deemed necessary after a risk-to-benefit balance. Urinary infection might lead to significantly high absorbed doses and it should be accurately monitored. Multiple time-point dosimetry is desirable, with late time point preferably acquired later than 5 days post-injection. Simplified, single-point dosimetry is feasible and can still provide useful information despite affected by higher uncertainty, to be properly taken into account.

## EP-0541

### Factors Predicting Response and Survival in Lutetium-177 DOTATATE Treatment of Neuroendocrine Tumours: Preliminary Results

***Z. MAMMADKHANLI***[1], *F. SOYLUOGLU*[1], *B. OZDEMIR GUNAY*[2], *C. AYDIN*[1], *U. KORKMAZ*[1];
[1]*Trakya University, School of Medicine, Department of Nuclear Medicine, Edirne, TÜRKIYE,* [2]*Sultan 1. Murat State Hospital, Clinic of Nuclear Medicine, Edirne, TÜRKIYE.*

***Aim/Introduction:*** Neuroendocrine tumors (NETs) are a heterogeneous group of tumors expressing somatostatin receptors (SSTR).177Lu-DOTATATE, a radioactively labelled SSRT analogue, is an approved treatment for SSRT receptor positive advanced metastatic or inoperable NETs.In this study, we aimed to evaluate the results and overall survival of patients treated with 177Lu-DOTATATE in our clinic in the light of factors such as haematological parameters and tumour heterogeneity ***Materials and Methods:*** Patients diagnosed with NET and admitted to our clinic for Lu-177 DOTATE treatment between 2016 and 2021 were retrospectively reviewed.The primary lesion SUVmax value,Krenning score(KS),visual tumour heterogeneity and metastatic involvement sites obtained from Ga68 PET/CT were recorded.Overall survival analyses were performed ***Results:*** 28 patients (mean age: 56±17 years) were included in the study. Tumour sites: 10 patients with pancreas,stomach-5, lung-3,small bowel-3,liver-2,colorectal NET-2, medullary thyroid cancer-1,neuroblastoma-1 and 1 patient with paraganglioma. Median Ki-67 was 10%. Four patients had Grade 1, 19 patients had Grade 2, and 5 patients had Grade 3 NETs.On PET/CT, 8 patients were evaluated as KS 2, 11 patients as KS 3, and 9 patients as KS 4. In visual evaluation,SSRT expression was heterogeneous in 15 patients. A total of 106 cycles of Lu-177 treatment were administered at intervals of 8-12 weeks with an average of 4 cycles per patient. After treatment, partial response was observed in 7 patients, stable disease in 8 patients and progression in 13 patients. There was a significant correlation between treatment response and bone metastasis andtreatment initiation time (p=0.016 and 0.008, respectively). Other organ metastases, platelet/lymphocyte, neutrophil/lymphocyte and monocyte/lymphocyte ratios were not correlated with treatment response. During the follow-up period (median 55.2±38.7 months), 14 patients died. Median survival time was 114.7±26.6 months and 2-year and 5-year survival times were 89% and 68%, respectively. The mortality rate was 21.4% in patients who received RNT within 16 months after diagnosis, while this rate was 78.6% in patients who received RNT later.Grade and heterogeneity (p=0.027 and 0.015, respectively) were found to be the determining factorsin survival analyses. In multivariate analysis, tumour heterogeneity (HR=0.2, 95%CI 0.060-0.843,p=0.027) was the only independent predictor of overall survival. ***Conclusion:*** In patients with advanced NET, Lu-177 DOTATATE treatment provides disease control in more than half of patients. Although tumor heterogeneity is the only independent factor affecting overall survival, tumor grade and time from diagnosis to treatment also seem to be effective factors in survival and prospective studies with a larger number of patients are needed.

## EP-0542

### Impact of the SBVR 177Lu activity quantification method on organ and tumor dosimetry results after PRRT and on patient management

***A. Chicheportiche****, S. Raskin, Y. Krausz, J. Godefroy, S. Grozinsky-Glasberg, S. Ben-Haim;*
*Hadassah Ein Kerem Hospital, Jerusalem, ISRAEL.*

***Aim/Introduction:*** Conventional calibration of gamma cameras involves calculating calibration factors (CFs) as a function of volume. However, this method yields inconsistent results when the background activity varies. We have recently proposed a new quantification method for $^{177}$Lu that aims to correct for background effects by considering the sphere-to-background counts/voxel ratio (SBVR) in addition to volume [1]. The SBVR method was validated on anthropomorphic phantoms and has been shown to be more accurate, improving the quantification of tumors and organs by 60% (from 14% error in quantification to 6%) and 80% (from 20% to 3%) in average, respectively. The aim of this study is to quantify the impact of SVBR on the dosimetry calculations and to evaluate its potential impact on patient management. ***Materials and Methods:*** $^{177}$Lu-DOTA-TATE SPECT/CT data after PRRT of 10 consecutive patients with metastatic neuroendocrine tumors (10 treatments, 4 therapy cycles per treatment, total of 40 therapy cycles) were retrospectively analyzed. Absorbed doses (ADs) were calculated for 40 kidneys, 40 livers, 32 spleens and 92 tumors using both the conventional and SBVR quantification methods and cumulative ADs were compared. The impact of the SBVR method on the decision of whether to stop PRRT because of "expected" kidney AD exceeding the 25 Gy safety threshold was evaluated. ***Results:*** Mean cumulative ADs of 146.4 ± 106.4 Gy, 13.9 ± 3.8 Gy, 5.9 ± 2.3 Gy, and 22.6 ± 12.3 Gy were respectively obtained for tumors, kidneys, liver, and spleen using the conventional quantification method, compared to 140.9 ± 103.4 Gy, 17.8 ± 4.7 Gy, 6.6 ± 2.3 Gy, and 28.1 ± 15.6 Gy with SBVR. The decision to administer the fourth treatment cycle was similar with the two methods for all patients. However, the maximum number of treatment cycles that a patient could receive without exceeding the kidney safety threshold was higher with the conventional method at 8 ± 1 cycles, compared to 6 ± 1 cycles with the SBVR method. ***Conclusion:*** These preliminary results show that the SBVR methodology has an impact on the cumulative absorbed dose calculations, with relative differences ranging between 10% and 20%. Furthermore, in the context of personalized dosimetry-based treatments, the SBVR method may improve patient management, enabling more accurate determination of the maximum number of treatments that can be administered safely. ***References:*** [1] Raskin, S. et al. Towards accurate 177Lu SPECT activity quantification and standardization using lesion-to-background voxel ratio. EJNMMI Phys 10, 5 (2023).

## EP-0543

### Neoadjuvant PRRT with 90Y-DOTATOC: preliminary results from a monocentric prospective study

***A. Barone***[1], *F. Mattana*[2], *L. L. Travaini*[2], *P. Rocca*[2], *M. Colandrea*[2], *L. Gilardi*[2], *S. Fracassi*[2], *S. Papi*[3], *I. Clerici*[3], *M. E. Ferrari*[4], *F. Botta*[4], *E. Bertani*[5], *F. Spada*[6], *N. Fazio*[6], *F. Ceci*[2], *C. M. Grana*[2];

***Aim/Introduction:*** Surgery is considered the only curative treatment for pancreatic neuroendocrine tumors (pNETs), but it is feasible only in a few patients. A new possible therapeutical strategy in pNETs is preoperative peptide Receptor Radionuclide Therapy (PRRT), as its cytoreductive effect could increase the efficacy of surgery. The aim of this prospective study is to evaluate the response and rate of R0 surgery in patients with unresectable or borderline resectable G1/G2 pNET eligible to PRRT with $^{90}$Y-DOTATOC and associate the response to circulating NET transcripts measured before and after PRRT. ***Materials and Methods:*** This study included patients with histopathologic diagnosis of unresectable or borderline resectable G1/G2 pNET, with limited liver disease based on pre-treatment $^{68}$Ga- DOTATOC PET/CT. To date, 8 out 30 patients (2 females and 6 males) were enrolled. All the patients received at least one cycle of 1.85 GBq/cycle of $^{90}$Y-DOTATOC; the protocol foresaw a cumulative activity of 9.25-11.1 GBq in 5-6 cycles. At first cycle, each patient received also $^{111}$In-OctreoScan activity in order to perform a dosimetric study on kidneys; moreover, a dosimetric study was also performed during the subsequent cycles on $^{90}$Y-DOTATOC SPECT/CT imaging for comparison. ***Results:*** PRRT was well tolerated by all the patients, without any toxicity. Four patients completed all scheduled 6 cycles of therapy, obtaining a SD (1), a CR (1), and a PR with resecability criteria (1); the fourth patient is scheduled to receive the imaging during the next month. One patient received only 4 cycles, because of elevated dose to the kidneys, obtaining a partial response but was not considered operable. One patient received only one cycle due to the worsening of clinical conditions. Two patients are still in treatment. ***Conclusion:*** These preliminary data of neoadjuvant PRRT with $^{90}$Y-DOTATOC confirm the good tolerability of $^{90}$Y-DOTATOC PRRT in a group of patients where surgery could be challenging. Based on literature reports, the objective response rates expected exceed the 35%[1 ]. ***References:*** [1 ] Imhof A, Brunner P, Marincek N, Briel M, Schindler C, Rasch H, Mäcke HR, Rochlitz C, Müller-Brand J, Walter MA. Response, survival, and long-term toxicity after therapy with the radiolabeled somatostatin analogue [90Y-DOTA]-TOC in metastasized neuroendocrine cancers. J Clin Oncol. 2011 Jun 10;29(17):2416-23.

## EP-0544

### Inflammatory markers as prognostic factor inTNE treated with 177Lu-DOTATATE

***J. Villa Palacios****, E. Triviño-Ibáñez, M. Muros de Fuentes, T. Aroui-Luquin, R. Sanchez-Sanchez;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** AIM: To assess the utility of different inflammatory markers as predictors of survival in patients with NETs treated with 177Lu-DOTATATE. Background: Neutrophil-to-Lymphocyte ratio (NLR) and Platelet-to-Lymphocyte ratio (PLR) are useful markers in assessment of inflammatory response and are prognostic markers in cancer patients. N-terminal pro-brain natriuretic peptide (NT-proBNP) is produced by cancer cells without cardiac faillure. These markers, when elevated, may be a poor prognostic factor in GEP-NETS. ***Materials and Methods:*** 28 patients with metastatic NETs of different origins (21GEP, 3 TOD, 2 pulmonary, 2 other origins) treated with four cycles of 177Lu-DOTATATE. The tumor variables analyzed were grade, Ki67, mitotic index, number of treatments received (surgery, somatostatin analogues, chemotherapy, everolimus QUETA) and inflammatory markers such as Neutrophil-to-Lymphocyte ratio (NLR), and Platelet-to-Lymphocyte ratio (PLR) and pro-brain natriuretic peptide (NT-proBNP). Survival results were recorded by Kaplan-Meier analysis. The functional status of the patient was also assessed (Karnofsky and ECOG scales). ***Results:*** The mean age at diagnosis was 56.14 years in our patients, with an average of 5.68 years of evolution (1-25 years) and 2 lines of previous treatment (1-4). Overall survival was assessed with a median of 36.75 months (12-55 months). The relationship between their overall survival and the above variables was analyzed. We have analyzed the predictive role of survival of the NLR and PLR. The NLR does come out significantly associated with survival, the higher the NLR, the worse survival. Using the ROC curve analysis, I have selected the point with the best discriminative capacity (cut-off) of 3 . An NLR >3 increases the probability/risk of dying by 4.43 (HR: 4.43, p=0.035). The PLR analysis does not reach statistical significance. ***Conclusion:*** NLR >3 increases the probability/risk of dying by 4.43 (HR: 4.43, p=0.035) and NT-proBNP greater than 300 pg/ml implies an increased risk of death of 7.76 in these patients. Inflamation markers may be useful to asses the usefulness and prognosis of therapy with177Lu-DOTATATE.

## EP-0545

### Kidneys functional volumes changes of patients undergoing 177Lu-DOTATATE treatment and the uncertainties measures in kidney dosimetry

***J. Khan****[1], T. Rydèn[2], J. Svensson[3], M. Van Essen[4], P. Bernhardt[5];*
*[1]Department of Medical Radiation Sciences, Institute of Clinical Sciences, Gothenburg, SWEDEN, [2]Department of Medical Physics and Biomedical Engineering (MFT), Sahlgrenska University Hospital, Gothenburg, SWEDEN, [3]Department of Oncology, Institution of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN, [4]Department of Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, SWEDEN, [5]Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Kidney dosimetry procedure after peptide receptor therapy using $^{177}$Lu-DOTATATE consist of multiple steps. The aim of this study was to determine the dosimetry uncertainties associated with manual segmentation of kidney parenchymal volume (KPV) in CT images. ***Materials and Methods:*** SPECT/CT images of 18 patients were acquired over the abdomen at ~ 4 hours (h) (D0), 24 h (D1), 48 h (D2) and 168 h (D7) after $^{177}$Lu-DOTATATE treatment. The reference kidney volumes were estimated by using the KPVs that correspond to the acquired SPECT acquisition for kidney activity measurements. For obtaining the uncertainties that depends on the accuracy of KPV based on all possible combinations of the four individual KPVs was used to determine the activity distributions in kidney at each time-point. Bi-exponential curve fit was used for determining the time-integrated activity. ***Results:*** For a single cycle of 7.4 GBq, the segmented kidney volumes were between 31 and 243 ml. The KPV was statistically significant at D1 compared to D7. With KPV acquired at D7 CT images as reference, the Bland-Altman analyse resulted in bias of 8.74%, 10.73%, 2.92% for D0, D1, D2, and the corresponding uncertainties were 12.4%, 16.32% and 8.31%, respectively. The absorbed dose uncertainties when using only one KPV and a constant RCs of 0.85 were 6.29%, 3.85%, 6.13%, and 3.91%, whereas, with patient-specific RCs 5.55%, 4.40%, 4.73%, and 3.43%, respectively. ***Conclusion:*** The kidneys volumes varied significantly from D0 to D7, which will influence the absorbed dose estimation. However, kidney dosimetry with only one delineated KPV can be performed with satisfying accuracy using either a constant RCs of 0.85 or patient-specific RCs.

## EP-0546

### Evaluation of RadioLigand Therapy response in GEP-NETs: the role of 177Lu-Dotatate imaging

***S. Valente***[1], *F. Linguanti*[1], *M. E. Abenavoli*[1], *L. Antonuzzo*[2], *V. Briganti*[3], *D. Lavacchi*[4], *M. Matteini*[3], *F. Mungai*[5], *R. Sciagrà*[1], *G. Simontacchi*[6], *L. Vaggelli*[3], *V. Berti*[1];
[1]*Nuclear Medicine Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, 50134, Florence, ITALY,* [2]*Clinical Oncology Unit, Careggi University Hospital, Florence, Italy; Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, Florence, ITALY,* [3]*Department of Nuclear Medicine, Azienda Ospedaliero-Universitaria Careggi, Largo Brambilla 3, 50134, Florence, Italy, Florence, ITALY,* [4]*Clinical Oncology Unit, Careggi University Hospital, Florence, Italy, Florence, ITALY,* [5]*Department of Radiology, Azienda Ospedaliero-Universitaria Careggi, Largo Brambilla 3, 50134, Florence, Italy, Florence, ITALY,* [6]*Radiation Oncology, Azienda Universitaria Ospedaliera Careggi, Florence, ITALY.*

***Aim/Introduction:*** Theranostic approach using 177Lutetium-Dotatate (Lutate) is approved in gastroenteropancreatic neuroendocrine tumors (GEP-NET). Imaging at 24 hours after Lutate treatment is used to evaluate radiotracer distribution and for dosimetry purposes. The aim of our study is to assess the potential value of Lutate imaging in evaluating treatment response and predicting 6 months clinical outcome. ***Materials and Methods:*** We enrolled 15 GEP-NET patients, eligible for radioligand therapy and treated with Lutate. Each Lutate scan (1, 2, 3, 4) has been analyzed drawing regions of interest (ROIs) on each lesion, which were classified according to the organ to which it belongs (hepatic, nodal, GEP tract, bone). Mean count values were extracted from each ROI, normalized to lumbar mean activity, and percentage differences between Lutate cycles were calculated (Δ%). Patients were divided according to 6 months follow-up into 3 groups (partial response -PR, stable disease -SD and progressive disease -PD). Differences between groups was analyzed using ANOVA, and statistical significance has been set at $p<0.05$). ***Results:*** At a lesion level, hepatic lesions demonstrated Δ% between 4$^{th}$ and 1$^{st}$ Lutate scans of -14,06 +- 29,46 %, nodal lesions of -18,26 +- 19,46 %, GEP tract lesions of 3,17 +- 26,99 %, and bone lesions of 21,44 +- 54,05 %. At a patient level, the Δ% between 4$^{th}$ and 1$^{st}$ Lutate scans of the "least responsive lesion" was the most significantly different variable between groups. At post-hoc analyses, the differences resulted particularly significant in differentiation of PR patients from both SD and PD patients. Also mean Δ% of each patients resulted different between groups at the limits of significance, but the difference was observed only between PR and the other 2 groups. ***Conclusion:*** Percentage differences of lesion activities between Lutate cycles measured at Lutate imaging may provide useful parameters to predict 6 months clinical outcome of GEP-NET patients treated with radioligand therapy. The most significant parameter resulted the percentage difference between 4$^{th}$ and 1$^{st}$ Lutate scans of the "least responsive lesion", which was able to successfully differentiate outcome of patients.

## EP-0547

### Efficacy of [177Lu]Lu-DOTA-TATE in metastatic neuroendocrine neoplasms of different locations: our experience.

***M. Pudis***[1], *J. L. Vercher-Conejero*[1], *J. J. Martín-Marcuartu*[1], *A. Teule-Vega*[2], *S. Bondia-Bescós*[1], *B. Hervás-Sanz*[1], *A. Rodríguez-Gasén*[1], *J. Diaz-Moreno*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [2]*Medical Oncology, Institut Català d'Oncologia (ICO), L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** The aim of the study is to present our experience with [$^{177}$Lu]Lu-DOTA-TATE therapy and to assess the tolerability and efficacy of this treatment in patients with tumors expressing somatostatin receptors. ***Materials and Methods:*** We retrospectively reviewed all the patients treated with [$^{177}$Lu]Lu-DOTA-TATE in our center (Bellvitge University Hospital, Barcelona, Spain) with at least 3 month follow-up after the last cycle. All of these patients had SSTR-overexpressing, histologically confirmed neoplasm. [$^{177}$Lu]Lu-DOTA-TATE was administered at a dose of 7.4 GBq iv per cycle, in 4 cycles with an interval of 8-10 weeks together with an amino acid solution to protect the kidneys. The data evaluated included demographic information (age, sex), the origin and primary tumor site, location of metastases, histopathological grade and Ki67, prior treatments, assessment of toxicity, clinical, immunohistochemical and radiological response to [$^{177}$Lu]Lu-DOTA-TATE. All patients were re-evaluated by post-therapy CT scans at the end of treatment (generally on the 3rd month) using RECIST 1.1 criteria. ***Results:*** In total, we treated 60 patients (27 women; mean age 58.7 years [38-82]) with a mean follow-up of 22,5 months [3-117 months] during the study. The origin of the tumor was gastroenteropancreatic in 54p (90%), paraganglioma in 3p (5%), pheochromocytoma, bronchopulmonary and urogenital tract (renal) with 1p each. The primary gastroenteropancreatic tumor site was ileal in 28p (52%), followed by pancreatic in 16p (30%), intestinal in 6p (11%) and colorectal in 4p (7%). 2 cervical and 1 pelvic paragangliomas. Hepatic (92%), nodal (80%), osseous (30%) and peritoneal (30%) were the most common metastatic sites. All the patients had well differentiated NEN, 25p (42%) Ki67<3% (grade 1), 33p (55%) Ki67 3-20% and 2p with Ki67>20%. 29p (48%) received lutetium as a 2nd line, 14p (23%) as a 3rd line and 10p (17%) as 4th line of treatment. The most common adverse effects were gastrointestinal (27%), hematological (25%): grade 3-4 in 7% and nephrotoxicity (5%). 13p did not complete the treatment, 8p because of progression and 5p because of the toxicity. 47p completed the therapy, 33p (55%) with stable disease, 19p (32%) with partial response and 8p (13%) with progression on the post-therapy CT scans. Median progression-free survival (PFS) was 23.2 months [6-ongoing]. ***Conclusion:*** Our experience confirms the efficacy and safety of [$^{177}$Lu]Lu-DOTA-TATE in a wide range of metastatic SSTR-expressing NENs. 87% of patients presented favorable responses (stable/partial). This treatment has been well tolerated, with scant adverse events that were generally mild.

## EP-0548

### Evaluation of the quality of life of patients with neuroendocrine tumors treated with Lutetium-177-DOTATATE

***S. Asadurova***, *D. Villasboas, J. Hernando, F. Velazquez, R. Bellviure, J. Echeverri-Diaz, N. Calviño, A. García-Burillo; Hospital Universitari Vall d´Hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** To evaluate the changes in the quality of life of patients with NETs treated with Lutetium-177-DOTATATE. ***Materials and Methods:*** a single center prospective study including 38 patients with NETs treated with Lutetium-177-DOTATATE. The patients filled out the QLQ-GINET21 quality of life questionnaire before each treatment cycle (4 questionnaires per patient). It was determined that each patient had to answer at least 2 questionnaires. Two patients were excluded for filling out just one questionnaire. The questionnaire includes 21 questions, grouped into 5 categories (endocrine symptoms, gastrointestinal symptoms, treatment-related, disease-related worries, social

functioning) and 5 individual questions - weight loss, weight gain, muscle and/or bone pain, information and sexual functioning. The response is on a scale from 1 (least symptomatology/problem) to 4 (greater symptomatology/problem) and some questions have the option of "not applicable". We analyze one hundred twenty one questionnaires in total. The responses were transformed into a score on a scale from 0 to 100 through a linear transformation, using the EORTC guidelines. A change by 5 to 10 points on the 0-100 scale is considered "a little" better (or worse), a change of 10 to 20 was described as a "moderate" change and a change greater than 20 is considered "very much" better (or worse). A statistical analysis was performed. ***Results:*** We observed a moderate improvement in the problem of weight loss. There is little improvement in the area of social functioning, especially in terms of the possibility of travelling (moderate improvement), which we associate with the reduction of the symptoms. Also, there is a little improvement in receiving information and a little improvement in the concerns related with the results of the tests. Surprisingly, we observed a little worsening of endocrine symptoms, especially of the night sweats. ***Conclusion:*** Treatment with Lutetium-177-DOTATATE in patients with NETs is related to an improvement in quality of life, especially in terms of symptoms.

## EP-0549

### Radiomics analysis in 177Lu-DOTATATE therapy: Extracting new information from theranostic images

***H. Abdollahi***[1], *X. Hou*[2], *J. Beauregard*[3], *C. Uribe*[1], *A. Rahmim*[1]; [1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA,* [3]*Cancer Research Centre and Department of Radiology and Nuclear Medicine, Université Laval, Quebec City, QC, CANADA.*

***Aim/Introduction:*** Radiopharmaceutical therapy using 177Lu-DOTATATE has shown promise for neuroendocrine tumor (NET) patients. Quantitative analysis of diagnosis and therapeutic images can aid in improving the therapy's effectiveness. In this study, we extracted quantitative measures from theranostic images, including SPECT and CT images, to investigate changes in SPECT features within therapy cycles, changes in CT radiomic features between the first and last cycles, and correlations between therapeutic activity and SPECT features. ***Materials and Methods:*** We enrolled four NETs patients undergoing 177Lu-DOTATATE therapy who underwent QSPECT/CT after each cycle. Radiomics features were extracted from the liver lesions segmented on all CT and QSPECT images. Changes in features were assessed between T0, T1, and T3, as well as between the first and last injection. Percentage changes were calculated and reported. Correlations between SPECT feature values and therapeutic activity were measured using the Pearson method and the correlation coefficient (CC) reported. ***Results:*** In total, 103 features were extracted from each lesion or kidney from the QSPECT images. Results showed that 34 radiomics features mimicked time activity curves, increasing from T0 to T1 and decreasing from T1 to T3. Intensity-based and intensity histograms had the highest changes (77%-91%), with Kurtosis, Variance, Energy, Mean, and 75thPercentile as the most varying features. In total, 108 radiomics features were extracted from each lesion in liver CT images. Several radiomic features changed due to 177Lu therapy, including 10th Percentile and Large Zone High Grey Level Emphasis as the most decreasing, and Strength and Minimum Grey Level as the most increasing radiomics feature changes. For correlation analysis, the range of therapeutic activity was found to be 108-543 millicuries. The CC ranged from -0.77-0.76 for lesions and -0.53-0.49 for kidneys. Three GLSZM features were found to be the most negatively correlated in lesions, and Kurtosis (Intensity Histogram), Normalised Inverse Difference (GLCM), Strength (NGTDM), and Normalised Grey Level Non-Uniformity (GLRLM) with CC; 0.75-0.77 were the most positively correlated features. ***Conclusion:*** Quantitative radiomics features analysis during RPTs can depict heterogeneities within uptake and aid in dosimetric measures. Changes in radiomics features inter-cycle of therapy may show the biological properties of tissue, correlating with receptor density and the success of therapy. Radiomics features can be a good marker for patient response to RPT, and several lesion radiomics features are highly correlated to therapeutic activity, which can be used as uptake measures for further clinical outcome modeling.

## EP-0550

### Assessment of response to therapy and safety of177Lu-DOTATATE in GEP-NET patients

***M. Raddi***, *F. Di Gennaro, F. De Lauro, V. Porfidia, C. Maisto, G. Ventanieri, S. Melone, P. Gaballo, L. D'Ambrosio, S. Lastoria; National Cancer Institute IRCCS Pascale, Naples, ITALY.*

***Aim/Introduction:*** Peptide receptor radionuclide therapy (PRRT) is a radionuclide treatment used for gastroenteropancreatic neuroendocrine (GEP-NET) tumors that express somatostatin receptors (SSTRs). Aim of this study is to assess the short-time efficacy of PRRT with [$^{177}$Lu]Lu-DOTATATE in patients with progressive metastatic gastroenteropancreatic NETs. ***Materials and Methods:*** We evaluated 41 patients (20 females and 21 males; median age 61 years) who received all 4 cycles of [$^{177}$Lu]Lu-DOTATATE (7.4 GBq each infusion) between 2019-2023. Interval between each administration was 8 weeks. Primary tumor site was pancreas in 22 (54%) patients, midgut in 9 (22%) patients, foregut in 3 (7%) patients, hindgut in 1 (2%) patient and unknown primary site with gastrointestinal profile in 6 (15%) patients. 17 of 41 patients had a partial or total resection of the primary tumor. Before each infusion and during the follow-up, patients were monitored with laboratory tests (hematological, renal and liver panel). SPECT/CT acquisitions were performed for dosimetric estimations at 3, 20 and over 90 hours after each cycle. Morphological imaging (CT and/or MRI) and [$^{68}$Ga]Ga-DOTATATE PET/CT were performed before starting the treatment and 3-4 months after the last therapy administration to assess the effects on primary tumor and on metastatic lesions. Median follow-up was 12 months. ***Results:*** Partial response (PR) was documented in 12 (29%) patients, stable disease (SD) in 23 (56%) patients and progressive disease (PD) in 6 (15%) patients. Of the 22 patients with the pancreatic primary site 10 showed PR, 9 SD and 3 PD; of the 9 patients with the midgut primary site 8 had SD and 1 had PD; of the 3 patients with foregut primary site 1 had PR and 2 SD; the patient with hindgut primary site had SD; and of the 6 patients with unknown primary site 1 had PR, 2 PD and 3 SD. Renal cumulative dose did not reach the threshold value (23 Gy) in any patient. In 3 patients, with high hepatic metastatic burden, bone marrow cumulative dose was higher than 2 Gy, however, no hematological toxicity was observed. Target lesions received an absorbed dose between 23 and 423 Gy. ***Conclusion:*** Our results confirm that [$^{177}$Lu]Lu-DOTATATE is an effective and well tolerated, therapeutic option in patients with GEP-NETs, obtaining PR or SD in 85% of patients without hematological and renal acute or chronic toxicity.

## EP-0551

### Evaluation of different infusion protocols and dosimetry assessment in patients undergoing peptide receptor radionuclide therapy with 177Lu-DOTATATE

***A. Varallo***[1], *L. Piscopo*[1], *V. Gaudieri*[1], *S. Grasso*[1], *E. Zampella*[1], *C. Nappi*[1], *C. Oliviero*[2], *M. Italiano*[1], *F. Volpe*[1], *M. Falzarano*[1], *S. Clemente*[2], *A. Cuocolo*[1], *M. Klain*[1];
[1]*Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY,* [2]*Unit of Medical Physics and Radioprotection, University of Naples "Federico II", Naples, ITALY.*

***Aim/Introduction:*** Peptide receptor radionuclide therapy (PRRT) is a radionuclide treatment used for gastroenteropancreatic tumors. The efficacy of the therapy depends on many factors, including the infusion procedure and the imposed flow rates also have impact on the injected and residual activity. Aim of this study is to analyze the impact of different flow rates used for the administration of $^{177}$Lu-DOTATATE and the preliminary results of personalized internal dosimetry. ***Materials and Methods:*** We evaluated 17 consecutive patients underwent PRRT with $^{177}$Lu-DOTATATE. 7.4 GBq were injected every eight weeks for four cycles. SPECT/CT imaging acquisitions were at 4 hours (h), 24 h, 48 h and 168 h for dosimetric estimations after each cycle. Differences between three different flow rate protocols were assessed: a) a constant flow rate throughout the treatment; b) one increase in flow rate at $T_1$=10 min and $T_2$=20 min; c) two increases in flow rate at $T_1$=10 min, $T_2$=20 min and $T_3$=30 min. The residual activity was measured using each protocol. Absorbed dose (AD) to organs and lesions was analyzed using the software MIM SurePlan MRT (MIM, Cleveland). ***Results:*** We treated 3 women and 14 men (median 61 years), for a total of 56 infusions. No extravasation of radiopharmaceutical was observed. The administrated and residual mean activity was 7.3 ± 0.2 GBq and 0.1 ± 0.1 GBq, respectively. The mean treatment time was 44.8 ± 5.9 min. 86% of infusions had a residual activity below the threshold (set at 2% of the initial average activity). The threshold was achieved in 55% of the cycles at $T_{treat}$= 30 min, in 73% of the cycles at $T_{treat}$= 40 min and in 86% of the cycles at $T_{treat}$= 45 min. The constant flow rate throughout the treatment protocol reached the threshold at the end of the treatment in a lower percentage of cases than the other protocols. For liver, kidneys and lungs the mean AD was 2.09 ± 3.80 Gy, 1.33 ± 0.44 Gy and 0.22 ± 0.18 Gy respectively. Mean AD to normal tissue was 0.21 ± 0.28 Gy. AD to lesions ranged from 5.08 ± 0.91 Gy to 16.39 ± 4.61 Gy. ***Conclusion:*** Infusion protocols that adapt flow rate have a significant impact on residual activity. The infusion protocol used should be taken into account in order to have a more accurate estimate of the absorbed dose.

## C: Therapy Clinical Study -> C1 Oncological Therapy Clinical Study -> C12 Prostate Cancer Therapy

## EP-0552

### TheraP-based Selection Criteria Do Not result in a Survival Benefit When Compared With VISION Trial Criteria in Prostate Cancer Patients Scheduled for PSMA-targeted Radioligand Therapy

***K. Michalski***[1], *A. Kosmala*[1], *R. A. Werner*[1], *S. Serfling*[1], *A. K. Seitz*[1], *C. Lapa*[2], *A. K. Buck*[1], *P. E. Hartrampf*[1];
[1]*Universitätsklinikum Würzburg, Würzburg, GERMANY,* [2]*Universitätsklinikum Augsburg, Augsburg, GERMANY.*

***Aim/Introduction:*** Two randomized clinical trials demonstrated the efficacy of prostate-specific membrane antigen (PSMA) radioligand therapy (PSMA RLT) in metastatic castration-resistant prostate cancer (mCRPC). While the VISION trial used criteria within PSMA PET/CT for inclusion, the TheraP trial used dual tracer imaging including [$^{18}$F]FDG PET/CT. Therefore, we investigated whether the application of the TheraP trial criteria compared to the VISION criteria lead to a survival benefit for patients with mCRPC after PSMA RLT. ***Materials and Methods:*** Thirty-five patients with mCRPC who had received PSMA RLT and pretherapeutic imaging with [$^{18}$F]FDG and [$^{68}$Ga]Ga-PSMA I&T or [18F]F-PSMA-1007 were studied. Therapeutic eligibility was retrospectively evaluated using the VISION and TheraP study criteria. ***Results:*** 26 of 35 (74%) treated patients fulfilled the VISION criteria (=VISION+) and only 17 of 35 (49%) fulfilled the TheraP criteria (=TheraP+). Significantly reduced overall survival after PSMA RLT was observed in patients rated VISION- with 3 months compared to VISION+ with 12 months (hazard ratio (HR) 3.1, 95% confidence interval (CI) 1.0-9.1, p<0.01). For patients rated TheraP-, no significant difference in survival after PSMA RLT was observed compared to TheraP+ patients (TheraP-: 5.5 vs. TheraP+: 11 months, HR 1.6, 95% CI 0.8-3.3, p=0.2). Within patients rated TheraP-, patients with discordant FDG-positive/PSMA-negative (=FDG+/PSMA-) tumor lesions (n=12) showed a significantly reduced OS of 4.5 months (HR 2.8, 95% CI 1.1-6.8, p<0.01) after PSMA RLT, whereas low PSMA expression alone (n=6) was not a significant prognosticator with a median OS of 15 months (HR 0.8, 95% CI 0.3-2.1, p=0.6). ***Conclusion:*** Retrospective application of the inclusion criteria of the TheraP study did not lead to a survival benefit after PSMA RLT compared to the criteria of the VISION study, even though FDG+/PSMA- lesions are a negative prognostic marker. This could be due to the definition of low PSMA expression used in the TheraP trial.

## EP-0553

### The efficacy of prognostic factors derived from Ga68-PSMA PET-CT images in predicting treatment response and survival in patients with metastatic castration-resistant prostate cancer treated with Lu-177PSMA

***M. Oflas***[1], *D. Has Simsek*[1], *Y. Sanli*[1], *S. Kuyumcu*[1], *E. Isik*[1], *S. Karadogan*[1], *M. Basaran*[2], *M. Ekenel*[2], *A. Mudun*[1], *Z. G. Ozkan*[1];
[1]*Istanbul Faculty Of Medicine Department Of Nuclear Medicine, Istanbul, Türkiye,* [2]*Istanbul University Institute Of Oncology, Department Of Medical Oncology, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** We aimed to determine the efficacy of metabolic parameters obtained from Ga68-PSMA PET/CT images performed in the early period after 2 cycles of Lu177-PSMA therapy to evaluate the therapy response and prognosis in patients with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Patients diagnosed with mCRPC, who were treated ≥2 cycles of Lu177-PSMA treatment in our department were retrospectively examined. Metabolic tumour volume (MTV) and total lesion PSMA (TLP) values were calculated on Ga68-PSMA PET/CT images performed before and after second Lu-177 PSMA treatment. In the evaluation of treatment response, ≥30% decrease in basal MTV and TLP values was accepted as consistent with partial responsive disease (PR), ≥30% increase with progressive disease (PD), and <30% increase/decrease with stable disease (SD),respectively. ≥ 50% reduction in basal PSA value was evaluated as PR ; ≥25 % increase as PD; the remaining group evaluated as SD, respectively. In addition, information about overall survival (OS) was obtained through medical records. ***Results:*** 89 male patients were included in

the study (mean age: 72 years). Pre- / post-treatment median serum PSA, MTV and TLP values are indicated in Table 1.OS was calculated as 17 months (4-55 months) from the start of Lu-177 PSMA treatment. When survival analysis is evaluated according to PSA change after 2 cycles; OS was calculated as 27 months in PR (n:40), 16 months in SD (n:20) and 10 months in PD (n:29), respectively. The differences in OS were statistically significant (p <0.001).When survival analysis is performed according to MTV values after 2 cycles; OS was calculated as 27 months in PR (n:30), 18 months in SD (n:23) and 12 months in PD (n:36), respectively. The OS differences were statistically significant (p:0.002).When survival analysis is evaluated according to TLP after 2 cycles ; OS was calculated as 20 months in PR (n:41), 13 months in SD (n:23), and 14 months in PD (n:25), respectively .The OS differences between these groups were not statistically significant (p=0.088). ***Conclusion:*** It was determined that change of MTV value obtained from Ga68-PSMA PET/CT images before and after the first 2 cycles of Lu-177 PSMA treatment was correlated with overall survival in mCRPC patients .However, change of TLP values was not correlated with overall survival .Therefore, MTV value has been found as a favorable parameter in addition to PSA in order to help the clinician for earlier evaluation of treatment response and providing prognostic information.

## EP-0554

### Dosimetric evaluation of 177Lu-PSMA-617 therapy: Feasibility of Single Time Point Imaging Protocol

***S. Rezaei****, E. Gharepapagh;*
*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Radiopharmaceutical therapies with Lutetium-177 prostate-specific membrane antigen (PSMA) ligands have shown promising results in metastatic castration-resistant prostate cancer (mCRPC). Patient-specific activity personalization is currently impossible due to the lack of absorbed dose-effect relationships. Dosimetry needs to be incorporated into the routine clinical workflow of radiopharmaceutical therapies using simplified methods such as single time point (STP) imaging protocols rather than multiple time point (MTP). This study aims to assess differences between image-based dosimetry for $^{177}$Lu-PSMA-617 therapy on lacrimal glands, salivary glands, and tumors using STP versus MTP. ***Materials and Methods:*** There were 40 patients with mCRPC with $^{177}$Lu-SPECT imaging data (24h, and 72h post-drug administration) available on the first and second $^{177}$Lu-PSMA-617 treatment cycles. We employed two different dosimetry methods: the MTP method, which incorporated images from both imaging time points, and the STP method. A method based on the difference between Gaussian curves was used to delineate tumors, while salivary glands and lacrimal glands were drawn manually. Support vector machines were used to classify tumors based on their mean density and coefficient of variation. ***Results:*** There were a few exceptions to the pattern of decreasing absorbed doses and the number of tumors with each therapy cycle. The 2-point method seemed to correlate well with the second imaging interval. Furthermore, the mean absorbed dose per time-integrated activity for lacrimal glands was 0.61 ± 0.11 (MTP method), 0.65 ± 0.13 (STP method 24h-image), and 0.52 ± 0.12(STP method 72h-image) Gy/GBq, to submandibular glands it was 0.41 ± 0.11(MTP method), 0.37 ± 0.15 (STP method 24h-image), 0.23 ± 0.12 (STP method 72 h-image) Gy/GBq, and for parotid glands 0.35 ± 0.10 (MTP method), 0.37 ± 0.11 (STP method 24h-image) and 0.24 ± 0.16 (MTP method 72h-image) Gy/GBq. ***Conclusion:*** Based on the low mean difference in absorbed dose compared to MTP, STP dosimetry for $^{177}$Lu-PSMA-617 therapy at 24 h was found to be sufficiently accurate for $^{177}$Lu-PSMA-617 therapy.

## EP-0555

### Safety and Efficacy of re-treatment with Lutetium-177 PSMA Beyond Six Cycles in Patients with Castration-Resistant Prostate Cancer

***E. Medhurst****[1], R. Alipour[2], T. Akhurst[2], A. Azad[3], J. P. Buteau[1], A. Cardin[2], B. Emmerson[1], M. B. Haskali[4], G. Kong[2], L. Kostos[3], P. Jackson[1], K. Raghava[2], A. Ravi Kumar[2], J. Saghebi[2], S. Sandhu[3], L. Spain[3], B. Tran[3], M. S. Hofman[1];*
*[1]Prostate Cancer Theranostics and Imaging Centre of Excellence; Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging,Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Department of Nuclear Medicine, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [3]Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [4]RadiopharmaceuticalProduction and Research Laboratory, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** Lutetium-177 PSMA radioligand therapy (LuPSMA) is a life-prolonging treatment for patients with metastatic castration-resistant prostate cancer (mCRPC). Landmark studies reported the outcomes of up to 6 cycles of LuPSMA. This study aimed to evaluate the safety and efficacy of re-treatment with LuPSMA in patients beyond the initial 6 cycles of LuPSMA. ***Materials and Methods:*** We conducted a retrospective analysis of patients with mCRPC who received over 6 cycles of LuPSMA therapy at a single centre. Patients were initially treated on clinical trials or registry with PSMA-617 (N=287) or compassionate access with PSMA-I&T (N=46). Administered radioactivity for additional (re-treatment) cycles was 6.0 GBq/cycle. The primary outcome was PSA response rate (PSA-RR). Secondary outcomes included treatment-emergent adverse events (AEs) and overall survival (OS). AEs were restricted to G2-4 xerostomia, haematological and renal toxicity, or any G3-4 toxicity attributed to Lu-PSMA (CTCAE v5). OS defined from date of PSMA PET prior to the first cycle. Data cut-off; 28Feb2023. ***Results:*** From 9/2015 to 2/2023, 36/333 (10%) patients (median age 76, IQR 71-80) received >6 cycles of LuPSMA. The median total number of LuPSMA cycles received was 8 (range 7-17, IQR 8-9). Prior to LuPSMA, 36/36 (100%) of patients received androgen-receptor pathway inhibitor (16% receiving >1), 91% docetaxel, 19% cabazitaxel and 3% carboplatin. During first 6 cycles, PSA50-RR and PSA90-RR occurred in 36/36 (100%) and 33/36 (91%), respectively. Median time between cycle 6 and cycle 7 was 7 months (range 2.7-34.9 months, IQR 5.7-10.7). A median of 2 (range 1-6) cycles were administered before pausing and waiting for progression with each re-treatment. Median cumulative administered radioactivity was 56.2 GBq (IQR 54.9-62.2). Following additional treatments beyond cycle 6, PSA50-RR and PSA90-RR occurred in 12/36 (33%, 95%CI 20-50%), and 5/36 (14%, 95%CI 6-29%), respectively. AEs were xerostomia (G2: 8.3%), anemia (G2: 13.8%, G3: 5.5%), thrombocytopenia (G2: 2.7%, G4: 2.7%), kidney dysfunction (G2: 13.8%, G3: 5.5%). Myelodysplastic syndrome occurred in 2/36 (5.5%) both with PSMA-I&T and causality uncertain. No treatment-related deaths. Median OS 38.1 months (95%CI 19.1-57.2). 11/36 (30%) continue to receive LuPSMA. ***Conclusion:*** This retrospective study indicates that administering LuPSMA beyond 6 cycles is feasible for a selected group of patients with mCRPC who initially responded to treatment.

## EP-0556

### Can a cutoff be set for pre-treatment 68Ga-PSMA-11 PET/CT parameters to predict 177Lu-PSMA-I&T response and patient survival?

***S. Mirshahvalad***[1,2], *R. Eisazadeh*[1], *G. Rendl*[1], *S. Gampenrieder*[3], *G. Schweighofer-Zwink*[1], *H. Griessner*[4], *C. Pirich*[1], *M. Beheshti*[1];
[1]*Division of Molecular Imaging & Theranostics, Department of Nuclear Medicine, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA,* [2]*Joint Department of Medical Imaging, University Health Network, University of Toronto, Toronto, ON, CANADA,* [3]*Division of Molecular Imaging & Theranostics, Department of Oncology, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA,* [4]*Division of Molecular Imaging & Theranostics, Department of Urology, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA.*

***Aim/Introduction:*** To evaluate the prognostic value of pre-treatment $^{68}$Ga-PSMA-11 PET/CT in prostate cancer (PCa) patients receiving $^{177}$Lu-PSMA-I&T, considering the treatment response and patient survival. ***Materials and Methods:*** Sixty PCa patients (age:73±8, baseline PSA:185±371) who received $^{177}$Lu-PSMA-I&T therapy between October 2018 and January 2023 were included. Eligible patients had metastatic castration-resistant prostate cancer, underwent $^{68}$Ga-PSMA-11 PET/CT before treatment, and had serum PSA levels available at baseline and after each treatment cycle. All patients underwent pre-treatment $^{68}$Ga-PSMA-11 PET/CT, and clinical follow-up data were recorded. SUVmax, SULmax, SUVpeak, and SULpeak of the most-avid tumoral lesion in each patient and SUVmean of the normal parotid and liver tissues (backgrounds) were measured. $^{177}$Lu-PSMA-I&T was administered based on a multidisciplinary recommendation. The standard approach of 4-6 therapy cycles was considered unless patients revealed a major adverse event or showed a significant progression, resulting in therapy termination. We considered clinical (PSA level; PCWG3 criteria) and imaging ($^{68}$Ga-PSMA-11 PET/CT; RECIP1.0 criteria) composite for the response assessment. The outcomes were dichotomised as "responder" (partial response) vs "non-responder" (stable and progressive disease). ***Results:*** Overall, 26/60 (43%) and 30/60 (50%) patients were responders and progressive in the final assessment, respectively. Regarding the baseline clinical or imaging differences, pre-treatment SUVmax, SULmax, SUVmax-to-backgrounds, and SULmax-to-backgrounds significantly differed between responders and non-responders. Notably, no baseline clinical characteristic was significantly different. To predict response outcome, SUVmax, SULmax, SUVmax-to-liver background, SULmax-to-liver background, SUVmax-to-parotid background and SULmax-to-parotid background were significant factors in the univariate regression. In the multivariate analysis, only the SULmax-to-liver background was significant (p-value=0.028). To find a cutoff, the SULmax-to-liver SUVmean of 8 was the optimal coordinate point, showing sensitivity and specificity of 69% and 72% for predicting response to $^{177}$Lu-PSMA-I&T. Regarding survival analysis, in a median follow-up of 360 (91-1114) days, 11/60 (18%) mortal events were documented. In univariate Cox analysis, SUVpeak (hazard ratio [HR]=3.8; 95%CI=1.1-14.2), SULmax (HR=3.5; 95%CI=1.0-13.2), SUVmax-to-parotid background (HR=3.6; 95%CI=1.0-13.5) and SULmax-to-parotid background (HR=4.0; 95%CI=1.1-15.0) were significant. In the multivariate analysis, only the highest SULmax-to-parotid background was significant (p-value=0.043; HR=4.0), having a cutoff of 2.4. ***Conclusion:*** Pre-treatment $^{68}$Ga-PSMA-11 PET/CT could potentially predict response to $^{177}$Lu-PSMA-I&T therapy and overall survival. The most prominent factors in this regard were the SULmax-to-background ratios. In searching for cutoffs, the SULmax-to-liver SUVmean of 8 and SULmax-to-parotid SUVmean of 2.4 were the best for predicting response outcome and overall survival, respectively. Our findings may help clinicians stratify patients at $^{177}$Lu-PSMA-I&T therapy initiation to enhance patient management.

## EP-0557

### Clinical outcomes after treatment following the use of 18F-PSMA PET/CT scans in patients with recurrent prostate cancer

***J. Rodriguez-Rubio Corona***, *F. Cañete Sánchez, Y. Santaella Guardiola, M. Piñero Fernandez-Reyes, C. Quintana Bolaño, M. Pajares Vinardell;
Hospital Universitario Puerta del Mar, Cádiz, SPAIN.*

***Aim/Introduction:*** The optimal treatment for recurrent biochemically recurrent prostate cancer (BCR) is still unknown. Positron emission tomography/computed tomography (PET/CT) with prostate-specific membrane antigen (PSMA) can visualize micrometastatic disease, thus expanding treatment options for BCR ranging from observation to androgen deprivation therapy (ADT), radiation therapy (RT/SBRT), chemotherapy (CT), and new generation hormonal agents (NHA). Our objective was to describe how BCR patients were managed after positive PSMA PET/CT with $^{18}$F-DCFPyL ($^{18}$F-piflufolastat), taking into account that a high percentage of patients had a PSA<1. ***Materials and Methods:*** We conducted a retrospective review of 151 patients from the province of Cadiz who underwent a $^{18}$F-DCFPyL PET/CT between July 2021 and March 2023. 93 of these 151 patients had a positive result (61.5%) and 77 met inclusion criteria: information on the type of treatment and follow-up with PSA determination 3 months after completion of treatment. Additionally, trigger-PSA levels were collected at the time of $^{18}$F-DCFPyL PET/CT, which was in the range of biochemical recurrence, considered as PSA>0.2. ***Results:*** Of the 77 positive PSMA patients who met inclusion criteria, in 38/77 (49.3%) had trigger-PSA levels below 0.49; in 27/77 (35.06%), it was between 0.5-0.99 and only in 12/77 (15.5%) was trigger-PSA greater than 1. Regarding the treatment received, 51.9% of cases underwent RT/SBRT, of which 90% had disease control at 3 months with a decrease in PSA levels below 0.2. CT treatment was given to 2 patients, both of whom had a PSA decrease of 100%. 13 patients were treated with NHA, and in 12/13, the PSA decreased after therapy, except for one patient who had poor adherence to treatment. ADT was performed in 6 patients with a good response except for one patient. There were 4 patients who received combined therapy (RT+ADT, RT+NHA) who were included in the above-mentioned groups. ***Conclusion:*** Despite low PSA levels, $^{18}$F-DCFPyL PET/CT can detect disease recurrence, allowing for personalized treatment planning and achieving disease control in a short period of time. The impact on patient survival will be assessed in the future.

## EP-0558

### The Tyr Phenomena: Hypo-calcemic Response in High Volume Treatment Responders to 177Lutetium PSMA Therapy

***M. Swiha***[1,2], *S. Kumar*[3], *M. Crumbaker*[1], *C. Harvey*[1], *S. Pathmanandavel*[1], *N. John*[1,4], *M. M. McDonald*[5,6], *R. Clifton-Bligh*[3,6], *A. Lee*[3,7,8], *P. Bastick*[9], *W. Counter*[1], *A. Nguyen*[1,4], *L. Emmett*[1,4,5];
[1]*St Vincent's Hospital, Sydney, AUSTRALIA,* [2]*Schulich School of Medicine and Dentistry, University of Western Ontario, London, ON, CANADA,* [3]*Royal North Shore Hospital, Sydney, AUSTRALIA,* [4]*St Vincent's Clinical School, University of New South Wales, Sydney, AUSTRALIA,* [5]*Garvan Institute of Medical Research, Sydney, AUSTRALIA,* [6]*School of Medical Science, Faculty of Medicine and Health, University of Sydney, Sydney, AUSTRALIA,* [7]*Northern Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, AUSTRALIA,* [8]*Genesis Care, Sydney, AUSTRALIA,* [9]*St George Hospital, Sydney, AUSTRALIA.*

***Aim/Introduction:*** $^{177}$Lutetium PSMA ($^{177}$Lu-PSMA) is an effective treatment for metastatic castrate-resistant prostate cancer (mCRPC). Rarer treatment-related adverse events, such as treatment response related hypo-calcemia have not yet been described. ***Materials and Methods:*** We present case reviews of two men with marked hypocalcemic osteosclerotic response following $^{177}$Lu-PSMA I&T therapy. Additionally, a clinical dataset of $^{177}$Lu-PSMA I&T therapy was evaluated to estimate incidence and clinical association with hypocalcemia. This dataset included 127 men with mCRPC who had disease progression after at least one androgen receptor axis-targeted agent (ARAT) and either failed or were ineligible for taxane-based chemotherapy. All patients were treated with $^{177}$Lu-PSMA I&T in a clinical treatment program (2022/ETH00924) and received a minimum of 2 doses at six-weekly intervals. A median of 8.0 GBq (IQR 8.0-8.5 GBq) was administered at each dose via slow intravenous injection. Blood samples were collected prior to each dose and at 3 weekly intervals for biomarkers including hemoglobin, platelets, lactate dehydrogenase (LDH), calcium, alkaline phosphatase (ALP), albumin and prostate specific antigen (PSA). ***Results:*** Of 127 patients treated, 41 (32%) had a fall in serum calcium of any magnitude at any point between starting treatment and dose 3 of $^{177}$Lu-PSMA (12 weeks). Two patients developed severe hypocalcemia (corrected serum calcium < 1.7 mmol/L (NR 2.15 - 2.55mmol/L)) requiring high dose steroid treatment. Both patients (cases 1&2) had high volume bone metastatic disease with marked PSA response (>90% reduction) to $^{177}$Lu-PSMA I&T. Overall, 6/127 (5%) developed clinical hypocalcemia despite denosumab cessation after commencing $^{177}$Lu-PSMA therapy. Mean PSA response in those with hypocalcemia was 78% (SD 24%) with one patient showing no PSA response (hypocalcemia due to progressive disease). Baseline $^{177}$Lu-SPECT total tumour volume in bone was higher in those who had a reduced calcium compared to those with normal calcium levels (median 1017mL (IQR 331-1831mL) vs 369mL (IQR 96-1035mL) (p= 0.01)) and in those who developed hypocalcemia compared to those who did not (median 3249mL (IQR 1856-3852mL) vs 465mL (IQR 135- 1172mL) (p= 0.002)). Patients with hypocalcemia following treatment developed marked osteosclerosis subsequently, despite excellent biochemical and imaging treatment response. ***Conclusion:*** Hypocalcemia may occur in response to $^{177}$Lu-PSMA I&T, particularly with both high-volume bone metastases and significant PSA response. Importantly, calcium and calcitriol supplementation were insufficient in managing severe hypocalcemia and glucocorticoid therapy was required. Further evaluation of $^{177}$Lu-PSMA I&T induced hypocalcaemia is required to better understand mechanisms, optimal treatments, and repercussions from subsequent osteosclerotic response.

## EP-0559

### Evaluation of Radium-223 Dichloride in the Treatment of Castration-Resistant Prostate Adenocarcinoma with Symptomatic Bone Metastases

***R. Maestre-Cutillas***[1], *A. M. Sanchez-Tornero*[2], *L. Baz-Sanz*[1], *G. Rubio-Fernández*[1], *L. Casas-Fernandez*[2], *M. Romero-Otero*[2], *J. A. Pérez-Iruela*[1];
[1]*Hospital Universitario Ramon y Cajal, Madrid, SPAIN,*
[2]*Hospital Clínico Universitario de Valencia, Valencia, SPAIN.*

***Aim/Introduction:*** To evaluate our experience with the use of Radium-223 Dichloride for the treatment of castration-resistant prostate adenocarcinoma in patients with symptomatic bone metastases and without visceral metastases. ***Materials and Methods:*** 50 patients from two different centres who received treatment with Radium-223 (6 doses of 55 kBq/kg at 4-week intervals) between March 2014 and January 2022 were included in the study. The variables studied were overall survival (OS), time to disease progression (TDP), time to bone progression (TBP), total alkaline phosphatase (AP) response, prostate-specific antigen (PSA) progression and blood haemoglobin levels. In OS, patients were stratified according to PSA levels at baseline. Treatment-related adverse events have also been reported. ***Results:*** The mean age of the patients was 75.54 ± 8.40 years. Radium-223 treatment was used as first (4%), second (32%), third (40%), fourth (16%) or fifth line (8%). Previous treatments used were antiandrogens (mainly abiraterone) (82%), enzalutamide (36%), docetaxel (48%), cabazitaxel (16%) and pembrolizumab (2%). The time taken between detection of bone metastases and initiation of treatment with Radium-223 was 31.04 ± 21.75 months, with a median of 24.5 months. Median OS was 15.5 months, with significant differences ($p < 0.05$) according to PSA level (10 months with PSA > 100ng/ml and 19.5 months with PSA < 100ng/ml). The medians for TBP and TDP were 9.5 and 8 months, respectively. Reduction of PSA levels was observed in 21% of cases and AP in 58%. Pain was reduced or controlled in 69% of patients. 18/50 (36%) patients experienced some type of treatment-related adverse reaction, including haematological toxicity and asthenia. Haemoglobin decreased in 43% of patients and ten patients (20%) required blood transfusions. Sixteen patients (32%) did not complete treatment, five of them (10%) due to haematological toxicity, implying a 68% compliance rate. ***Conclusion:*** In our experience, Radium-223 Dichloride is an effective treatment in reducing bone pain, well tolerated and with high compliance. Patients with less advanced disease (PSA<100ng/ml) benefit more from treatment, with higher OS, which implies great importance of early diagnosis and speed of action. The results (OS, TBP and TDP) are consistent with published literature.

## EP-0560

### Personalized [177Lu] Lutetium-PSMA therapy for patients with pre-treated castration-resistant prostate cancer: a single institution experience

***J. Friedrich***[1], *W. Thaiss*[1,2,3], *F. Zengerling*[4,3], *V. Hechler*[4], *M. Grunert*[5,1], *C. Bolenz*[4,3], *T. Wiegel*[6], *A. J. Beer*[1,3], *V. Prasad*[1,3];
[1]*Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY,* [2]*Department of Diagnostic and Interventional Radiology, University Hospital Ulm, Ulm, GERMANY,* [3]*Surgical Oncology Ulm, i2SOUL Consortium, Ulm, GERMANY,* [4]*Department of Urology and Pediatric Urology, University Hospital Ulm, Ulm, GERMANY,* [5]*Department of Nuclear Medicine, German Armed Forces Hospital, Ulm, GERMANY,* [6]*Department of Radiation Oncology, University Hospital Ulm, Ulm, GERMANY.*

***Aim/Introduction:*** Castration resistant prostate cancer (CRPC) patients have in general shorter overall survival. [177Lu]-Lutetium-PSMA (Lu-PSMA) treatment has proven efficacy in these patients. However, little is known about the success of Lu-PSMA if offered in personalised approach based on laboratory, clinical and PSMA PET features. ***Materials and Methods:*** For this retrospective study 86 CRPC patient charts were evaluated. Overall survival (OS), PSMA PET/CT response, PSA-response, safety, and tolerability (CTCAE adverse event reporting) in all patients was assessed. PSMA expression profile was taken into consideration: patients with high PSMA heterogeneity, assessed visually, PSMA negative suspicious lesions on CT/MRI were either not offered the treatment or the lesions were biopsied prior to the therapy. Interim PSMA PET/CT was performed after 2$^{nd}$ or 3$^{rd}$ cycle. Efficacy endpoints were

calculated using stratified Kaplan Meier methods, univariate and Cox regression models. ***Results:*** Patients received an average of 3.6 (range 1-8) therapy cycles with total median applied dose of 17.7 GBq (median 5.3 ± 1.1 GBq per cycle) Patients were followed up for a median of 12.4 months (range 1-39). The median OS was found to be 15 months (95% CI 12.8-17.2). The best overall response rate in patients assessed with PSA response and PSMA PET/CT was 27.9% whereas 50.0% had at least stable disease. Twenty-three patients had a ≥ grade 3 adverse event with anaemia being the most frequent adverse event. Positive predictors for a prolonged OS were number of cycles > 3, pre-treatment haemoglobin level of ≥ 10 g/dL, a >50% best overall PSA response and time to PSA progression >60 days of Lu-PSMA therapy. Patients achieving partial response or disease stabilisation on PET/CT were also found to have favourable OS. Interestingly OS in patients with visceral metastases was not worse however, liver metastases was found to be negative prognostic marker in univariate analyses. ***Conclusion:*** Individualized Lu-PSMA treatment approach appears to be feasible. Patients with dose-limiting factors or intensely PSMA avid visceral metastases can still be treated with good efficacy without negatively influencing the safety profile.

## EP-0561

### No substantial subacute nephrotoxicity in patients with mCRPC treated with Lu-177 PSMA I&T regardless of mean absorbed kidney dose

***M. Dotinga***[1,2], *E. C. Owers*[1], *E. J. Rijkhorst*[1], *D. M. V. de Vries-Huizing*[1];
[1]*NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Leiden University Medical Center, Leiden, NETHERLANDS.*

***Aim/Introduction:*** Nephrotoxicity is a rare adverse event in patients treated with peptide radioligand therapy (PRLT). The aim of this study was to assess changes in kidney function in relation to the mean absorbed dose (MAD) of the kidneys in patients with metastatic Castration-Resistant Prostate Cancer (mCRPC). ***Materials and Methods:*** A total of 22 patients with mCRCP with a baseline estimated glomerular filtration rate (eGFR) >30 ml/min/1.73m² were included in this retrospective study. PRLT consisted of two cycles of 7.4 GBq [$^{177}$Lu]Lu-PSMA-I&T, administered two weeks apart. This sequence was repeated in a subset of 5 patients after 12±1 weeks after the first administration. Post-therapy SPECT/CT scans were performed 24 hours and 5-7 days after each administration. The kidney cortex was segmented in PLANET Onco and the dose rate (convolution with CT density correction) was assessed in PLANET Dose (DOSIsoft SA). The MAD was accordingly calculated using a mono-exponential curve. Creatinine levels and eGFR were evaluated at baseline and 8 weeks after cycle 2 and 4 after which nephrotoxicity (eGFR and increase in creatinine levels) was scored according to CTCAE 5.0. Subsequently, absolute changes in eGFR and creatinine levels (%) were analyzed and related to the average MAD of both kidneys. ***Results:*** After two cycles, changes of -5.1±7.6% (range: -20.6-19.0%) were observed in creatinine levels and the eGFR changed 4.7±6.3% (-10.8-21.4%) with a MAD of 8.4±2.9 Gy (3.5-15.1 Gy). For this group, no relation was found between MAD and absolute changes in creatinine levels and eGFR (p>0.6). For the 5 patients receiving four cycles, the MAD was 13.8±4.4 Gy (6.3-23.1 Gy), creatinine level changes were 15.5±21.9% (-29.3-70.0%), and the eGFR changed with -6.7±12.2% (-27.8-17.7%). Subacute nephrotoxicity after therapy was limited to grade 2, regardless of the number of cycles and average MAD. ***Conclusion:*** No substantial subacute nephrotoxicity was observed in mCRPC patients undergoing two to four cycles of Lu-177 PSMA I&T therapy. Currently, retrospective analyses are ongoing for a larger population and other organs-at-risk. Long-term effects of [$^{177}$Lu] Lu-PSMA therapy on kidney function in relation to the MAD are yet to be assessed and analyzed.

## EP-0562

### Prognostic Role Of 18F-Choline PET/CT Vs Bone Scintigraphy In Prostate Cancer Patients Treated With 223Ra-Dichloride.

***L. García Zoghby***[1], *M. Cruz Montijano*[1], *A. García Vicente*[1], *M. Amo Salas*[2], *A. Padilla Bermejo*[3], *C. Lucas Lucas*[3], *N. Sicilia Pozo*[3], *M. Contreras Ameduri*[3], *F. Pena Pardo*[3], *E. Noriega Álvarez*[3], *M. Talavera Rubio*[3], *V. Poblete García*[3], *Á. Soriano Castrejón*[1];
[1]*University Hospital of Toledo, Toledo, SPAIN,* [2]*Castilla-La Mancha University, Ciudad Real, SPAIN,* [3]*University General Hospital of Ciudad Real, Ciudad Real, SPAIN.*

***Aim/Introduction:*** To determine the prognostic capacity of bone scintigraphy (BS) and 18F-Choline PET-CT (FC-PET/CT) in castration resistant prostate cancer patients treated with $^{223}$Ra; as well as to establish advantages that FC-PET/CT can provide in therapeutic failure prediction. ***Materials and Methods:*** Multicentre, prospective, and non-randomized study (ChoPET-Rad) where all patients treated with $^{223}$Ra from November/2015 to March/2022 were studied. Those who fulfilled all inclusion criteria and no exclusion criteria were selected, previous BS and FC-PET/CT evaluation (basal). Both clinical and imaging variables were collected: Gleason score, previous Docetaxel treatment, metabolic vs osteoblastic activity, superscan pattern, location, and bone metastasis (BM) number, among others. Progression free survival (PFS) and overall survival (OS) were assessed performing Kaplan-Meier curves and Cox regression. Concordance analysis between techniques (Kappa=k) for homonymous variables and relationship of all variables with therapeutic failure (non-completion of $^{223}$Ra entire regimen) were evaluated using Pearson's chi-squared test. ***Results:*** 77 patients were included with a median age of 72.73 years (±8.76). Gleason score was ≥8 in 48%. 59.7% did not complete entire regimen and 90.9% died during the follow up. Median PFS and OS were 3 and 16 months, respectively. Concordance degree between techniques regarding BM number and location was good/moderate, k= 0.701 and k=0.703 respectively (p<0.001). Variables statistically associated with a lower PFS and OS were: good concordance degree between techniques (p=0.048, $\chi2$=6.07 and p=0.028, $\chi2$=7.16, respectively), superscan pattern (p=0.018, $\chi2$=5.60 and p<0.001, $\chi2$=37.15, respectively) and BM SUVmax higher than liver pool (p=0.035, $\chi2$=4.45 p=0.008, $\chi2$=7.15, respectively). BM number showed in both, BS and FC-PET/CT, was statistically associated with PFS (p=0.005, $\chi2$=12.82) and OS (p=0.006, $\chi2$=12.30). Dose number and basal PSA were inversely and directly associated, respectively, with OS (HR=0.729, p>0.001 and HR=1.025, p=0.019; respectively). PSA rise ($\chi2$=16.52 p<0.001), BM location and number showed in FC-PET/CT ($\chi2$=4.90; p=0.027 and $\chi2$=9.948; p=0.002, respectively), BM types (osteoblastic vs osteolytic) ($\chi2$=7.02 p=0.031), superscan pattern on FC-PET/CT ($\chi2$=5.61; p=0.018) and BM SUVmax higher than liver pool ($\chi2$=6.57; p=0.01), were all statistically associated with therapeutic failure. ***Conclusion:*** Higher disease spread showed in FC-PET/TC and major extension of disease in both techniques were statistically significant prognostic factors in patients who received $^{223}$Ra. Metabolic pattern of BM showed with FC-PET/TC the most reliable marker of therapeutic failure.

## EP-0563

### Evaluation of the clinical significance of parametric data of PSMA uptake in the prostate bed and its contribution to prognosis.

***Z. Mammadkhanli***[1], *B. Ozdemir Gunay*[2], *E. Gokdemir*[1], *F. Ustun*[1]; *[1]Trakya University, Faculty of Medicine, Department of Nuclear Medicine, Edirne, TÜRKIYE, [2]Sultan 1. Murat State Hospital, Clinic of Nuclear Medicine, Edirne, TÜRKIYE.*

***Aim/Introduction:*** Prostate cancer is a common malignancy in men worldwide. 68 Ga-PSMA PET/CT is a non-invasive imaging technique used to diagnose, stage, and evaluate response to treatment in patients with prostate cancer. 177 Lu-PSMA treatment is a targeted therapy for patients with resistant prostate cancer. However, the relationship between PSMA expression and tumor biology is still not well understood. Our aim in this study was to investigate the clinical significance of PSMA receptor affinity in the prostate bed, its effect on prognosis, and whether it affects normal physiological uptake in patients with prostate cancer who underwent 68 Ga-PSMA PET/CT imaging. ***Materials and Methods:*** We retrospectively analyzed preoperative 68 Ga-PSMA PET/CT images of 82 patients with histopathological diagnosis of prostate cancer and available follow-up data. Two groups were formed based on the presence or absence of pathological radiopharmaceutical uptake in the prostate bed. We compared metabolic parameters of the primary lesion, PSA values, SUVmax values of organs with physiological receptor affinity, presence of metastasis, and their SUV values between the two groups. ***Results:*** 39 of the 82 patients had physiological PSMA receptor affinity in the prostate lumen (group 1), while 43 patients had pathological and focal PSMA receptor affinity in the prostate lumen (group 2). Patients without pathological PSMA uptake in the prostate lodge had a longer survival time compared to group 2 (p=0.015).Statistically significant PSA elevation was found in the group with prostatic involvement compared to the group without (p=0.034).The mean value of metastasis was found to be higher in group 2 compared to group 1 (p=0.008).There was no statistically significant difference between the groups in terms of SUVmax values of liver (p=0.156), spleen (p=0.145), kidney (p=0.958), submandibular and parotid glands (p=0.311). ***Conclusion:*** In conclusion, our study demonstrates the clinical significance of PSMA receptor affinity in the prostate bed and its impact on prognosis in patients with prostate cancer. The results of this study provide important insights into the use of 68 Ga-PSMA PET/CT imaging for the diagnosis and management of prostate cancer.

## EP-0564

### Health-related quality of life in mCRPC patients receiving treatment with[177Lutetium] prostate specific membrane antigen targeted radioligand therapy

***A. Karimzadeh***[1], *B. Feuerecker*[2], *K. Knorr*[2], *M. Heck*[3], *R. Tauber*[3], *C. D`Alessandria*[2], *W. Weber*[2], *M. Eiber*[2], *I. Rauscher*[2]; *[1]Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY, [2]Department of Nuclear Medicine, School of Medicine, Technical University of Munich, Munich, GERMANY, [3]Department of Urology, School of Medicine, Technical University of Munich, Munich, GERMANY.*

***Aim/Introduction:*** In patients with metastatic castration resistant prostate cancer (mCRPC), prostate-specific membrane antigen (PSMA) targeted radioligand therapy (RLT) has emerged as a promising treatment option. The most common metastatic site in mCRPC patients are bone metastases, often causing pain and impaired mobility with a concordant decline in health-related quality of life (HRQoL). Therefore, the aim of this retrospective analysis was to assess changes in HRQoL in mCRPC patients during treatment with $^{177}$Lu-PSMA RLT. In addition, we analyzed differences in HRQoL in patients dichotomized according to Eastern Cooperative Oncology Group 0 (no functional impairment) and 1/2 (moderate functional impairment). Moreover, the impact of early treatment discontinuation was analyzed. ***Materials and Methods:*** A total of 60 mCRPC patients were included in this analysis. EORTC QLQ C-30 questionnaires were analyzed prior each treatment cycle up to the 5$^{th}$ treatment cycle. A mixed effects model was performed to analyze repeated measures data of HRQoL in the total patient cohort and in patients stratified according to their ECOG performance status at baseline (ECOG 0 and ECOG 1/2). DFS curves were estimated using the Kaplan-Meier method for estimation of event time distributions and logrank tests were used for group comparisons. ***Results:*** HRQoL was significantly improved revealing an improved global health status at the 2$^{nd}$ and 4$^{th}$ cycle of $^{177}$Lu-PSMA RLT (p=0.014 and p=0.039, respectively). Concordantly, functional scales such as emotional functioning showed significant improvements (at 2$^{nd}$ and 4$^{th}$ treatment cycle: p=0.035 and p=0.007, respectively). In addition, disease-related symptoms were significantly alleviated at 2$^{nd}$ and 4$^{th}$ treatment cycle as well (e.g. pain: p=0.035 and p=0.034, respectively). Patient stratification according to the ECOG performance status was clearly associated with an impact on HRQoL (e.g. mean physical functioning at baseline in ECOG 0 vs. ECOG 1/2, p<0.0001). Additionally, patients who discontinued treatment after two treatment cycles due to disease progression presented with a concordant decline in HRQoL (e.g. mean physical functioning at baseline vs. after 2$^{nd}$ treatment cycle: 61.7 vs. 53.9, p=0.0495) and had a higher risk of deterioration in quality of life compared to patients who responded after the initial two cycles (e.g. physical functioning: HR=2.2, 95% CI, 1.1-4.8; p=0.013). ***Conclusion:*** MCRPC patients presented with significant improvements in HRQoL during treatment with $^{177}$Lu-PSMA RLT. Furthermore, patients with an early discontinuation of treatment presented with an analogue decline in HRQoL and had a higher risk of quality of life deterioration.

## EP-0565

### Safety and Efficacy of [177Lu]Lu-rhPSMA-10.1 Re-Challenge Therapy in Progressive mCRPC after [177Lu] Lu-PSMA I&T Therapy: Preliminary Results

***A. Gäble***[1], *J. Enke*[1], *A. Amerein*[1], *O. Viering*[1], *A. Rinscheid*[2], *M. Kircher*[1], *G. Wienand*[1], *C. Pfob*[1], *C. Lapa*[1], *A. Dierks*[1], *R. Bundschuh*[1]; *[1]Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY, [2]Medical Physics and Radiation Protection, University Hospital Augsburg, Augsburg, GERMANY.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-rhPSMA-10.1 is a new PSMA derivative that has shown promising results in dosimetric studies for the treatment of metastatic castration-resistant prostate cancer (mCRPC) with a higher therapeutic index as compared to [$^{177}$Lu]Lu-PSMA I&T. Therefore therapy re-challenge with [$^{177}$Lu]Lu-rhPSMA-10.1 is a viable therapeutic option after initial disease progression under treatment with [$^{177}$Lu]Lu-PSMA I&T. This study aims to determine the feasibility, efficacy, and safety of [$^{177}$Lu]Lu-rhPSMA-10.1 re-challenge therapy. ***Materials and Methods:*** Eight patients (age, 73±7 years) with progressive mCRPC after previous 2-6 cycles of standard [$^{177}$Lu]Lu-PSMA I&T were subsequently treated with up to two cycles of [$^{177}$Lu] Lu-rhPSMA-10.1 every 6 weeks. Response assessment with

[$^{68}$Ga]Ga-PSMA-I&T-PET/CT using RECIP 1.0 criteria was done after 2 cycles or if disease progression was clinically suspected. PSA response was assessed according to the PCWG3 criteria 8-12 weeks after the first [$^{177}$Lu]Lu-rhPSMA-10.1 cycle. Safety was evaluated according to Common Terminology Criteria for Adverse Events (CTCAE) v5.0 criteria. ***Results:*** Mean per cycle and cumulative administered activities were 7.4 ± 0.04 GBq and 13.9 ± 2.3 GBq, respectively. Generally, therapy was well tolerated with no acute adverse events. According to CTCAE v5, grade 4 thrombocytopenia and grade 3 anemia occurred in one patient, in the remaining subjects, no relevant toxicity (> grade 2) was observed. Regarding serum PSA values, biochemical partial response, stable disease, and progressive disease were seen in 1/8 (12.5%), 4/8 (50%), 3/8 (37.5%) patients. RECIP 1.0 criteria revealed disease stabilization in 4/8 (50 %) subjects with partial remission in one individual (12.5 %) and stable disease in 3/8 (37.5%) cases. Outcome data in terms of PFS and OS are still pending at the time present. ***Conclusion:*** Despite very limited numbers, the results of this study suggest that [$^{177}$Lu]Lu-rhPSMA-10.1 may induce therapeutic effects in mCRPC patients who have experienced progressive disease under [$^{177}$Lu]Lu-PSMA I&T. Further studies to corroborate these preliminary findings are highly warranted.

## EP-0566

### PSMA avidity-based recurrent patterns after 177Lu-PSMA I&T in metastatic castration-resistant prostate cancer

***S. Kwon***[1,2], *I. Rauscher*[1], *C. D'Alessandria*[1], *M. Eiber*[1], *W. Weber*[1]; *[1]Rechts der Isar Medical Center, Technical University of Munich, Munich, GERMANY, [2]Chonnam National University Medical School and Hwasun Hospital, Jeonnam, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** PSMA targeted radioligand therapy (PSMA-RLT) can be highly effective for treatment of metastatic castration resistant prostate cancer (mCRPC) but virtually all patients develop recurrent disease eventually. The mechanisms for resistance to PSMA RLT are not well understood. In this study we evaluated whether loss of PSMA expression is a resistance mechanism. ***Materials and Methods:*** Thirteen consecutive patients, who had an exceptional response to PSMA RLT (≥ 90% PSA decline) after $^{177}$Lu-PSMA I&T and developed recurrent disease during follow-up were analyzed. Recurrent lesions were classified into three groups: 1) recurrent group (RG, recurrence from complete response), 2) progressive group (PG, progression from partial response (≥ 50% decrease in SUVmax)), or 3) newly developed group (NG, no lesion on initial PET/CT). SUVmax of all lesions were measured from both pretherapeutic (preSUV) and follow-up (postSUV) $^{18}$F-rhPSMA-7 PET/CT. We compared postSUV among three groups and investigated whether there was a difference between preSUV and postSUV in RG and PG. ***Results:*** Among 49 metastatic lesions out of 13 patients, there were 20 lesions in RG, 13 lesions in PG, and 16 lesions in NG, respectively. There was no significant difference of preSUV between RG and PG (28.99 ± 21.10 vs. 40.56 ± 39.70, P = 0.283) and postSUV between PG and NG (36.26 ± 23.23 vs. 37.12 ± 18.60, P = 0.912). postSUV in RG (19.56 ± 13.09) was significantly lower than that in PG (P = 0.013) or NG (P = 0.004). There was no statistically significant difference between preSUV and postSUV in RG (P = 0.075) and PG (P = 0.563), respectively. ***Conclusion:*** PSMA expression was not significantly reduced in patients recurring after PSMA-RLT. This suggests that loss of PSMA is not a common resistance mechanism. Further research is warranted why PSMA expression is not reduced despite the selective pressure of effective PSMA-RLT.

## EP-0567

### Effect of [223Ra]Radium dichloride on bone health

***K. Krieger****, A. Afshar-Oromieh, A. Rominger, S. Weidner; Inselspital Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** [223Ra]Radium chloride is approved for the treatment of painful osseous metastases in prostate cancer. In 2018, the ERA223 trial found increased risks of fractures and premature deaths from [223Ra]$RaCl_2$ when combined with abiraterone and prednisolone [1]. In response, we instated a standard monitoring of serologic markers of bone metabolism in patients undergoing [223Ra]$RaCl_2$ treatment. In this case series we offer evidence that bone health is grossly unaffected by [223Ra]$RaCl_2$ and the adverse effects observed in ERA223 were likely due to the combination regimen used. ***Materials and Methods:*** Available records were screened for patients who underwent at least two cylces of [223Ra]$RaCl_2$ treatment while the aforementioned policy was in effect. Levels of beta-Crosslaps (β-CTx), intact N-terminal procollagen type 1 (P1NP) and alkaline phosphatase activity (AP) were obtained from the laboratory database. Demographical information was extracted from patient files. Statistical analysis was performed in IBM SPSS Version 28. ***Results:*** 40 patients met eligibility criteria, of which 18 patients had undergone six or more cycles. Median age at the start of treatment was 73.4 years. β-CTx levels did not change significantly under treatment (median +8 pg/ml, 95% CI -2.3 to 18.3), neither did P1NP (median -0.3 µg/l, 95% CI -5.9 to 5.3). AP activity significantly declined (median -27 U/l, 95% CI -34.7 to -19.3, p<0.0001). At the time of writing, 30 patients had expired at a median age of 74.5 years (median survival 296 days after the last cycle). ***Conclusion:*** Markers of osteoblastic and osteolytic activity did not change under treatment with [223Ra]$RaCl_2$, while AP activity significantly declined. This suggests overall bone turnover is not affected by [223Ra]$RaCl_2$ and the excess of adverse events observed in ERA223 was due to the combination regimen, with prednisolone being a likely culprit. Lowering AP levels may reflect lessening osseous tumor burden. These results encourage efforts to broaden the use of [223Ra]$RaCl_2$ to other entities and diseases. ***References:*** 1. Smith M, Parker C, Saad F, Miller K, Tombal B, Ng QS, Boegemann M, Matveev V, Piulats JM, Zucca LE, Karyakin O, Kimura G, Matsubara N, Nahas WC, Nolè F, Rosenbaum E, Heidenreich A, Kakehi Y, Zhang A, Krissel H, Teufel M, Shen J, Wagner V, Higano C. Addition of radium-223 to abiraterone acetate and prednisone or prednisolone in patients with castration-resistant prostate cancer and bone metastases (ERA 223): a randomised, double-blind, placebo-controlled, phase 3 trial. Lancet Oncol. 2019 Mar;20(3):408-419.

## EP-0568

### First preliminary results on safety and efficacy of non carrier added (n.c.a.) 177Lutetium PSMA-I&T radioligand therapy, in a Single Institute

***G. Limouris***[1,2], *M. Paphiti*[3], *A. Manetou*[2], *A. Zafeirakis*[2]; *[1]Nuclear Medicine, Medical School, National and Kapodistrian University of Athens, Athens, GREECE, [2]Nucl Med Dept, Army Share Fund Hospital of Athens, Athens, GREECE, [3]Cyclotron Section, Pharmazac SA, Athens, GREECE.*

***Aim/Introduction:*** Radioligand therapy with 177Lutetium labeled peptides gained popularity and has been increasingly implemented in the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC). By the present, we aimed to assess the safety and efficacy of n.c.a. 177Lutetium-PSMA-I&T in metastatic castration-resistant prostate cancer (mCRPC) patients for further routine settle in our Institution.

***Materials and Methods:*** In nine men (median age 73 years, range 73-81 years) with progressive mCRPC, n.c.a. 177Lutetium-PSMA-I&T was i.v. infused. The non-carrier added 177LuCl3 is predilected due to its exceptionally high specific activity (since almost every single atom is radioactive) and radionuclidic purity (absence of the long-lived high-spin Isomer Lutetium -177m). To reduce myelotoxicity, 75 mg of DTPA in trip-trop diluted in about 200 ml normal saline water was infused 30 min before the initialization of the radiopeptide therapy, lasting for about 4 hrs. Whole-body scintigraphy was performed immediately, 24 h and 48 hrs post-infusion. Absorbed doses delivered to metastases, kidneys, and red marrow were calculated according to OLINDA/EXM 1.1 program. Toxicity (World Health Organization criteria) was measured using blood and urine tests of renal and bone marrow function. ***Results:*** A mediocre PSA response [≥ 28% PSA decline 16 weeks after the first (initial) 177Lutetium-PSMA-I&T cycle] was observed in 4/9 (44.4%) patients whereas in the rest 5/9 (55.6%) a ≥ 40% PSA decline was noticed. Median imaging-based progression-free survival (PFS) was 8 months and median overall survival (OS) was 13 months. Grade ≥ 3 hematological toxicity was observed in 2/9 (22.3%) a temporary slight xerophthalmia in 1/9 (11.1%) and temporary mediocre xerostomia in 7/9 (77.8%). In a median of 6 sessions with a mean treatment activity of 6.8 ± 1.2 GBq per session, a mean cumulative activity of 40.8 ± 14.3 GBq was reached. The median absorbed dose for the lacrimal and parotid glands was 2.6 ± 1.4 and 2.1 ± 1.2 Gy/GBq respectively, for kidneys 0.81 ± 0.28 Gy/GBq, for liver 0.14 ± 0.36 Gy/GBq, for spleen 0.18 ± 0.24 Gy/GBq, for osseous metastatic lesions in a range of 2.20 -12.38 Gy/GBq and for bone marrow 0.038 ± 0.009 Gy/GBq. ***Conclusion:*** In mCRPC patients, the introduction of n.c.a. 177Lutetium-PSMA-I&T is well tolerated and effective with an acceptable toxicity profile. Dosimetry of kidneys, lacrimal and salivary glands, considered dose-limiting organs and exhibiting high physiological 177Lu-PSMA uptake, should be a necessary appendage.

## EP-0569

### Radium-223 dichloride ([223Ra]RaCl2) for metastatic Castration-Resistant Prostate Cancer (mCRPC): results of a real-world experience from a seven-year clinical practice

***D. Barbosa***, *H. Duarte, J. Ferro, I. Próspero, D. Silva, S. Fontão de Castro, G. Ferreira, L. Violante, F. Lopes, I. Lucena Sampaio; Portuguese Institute of Oncology, Oporto, PORTUGAL.*

***Aim/Introduction:*** Radium-223 dichloride ([223Ra]RaCl2) is an alpha-emitter therapeutic agent indicated for metastatic castration-resistant prostate cancer (mCRPC), with symptomatic bone metastases but no visceral metastases. Despite the promising results of ALSYMPCA trial, real-world experience appears to be less positive. The aim of this study is to report our Cinical experience with [223Ra]RaCl2 in patients with mCRPC. ***Materials and Methods:*** Retrospective analysis of demographic, clinical and laboratory data from all patients with bone mCRPC who received [223Ra]RaCl2 in our institute over a 7-year period. T-test and Kaplan-Meier method were used for statistical purposes (p-value/Logrank-test <0,05 were considered statistically significant). ***Results:*** Twenty-four men, mean age 74 years-old (SD = 9) at the time of [223Ra]RaCl2 first treatment; total of 109 cycles, between 2016 and 2023. Median activity of 4,30MBq (range 3,90-4,60). Median Gleason-score, Prostate-Specific Antigen, Alkaline Phosphatase and Lactate Dehydrogenase were, respectively, 8 (range, 7-9), 86ng/mL (range, 43-345), 287U/L (range, 132-504) and 264U/L (range, 228-312).Mean Hemoglobin, Neutrophils and Platelets counts were, respectively, 12,4g/dl (SD=1,38), 5,56x10^9/L (SD=2,58) and 220x10^9/L (SD=58,7) at the beginning of treatment.All patients had symptomatic bone pain, a positive bone scan (10 or more uptake foci) and no visceral metastases.Eleven patients (46%) were previously treated with chemotherapy and new androgen receptor pathway inhibitors (ARPis); the others were treated after one therapeutic line (6 after chemotherapy; 7 after ARPis).Eleven patients (46%) completed all 6 [223Ra]RaCl2 cycles and 14 (58%) underwent at least 5.Thirteen patients discontinued treatment due to clinical deterioration or hematological toxicity.Hematological toxicity (G2/G3) was seen in 14 patients, with anemia being the most common (12 events). Most common adverse effects were nausea/vomiting (42%) and diarrhea (30%). Eight patients (33%) reported pain improvement with an impact on quality of life: 7 completed all 6 [223Ra]RaCl2 cycles and 1 patient completed 5.Median overall survival (OS) since [223Ra]RaCl2 first infusion was 10 months (17 months in patients that received at least 5 cycles). There was no significant difference in OS whether [223Ra]RaCl2 was used as 2nd or 3rd line therapy (12 vs 9,5 months; p-value 0,425). ***Conclusion:*** Despite the limitations of this study (small sample size and retrospective analysis), our results appeared to be unfavorable in terms of OS, number of treatments completed, hematological toxicity and/or clinical progression, compared to those reported in studies under ideal conditions, even when [223Ra]RaCl2 was used as a second-line therapy, possibly due to advanced stage disease with extensive bone involvement of our patients.

## EP-0570

### The Relationship Between F-18 FDG Avidity and Response to Lu-177 PSMA Therapy in Prostate Cancer Metastases

***N. Coskun***[1], *M. Kartal*[2], *A. Erdogan*[2], *E. Ozdemir*[1]; [1]*Ankara Bilkent City Hospital, Ankara Yildirim Beyazit University, Ankara, TÜRKIYE,* [2]*Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The development of appropriate patient selection criteria for lutetium-177 prostate-specific membrane antigen (Lu-177 PSMA) therapy is crucial, given the variability of treatment outcomes among different patients and among different lesions within the same patient. Increased F-18 FDG uptake in metastatic prostate cancer lesions is thought to be associated with tumor aggressiveness, poor treatment response, and decreased survival. In this study, we aimed to investigate the possible role of F-18 FDG PET/CT in patient selection by evaluating the relationship between pre-treatment F-18 FDG uptake and response to treatment in metastatic lesions of mCRPC patients receiving two cycles of Lu-177 PSMA therapy. ***Materials and Methods:*** Patients who received at least two cycles of Lu-177 PSMA therapy and underwent both Ga-68 PSMA PET/CT and F-18 FDG PET/CT before the first cycle between January 2021 and July 2022 at our center were included. Lesions with SUVmax value higher than the liver SUVmean in the baseline F-18 FDG PET/CT study were deemed FDG-avid. Patients with a second primary malignancy and patients with clinical, imaging, and/or laboratory findings consistent with neuroendocrine differentiation were excluded from the study. Response levels achieved after two cycles of Lu-177 PSMA therapy were categorized as responsive (≥30% increase) or unresponsive (≥30% decrease) according to the SUVmax values on Ga-68 PSMA PET/CT imaging performed three weeks after the second cycle. Independent T-test and logistic regression analysis were used to evaluate the relationship

between treatment response and baseline glucose metabolism. ***Results:*** A total of 227 metastatic lesions (188 bone metastases, 35 lymphatic metastases, and 4 visceral metastases) from 11 patients (mean age 72±7) were included in the study. The median (min-max) time difference between Ga-68 PSMA PET/CT and F-18 FDG PET/CT was 20 (3-57) days. The lesion-based response rate to two cycles of Lu-177 PSMA therapy was 46.7% (n=106). Increased F-18 FDG uptake was observed in 80 lesions (35.24%). The rate of FDG avidity was significantly higher in unresponsive lesions compared to responsive lesions (43.4% vs 28.1%, p=0.016). Logistic regression analysis revealed a significant relationship between lesion-based FDG avidity and unresponsiveness to two cycles of Lu-177 PSMA therapy (odds ratio: 1.96; 95% confidence interval: 1.13-3.41, p=0.017). ***Conclusion:*** Our results suggest that insufficient response to two cycles of Lu-177 PSMA therapy is associated with lesion-based FDG avidity. If confirmed with future prospective cohorts, this phenomenon can contribute to the development of optimal patient selection criteria and effective patient management strategies.

### EP-0571

**Correlation Of Y90-Absorbed Radiation Dose To Albi Scores In Liver Malignancies: Is It Safe Over 500 Gy Tumor Absorbed Dose With Voxel Based Dosimetric Approach?**

***E. Akgun****;*
*University of Health Science Turkey, Basaksehir Cam and Sakura City Hospital, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** We planned this retrospective study to assess the correlation between the absorbed doses using Y90 radioembolization and liver function tests results in liver malignancies. ***Materials and Methods:*** Thirty-five patients treated with Y90 embedded glass microsphere included the study. Twenty-two patients were diagnosed with hepatocellular carcinoma (HCC). In all patients absorbed doses were calculated with voxel-based dosimetric approach. Pretreatment, posttreatment 2. Week and 4. Week liver function test results were recorded and albumin-bilirubin (ALBI) scores were calculated. Associations between dose and ALBI scores were studied. Response to treatment were assess according to modified Response Evaluation Criteria in Solid Tumors and Positron Emission Tomography Response Criteria in Solid Tumors after 2 months of treatment. ***Results:*** Thirty-one (89%) patients underwent selective treatment, and 4 (11%) patients underwent lobar treatment. Only 5 (14%) patients had progressive disease after the treatment. Median radiation doses were 618 Gy (min-max: 500-1000) for tumor, 497 Gy (min-max: 270-843) for total perfuse liver, 281 Gy (min-max: 97-764) for perfuse normal liver, 8.5 Gy (min-max: 1-49) for normal liver, 52.5 Gy (min-max: 11-204) for total liver. Twenty-eight (80%) patients' ALBI scores were Grade 1, and rest of all were Grade 2 before the treatment. In 2 HCC patients, ALBI scores were increased up to 2 in second week of the treatment. Their treatment response was consistent with partial regression. Tumor, perfused normal, and normal liver absorbed doses ere 618/550 Gy, 116/97 Gy, 12/8 Gy, respectively. Perfused normal liver to whole liver ratios were only 0.2/0.7%. When compared with all cases, it was concluded that the absorbed doses were not significantly higher in these cases. However, tumor/whole liver ratios were significantly higher than rest of cases (27-35%). In 1 metastatic patient, score increased to Grade 2 in 4. week of the treatment. However, in this patient, liver function failure attributed progressive disease after the treatment. None of Grade 2 patients' scores increased to Grade 3. ***Conclusion:*** It was concluded that; with voxel based dosimetry, and selective approach higher tumor doses with low whole liver normal absorbed doses were safe.

### EP-0572

**Differences in PET/MRI and PET/CT post-therapy dosimetry in hepatocellular carcinoma (HCC) treated with yttrium-90 microspheres**

***K. Knesaurek****, A. Abdelrahman, M. Ghesani;*
*Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The aim of our study was to investigate the relationships between tumor (T) and normal tissue (N) absorbed dose obtained from PET/CT and PET/MRI post-therapy studies in hepatocellular carcinoma (HCC) treated with yttrium-90 microspheres (1). ***Materials and Methods:*** After treatment with Y-90 microspheres, 12 patients (1 female and 11 males, mean age 69.0± 7.8y), underwent PET/MRI and PET/CT imaging. For a PET/MRI study, the acquisition time was 20 min, and attenuation correction was done using the scanner standard 4 segment (air, soft tissue, lung, and fat) MR based attenuation map. The reconstruction matrix size was 172x172x127 and voxel size 4.17x4.17x2.03 $mm^3$. The acquisition time for a PET/CT study was 15 min. The reconstruction matrix size was 200x200x75 and voxel size 4.07x4.07x3.00 $mm^3$. The low dose, non-diagnostic CT images were used for attenuation correction for the PET/CT studies. PET/MRI and PET/CT reconstructed images were transferred to a common platform and used to calculate Y-90 dosimetry using MIM 7.1 software (MIM Software Inc., Cleveland, Ohio). Local deposition method was used to calculate dosimetry. For each patient, regions-of-interest (ROIs) for whole liver and tumor(s) were manually created; the normal tissue ROI was created automatically. ***Results:*** For 12 patients, the mean liver, tumor and normal tissue doses (mean ± SD) were, 48.10±23.21 Gy, 806.66±1010.57 Gy and 41.50±15.28 Gy, respectively from PET/CT studies, and 40.84±22.53 Gy, 689.00±871.60 Gy and 35.87±16.59 Gy, respectively from PET/MRI studies. Although, the mean dose to the tumor can be significantly different, up to 38% difference, mean dose from both modalities for liver and normal tissue were relatively close, with less than 17% difference. ***Conclusion:*** PET/MRI usually provides better delineated of liver and tumor contours due to superior MRI soft tissue contrast. On the other side, PET/CT provides better quantification of PET images due to better attenuation correction. In addition to these factors, different voxels and matrix sizes also contribute to relatively small and clinically acceptable differences in between PET/MRI or PET/CT Y-90 dosimetry results. ***References:*** 1.Knešaurek K, Tuli A, Kim E, Heiba S, Kostakoglu L. Comparison of PET/CT and PET/MR imaging and dosimetry of yttrium-90 ($^{90}Y$) in patients with unresectable hepatic tumors who have received intra-arterial radioembolization therapy with $^{90}Y$ microspheres. ## EP-0573

### Predicting response in HCC selective internal radiation therapy with Y-90 microspheres using advanced PET/CT based dosimetry; LATAM and USA centers experience

***D. Mena***[1], *I. Hume*[2], *R. García Monaco*[2], *C. Collaud*[2], *O. Peralta*[2], *A. Mollerach*[2], *P. Rodriguez*[2], *V. Jager*[2], *I. Arma*[2], *C. Cianciarelli*[2], *M. Chacon*[2], *V. Gonzalez*[2], *S. Sunagua*[2], *N. Pabstleben*[2], *K. Knešaurek*[3]; [1]*Nuclear Medicine World, CDMX, MEXICO,* [2]*Hospital Italiano de Buenos Aires, Buenos Aires, ARGENTINA,* [3]*Mount Sinai, NY, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The aim of our work is to evaluate the role of advanced PET/CT based dosimetry for predicting response in patients undergoing locoregional therapy to the liver with Y-90 microspheres. ***Materials and Methods:*** To assess response to Y-90 treatment, mRECIST criteria done on contrast enhanced MRI and/or CT were used at a month post treatment and subsequently every three months after it. Due to the limited number of partial response and stable disease cases, only 60 patients (11 female:49 male, mean age 66.2±8.4y) with complete response (CR) and progression of disease (PD) were selected. PET/CT images were acquired for 15 min. The low dose, non-diagnostic CT images from PET/CT were used for localization of the Y-90 microspheres and attenuation correction. The reconstruction matrix size was 200x200x75 mm and voxel size 4.07x4.07x3.00 mm. Local deposition method was used for dosimetry calculations. For each patient, volume-of-interest (VOI) for whole liver and tumor(s) was manually created and a program automatically created normal tissue VOI. ***Results:*** 60 patients (11 female:49 male, mean age 66.2±8.4y) are the subject of the study. The mean liver, tumor, and normal tissue doses (mean ± SD) were 49.22±24.69 Gy, 830.71±764.09 Gy and 40.12 ±20.90 Gy respectively. Among these patients, 50 (83%) showed CR and 10 (17%) showed PD. For CR patients the mean tumor dose was 943.53±781.40 Gy and for patients with PD, the mean tumor dose was significantly lower 266.61±280.64 Gy. The mean liver and normal tissue doses were similar; for CR patients, liver and normal tissue doses were 49.43±22.64 Gy and 40.55±21.23 Gy, respectively and for PD patients the same values were 48.17±34.71 Gy and 38.01±20.13 Gy, respectively. ***Conclusion:*** Although the number of PD cases was limited and partial volume effect was not considered, our data shows that patients with complete response have a statistically higher (P = 0.0001) tumor dose than those with progression of disease.

## EP-0574

### Correlation of 90y Microsphere Dose Planned with Voxel-Based Dosimetry with Actual Absorbed Tumor Dose

***A. Dere****, E. Akgun, K. Bozkurt, B. Armutlu, B. E. Akkas, M. Kaya; University of Health Sciences,Basaksehir Cam ve Sakura City Hospital, ISTANBUL, TÜRKIYE.*

***Aim/Introduction:*** We aimed to retrospectively compare voxel-based dosimetric calculations obtained from Tc99mMAA SPECT/CT images with the absorbed doses and volumes applied on treatment. ***Materials and Methods:*** MAA SPECT/CT images and PET/CT images after 90Y treatment of 40 liver lesions treated with intra-arterial 90Y glass microsphere were analyzed. Volumes of tumor, perfused tissue, normal liver and whole liver were plotted and absorbed doses were recorded both for MAA SPECT/CT and for Y90 treatment PET/CT images. The volumes and planned doses using MAA SPECT/CT data were compared with the real absorbed doses and volumes on Y90 treatment PET/CT images. From the histogram curves, the planned and received doses of 50-70-95% of the tumor volume were compared. ***Results:*** Tumor volumes measured from SPECT and PET images of 40 lesions (r=0.97, p<0.001), perfused area (r=97,p<0.001), total liver (r=0.96,p<0.001), normal liver tissue volumes (r=0.78,p<0.001) were highly correlated. Tumor (r=0.81,p<0.001), perfused tissue (r=0.81,p<0.001), normal perfused (r=0.37,p<0.002), normal liver (r=0.73, p<0.001) and whole liver (r=0.99 p<0.001) absorbed doses were also highly correlated. When absorbed doses of 50%, 70% and 95% of the perfused volumes were compared in MAA and 90Y dosimetric analysis, statistically strong correlation was observed (r=0.77 p<0.001, r=0.67 p<0.001, r=0.61 p <0.001).When the same comparison was performed for the tumor absorbed doses, the doses absorbed by 50% and 70% of the tumor volume were correlated (r=0.75 p<0.001, r=0.61 p<0.01), while the doses received by 95% of the tumor volume were not (r=0.026 p>0.05). On head- to- head correlation, treatment absorbed doses did not differ from the planned doses in 27 of 40 lesions. However, in 13 lesions, we observed that the applied doses were significantly higher within a range of 25%- 87% from the scheduled doses (mean: 51%). When evaluated the effect of temporary embolization of hepatic arterioles, split dosage delivery, pre/post calibrated dosage use, and the interval between MAA and 90Y treatment on this dosimetric difference, we observed that the rate of split dosing was slightly higher in these 13 lesions (p:ns , % 38 vs. 22%). ***Conclusion:*** Absorbed doses and volumes planned with voxel-based dosimetry were significantly correlated with the absorbed doses and volumes achieved in the majority of patients. However, significant deviations were seen in some tumor absorbed doses. In addition, Tc99m MAA and 90Y distribution may differ when 95% of the tumor volume is compared. This situation may be explained by the different nature of MAA and Y90 particles.

## EP-0575

### Development of a Topical Application Device for Non Melanoma Skin Cancer Therapy

***M. Buonanno****, M. Aurilio, A. Esposito, A. Morisco, R. De Marino, L. D'ambrosio, C. Maisto, V. Porfidia, S. Lastoria; IRCCS TUMORI FONDAZIONE G. PASCALE, Napoli, ITALY.*

***Aim/Introduction:*** Non-melanoma skin cancers (NMSC) can usually be eradicated by surgery and local radiation treatment. A new method using topical application of radionuclides, as an effective alternative, has been proposed. The aim of this research is to produce radioactive skin patches; fully individualized preparations designed considering the effective shape of the lesion/s to treat. ***Materials and Methods:*** We have focused our interest in producing "therapeutic" using the radionuclide [$^{223}$Ra]-Ra, as RaCl solution, that was impregnated in a scaffold, or mixed with a resin material to form a uniform layer. A homogeneous distribution of radioactivity was determinated by phosphorescence imaging using Cyclone, to create a standard that allows us to calculate the activity present in each prepared device.As a basic material to form the scaffold or device we used polymeric type mixtures with cornstarch dispersions at concentrations between 10-30%, polyvinylpyrrolidone solution at 15%, gelatin solutions at concentrations between 20-30% and hydroxypropyl methylcellulose (HPMC) dispersions at different concentrations 2-30% with the inclusion of 10% glycerol in all case, as a plasticizing agent. In each case, rheological characteristics were observed at the time of making the patch, and the distributions of the Ra-223 activity were determined using the elaborated calibration curve ***Results:*** The scaffold made by gelatin and polyvinylpyrrolidone solutions,

showed an insufficient viscosity, that was unable to maintain the radioactive dispersion on the polymeric base. Such limit makes impossible to avoid the contamination of the patient. The scaffold made by cornstarch did not guarantee a uniform distribution of radioactivity. Conversely, HPMC dispersion at 30% with glycerin at 10% showed the best characteristics for viscosity and a uniform distribution of the radioactivity. The efficacy of patches containing up to 4 MBq of $^{223}$Ra-Cl is currently being tested on cell culture of NMSC OF different thickness in order to define the proper timing to obtain the most effective therapeutic results. ***Conclusion:*** HPMC dispersion showed the best results in terms of future clinical applicability. The production of lesion-shaped patches, by 3D printers is the optimization of the manufacturing process. ***References:*** Pashazadeh A et al., Conceptual design of a personalized radiation therapy patch for skin cancer. Current Directions in Biomedical Engineering, 2018, 4,1.Li, Y., Sun, X., Liang, Y. et al. Monte Carlo simulation of linac using PRIMO. Radiat Oncol (2022) 17, 185.

## EP-0576

### Is There Any Affect Of Tumor Location On Radioembolisation Treatment Response In Hepatocellular Carcinoma?

***E. Akgun****;*
*University of Health Science Turkey, Basaksehir Cam and Sakura City Hospital, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** We planned this retrospective study to compare 90Y glass radioembolization treatment response between central and peripheral located hepatocellular carcinoma (HCC). ***Materials and Methods:*** Thirty-nine patients treated with Y90 embedded glass microsphere included the study. Absorbed doses were calculated with voxel-based dosimetric approach.The location being central (Group 1, n=19) versus peripheral (Group 2, n=20) was defined by the coefficient of the HCC, which is ratio of the distance from the hilum of the liver at the portal vein bifurcation to the central of the HCC divided by the diameter of the whole liver on the same line.Treatment response according to AFP value, modified Response Evaluation Criteria in Solid Tumors (mRECIST, n=30), and Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST, n=31) criteria's were analyzed after 2 months of treatment. ***Results:*** In Group 1; mean age was 65.6. In 5 cases split infusion, in 11 cases tumor selective treatment approach were applied. According to PERCİST/mRECIST criteria treatment responses categories: complete response in 2/1 cases, partial response in 7/7 cases, stable disease in 2/2 cases, progressive diseases in 3/4 cases; respectively. AFP value decreased in 3 cases, increased in 6 cases, and was stable in 1 case. Median (min-max) absorbed doses were 325 Gy (115-600) for tumor, 114 Gy (35-304) for perfused normal tissue, and 12 Gy (3-70) for normal liver. Ratio of perfuse tissue volume to tumor volume ranged between 1.1 to 19.8 (median 1.90).In Group 2; mean age was 65.2. In 4 cases split infusion, in only 1 case non-selective treatment approach were applied. According to PERCİST/mRECIST criteria treatment responses categories: complete response in 6/4 cases, partial response in 6/9 cases, stable disease in 2/0 cases, progressive diseases in 3/3 cases; respectively. AFP value decreased in 9 cases, increased in 2 cases, and was stable in 1 case. Median (min-max) absorbed doses were 475 Gy (150-800) for tumor, 157 Gy (35-652) for perfused normal tissue, and 14 Gy (1-69) for normal liver. There is no statistically significant difference in gender, treatment responses, tumor volumes, perfuse tissue volumes, perfuse tissue to tumor ratios between 2 groups. However, tumor selective approach, and perfuse tissue absorbed doses were significantly higher in Group 2 (p=0.007, and p=0.004; respectively). ***Conclusion:*** Contrary to expectation, centrally located HCC cases could be treated as successfully as peripherally located HCC cases.

## EP-0577

### Factors Affecting Outcome in Hepatocellular Cancer Patients Treated with Selective Intra-arterial Radiomicrosphere Therapy

***B. Soydas Turan***[1]*, B. Volkan-Salancı*[2]*, M. F. Bozkurt*[2]*, G. Eldem*[3]*, E. Karabulut*[4]*, S. Yalcin*[5]*, F. Çay*[3]*, B. Peynircioğlu*[3]*, O. Ugur*[2]*;*
*[1]Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Hacettepe University Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE, [3]Hacettepe University Faculty of Medicine, Department of Interventional Radiology, Ankara, TÜRKIYE, [4]Hacettepe University Faculty of Medicine, Department of Biostatistics, Ankara, TÜRKIYE, [5]Hacettepe University Faculty of Medicine, Department of Medical Oncology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** To explore which factors may influence outcome of hepatocellular cancer (HCC) patients after selective intra-arterial radiomicrosphere therapy (SIRT). ***Materials and Methods:*** HCC patients treated with SIRT between 2008 and 2018 were retrospectively enrolled. Previous therapies, baseline liver function tests and alfa-fetoprotein (AFP) levels, Barcelona Clinic Liver Cancer (BCLC) stage and Child-Pugh score were noted. Baseline CT/MRI were re-assessed for tumor size and number, presence of portal vein invasion and extrahepatic metastases. SIRT was applied using either resin or glass microspheres. Treatment dose of glass microspheres was calculated by non-compartmental partition model whereas dose of resin treatments was calculated by using the body surface area method. Univariate analysis was carried out using Kaplan-Meier survival curves and for statistical comparison log rank test was used. The effect of microsphere type, BCLC stage, Child-Pugh score, prior liver resection, baseline liver functions and AFP levels were assessed using multivariate Cox regression model. ***Results:*** 106 HCC patients treated with SIRT (49 resin, 57 glass) were included. The median overall survival (OS) was 13.9 months (range: 10.1-17.7). In univariate analysis, survival was significantly longer in patients with prior liver resection (33.8 vs 11.9 months, p: 0.01). Patients with portal vein invasion (5.9 vs 15.3 months, p: 0.016), BCLC class C (5.9 vs 15.5 months, p: 0.007), Child-Pugh score B (7.9 vs 15.3 months, p:0.012) and progressive disease after SIRT (9.7 vs 17.6 months, p: 0.003) had significantly low survival, as expected. Although baseline characteristics of two microsphere groups were similar with regard to demographics, BCLC stage, Child-Pugh score, liver function tests and AFP levels (Table 1), patients treated with glass microspheres had lower median OS when compared to resin (10.1 vs 23.1 months, p: 0.012). Multivariate analyses showed treatment with glass microspheres (Hazard Ratio [HR]: 2.537, p: 0.001), BCLC class C (HR: 1.706, p: 0.058), lower baseline albumin (HR: 0.501, p: 0.017) and higher baseline aspartate aminotransferase level (HR: 1.01, p<0.001) were associated with worse survival. Gender (p: 0.306), prior trans-arterial chemotherapy (p: 0.792), prior radiofrequency ablation (p: 0.465), presence of extrahepatic disease (p: 0.146), bi-lobar involvement (p: 0.079) and number of lesions (p: 0.190) did not have impact on OS. ***Conclusion:*** Treatment with glass microspheres, BCLC class C, lower baseline albumin and higher baseline aspartate aminotransferase level had a negative effect on OS of HCC patients who received SIRT. Further larger prospective dosimetric studies are warranted to confirm these findings.

## EP-0578

### A Case of Meningioma Applied İntraarterial Lu-177 DOTATATE

***K. Mammadli***, *B. Karaşah Erkek, M. Parıldar, Ö. Şanlı;*
*Ege University Faculty Of Medicine, Department Of Nuclear Medicine, Bornova, TÜRKIYE.*

***Aim/Introduction:*** Peptide receptor radionuclide therapy (PRRT) has been used for over 20 years as a systemic treatment for advanced neuroendocrine tumors (NENs) and is a continuously evolving treatment modality. The basic mechanism of action of PRRT is based on the principle of using a beta or alpha particle-emitting radionuclide to deliver somatostatin analogues to the interior or surface of tumor cells. The treatment of meningiomas that are resistant to surgery and radiotherapy is challenging, and the effects of various systemic treatments are often limited with low rates of progression-free survival. Somatostatin receptors are overexpressed in meningiomas and are one of the most specific immunohistochemical markers. The number of studies on PRRT in meningioma patients is limited and much less compared to NENs . ***Materials and Methods:*** A 67-year-old male patient presented to our clinic with symptoms of headache, numbness on the face, and nausea. The patient had previously undergone surgery and postoperative radiotherapy for a left temporal mass. Subsequent follow-up revealed recurrence, and the patient was symptomatic with no option for reoperation or radiotherapy. Prior to treatment, MRI and Ga68 DOTATATE PET/CT were performed for evaluation. MRI showed a mass consistent with meningioma at the sphenoid wing on the left, and Ga68 DOTATATE PET/CT showed increased DOTATATE uptake in this area. Diagnostic angiogram was performed to identify the arterial structure perfusing the tumor, and then intra-arterial selective method was used to demonstrate tumor uptake by injecting 2.5 mCi of Ga68-DOTATATE from the internal maxillary artery-A. meningea junction. After this procedure, intense Ga68 DOTATATE uptake was observed in the recurrent meningeal lesion located caudal to the craniectomy defect on Ga68 DOTA PET/CT imaging. Subsequently, the patient received a total of 4 doses of intra-arterial Lu-177 DOTATATE treatment, totaling 650 mCi. No adverse effects were observed with the treatments. After treatment, partial regression was observed in the lesion on Ga68 DOTA PET/CT, while MRI images showed complete regression of the intracerebral extension of the lesion and partial dimensional regression with cystic necrotic features in the component adjacent to the sphenoid bone. ***Results:*** Intra-arterial PRRT can significantly increase tumor radiotherapeutic accumulation due to the first-pass effect and may provide safe and promising improvement in symptomatic and inoperable meningioma patients resistant to conventional treatments. In addition patient symptoms decreased after treatment. ***Conclusion:*** Futher studies are nedeed to better understand the effectivesess and safety of intraarterial PRRT in meningioma patients.

## EP-0579

### Hepatic transarterial radioembolization (TARE) with 90Yttrium glass microspheres for treatment of liver tumours: safety and survival outcomes.

***A. De Agrela Serrao***, *A. M. Leiva Montejo, C. Ruiz Corbalan, M. Castellón Sanchez, J. L. Navarro Fernandez, T. E. Rodriguez Locarno, A. C. Hernández Martínez, L. Frutos Esteban, D. R. Cáceres Silva, L. Mohamed Salem, J. F. Contreras Gutierrez;*
*Hospital Clinico Universitario Virgen de Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** The aim of this study was to analyse the overall survival (OS) outcomes of hepatic transarterial radioembolization with $^{90}$Yttrium glass microspheres (TARE) for patients diagnosed with hepatocellular carcinoma (HCC), liver metastasis of neuroendocrine tumours (NETs), intrahepatic cholangiocarcinoma (ICC) or liver metastasis of colorectal adenocarcinoma (CRC). ***Materials and Methods:*** Retrospective, monocentric study which included 39 patients that underwent TARE treatment for liver tumours between January 2019 and January 2023. (2 patients were excluded due to lack of follow up). previous chemotherapy and local treatments to TARE were noted, radiation dosimetry and immediate complications were recorded. The therapeutic response was categorised as complete response, partial response or progressive disease. Survival outcomes and clinical or biochemical adverse events were analysed. ***Results:*** 52 TARE were performed in 39 patients (age 66.85±10.34 years, 89.7% men, mean follow-up 17.38±12.66months). Thirty patients (76.9%) had localized HCC, five patients (12.8%) had liver metastases from NETs, two patients (5.1%) had ICC and two patients had liver metastases from CRC. Sixteen patients (41%) had received at least one previous systemic treatment and fourteen patients (35.9%) had received at least one previous local treatment. Fourteen (35.9%) cases presented bilobar liver involvement. In unilobar cases (64.1%) the most frequent involvement was in the right hepatic lobe (82.1%). The mean of perfused volume and Yttrium-90 activity was 777.18±410.96 cm3 and 2.63±1.25 Gbq respectively with an absorbed dose in the tumour tissue of 153.27±50.61 Gy in a monocompartment dosimetry system, lung absorbed dose was 13.76±9.33 Gy. In the follow up a complete response to treatment was observed in six patients (15.4%), partial response in eight patients (20.5%), stable disease in ten patients (25.6%), and progressive disease in 15 patients (38.5%). The estimated time until progression was 22,48±3,56 months. There were acute complications in 4 patients (10.3%), 50% fever and 50% abdominal pain. Eighteen (46.2%) patients died, six (15.4%) of which died from unrelated causes to the cancer. Mean OS was 32.58±3.32 months (95% CI 26.07-39.106) from TARE to death. None of the patients with NETs died during the follow-up and 80% had a complete response. Histology of HCC was associated with a better OS (34.3±3.21 months) than CRC and ICC (20±11 and 7.5±4.5 months) ($p<0.0001$). ***Conclusion:*** TARE is an effective am safe treatment for liver tumours specially HCC an NETs, but more data is needed to properly assess the OS in ICC and CRC.

## EP-0580

### Efficacy and safety of Y-90 radioembolization for colorectal cancer liver metastases.

***J. Villa Palacios***, *E. Triviño-Ibáñez, E. González-Flores, P. Pardo-Moreno, A. Rodríguez-Fernández;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** To analyze the efficacy, toxicity, and survival outcomes of transarterial hepatic radioembolization with yttrium-90 (TARE) for colorectal cancer (CRC) liver metastases. ***Materials and Methods:*** We performed an observational and prospective study that patients with CRC liver metastases treated by TARE, between November 2015 and August 2022. Data on previous treatments, biochemical parameters before and after treatment, dosimetry, and complications were recorded. Therapeutic response was evaluated at 3 and 6 months after TARE (using RECIST1.1 criteria). Clinical and/or biochemical adverse events were also recorded. ***Results:*** 42 TARE were performed in 33 patients (mean age 61.730±8.31 years, 63.6% male, mean follow-up 41.84±23.12 months). Of these patients, 90.1% (30/33) had received at least one line of systemic chemotherapy. Bilobar liver involvement was present in 51.5% (17/33) cases, with tumour burden greater than 25% in 51.5% of cases. The administered yttrium-90 activity was 3.11 ± 2.02 Gbq, with a mean absorbed

dose in tumour tissue of 193.15 ± 111.21 Gy and a mean tumour-to-normal liver ratio of 27.76 ± 44.47. At 3 months, one patient (3.1%) had a complete response (CR), 7 (21.2%) had a partial response (PR), 11 (33.3%) had stable disease (SD), and 13 (39.4%) had disease progression (PD). At 6 months, one patient remained in CR, 5 had SD, and 18 had PD. Twelve patients experienced acute or delayed toxicity, with hyperbilirubinemia being the most frequent adverse event (grade 3 or 4 in 5 patients). ***Conclusion:*** In our study, TARE was a safe and effective treatment for unresectable CRC liver metastases.

## EP-0581

### Factors impacting survival in colorectal liver metastases treated with Y-90 radioembolization.

***J. Villa Palacios***, *E. Triviño-Ibáñez, J. Ciampi-Dopazo, E. González-Flores, A. Rodríguez-Fernández;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** To investigate factors associated with survival in colorectal carcinoma (CRC) with liver metastases treated with yttrium-90 (Y-90) radioembolization (TARE). ***Materials and Methods:*** Observational and prospective study that included 33 patients with CRC liver metastases treated by TARE between November 2015 and August 2022. Data related to previous treatments, biochemical parameters, dosimetry, and complications were collected. Therapeutic response was evaluated at 3 and 6 months after TARE using RECIST 1.1 criteria. Survival probabilities (overall survival [OS] and progression-free survival [PFS)]) were generated using the Kaplan-Meier method, and a Cox regression model was used to study the association of different predictive biomarkers. ***Results:*** Forty-two TARE procedures were performed in 33 patients (mean age 61.730±8.31 years, 63.6% male, mean follow-up 41.84±23.12 months). Ninety-one percent (30/33) of the patients had received at least one line of systemic chemotherapy. Bilobar hepatic involvement was present in 51.5% (17/33) of cases, with a tumour burden greater than 25% in 51.5% of cases. The administered yttrium-90 activity was 3.11 ± 2.02 GBq, with an absorbed dose in the tumour tissue of 193.15 ± 111.21 Gy. Seventy-eight-point eight percent (26/33) of patients died during follow-up. The median OS was 36.35 months from the diagnosis of liver metastases and 11 months from TARE. Factors associated with lower OS were: extrahepatic metastases (HR: 2.72, p=0.044), aspartate aminotransferase (HR: 1.03, p=0.044), neutrophil-to-lymphocyte ratio (HR: 1.40, p=0.013), and platelet-to-lymphocyte ratio (HR: 1.01, p<0.01) pre-TARE, injected activity (HR: 1.21, p=0.037), perfused volume (HR: 1.01, p=0.029), absorbed tumour dose <120 Gy (HR: 2.5, p=0.042), and toxicity after TARE (HR: 2.33, p=0.049). ***Conclusion:*** Predictive factors for survival in colorectal liver metastases treated by TARE include biochemical, dosimetry and toxicity parameters.

## EP-0582

### Tumoricidal dosing approach with parenchymal sparing using voxel-based dosimetry in the Y90 glass microspheres treatment of liver lesions

***C. Sin***, *B. E. Akkas, M. Kaya, E. Akgun;*
*University of Health Sciences,Basaksehir Cam ve Sakura City Hospital, İSTANBUL, TÜRKIYE.*

***Aim/Introduction:*** Investigate the effect of absorbed doses and tumor volume on ALBI scores in patients treated with 90Y glass microspheres. ***Materials and Methods:*** 81 patients ( HCC n:46, cholangiocellular cancer (ICC) n:6, metastatic tumor n: 29) were included (49 M, 32 F, mean age: 62.4 (13-91). ECOG and Child Pugh scores, laboratory values and ALBI scores were recorded. Patients were grouped as ALBI-1 (≤-2.60), ALBI-2 (-2.60< ALBI≤-1.39) and ALBI-3 (>-1.39). Follow-up PET/CT was performed for treatment response evaluation 6 weeks after therapy. ***Results:*** Child Pugh scores were A in 40 patients and B in 6 patients. Baseline ALBI scores were 1 in 55 cases, 2 in 25 cases and 3 in 1 case. Tumor absorbed dose (TAD) averaged 427.2 Gy (120-1000 Gy); average tumor volume was 192.3cc (21-2871 cc). Total liver absorbed dose was 31.1 Gy (1.1- 68.9 Gy); perfused normal parenchyma dose was calculated as 210 Gy (22.1-602.4 Gy). On follow-up PET/CT, complete metabolic response (CR) was observed in 8 patients and partial response (PR) was observed in 30 patients with the absence of non-target progression. In 7 patients, PR was observed in the target lesion, with non-target hepatic and/or systemic progression. Progression of the target lesion (PD) was observed in 10 patients. 11 patients died in the first 6 months on follow-up. PET/CT examination could not be performed in 15 patients. We observed a gradual significant increase in objective treatment response with increasing TAD; 575 Gy in CR, 417.6 in PR, 308.3 in PD and 233.6 Gy in exitus patients; (p<0.001). After treatment, ALBI score groups 72/81 (89%) patients (Group1) did not change. However, 9/81 (11%) patients ALBI score was impaired (Group2). There was no statistically significant difference between absorbed doses of non-tumoral parenchyma (140 Gy vs. 130 Gy) and the total liver absorbed doses (72 Gy vs 79 Gy) between groups. TAD was significantly higher in Group1 (402 Gy vs 253 Gy, p=0.01). Tumor volumes were significantly lower in Group1 (320 cc vs 525 cc, p=0.02). Five of the 9 patients whose ALBI scores deteriorated, died on follow-up. ***Conclusion:*** The lower TAD and higher tumor volumes in patients with impaired ALBI scores compared to the other group showed that developing hepatic dysfunction was due to high tumor burden and/or tumor-related causes other than radiotoxicity. Tumoricidal ablative doses can be achieved with sparing future liver functions using voxel-based dosimetric approach in 90Y glass microspheres treatment.

## EP-0583

### PET/CT-based Y-90 microsphere dosimetry to predict contralateral lobe hypertrophy after unilobar radioembolization in treatment-naive hepatocellular carcinoma

***Y. Kang***, *J. Paeng;*
*Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Radioembolization is a treatment option for hepatic tumors that can lead to the control of tumor growth, and cause hypertrophy of the future remnant liver for surgical resection. Despite the increasing use of PET-based dosimetry in radioembolization, its effectiveness for predicting contralateral lobe hypertrophy has not been fully evaluated in solid patient groups. This study aimed to identify potential predictors of contralateral lobe hypertrophy after radioembolization in treatment-naive hepatocellular carcinoma (HCC) patients, based on Y-90 microsphere PET/CT dosimetry and clinical factors. ***Materials and Methods:*** Twenty patients that underwent unilobar radioembolization for right lobar treatment-naive HCCs were retrospectively enrolled. In all patients, contrast-enhanced CT scans were performed before treatment (within a month), and two to four months after treatment. Post-treatment Y-90 PET/CT scans were performed in 16 to 24 hours after Y-90 microsphere injection. PET/CT images were realigned to match the pre-treatment CT images, and voxel-based absorbed dose was calculated from PET/CT images using a dedicated analysis

software. Dose histograms were obtained for each region, including the tumor, target liver (right lobe), target non-tumor liver, and future remnant liver (FRL, left lobe). To evaluate the degree of contralateral lobe hypertrophy, the volume of the FRL was calculated based on manually defined volumes of interest (VOIs) on both pre-treatment and post-treatment CT images. Relative increase in FRL volume was calculated as the difference between post-treatment and pre-treatment volumes, divided by the pre-treatment volume. PET dosimetry factors were tested with pre-treatment clinical factors, including tumor size, portal vein thrombosis, ascites, splenomegaly, and laboratory test results, for prediction of FRL volume increase by multivariate regression analyses. ***Results:*** The mean relative FRL volume increase was 12.4% (95% CI 4.6-20.1%). In univariate Pearson correlation analyses using dosimetry factors, the mean absorbed dose of target non-tumor liver was the most significant predictors for relative FRL volume change (r=0.660; p=0.002). Among clinical factors, platelet count exhibited significant positive correlation (r=0.667; p=0.001). In multivariate regression analysis, both the mean absorbed dose of target non-tumor liver, and platelet count were demonstrated as independent predictors for FRL volume increase (r = 0.595 and 0.604, respectively; overall model p<0.001). ***Conclusion:*** This study suggests that the mean absorbed dose of target non-tumor liver, and platelet count have the potential to predict contralateral lobe hypertrophy after radioembolization for treatment-naive HCCs. Further studies with large cohorts are needed to validate the results and establish the clinical significance of these predictors.

## EP-0584

### The Role of Tumor FDG Metabolism and AFP Level in Predicting Treatment Response In HCC Patients Treated with 90Y Microspheres

***G. Yilmaz***, *B. E. Akkaş, M. Kaya, E. Akgün, Ö. Vural Topuz; University of Health Sciences Basaksehir Cam and Sakura City Hospital, İstanbul, TÜRKIYE.*

***Aim/Introduction:*** Tumor FDG uptake and serum AFP levels are inversely correlated with tumor differentiation in hepatocellular carcinomas (HCC). The aim of this study is to compare the Y90 microsphere treatment response with the differentiation features of the tumor predicted by pretreatment serum AFP value and FDG uptake. ***Materials and Methods:*** 32 HCC patients who were treated with selective intra-arterial 90Y glass microspheres were included. Barcelona Clinic Liver Cancer (BCLC) stages were as follows; Stage A: 18 patients, Stage B :13 patients, Stage C: 1 patient. Child Pugh scores were A in 26 patients, B in 6 patients. Pretreatment 18F-FDG PET/CT examination was performed and SUVmax/mean/peak of the lesions and normal liver parenchyma were measured. Tumor-to-normal liver SUV ratios (T/Li) were recorded. Absorbed tumor and normal liver doses were calculated by voxel-based multi-compartment dosimetric analysis on hepatic artery 99mTc-MAA SPECT/CT images. Treatment response was evaluated by 6th week PET/CT and 8th week MR images according to PERCIST and mRECIST criteria. ***Results:*** 32 HCC cases ( 25 M, 7 F, mean age: 66.8± 9.5 years) were included. The tumor-absorbed dose range was 116-800 Gy (mean 387±165). On follow up PET/CT, treatment responses for target lesions were as follows; Complete response (CR) in 5 patients, partial response (PR) in 15 patients, stable disease (SD) in 4 patients, and progression (PD) in 8 patients. Non-target intrahepatic progression (NTP) and/or extrahepatic disease were observed in 9 of 20 patients with complete and partial response. Tumor absorbed doses were significantly higher in CR compared to PR, SD and PD (564.6 Gy vs.381.4 vs 401.5 and 281.2 Gy, respectively, p:0.01). There was no significant correlation between the T/Li SUV and AFP values with regard to treatment responses. Follow-up PET/CT detected NTP and systemic progression in 17 of 32 patients. Progression was not correlated to BCLC stages. T/Li SUV ratios did not differ in these patients compared to others. However, serum AFP levels were significantly higher in patients with NTP compared to others (median: 3.9 min-max:1.59-3170 ng/dl vs median:47.5 min-max:2.77-50864, p <0.001). ***Conclusion:*** In this study, there was no significant correlation between tumor FDG metabolism and serum AFP values and the response of the target lesion to 90Y therapy. In 90Y microsphere treatment, the most important parameter determining the early treatment response is the tumor absorbed dose. We observed that even in poorly differentiated HCC, successful treatment response can be achieved when tumoricidal doses were administered.

## EP-0585

### Hepatic transarterial radioembolization with three different compounds: are there any survival-related biomarkers?

***L. Asensio Valero***, *H. Rodriguez Parra, J. Orozco Cortes, C. Castillo Arias, L. Blanco Verdejo, A. Sanchez Tornero, M. Redal Peña, R. Díaz Expósito;*
*Hospital Clínico de Valencia, Valencia, SPAIN.*

***Aim/Introduction:*** The main objective of this study was to assess the survival of patients with liver lesions treated with radioembolization using Y90 and Ho166 loaded microspheres in relation to their clinical and paraclinical context. ***Materials and Methods:*** A total of 100 patients were evaluated, of which 96 were treated and four were dropped due to contraindications. The sample included 70 men (67.2%) and 26 women (32.8%), with an age range between 22 and 87 years old (mean±SE: 67.1±1.2). Overall, 78 patients were treated with 90Y-resin, 13 with Y90-glass and five with 166Ho loaded microspheres. Among them, there were 70 cases of hepatocarcinoma (67,3%), 19 colorectal cancer (18,3%), nine cholangiocarcinoma (8,8%), one gastrointestinal stromal tumor (0,9%), one intraductal papillary mucinous neoplasm (0,9%), one carcinoma of unknown primary (0,9%), and one gastric cancer (0,9%). Mean tumor volumes (TV) ranged from 3cc to 1433cc (220.48±27.7cc), and tumor burden (TB) ranged from 0.13% to 88.23% (12.2±1.5%). Of the 96 subjects, 80 died at the time of analysis, with overall survival (OS) ranging from one to 82 months (m) (17.25±1.5m). Statistical analysis was performed using SPSS STATISTICS v28. ***Results:*** Multi-segmental involvement was observed in 65% of cases, with two-segment or three-segment implication predominating, accounting for 26% and 20%, respectively. Amidst the different compounds, no statistical difference in OS was detected between yttrium-resin and yttrium-glass microspheres, while data from holmium-treated patients were insufficient for proper assessment. A total of 124 procedures were performed. OS in the single treatment group (72 patients, 75%) was significantly lower than in the two (20 patients, 20,8%) or three (four patients, 4,2%) treatment groups (14.5±1.4m vs 25.2±4.7m vs 26.7±5.2m; Kruskal-Wallis p:0.027). Re-treatment was considered in subsequent controls with tumor viability or in two-stage procedures. Parametric analysis showed that non-cirrhotic patients (23.00±3.04m) survived longer than cirrhotic patients (14.14±1.44m) (T p: 0.002). Furthermore, the enolic habit group had also a significantly lower OS than nondrinkers (3.54±2.4m vs 19.62±1.9m; T p:0.03). Among all pre-treatment liver function parameters studied, those subjects with higher levels of GOT (Kruskal-Wallis p:0.02) and GPT (Kruskal-Wallis p:0.07)

showed lower OS. No other differences were found between survival and lesion characteristics (TV, TB). ***Conclusion:*** The data suggests that it is possible to consider cirrhosis, alcoholism, and elevated pretreatment GOT and GPT values as biomarkers of poor prognosis.

## EP-0586

### Quantification of 99mTc-MAA for lung shunt estimation before 90Y radioembolization: comparison of three methods

***E. Milan***, *D. Barbisan, G. Zambon, C. La Verde, P. Barzi, M. Sutto, S. Barbiero, F. Nistri, L. Vendramin;*
*Ospedale Cà Foncello ULSS2, Treviso, ITALY.*

***Aim/Introduction:*** In order to avoid radiation pneumonitis, planning for 90Y microspheres SIRT requires estimation of liver-lung shunt fraction (LSF) by using 99mTc-MAA procedure. Currently, regions of interest over liver and lungs in 2D planar imaging of 99mTc-MAA are manually drawn. This method, although mandatory, has some limits: it's time-consuming, observer dependent, limited by absence of both attenuation and scatter correction. Aim of the study was to compare the performances for LSF quantification of the manual method versus a nearly automatic one based on the use of a commercially available software analysing both 2D and 3D SPECT/CT images. ***Materials and Methods:*** 54 planar and SPECT/CT scans acquired after injection of 99mTc-MAA were evaluated using three approaches: 1) manual 2D (m2D), 2) semiautomatic 2D (s2D) and 3) SPECT/CT with attenuation (AC) and scatter correction (SC) (3D) ***Results:*** the mean LSF from m2D was 5.34 % (range from 0.8 % to 24.5 %) and was not significantly different from s2D 5.39 % (from 1,7% to 27.4 %) (p=NS). The mean LSF from 3D was 3.63 % (range from 0.5 % to 14.7 %) and was significantly different from m2D (p<0.0005) and from s2D (p<0.0005), respectively. The quantification of LSF was not significanly different by using m2D or s2D (R= 0,87). There was a substantial overestimation of LSF using planar imaging compared to SPECT/CT with AC and SC: m2D vs 3D (R=0.69) and s2D vs 3D (R= 0.60). Only 4 patients showed lesions localized in the dome of the liver and in all of them the LSF was higher using both m2D and s2D in comparison to 3D method ***Conclusion:*** semiautomatic evaluation of LSF is a reliable tool that helps reducing processing time. Our results confirm that planar imaging overestimates LSF in comparison to SPECT/CT especially in presence of lesions in the dome of the liver.

## EP-0587

### Dose-response relationship for yttrium-90 resin microspheres in patients with liver metastases from colorectal carcinoma.

***L. Sancho Rodriguez***[1], *C. Carballo Menayo*[2], *J. González-Martín*[2], *J. Bastidas Tamayo*[3], *E. Guillén Valderrama*[1], *M. Rodríguez-Fraile*[3];
[1]*CLINICA UNIVERSIDAD DE NAVARRA, MADRID, SPAIN,* [2]*Complejo Hospitalario Universitario Insular Materno Infantil de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, SPAIN,* [3]*CLINICA UNIVERSIDAD DE NAVARRA, PAMPLONA, SPAIN.*

***Aim/Introduction:*** To analyze which voxel-based dosimetry parameters obtained from post-radioembolization $^{90}$Y-PET/CT study are able to predict the relationship between the dose absorbed by the tumor and its radiological response in patients with liver metastases of colorectal carcinoma(mCCR). ***Materials and Methods:*** Retrospective review of prospectively collected data (May/2012-September/2019) that included patients with mCRC treated with radioembolization using $^{90}$Y-resin microspheres(SIR-Spheres) who underwent a $^{90}$Y-PET/CT study(Siemens Biograph_mCT) and had at least 3 months of follow-up. Dosimetric parameters were obtained using a 3D voxel dosimetry software(Planet Dose; Dosisoft). The total liver, target healthy liver tissue and tumors were segmented. Tumors selected for the dosimetric analysis were the five largest or most representative for each patient. From the dose-volume histograms, the parameters that quantify the heterogeneity of the absorbed dose by the tumor were obtained: minimum dose received by 98% of the volume (D98), D95, D90, D70, D50, D40 and D20, or the percentage of lesion that received ≥120 Gy(V120), 100, 70, 50, 40, and 30 Gy. Tumor response was evaluated at least three months after treatment, quantified according to RECIST1.1 criteria. In the analysis, response was considered when there was partial response (PR)(≥30% decrease in lesion diameter on CT/MR images) or stable disease (SD)(neither PR no PD) and non-response when there was progression disease (PD)(≥20% increase in lesion diameter). ROC analysis was performed to determine the area under the curve(AUC) and the cut-off point of the dosimetric parameters to assess their diagnostic accuracy. ***Results:*** Twenty-six patients with mCRC(105 lesions) were analysed. Thirteen were bilobar treatments(50%), 11 unilobar(42.3%) and 2 segmentectomies(7.7%). Most patients(96%) were progressions to second line chemotherapy. Ninety lesions (85.7 %) responded, 16(15.2%) showed PR and 74(70.5%) SD, and 15 lesions(14.3%) did not response (PD). In the analysis per patients, 22 patients(84.6 %) were responders (3 (13.6%) showed PR and 19 (86.4%) SD) and 4 patients(15.4 %) had PD. The parameters most related to radiological response were D98(cut-off-point =23.83 Gy showed an AUC=0.82; and an accuracy=86%) and V30(cut-off-point=90.69% showed an AUC=0.79; and an accuracy =79%). Therefore, a dose >23.83Gy received by 98% of the tumor volume, and a tumor volume >90.69% receiving at least 30Gy are related to a tumor response (≥30% reduction in tumor diameter). ***Conclusion:*** This study, despite its small sample size, identifies two dosimetric parameters (D98 and V30) obtained by 3D voxel dosimetry related to tumor response in patients with mCRC treated with radioembolization. ***References:*** JClinOncol.2021. Dec10;39(35):3897-3907. LancetOncol2017Sep;18(9):1159-1171.

## EP-0588

### Assessment of Similarity Between the Distributions of Tc-99m MAA Particles and Y-90 Resin Microspheres in Patients Receiving Transarterial Radioembolization for Liver Tumors

***N. Coskun***[1], *A. Erdogan*[2], *M. Kartal*[2], *E. Ozdemir*[1];
[1]*Ankara Bilkent City Hospital, Ankara Yildirim Beyazit University, Ankara, TÜRKIYE,* [2]*Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Transarterial radioembolization (TARE) for the treatment of liver tumors is based on the injection of Y-90-loaded microspheres into the hepatic arteries. Precise prediction of microsphere distribution is crucial for an effective dosimetric approach. However, the reliability of macroaggregated albumin (MAA) particles for predicting microsphere distribution remains a subject of ongoing debate. The aim of this study was to evaluate the level of similarity between the distributions of MAA particles and resin microspheres, and to evaluate the agreement between the absorbed doses according to the two procedures. ***Materials and Methods:*** Patients who underwent hepatic perfusion scintigraphy with Tc-99m MAA and TARE with Y-90 loaded resin microspheres in our center between January 2021 and January 2023 were included in the study. Whole liver volume, total perfused volume,

tumoral foci, and healthy liver parenchyma were segmented in both modalities by overlapping Tc-99m MAA SPECT/CT and Y-90 PET/CT images of each patient. The similarity of distributions was evaluated using the Jaccard similarity index and the Szymkiewicz-Simpson overlap coefficient. Spearman correlation coefficient and Bland-Altman analysis were used to evaluate the level of agreement between the doses determined by the two modalities. ***Results:*** Sixty-one patients were included in the final analyses (74% male, mean age 61±12 years). The mean Jaccard similarity index between Tc-99m MAA and Y-90 microsphere distributions was 56%, and the mean Szymkiewicz-Simpson overlap coefficient was 83%. The median tumor doses according to Tc-99m MAA and Y-90 resin microspheres were 143 and 171 Gy, respectively, while the median doses to healthy parenchyma were 80 and 75 Gy, respectively. There was a strong correlation between the median tumor doses (Spearman's rho=0.847, p<0.001) and between the parenchymal doses (Spearman's rho=0.768, p<0.001). Bland-Altman analysis showed that the absorbed tumor doses determined with both modalities were mostly within the 95% agreement interval, and there was no systematic bias between the two modalities. ***Conclusion:*** These results suggest a distribution similarity between Tc-99m MAA particles and resin microspheres ranging from 56% to 83% according to the adopted similarity approach. Variations of distribution can occur due to possible differences between the position of the angiographic catheter and the physical characteristics of the beads. Nevertheless, a comparison of predicted and achieved doses revealed a strong positive correlation. No systematic error was observed between the two procedures. This finding emphasizes the predictive value of Tc-99m MAA SPECT dosimetry for resin-based microspheres.

## C: Therapy Clinical Study -> C1 Oncological Therapy Clinical Study -> C14 Thyroid Therapy

### EP-0589

**Association between successful adjuvant therapy and quantitative evaluation of radioactive iodine accumulation in the thyroid bed in patients with differentiated thyroid cancer**

***Y. Iizuka***[1,2], *T. Katagiri*[1], *R. Nakashima*[1], *M. Inoue*[1], *K. Nakamura*[1], *T. Mizowaki*[1];
[1]*Kyoto University, Kyoto, JAPAN,* [2]*Shizuoka City Shizuoka Hospital, Shizoka, JAPAN.*

***Aim/Introduction:*** Adjuvant therapy (AT), which involves administration of radioactive iodine (iodine-131 [I-131]) is widely accepted to reduce the risk of recurrence and prolong survival in patients with differentiated thyroid cancer (DTC) without metastases. Using I-131 scintigraphy, we investigated the association between the outcomes of AT and quantitative parameters of iodine uptake at the thyroid bed. ***Materials and Methods:*** We retrospectively analysed 25 sets of images obtained from patients with DTC, who received I-131 as AT at our hospital between February 2017 and December 2018. All patients were treated with I-131 (3.70 GBq [100 mCi]) after total thyroidectomy without metastasis. We performed an I-131 whole-body scan and single-photon emission computed tomography/computed tomography 3 days after I-131 administration using a reference I-131 capsule in the same field of view. The radioactivity of the capsule was able to be calculated from its test date. Using our quantitative method [1] for estimation of the dose based on regression lines derived from reference capsule doses, we calculated radioactivity (MBq) levels at the thyroid bed. Initial successful AT was defined as absence of I-131 accumulation in the thyroid bed confirmed on diagnostic I-131 scintigraphy and a serum thyroglobulin concentration of <2.0 ng/mL without thyroid-stimulating hormone stimulation, 6-12 months after AT. We investigated the association between quantitative I-131 values measured at the thyroid bed and successful and failed AT. ***Results:*** Among 25 patients, AT was successful in 16 (64.0%). The mean and median activities of I-131 at the thyroid bed in all patients were 3.9 and 2.6 (range 0.2-14.0) MBq, respectively. The mean and median activities of I-131 were 3.2 and 2.5 MBq and 3.9 and 1.5 MBq in the successful and failed groups, respectively. Although, the median radioactivity of I-131 tended to be higher in the successful group, we observed no statistically significant intergroup differences in the association between radioactivity levels measured at the thyroid bed and AT outcomes (p=0.34). ***Conclusion:*** We observed no significant association between AT outcomes and I-131 accumulation in the thyroid bed in patients with DTC. ***References:*** [1] Iizuka Y, Katagiri T, Inoue M, et al. Comparison between planar and single-photon computed tomography images for radiation intensity quantification in iodine-131 scintigraphy, Sci Rep. 2021 11.21858

### EP-0590

***H. Wang****, R. Tian;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** To evaluate the performance of the 2015 American Thyroid Association (ATA) recurrence risk stratification system (RSS) in predicting the response to treatment one year after the initial treatment in Chinese population diagnosed with differentiated thyroid cancer (DTC). ***Materials and Methods:*** Retrospective analysis of thyroid cancer patients from the thyroid cancer Electronic Medical Records (EMR)-based database of West China Hospital, Sichuan University was performed. We reviewed all records in the database and selected consecutive cases that satisfied the following criteria: (1) patients underwent thyroid surgery from January 1, 2009, to November 1, 2019 and diagnosed with DTC; (2) available data for RSS evaluation; (3) data of the one-year follow-up visit were available (carried out 6-18 months after the initial treatment) to classify response to treatment. Initial treatment was categorized into three groups: (1) thyroid lobectomy (TL); (2) total/near-total thyroidectomy (TT/near-TT); (3) TT/near-TT plus RAI treatment. The performance of the RSS in predicting the response was evaluated using the ordinal logistic regression analysis. ***Results:*** Out of 12452 case records in the database at data lock, a total of 6959 patients were included in the final study cohort, 1260 (18.1%) patients underwent TT/near-TT as initial treatment, 5190 patients (74.6%) underwent TT/near-TT plus RAI treatment, and other 509 patients (7.3%) underwent TL. The RSS was classified as low-risk in 2226 (32.0%), intermediate-risk in 3177 (45.7%), and high-risk in 1556 (22.4%) patients. At the 1-year follow up visit, excellent response, indeterminate, biochemical incomplete, and structural incomplete responses were documented in 3885 (56 %), 2123 (31%), 545 (8%), and 406 (6%) patients, respectively. The RSS was able to predict the response to treatment (intermediate-risk: OR=1.42, 95%CI=1.27-1.58, P<0.001; high-risk: OR=2.76, 95%CI=2.42-3.15, p<0.001). Among patients who underwent different initial treatments, intermediate- and

high-risk patients had a significantly increased chance of having less than excellent response as well (OR for TL: 6.12, 38.72; OR for TT/near-TT: 3.23, 5.67; OR for TT/near-TT plus RAI treatment: 1.61, 3.33). ***Conclusion:*** The RSS is a reliable system for predicting the short-term response in patients with DTC treated with TL, TT/near-TT, and TT/near-TT plus RAI treatment in a real-world clinical setting in China.

## EP-0591

### Follow-up Findings in the Group of Patients with Tall Cell Papillary Thyroid Cancer

***B. Karasah Erkek****, H. Sarıyıldız Gümüşgöz, R. Halit Tokaç, B. Sarıkaya, Y. Ertan, A. Akgün;*
*Ege University, Izmir, TÜRKIYE.*

***Aim/Introduction:*** The tall cell variant of papillary thyroid carcinoma (TCVPC) is the most common aggressive variant of papillary thyroid cancer (PTC). In our study, we aimed to evaluate the clinical status, outcomes of I-131 treatment, and follow-up findings of patients with histopathologically confirmed TCVPC. ***Materials and Methods:*** For this purpose, the clinical data of 37 patients diagnosed with TCVPC in our clinic were retrospectively analyzed. During follow-up, I-131 whole-body scanning (WBS), stimulated thyroglobulin (sTg) and anti-Tg values, ultrasound (US), and chest CT findings were evaluated. ***Results:*** The patient age range at diagnosis was 24-77 years, with 33 females and 4 males. The tumor sizes of patients who underwent total thyroidectomy were between 0.1-5 cm (mean: 1.45 ± 0.97), and central compartment and lateral cervical lymph node dissection were performed in 9 and 3 patients, respectively. Histopathological evaluation revealed lymphovascular invasion in 20/37 patients, parancimal invasion in 1/37 patients, extrathyroidal extension in 5/37 patients, and lymph node metastasis in 5/37 patients. At initial staging, none of the patients had findings consistent with distant metastasis. Cumulative doses of I-131 treatment ranging from 30-350 mCi (mean: 111.8 ± 55.96) were administered to the patients. The follow-up period ranged from 11-240 months (mean:37.7 ± 40.63). According to the ATA criteria, in the group of patients diagnosed with TCVPC, considering the 9th month sTg level, I-131 WBS and US findings, complete response was detected in 89% (33/37), indeterminate response in 2.7% (1/37), biochemical incomplete response in 2.7% (1/37), and anatomical incomplete response in 5.4% (2/37). In one patient who achieved complete response, a metastatic nodule in the lung, confirmed histopathologically as PTC metastasis, developed in the 17th postoperative year. After high-dose I-131 treatment, I-131 WBS was negative, sTg was <0.1 ng/mL, and normal US and chest CT findings were observed during follow-up. In a patient with anatomical incomplete response, metastatic lymph nodes were detected on US in the first postoperative year, confirmed histopathologically. The patient progressed after metastatic I-131 treatment and was evaluated as iodine-refractory. During oncology follow-up, the patient died (2.7%). ***Conclusion:*** Although TCVPC is defined as an aggressive variant according to the ATA criteria, our findings indicate a high rate of complete response with high-dose I-131 ablation treatment and a low rate of local recurrence, distant metastasis, and mortality during follow-up. According to the literature, a high response rate is due to early diagnosis and developing surgical techniques.

## EP-0592

### Effectiveness of Empirical High-Dose I-131 Therapy in Patients with Differential Thyroid Cancer with Biochemical Incomplete Response

***B. Kocabeyoglu***[1]*, M. Guven*[1]*, G. Kavukcu*[2]*, A. Akgun*[1]*;*
[1]*Department of Nuclear Medicine, Ege University, Izmir, TÜRKIYE,*
[2]*Department of Radiology, Ege University, Izmir, TÜRKIYE.*

***Aim/Introduction:*** In this study, we aimed to evaluate the benefit of empirical high-dose I-131 treatment in patients with differentiated thyroid cancer (DTC) with biochemical incomplete response after RAI ablation according to the American Thyroid Association (ATA) classification. ***Materials and Methods:*** Records of 24 patients with DTC who were treated with total thyroidectomy and RAI ablation between 1994-2022 and were given empirical high-dose I-131 treatment due to biochemical incomplete response were retrospectively analyzed. Patients were followed with risk-appropriate follow-up studies and imaging modalities. Treatment success was defined as a 25% decrease in Tg level. ***Results:*** There were 17 women and 7 men, 21 to 71 years of age (mean: 50.6±13.59 years) at the time of diagnosis. Tumor sizes ranged from 0.5 to 9 cm (mean: 4.06±2,41cm). Eleven patients underwent cervical lymph node dissection in addition to total thyroidectomy. The types of primary thyroid cancer were as follows: Papillary carcinoma (n=20), poorly differentiated carcinoma (n=1), Hurle cell carcinoma (n=1), and follicular carcinoma (n=1). Lymphovascular invasion was observed in 16/24, parenchymal invasion in 15/24, extrathyroidal spread in 7/24, and lymph node metastasis in 8/24 of the patients histopathologically. None of the patients had distant metastasis at initial staging. FDG PET/CT imaging performed before empirical high-dose I-131 treatment in 18 patients revealed no findings consistent with metastasis/relapse. The patients received I-131 treatment as a cumulative dose ranging between 300-1275 mCi (mean: 619.5±270.14). The follow-up period was between 24-240 months (mean 103.6 months). The fTg values ranged from 9.7 to 300+ (mean: 73.9±100.41) ng/dl , and from 0.42 to 300+ (mean: 51±96.7) ng/dl respectively before and after the empirical high-dose I-131 treatment. There was a significant decrease in 41.6% (10/24) of the patients . During the follow-up, metastatic lesions (5 lungs, 6 lymph nodes) were detected in 11 (45.8%) patients with imaging studies on the 6th to 120th months. Currently, 58.3% (14/24) of the patients are followed up with an incomplete biochemical response, while 37.5% (9/24) were referred to tyrosine kinase inhibitor therapy due to metastases without I-131 uptake on imaging. One patient died not related to thyroid cancer. ***Conclusion:*** Although there was a significant decrease in fTg level in nearly half of the patients after the empirical high-dose I-131 treatment, the development of structural disease could not be prevented. Therefore, we concluded that its clinical benefit was limited in long-term in patients with differentiated thyroid cancer with biochemical incomplete response.

## EP-0593

### The evaluation of the value of human recombinant thyrotropin administration for the patients with differentiated thyroid cancer during thyroid hormone withdrawal preparation for high dose radioiodine treatment.

***J. Cha****, W. Kang1;*
*Department of Nuclear Medicine, Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Among the patients with differentiated thyroid cancer (DTC) preparing radioiodine treatment (RIT) with thyroid hormone withdrawal, there were patients whose pre-ablative thyrotropin (TSH) was ≤ 30 μIU/mL. Our purpose was to evaluate the relationship between administration of human recombinant TSH (rhTSH) with excellent response (ER) for these patients. ***Materials and Methods:*** Among the patients who had received initial high dose RIT (100-150 mCi), 218 patients had pre-admission TSH level of ≤ 30 μIU/mL which was done at 2-5 days before RIT. Treatment response was classified according to 2015 ATA guideline. ***Results:*** A total of 218 patients were enrolled. Among them, 145 patients had been received rhTSH administration. The pre-admission TSH level was significantly lower in the rhTSH administration group (15.58 ± 8.12 vs. 26.56 ± 4.42, p<0.001). A total of 129 (59.2%) of patients showed ER. In the logistic regression model analysis, administration of rhTSH (HR 1.86 [CI, 1.04-3.32]; p=0.037) and dose of RIT (HR 1.92 [CI, 1.09-3.37]; p=0.023) were significant independent factors associated with ER. Among the patients who proceed with RIT without administration of rhTSH or postponement of a schedule, TSH level of >35.67 μIU/mL at the day of RIT was significant factor predicting ER (HR 3.23[1.19-8.19]; p=0.022). ***Conclusion:*** Administration of rhTSH was associated with higher rate of ER for the patient who received high dose RIT. For the patients who proceed with RIT without administration of rhTSH or postponement of a schedule, TSH level of >35.67 at the day of RIT was related to higher rate of ER.

## EP-0594

### Effectiveness of Iodine-131 therapy in patients with hyperthyroidism: The experience in the Nuclear Medicine Department of "Saints Anargyri" Cancer Hospital

***S. Saranti***, *C. Altani, T. Karianos, K. Kouvelis, M. Bella, E. Taktikou;*
*"Agioi Anargyroi" Cancer Hospital, Athens, GREECE.*

***Aim/Introduction:*** Iodine-131 (I-131) therapy is a safe treatment for hyperthyroidism concerning either aged patients or younger patients with recurrence after ATD therapy . Dosimetric and fixed I-131 doses have been used. The goal of the I-131 therapy is to cure the patients by a single dose. The aim of this study is the evaluation of the effectiveness of I-131 therapy with a variable iodine dose based on the degree of hyperthyroidism as expressed mainly by the I-131 uptake (4 and 24 hours) in patients with Graves disease and thyroid toxic adenoma. ***Materials and Methods:*** A total of 93 patients were included in the study : Group 1 with 76 patients ( 11 men, 65 women) with Graves disease and Group 2 with 17 patients (5 men, 12 women) with toxic adenoma. Among the patients with Graves disease, 13 presented with ophthalmopathy (inactive for 8/13 and low to moderate active for 5/13 patients). All patients underwent a Tc99m thyroid scintigraphy during the last 6 months and a recent 4 and 24 hours I-131 uptake 5-7 days after the discontinuation of ATD treatment and with desirable TSH levels <0.1 μIU/ml while I-131 therapy took place under identical conditions . All patients also had a thyroid ultrasonography. The 5/13 patients with active ophthalmopathy underwent prophylactic corticosteroid treatment. The efficacy of I-131 treatment -meaning euthyroid or hypothyroid status- was estimated 1 year after therapy (low term efficacy) and for a 3-10 years period (long term efficacy) for both groups. ***Results:*** For Group 1 the thyroid uptake was 39.44±23.78% at 4 hours and 59.66±24.38% at 24 hours while for Group 2 it was 13.56±9.13% and 31.05±21.61% respectively. The given I-131 dose was inversely proportional to thyroid uptake. Therefore for Group 1 patients (Graves disease) the I-131 therapeutic dose was 14.31±5.69 mCi while for Group 2 patients (toxic adenoma) it was 17.84±2.55 mCi. All patients became euthyroid or hypothyroid within a year. In particular 25/76 (32.89%) patients of Group 1 and 11/17 patients of Group 2 (64.71%) became euthyroid while 51/76(67.11%) patients of Group 1 and 6/17(35.29) patients of Group 2 became hypothyroid . None of the patients demonstrated relapse the following 3-10 years. ***Conclusion:*** I-131 therapy for Graves disease and thyroid toxic adenoma is very effective. According to our study, the calculation of I-131 therapeutic dose on the basis of I-131 uptake is a very determining factor for achievement of a successful therapy.

## EP-0595

### Prognosis of Differentiated Thyroid Cancer after Reoperation

***J. Cha***, *W. Kang, H. Cho;*
*Department of Nuclear Medicine, Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Despite patients with differentiated thyroid cancer (DTC) have excellent survival, recurrence is common. We examined the outcome in patients with DTC after reoperation due to recurrence and assessed the role of radioactive iodine therapy (RIT). ***Materials and Methods:*** We retrospectively reviewed patients who underwent reoperation due to recurrence, and initially received bilateral total thyroidectomy and RIT from March 2006 to March 2020. Clinicopathological characteristics including age, sex, AJCC stage, time to recurrence (the time interval from initial surgery to reoperation), presence of soft-tissue recurrence, ratio of positive to resected lymph nodes, size of recurred lesion, presence of perilesional extension, and the dose of RIT after reoperation were assessed for the risks of recurrence. Hazard ratios (HRs) were estimated from Cox proportional hazards regressions. ***Results:*** During the median follow-up of 28.45 months, 30/150 (20.0%) patients had recurrence. Older age (years, 50.47±12.63 vs. 41.05±13.92; p=0.001), male sex than female (17/30 vs. 34/120; p=0.003), AJCC stage II-IV than stage I (10/30 vs. 16/120; p=0.010), presence of soft-tissue recurrence than absence (6/30 vs. 8/120, p=0.025), and shorter time to recurrence (years, 3.64±2.71 vs. 5.08±2.83; p=0.003) were related to recurrence. In the multivariate Cox-regression analysis, male sex (HR 2.23 [confidence interval (CI), 1.04-4.77]; p=0.039), time to recurrence ≤3.61 (HR 2.85 [CI, 1.28-6.32]; p=0.010), presence of soft-tissue recurrence (HR 3.44 [CI, 1.36-8.70]; p=0.009) were significant independent factors predicting recurrence. The dose of RIT (GBq, <3.7 vs. ≥3.7) after reoperation did not predict recurrence. ***Conclusion:*** Male sex, time to recurrence, and presence of soft-tissue recurrence were associated with recurrence in DTC patients after reoperation. In recurrent disease, the addition of RIT to reoperation does not appear to improve outcome.

## EP-0596

### Aggressiveness and efficacy of 131I therapy in papillary thyroid carcer with peripheral nerve invasion: a propensity score matching study

***X. Xiong***;
*Zhujiang Hospital, Southern Medical University, Guangzhou, CHINA.*

***Aim/Introduction:*** To analyze the invasiveness of papillary thyroid cancer with peripheral nerve invasion and the influence of papillary thyroid cancer with peripheral nerve invasion on the short-term curative effect and the long-term curative effect.

***Materials and Methods:*** Logistic regression analysis was used to determine the relationship between clinicopathological factors and short-term efficacy. Survival analysis and Cox regression analysis the relationship between clinicopathological factors and long-term efficacy. Propensity scorematching method was used to equalize the data bias, then the above steps were repeated to further clarify the impact of PNI on the efficacy of PTC. ***Results:*** Efficacy was assessed in 842 patients with a median follow-up of 57 months. According to propensity score matching method, 63 cases were matched in PNI group and nPNI group respectively. It was found that there was no difference in persistence/progression survival between PNI and nPNI group (P =0.88), which was still not an independent factor of short-term and long-term efficacy, while male patients were significantly associated with worse short-term and long-term efficacy. ***Conclusion:*** Peripheral nerve invasion was a predictor of more aggressive disease status at the time of assessment, but was not independent influencing factor of short-term or long-term outcome.

## EP-0597

### Quantitative analysis of residual thyroid gland radioactive counts and peripheral lymphocyte subsets before and after first radioactive iodine therapy in papillary thyroid carcinoma with Braf mutation

***J. Zhang***, *H. Liu;*
*First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

***Aim/Introduction:*** The aim of the study was to investigate the differences of residual thyroid gland $I^{131}$ uptake and changes in peripheral lymphocyte subsets before and after the first radioiodine treatment(RAIT) after total thyroidectomy for PTC patients with Braf mutation. ***Materials and Methods:*** The residual thyroid gland was outlined as region of interest (ROI) on $I^{131}$ Whole-body Scan (WBS) getting the maximum value of the unit pixel. Tumor and serum samples were collected from 37 patients with papillary thyroid carcinoma (PTC). The Braf gene of these patients was assessed by direct DNA sequencing of PTC specimens using quantitative real-time polymerase chain reaction (qPCR). The absolute number and percentage of peripheral lymphocyte subsets (T, B, $CD4^+$ T, $CD8^+$ T, NK, Th1, Th2, Th17, and Treg cells) were measured by flow cytometry. ***Results:*** We found there were no significant difference between $Braf^{V600E}$-mutant and $Braf^{WT}$-mutant PTC patients in residual thyroid gland radioactive counts (P=0.065). More types of lymphocyte subsets (T(P<0.001), B(P<0.001), CD4+T(P<0.001), NK(P<0.05), Th1(P<0.05), Th2(P<0.05), Th17(P<0.05), and Treg (P<0.01) cells) of $Braf^{V600E}$-mutant PTC patients were decreased by RAIT compared to $Braf^{WT}$-mutant PTC patients. In addition, the number of multiple lymphocyte subsets (T(P<0.05), NK(P<0.05), Th1(P<0.05) and Th17 cells(P<0.05)) in the peripheral circulation of $Braf^{WT}$-mutant PTC patients were higher than $Braf^{V600E}$-mutant PTC patients before RAIT and the similar result was also observed after RAIT (T(P<0.01) and Th17(P<0.05)). RAIT inhibited the number of Th1(P<0.01) cells in $Braf^{WT}$-mutant PTC patients to a greater extent. ***Conclusion:*** RAIT inhibited more Th1 cells of $Braf^{WT}$-mutant PTC patients than that for $Braf^{V600E}$-mutant PTC patients, whereas lymphocyte subsets of $Braf^{V600E}$-mutant PTC patients were more broadly inhibited. For PTC patients with different Braf genes, their peripheral blood immune cell subsets respond differently to RAIT and the peripheral blood immune cell subsets of $Braf^{WT}$-mutant PTC patients are more tolerant to RAIT. There might be no differences between the two groups in $I^{131}$ uptake of residual thyroid gland.

## EP-0598

### Development and validation of a lung metastasis-predicting Nomogram for intermediate- to high-risk differentiated thyroid carcinoma patients

***F. Yu***, *J. Wang, W. Yang, Z. Yang, W. Ma;*
*Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** Differentiated thyroid carcinoma (DTC) with distant metastasis led to worse prognosis than those without metastasis. Therefore, early diagnosis of lung metastasis is essential for adequate therapy and better response. This study aimed to develop a clinically predictive nomogram model to predict the lung metastasis probability from DTC with intermediate- to high-risk. ***Materials and Methods:*** 375 DTC patients with intermediate- to high-risk were enrolled in the present study. For the established model's accuracy and clinical application efficiency, patients were randomly separated into training set (70%) and validation set (30%). The univariate and multivariate analysis were conducted to investigate the influence of age, gender, histological type, multifocality, tumor size, T status, N status, AJCC stage, $BRAF^{V600E}$ mutation, postoperative stimulated TSH (ps-TSH) and postoperative stimulated thyroglobulin (ps-Tg) levels before $^{131}I$ therapy on DTC with lung metastasis. The nomogram was developed based on the training cohort to explore lung metastasis rates for intermediate- to high-risk DTC patients. Finally, the reliability and accuracy of the constructed nomogram was verified in the validation cohort via the calibration, receiver operating characteristic (ROC) curve, and decision curve analysis (DCA). ***Results:*** Univariate analysis showed that histological type, multifocality, tumor size, T status, N status, AJCC stages, $BRAF^{V600E}$ mutation, and ps-Tg levels were significantly associated with lung metastasis from DTC. Multivariate analysis indicated that histological type, multifocality, tumor size, $BRAF^{V600E}$ mutation, and ps-Tg levels were independent predictors of lung metastasis from DTC. The nomogram had a high C-index 0.86 (95% CI: 0.818-0.911), for predicting lung metastasis, which indicated that the models had a high accuracy prediction. The calibration curves demonstrated excellent consistency between the predicted result and the actual probability of lung metastasis in intermediate- to high-risk DTC patients. ROC analysis showed that the AUC for lung metastasis rate in the training cohort was 0.865 and 0.845 in the validation cohort. Also, the DCA curve indicated that this nomogram had better clinical utility in predicting lung metastasis rate in intermediate- to high-risk DTC patients. ***Conclusion:*** Follicular, multifocality, bigger tumor size, BRAFV600E mutation-positive, and higher ps-Tg levels might predict higher rate of lung metastasis from DTC. In addition, a novel nomogram was constructed to comprehensively estimate the lung metastasis probability of DTC patients with intermediate- to high-risk. The model might be able to predict the lung metastasis probability visually and accurately with a higher net benefit.

## EP-0599

### Second Neoplasms in Patients with Differentiated Thyroid Carcinomas (CDT) Treated With 131I (RAIT).

***A. Peña***, *I. Vinagre Perez, M. Astudillo Sarmiento, R. Nuñez Muñoz, Y. Carreres Ortega, M. Muñoz del Diego, T. Ruiz Juan, S. Perez Fernandez, E. Rodeño Ortiz de Zarate;*
*Hospital Universitario de Cruces, Barakaldo, SPAIN.*

***Aim/Introduction:*** To investigate the association of second neoplasms (SN) with RAIT in a cohort of patients with CDT treated at a single tertiary medical center. We have compared these patients with a group of CDT not treated with 131I.

***Materials and Methods:*** We have performed a retrospective study of 505 patients (398 women, 107 men; median age: 48.0 years, 25th: 36.0, 75th: 60.0) with CDT (83.2% papillary, 16.8% follicular). 450 patients received RAIT and 55 patients did not. Patients treated with 131I were divided into 5 groups according to the activity received: 1.110 MBq (55), from 1.147-7.363 (268), 7.400-14.763 (61), 14.800-22.163 (32) and >22.200 (33). For the statistical analysis, the statistical software R Core Team version 4.0.1 was used. ***Results:*** In the total group, the median follow-up was 12.9 years (25th: 8.83, 75th: 20.6). The median time to onset of the second neoplasm was 10.7 years (25th: 4.49, 75th: 18.2) since first doses. Median age at second tumor diagnosis was 68 years (25th: 57.0, 75th: 75.2). In the whole group 76 (15%) SN was diagnosed. RAIT group showed 64 SN (14.2%), distributed as follows: 9 breast cancers, 6 bladder, 3 hematologic, 3 gastric and 43 solid tumors. In the group that did not receive 131I 12 SN was observed (21.8%): 3 breast cancers, 2 bladder, 1 hematologic and 6 solid tumors. We did not find significant differences between the ages of both groups (p: 0.210). When SN were considered, we did not find statistical significant differences between patients treated with RAI and the other group (p: 0.198). We also did not observe differences when comparing the different RAIT groups (p: 0.109). However, when we compare the group of patients treated with less than 22,200 MBq with those treated with more, we did find statistically significant differences (p: 0.042). ***Conclusion:*** RAIT appears not to be associated with an increased risk of SN compared with subjects receiving no RAI treatment (p: 0198). However, the risk appears to be higher in patients treated with more than 22,220 MBq. ***References:*** 1-Edmons CJ, Smith T. The long-term hazards of the treatment of thyroid cancer with radioiodine. Br J Radiol, 59 (1986), pp. 45-512-Hall P, Holm LE, Lundell G, Ruden B. Cancer risk in thyroid cancer patients. ## EP-0600

### Radioiodine Avidity and Prognosis of Diffuse Sclerosing Subtype of Papillary Thyroid Cancer

***C. Turkan***[1], *G. Güler*[2], *M. Tuncel*[1];
[1]*Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University Department of Pathology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Diffuse sclerosing subtype of papillary thyroid cancer(DSS-PTC) is a rare subtype of PTC.It is well known for its aggressive behavior at presentation,but its response to surgery&radioiodine(RAI)therapy and overall prognosis are not well studied.Therefore we aimed to describe its RAI avidity and clinical outcomes. ***Materials and Methods:*** We have retrospectively analyzed the clinical and imaging data of 1751 patients with thyroid cancer.All patients were followed at the Nuclear Medicine Department between 2008-2023. Out of 1751 patients, we had 30 patients diagnosed with DSS-PTC.These patients' clinical and pathological data were recorded from the hospital's database. RAI avidity of these tumours was also analysed in patients with biopsy-proved residual disease during RAI therapy. Patients were followed,and treatment response was evaluated by ATA response criteria. ***Results:*** Out of 30 patients,20(%66) were females.The median-age at the presentation was 27.5(range 15-65).The median follow-up time was 48 months(range:7-154). Seven patients had total thyroidectomy(TT),23 had TT+lymph node dissection(LND) as an initial treatment.Seven patients had additional surgery for persistent disease before RAI-therapy.Histologically,bilateral tumors were present in 53.3%(16/30) of patients, 40%(12/30) had an extrathyroidal extension and 20%(6/30) showed lymphovascular invasion.Patients most frequently staged with pT1b(33.3%,10/30) disease.Twenty-four patients(80%, 24/30) had lymph node(LN) metastasis, extra-capsular extension was documented in 11/24 patients (45.8%) with LN metastasis.One patient presented with lung metastasis,and none developed distant metastasis during the follow-up.All of the patients were treated with RAI at least once with a median activity of 5.55 GBq(3.7-7.4GBq).Five patients(16.7%) had treated with multiple RAIs and median cumulated activity was 11.1 GBq(range 11.1-22.2GBq). During the first RAI-therapy 21 patients(70%) had no evidence of persistent disease other than RAI uptake in remnant thyroid tissue. One patient(3.3%) had RAI non-avid LN metastases,7(23.3%) had RAI avid LN, and 1(3.3%) had RAI avid LN and lung metastases.After the first RAI treatment, two patients(one RAI negative and one RAI positive) underwent LND without additional RAI. Three patients underwent LND and treated with additional RAI. Two patients with LN met and 1 patient with LN and lung met received additional RAI without surgery.Two RAI-positive patients did not receive other therapies during their follow-up.None of the patients died during the follow-up.At the last appointment, 25 patients(83.3%) had excellent response, one patient(3.3%) had a structural incomplete response and 4 patients(13.3%) had indeterminate response. ***Conclusion:*** DSS-PTC may present with advanced disease,mainly with LN metastases, and requires extensive surgical treatment. Despite this presentation, considerable amount of these patients showed RAI avidity, supporting patients' good overall survival.

## EP-0601

### Analysis of hematological complications in patients with differentiated thyroid cancer

***A. Savchenko****;*
*V. N. Karazin Kharkiv National University, Kharkiv, UKRAINE.*

***Aim/Introduction:*** ***The aim*** of this retrospective case-control study was to analyze and search for predictors of hematological complications of therapy in patients with differentiated thyroid cancer. ***Introduction***. Differentiated thyroid cancer (DTC) is the most common endocrine tumor. The standard of care for DTC is surgery, radioiodine therapy and hormone therapy. Theoretically, each component of the treatment process can cause adverse somatic consequences in future, the study of which can help to prevent and correct them. One of the possible complications arising upon therapy thyroid cancer treatment is anaemia. ***Materials and Methods:*** The study was based on follow-up data of 120 individuals who were undergoing treatment of DTC at the Institute clinic from 2013 to 2017, and underwent regular screening examinations after treatment. The database created for the study contained, digitized arrays of the medical records and its consequences in patients with a follow-up period exceeding 1 year after special treatment. The database contained information on the levels of calcium, the levels of parathyroid hormone, the indicators of a complete blood cell count(after surgery, before and after radioiodine therapy and every next 2 months in the post-treatment monitoring phase, as well as information on age, weight, somatic complications, surgical complications, etc. WizWhy packages (Data Mining category) and the general purpose software package STATISTICA were used to make hypotheses and test them. ***Results:*** The anaemia was observed in 15.8 ± 3.3% of patients (19 individuals). The onset of secondary anaemia was shown to be inducible by post-operative hypoparathyroidism (p

< 0.01, chi-squared Pearson test). Indeed, 15 (30 ± 6.5%) of the 50 patients with hypoparathyroidism (HPT) developed anaemia. On the other hand, only four (5.7 ± 2.8%) of the 70 patients without HPT developed anaemia. The relation between onset of secondary anaemia as an early treatment complication, and reduced blood calcium prior to radioiodine therapy, was also statistically significant (p < 0.01, Mann-Whitney test). Patients who developed anaemia over the course of treatment presented a median calcium level under 2.05 mmol/L prior to radioiodine therapy. Patients that were nonanaemic after radioiodine therapy presented a median calcium level of 2.4 mmol/L beforehand. ***Conclusion:*** These results suggest an association between hypocalcaemia, and onset of secondary anaemia in patients with hypoparathyroidism. Given the probability of asymptomatic hypocalcaemia and post-operative hypoparathyroidism, these observations call for monitoring and therapeutic correction of blood calcium prior to radioiodine therapy.

## EP-0602

### Comparison of Malignities Accompanying Thyroid Cancer According to RAI Treatment

***D. Yüksel***, *M. Yücel, O. Yaylalı, T. Şengöz, A. Gültekin, F. S. Şimşek; Pamukkale Universitesi Tip Fakültesi, Denizli, TÜRKIYE.*

***Aim/Introduction:*** It is the view of the relationship between thyroid cancer and other cancer types that are seen together. ***Materials and Methods:*** Data of 2282 patients sent to RAI treatment was reviewed. Among these patients, patients with thyroid cancer and another type of cancer were identified. These patients were examined in two groups; Group1: first non-thyroid cancer-second thyroid cancer; Group2: first thyroid cancer-second non-thyroid cancer. Demographic data, the time between the two cancers, the other cancer type and the RAI treatment, the size of the tumor (<1cm;>1cm), and the presence of metastases were recorded. ***Results:*** In 116 of 2282 patients, another tumor with thyroid cancer was detected. Group 1: 40 patients (15M, 25F) with a mean age of 62±13 years (range: 40-91 years). The interval between two cancers was 37±51 months (range: 0-216 months). 20 of the patients received RAI treatment. While two of those receiving RAI died, 18 were still alive. Metastasis was observed in only one of 20 patients who did not receive RAI treatment, while metastasis of DTC was not observed in 19 patients. While 6 died, 14 are still alive. Group 2: 76 patients (19M, 57F) with a mean age of 61±12 years (range:31-88 years). The time between two cancers was 67±61 months (range: 0-396 months). 70% of the patients (53 patients) received RAI treatment. Of the 7 patients with metastases, 5 were papillary cancer and 2 were follicular cancer. While 13 of the patients who received RAI treatment died, 40 are still alive. Metastasis was observed in 2 of 23 patients who did not receive RAI treatment, and no metastasis of DTC was observed in 21 patients. While 7 patients died of papillary cancer, 16 are still alive. While age (p=0.001) and time between two cancers (p=0.037) were associated with survival, no significant correlation was observed with whether the patient received RAI, the dose of RAI and the number of RAI, the order of occurrence of tumors, the type and size of thyroid cancer, and the metastasis. ***Conclusion:*** Among the cases with secondary cancer after thyroid cancer and the cases with primary non-thyroid cancer, and then secondary thyroid cancer, taking RAI has no effect on survival in gender, thyroidal tumor type, tumor size, order of tumor occurrence and metastasis. This suggests that RAI treatment may not have an additional contribution in terms of secondary cancer development and survival.

## EP-0603

### Prognostic Associations and Oncological Outcomes Regarding Intermediate Risk Differentiated Thyroid Cancer in Latin-American Population: A 13 Years Follow Up Retrospective Cohort

***S. Gonzalez Rueda***[1], *A. Calderon Avila*[2], *J. Vargas Ahumada*[1], *P. Casanova Triviño*[1], *F. Garcia Perez*[1], *E. Gomez Argumosa*[1]; [1]*Instituto Nacional de Cancerología, Tlalpan, Ciudad de México, MEXICO,* [2]*Centro Medico Nacional S. XXI, Cuahutemoc, Ciudad de México, MEXICO.*

***Aim/Introduction:*** American Thyroid Association's(ATA) intermediate-risk for well-differentiated thyroid carcinoma(DTC) comprises a wide variety of patients with different risk factors and disease's behaviour;in Latin-American population, it often displays a much darker spectrum of the disease.The main objective of this study was to identify prognostic factors between intermediate risk DTC and American Joint Committee on Cancer(AJCC)prognostic groups,impact of first radioiodine therapy(RAIT),histopathological risk factors and locoregional and distant metastases.Secondary objectives were to determine disease persistency, as well as mean overall survival(OS),disease-free survival(DFS),progression-free survival(PFS) and mortality ratio. ***Materials and Methods:*** We performed a single centre(National Cancer Institute, México), non-randomized,retrospective cohort study, where thirty-two patients with intermediate-risk DTC were recruited from January 2007-2010 and followed-up through 13-years since diagnosis. SPSS V24.0 was used for statistical analysis, linear trend $X^2$ test was used for differences between frequencies and Kaplan Meier curves were used for OS,DFS and PFS,statistically significant data was consider with a p value of<0.05. ***Results:*** Thirty-two patients who were diagnosed at our centre with DTC, underwent total thyroidectomy and adjuvant RAIT with 3.7-5.5 GBq,after which a post-therapy whole-body-scan was performed,leading to a change in TNM(AJCC groups)staging in 21.9%(6.3%upstaging N1+, 15.6%upstaging M1+).Regarding RAIT effects on thyroglobulin(Tg) behaviour;Tg diminished in 75%, stayed stable in 12.5% and increased in 12.5%. AJCC prognostic groups were associated in both 6° and 8° editions(previously effective vs. currently in use) as follows: I(40.6%), II(12.5%), III(25%),IVA(6.3%),IVC(15.6%)and I( 53.1%),II(34.4%),III(3.1%),IVB(9.4%)for 6° and 8° editions, respectively(p=0.019,p= 0.016).Histopathological risk factors evaluated were multifocality, extrathyroid extension(ETE) and surgical margins(R1 and R2) which also were positively associated with locoregional(32.1%) and distant metastases(42.9%).Within time, 25%of patients did not present any type of metastases,while 31.3%developed locoregional lymph-node metastases and 43.8%progressed to distant metastases(p=0.038), the latter distributed as: lungs 9.4%,non-neck lymph-nodes 15.6%,other sites 18.8%(bone, central nervous system, skin)(p=0.05).Disease was persistent in 71.9% of patients.Furthermore,mean OS,DFS and PFS in months were 136,38.21 and 96.59.Mortality ratio was 21.8%. ***Conclusion:*** Intermediate-risk DTC is a broad scope category,nevertheless,regarding Latin-American population,it appears to be a more aggressive entity than historically stated in European and north American populations.First radioiodine dose administered can lead to a change in AJCC staging and diminishes post-surgical Tg importantly.AJCC prognostic groups have a statistically significant association with intermediate-risk patients.Multifocality,ETE and surgical margins were associated with locoregional and distant metastases. Intermediate-risk DTC in Latin-American population has still a good overall prognosis when compared to other neoplasms,yet it does have an elevated persistency percentage,worst oncological outcomes(OS,DFS and PFS) and a higher mortality rate compared to those currently reported worldwide.

## EP-0604

### Evaluation of the efficacy of treating Graves Disease with low doses of 131-iodine compared to high doses

***B. Manzarbeitia Arroba***, *G. Guijarro de Armas, D. Rodriguez Oviedo, M. Alvarez Moreno, A. Ortega Valle, L. Castillejos Rodriguez, P. García Alonso, C. Sandoval Moreno;*
*Hospital Universitario de Getafe, Getafe, SPAIN.*

***Aim/Introduction:*** To compare the efficacy of treating Graves Disease (GD) with low doses of 131-iodine (9mCi) to that of the treatment with high doses (20 mCi) reflected in literature. ***Materials and Methods:*** 107 patients were followed up for 18 months following the administration of 131-I treatment (keeping track of TSH, T4 and T3).Every patient underwent a thyroid scintigraphy using 5 mCi (185 MBq) of 99mTc, with a pattern compatible with GD. 5 days after, a dose of 9 mCi (185 MBq) of 131-I was administered orally.For our study, we considered therapeutic success when patients achieve euthyroidism or hypothyroidism within a year of the treatment. ***Results:*** 75 patients completed follow-up: 21.3% achieved euthyroidism (16 patients), 64% hypothyroidism (48 patients) and 14.7% hyperthyroidism (11 patients), translating a success rate of 85.3%. This result is similar to that described using high doses in literature (with a success rate of up to 86% and a hypothyroidism rate of 64%). ***Conclusion:*** Even though 131-I treatment for GD has been used for a long time, there is no international consensus or clinical guidelines regarding the doses that should be used. In some countries, particularly in America, the doses used tend to be higher than those used in Europe. In our experience, treating GD with low doses of 131-I has a similar success rate than that described in literature with high doses (20 mCi-740 MBq), with a comparable hypothyroidism rate. These findings support the use of low dose therapy in comparison to high doses given the similar efficacy and the superior radioprotection profile.

## EP-0605

### Evaluation of the efficacy of treating Graves Disease with fixed doses of 131-iodine compared to calculated doses

***B. Manzarbeitia Arroba***, *G. Guijarro de Armas, M. Alvarez Moreno, D. Rodriguez Oviedo, M. de la Rubia Marcos, A. Herrero Muñoz, C. Paniagua Correa, P. Garcia Alonso, C. Sandoval Moreno;*
*Hospital Universitario de Getafe, Getafe, SPAIN.*

***Aim/Introduction:*** To compare the efficacy of treating Graves Disease (GD) with empiric fixed doses of 131-iodine to that of the treatment with calculated doses using Marinelli's formula in literature. ***Materials and Methods:*** 107 patients were followed up for 18 months following the administration of 131-I treatment (keeping track of TSH, T4 and T3).Every patient underwent a thyroid scintigraphy using 5 mCi (185 MBq) of 99mTc, with a pattern compatible with GD. 5 days after, a dose of 9 mCi (185 MBq) of 131-I was administered orally.For our study, we considered therapeutic success when patients achieve euthyroidism or hypothyroidism within a year of the treatment. ***Results:*** 75 patients completed follow-up, succeeding in 85.3% of cases (16 patients achieved euthyroidism and 48 hypothyroidism). These results translate a higher success rate than that described in literature using calculated doses (77% success rate in the series described by Zhao et al.), but at the expense of a greater number of hypothyroidism cases (16.6% against our 64%). ***Conclusion:*** These findings support the use of empiric fixed doses of 131-I given that the success percentage is higher than using calculated doses. However, calculated doses might be better to avoid iatrogenic side effects, with a lower rate of hypothyroidism.

## EP-0606

### Efficacy of empirical radioiodine therapy in patients with differentiated thyroid cancer and elevated serum thyroglobulin without evidence of structural disease

***L. Piscopo***[1], *E. Zampella*[1], *C. Nappi*[1], *F. Volpe*[1], *V. Gaudieri*[1], *D. Bianco*[2], *F. Volpicelli*[1], *M. Falzarano*[1], *L. Pace*[3], *A. Cuocolo*[1], *M. Klain*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Napoli, ITALY,* [2]*CIRA-Centro Italiano Ricerche Aerospaziali, Capua (CE), ITALY,* [3]*Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, ITALY.*

***Aim/Introduction:*** In patients with differentiated thyroid cancer (DTC) the treatment of choice consists of surgery followed by radioactive iodine (RAI) therapy. In patients with raising serum thyroglobulin (Tg) during follow-up, empiric RAI therapy may be considered also without evidence of structural disease. However, the survival benefit of this approach remains controversial. We assessed the outcome of patients with DTC according to the administration of empiric $^{131}$I therapy. ***Materials and Methods:*** We retrospectively evaluated 1112 patients with DTC submitted to total thyroidectomy followed by remnant ablation with $^{131}$I and without distant metastases after the first treatment. Response to initial treatment was assessed 12 months later and 225 patients with detectable Tg (>1 ng/dl) but without evidence of structural disease were enrolled. Patients were categorized according to the administration of empiric RAI therapy. Follow-up was then performed every 6-12 months with serum Tg determination and imaging procedures: the need of additional therapy and the occurrence of structural disease were considered as end-point. Hazard ratios were obtained by Cox regression analyses. Disease free survival analysis was performed by Kaplan-Meier method. ***Results:*** Among 225 patients, 127 (56%) received empiric treatment and 98 (44%) did not. The post-therapy whole-body scan performed at 7 days was positive in 49 (39%) patients; of those, neck uptake was found in 30 (24%) patients, lung uptake in 7 (6%) and bone disease in 2 (2%). During a mean time of 64±53 months, 75 structural events occurred (33% cumulative event rate). The patients with events were older (49±17 vs. 41±18 years, $p<0.01$) and showed higher 12-months Tg values (56±23 vs. 16±34 ng/dl, $p<0.05$) as compared to those without. The rate of events was lower in patients who received empiric therapy (n=34) as compared to those without (n=93) (45% vs. 62%, $p<0.05$). At COX regression analysis 12-months Tg ($p<0.001$) and the administration of empiric therapy ($p<0.01$) resulted independent predictors of events. At Kaplan-Meyer analysis, the worst prognosis was observed in patients who did not receive empiric therapy ($p<0.001$). ***Conclusion:*** In patients with DTC treated with surgery with detectable Tg values at 12-months evaluation but without evidence of structural disease, prognosis seems to be affected by Tg values and empiric treatment. The identification of candidates to this approach may improve prognosis.

### Occurence of hematotoxic side effects during 90Y-FAPI-46 radioligand therapy (RLT) in patients with advanced metastatic tumor diseases

***K. Pabst***[1], *R. Hamacher*[2], *H. Lanzafame*[1], *I. A. Mavroeidi*[2], *T. Bartel*[1], *M. Nader*[1], *S. Bauer*[2], *J. T. Siveke*[2,3,4], *M. Weber*[1], *D. Kersting*[1], *W. Jentzen*[1], *M. Ahrens*[5], *K. Herrmann*[1], *W. P. Fendler*[1], *P. Fragoso-Costa*[1];
[1]*Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [2]*Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany, Essen, GERMANY,* [3]*Bridge Institute of Experimental Tumor Therapy, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [4]*Division of Solid Tumor Translational Oncology, German Cancer Consortium (DKTK, Partner Site Essen) and German Cancer Research Center, DKFZ, Heidelberg, GERMANY,* [5]*Medical Clinic II, University Hospital Frankfurt, Frankfurt am Main, Germany, Frankfurt am Main, GERMANY.*

***Aim/Introduction:*** Repeat treatment with 90Y-based FAP inhibitor (FAPI) RLT may lead to disease stabilization in patients with advanced, metastatic tumor diseases. However, some patients demonstrated therapy continuation-limiting hematoxicity. Thus for optimal treatment planning radiotoxicity of the bone marrow needs to be defined. ***Materials and Methods:*** 20 patients that received one ore more cycles of 90Y-FAPI-46 RLT at intervals of 4-7 weeks with available bone marrow dosimetry were included. Hematologic parameters including white blood cells (WBC), neutrophils, lymphocytes, hemoglobin and platelets were assessed (CTCAE criteria) at different time points (at each cycle/between two cycles). Kaplan-Meier curves for occurrence of an adverse event, subdivided by each blood count parameter, were shown. The impact of bone marrow absorbed dose (BMAD) on hematological parameters was investigated using Pearson correlation. Multivariate Cox regression analysis was performed to evaluate the influence of additional factors (hematotoxic therapy within the last month prior to 90Y-FAPI-46 RLT, presence of bone metastases, MTV (metabolic tumor volume) of bone metastases, baseline toxicity, and ≥4 hematotoxic therapies) on occurring hematologic AEs. MTV of bone metastases was measured in the performed 68Ga-FAPI-46 PET/CT prior to RLT with a predefined VOI (volume of interest) consisting of 41% threshold from SUVmax. ***Results:*** Under and/or after treatment n=13/20 patients (65%)/n=6/20 (30%) demonstrated at least one hematological AE/SAE (CTCAE ≥ grade 3: thrombocytopenia: n=3/20 (15%), lymphocytopenia: n=3/20 (15%), neutropenia: n=1/20 (5%), leucopenia: n=1/20 (5%)). N=16/20 (80%) showed baseline hematotoxicity. Bone metastases were present in n=10/20 (50%) patients with an MTV spanning from 0.6 to 485.54 $cm^3$. N=8/20 (40%) patients received ≥4 prior hematotoxic therapies, n=11/20 (55%) received hematotoxic therapy within the last month prior to 90Y-FAPI-46 RLT. Pre-treatment with hematotoxic therapy within the last month prior to RLT showed a significant association with the occurrence of hematologic AE (p=0.011). The cumulative median BMAD was 0.46 Gy (± 0.29 Gy, range: 0.11-0.98 Gy). No significant correlation was observed between BMAD and changes in the aforementioned hematological parameters (WBC: p=0.49, hemoglobin: p=0.26, platelets: p=0.98, neutrophils: p=0.51, lymphocytes: p=0.72). ***Conclusion:*** Administration of 90Y-FAPI-46 RLT in patients with advanced, metastatic tumor diseases was associated with a low rate of new hematotoxic events. Previous hematotoxic therapy was associated with occuring hematological AE. Under dosimetry guidance, BMAD was not associated with hematotoxicity.

## EP-0608

### Feasibility of high-dose targeted radiation with I131-apamistamab in patients with relapsed/refractory AML: Dosimetry and radiation safety experience from the phase 3 SIERRA trial

***N. Pandit-Taskar***[1], *K. Prasad*[2], *L. Chen*[3], *T. Senglaub*[4], *M. Zgaljardic*[5], *P. Brodin*[6], *B. Serencsits*[7];
[1]*Molecular Imaging and Therapy, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*University of Pennsylvania Health System, Philadelphia, PA, UNITED STATES OF AMERICA,* [3]*Banner MD Anderson Cancer Center, Gilbert, AZ, UNITED STATES OF AMERICA,* [4]*Medical College of Wisconsin, Milwaukee, WI, UNITED STATES OF AMERICA,* [5]*Weill Cornell Medical Center, New York, NY, UNITED STATES OF AMERICA,* [6]*Actinium Pharmaceuticals, Inc., New York, NY, UNITED STATES OF AMERICA,* [7]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** High-dose targeted radiation as induction and conditioning prior to allogeneic hematopoietic cell transplant (aHCT) was investigated using I131-apamistamab delivered with a personalized prescribed activity ranging from 11.1 GBq to 38.1 GBq. Strategies were devised in collaboration with nuclear medicine and radiation safety staff at treating institutions for dosimetry, safe administration, patient isolation and minimizing exposure. Here, we present our experience related to dosimetry and radiation safety, demonstrating the feasibility of delivering this treatment in various settings. ***Materials and Methods:*** Patients with active relapsed/refractory AML were randomized to receive either I131-apamistamab or conventional care (CC). Patients on the I131-apamistamab arm received study drug in combination with fludarabine and total body irradiation (2 Gy) followed by aHCT. Patients on the CC arm not achieving disease control were eligible to cross over to I131-apamistamab. Personalized dosimetry was performed based on gamma camera imaging (0h, 24h, 72-96h) following tracer dose administration and the therapeutic dose was administered intravenously over a median of 5h. Patients remained in radiation isolation for 3-7 days after treatment, with training for infusion procedures, room preparation, safety precautions and site-specific evaluations conducted at each participating site, including the use of mobile shielding. ***Results:*** Of 153 patients enrolled in the SIERRA trial, a total of 106 patients received the therapeutic dose of I131-apamistamab, 40 of which were crossover patients. All patients that received the therapeutic dose went on to receive aHCT. Patients were treated at 22 participating sites, 38% with lead-lined rooms, 33% with partially shielded rooms and 29% with non-shielded rooms. Median administered activity was 24.6 GBq in the I131-apamistamab arm and 22.7 GBq for the crossover patients, with respective absorbed bone marrow doses of 16 Gy (range: 5 to 45 Gy) and 16 Gy (range: 6 to 40 Gy). From dosimetry analyses, I131-apamistamab cleared from the body with a median effective half-life of 42.5h (IQR: 39.2h to 51.3h). Radiation exposure to staff caring for these patients measured at 5 participating sites

demonstrated average exposure of 0.09 mSv, well below the 50 mSv/yr limit for radiation workers, and adjacent public areas were successfully below regulatory limits of 0.02 mSv/hr. ***Conclusion:*** Safe administration and delivery of high-dose targeted radiation using I131-apamistamab was demonstrated with minimal exposure to staff caring for these patients, despite high activities of I-131. Furthermore, the feasibility of delivering this treatment was demonstrated in a variety of clinical settings, with or without lead-lined rooms.

## EP-0610

### SSTR-directed Peptide Receptor Radionuclide Therapy in recurrent Meningioma

***P. Hartrampf***[1], *M. Müller*[1], *S. E. Serfling*[1], *A. K. Buck*[1], *B. Polat*[2], *R. A. Werner*[1];
[1]*Klinik und Poliklinik für Nuklearmedizin, Würzburg, GERMANY,*
[2]*Klinik und Poliklinik für Strahlentherapie, Würzburg, GERMANY.*

***Aim/Introduction:*** Given high levels of SSTR expression in meningioma in an ex-vivo setting, SSTR-targeting peptide receptor radionuclide therapy (PRRT) may emerge as a suitable therapeutic option for patients after surgery or radiotherapy. We aimed to determine prognosticators for overall survival (OS) in patients with recurrent meningioma under PRRT and to characterize treatment-related toxicity. ***Materials and Methods:*** We identified 35 patients with recurrent meningioma treated with PRRT. We investigated SSTR-PET positive tumour burden at baseline, along with aspartate aminotransferase (AST), alkaline phosphatase (AP), lactate dehydrogenase (LDH) and C-reactive protein (CRP). To determine haemato- and nephrotoxicity, haemoglobin, leukocytes, platelet counts (n=33) and eGFR (n=32) at baseline and after therapy were also recorded. Adverse events were classified according to the Common Terminology Criteria for Adverse Events (CTC) v5.0. We performed univariable cox regression analysis, followed by Kaplan Meier analyses. ***Results:*** Median age of patients was 63 years (30-84). Most patients were diagnosed with WHO grade II (15/35, 43%), followed by WHO I (12/35, 34%; WHO III, 6/35 [17%]; unknown, 2/35 [6%]). A median of two (1-8) cycles of PRRT were administered (cumulative activity: 15.6 GBq (6.9-60.3)). Median SSTR-positive volume was 14.7 (0.42-217.5) ml (median SUVmax, 24.3 [5.3-297.1]). Median decreases of 26%, 21% and 5% were seen in leukocytes, platelets and haemoglobin, while eGFR increased by 2%. CTC grade III/IV toxicity for leukocytopenia, thrombocytopenia and anaemia occurred in 6%, 3% and 3%, respectively. No CTC grade III/IV nephrotoxicity was recorded. Radiographic progression was documented in 4/12 (33.3%) patients with WHO I (median after 17 months), in 10/15 (66.7%) patients with WHO II (after 17 months) and 6/6 (100%) patients with WHO III (after 4.5 months). Median OS was 49 months, while 14/35 (40%) patients died. Univariable analysis provided only LDH (per U/l, HR, 1.008, 95% CI 1.000-1.015; P=0.03) and WHO grade (per grade, HR, 2.3, 95% CI 1.03-5.6; P<0.05) as prognosticators for OS. WHO grade III patients (17 months) exhibited shorter median OS relative to WHO grade I (56 months, HR 0.25, 95% CI 0.04-1.40; P=0.02) and II (47 months, HR 0.3, 95% CI 0.06-1.57; P=0.04), while no difference was seen between WHO grade I and II (P=0.6). ***Conclusion:*** PRRT in patients with recurrent meningioma achieves considerable anti-tumour effects with an acceptable safety profile. Baseline LDH and WHO grade showed prognostic ability for survival, while PET-based quantification failed.

## EP-0611

### Sequential treatment of High-risk Neuroblastoma combining I-131 MIBG high-dose and Topotecan. First experience

***N. Orrego***, *S. Prado-Wohlwend, J. Balaguer-Guill, I. Torres-Espallardo, M. Part-Lopez, C. Guerrero-Calatayud, J. Cañón-Sanchez, S. Montesinos-Gonzalez, P. Bello-Arques;*
*Hospital Universitari i Politecnic La Fe, Valencia, SPAIN.*

***Aim/Introduction:*** Neuroblastoma is the most common extracranial tumor in childhood. High risk neuroblastoma (HR-NB) is related to those patients older than 1 year, with a metastatic debut, stage 2, 3, or with N-Myc amplification. 5-year survival rate in this group does not exceed 50 %. Current treatment includes an induction therapy before surgery, conditioning chemotherapy followed by haematopoietic progenitor rescue and treatment of minimal residual disease. The response rate is between 60-80% of all patients, but many patients relapse. The aim of this study is to describe our experience by treating children with HR-NB combining high-dose I-131 MIBG and topotecan followed by autologous progenitor cell transplant, as an intensification phase after induction therapy with busulfan and melphalan. ***Materials and Methods:*** Retrospective analysis of patients treated with high-dose 131-I-MIBG and topotecan, from 2017 to date. 85% of cases were male, with metastatic disease at diagnosis, none had amplified N-myc. 57.14% of primary tumor were abdominal/adrenal, 28.57% paravertebral and 14.29% pelvic. The average age at diagnosis was 6 years (2.6-15.6) and at treatment administration was 10 years (4.7-18.8). Statistical analyses were performed using IBM SSPS Statics version 29. ***Results:*** From 2017 to 2023, 7 patients with HR-NB underwent sequential treatment with high-dose I-131 MIBG and Topotecan as an intensification phase of their treatment. Administered average activity was 10.07 MBq (7.42-11.99), with a whole-body absorbed dose of 1.476 Gy (0.74-2.323) after first treatment and 8.84 MBq (4.22-12.99), with a whole-body absorbed dose of 1.145Gy (0.603-1.711) after the second. After completion of 2 cycles, the average whole-body absorbed dose was 2.65 Gy (1.463-3.990). With an average follow-up of 31.28 months (0-74), the disease-free survival time was 16.7 months. No treatment-related deaths were observed. The most frequent toxicity was gastrointestinal and the highest grade toxicity (3-4) was haematological (20% and 28% after first and second treatment respectively) and one case of neurological toxicity (autoimmune encephalitis). We have no reported cases of treatment-associated hypothyroidism. ***Conclusion:*** Sequential administration of high-dose 131I-mIBG and topotecan followed by autologous progenitor cell transplant after induction therapy is safe, complex but feasible, and improve the disease-free survival in patients with advanced neuroblastoma. More studies are necessary, especially compared to other myeloablative treatments.

## EP-0612

### New development Paradigm for Rare CNS cancers: Real World Data (RWD) Compared to Ongoing Safety and Feasibility Results from a Phase 1/2 Clinical Trial of 186RNL (Rhenium-186 Nanoliposome) (186Re) Obisbemeda in Recurrent Glioma: The ReSPECT-GBM Trial

***N. LaFrance***[1], *A. Brenner*[2], *J. Michalek*[2], *T. Patel*[3], *A. Bao*[4], *W. Phillips*[2], *M. Hedrick*[5], *M. Moore*[5], *J. Weinberg*[6], *M. Youssef*[3], *J. Floyd*[2];
[1]*Norman LaFrance, Austin, TX, UNITED STATES OF AMERICA,* [2]*UT Health San Antonio, San Antonio, TX, UNITED STATES OF AMERICA,* [3]*UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA,* [4]*Case Western Reserve University, Cleveland, OH, UNITED STATES OF AMERICA,* [5]*PLUS Therapeutics, Austin, TX, UNITED STATES OF AMERICA,* [6]*MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** $^{186}$RNL is a BMEDA-chelated $^{186}$Re encapsulated in nanoliposomes delivered via convection enhanced delivery (CED) with ongoing Phase 1 dose escalation and Phase 2 study. Unique $^{186}$Re properties (1-MeV β-decay and simultaneous γ-decay of 137 keV, allows therapy and imaging and has achieved durable, localized tumor retention, and high absorbed radiation doses[ARD]. We present updated results from ongoing trial ReSPECT-GBM (NCT01906385) with comparison to RWD in $^{186}$RNL in recurrent glioma patients. ***Materials and Methods:*** An analysis [data sourced from the Medidata Enterprise Data Store (MEDS)] was performed to determine if bevacizumab patients is an appropriate external control group for evaluating the treatment effect in current and upcoming CED trials. Deidentified patient-level historical clinical trial data, study and patient-level data from historical rGBM CED studies [D'Amico, J Neurooncol 2021] and an on-going Plus Therapeutics CED study were analyzed. Aggregate summary statistics were based on combined study- and patient-level data using weighted (by sample size) means, median of medians, incidence and OS rates (completed studies). Statistical analyses by log rank, proportional hazards and accelerated failure time (AFT) models were performed on the Phase 1 cohorts leading to the Phase 2 dose selection and trial initiation. ***Results:*** Twenty-one adult recurrent glioma patients across the first six dose-cohorts were analyzed. Single $^{186}$RNL dose ranged from 1.0-22.3 mCi in a volume of 0.6-8.8 mL, CED administration rate was 5-20 µl/min using 1-4 catheters and was well-tolerated. For the Phase 1 cohorts[6] leading to the ongoing Phase 2, three patients remain alive and 18 have died. The median overall survival (N=21) by log-rank analysis for patients receiving AARD of >100 Gy was 30 months. Proportional hazards and AFT modeling demonstrated AD and %tumor treated significantly correlated with OS. For RWD control analysis, all cohorts reported similar characteristics over a broad set of demographics, disease characteristics and medical history [age, race, gender, recurrence, grade and prior treatment]. While the baseline composition of rGBM study patients world-wide has changed over time to enroll healthier patients (ECOG=0) with smaller tumors, median OS has remained constant (bevacizumab:7.9 months; CED studies:8.4 months). ***Conclusion:*** Single-dose $^{186}$RNL by CED in adult patients with rGBM achieves high absorbed doses without significant toxicity, is well tolerated, with favorable overall survival compared to RWD controls. We are enrolling two studies in rGBM: larger tumors in the Phase 1 dose- escalation [>20 cm$^3$]; Phase 2 [tumor ≤20 cm$^3$]. Developing and Current results will be presented.

## EP-0613

### Peptide Receptor Radionuclide Therapy In Advanced Refractory Meningiomas: Tocicixy And Efficacy In A Long Therm Follow Up

***S. Severi***[1], *I. Grassi*[2], *A. Bongiovanni*[2], *A. Sarnelli*[2], *V. Di Iorio*[2], *N. Ranallo*[2], *F. Matteucci*[2], *I. Marini*[2], *E. Amadori*[2], *I. Azzali*[2], *N. Riva*[2], *L. Gurrieri*[2], *S. Nicolini*[2], *P. Caroli*[2], *M. Sansovini*[1];
[1]*IRST IRCCS, Meldola, ITALY,* [2]*IRST IRCCS, Forlì-Cesena, ITALY.*

***Aim/Introduction:*** Recurrence of meningiomas deserve specific attention for the lack of active therapies after surgery and radiotherapy. The high frequency of somatostatin receptors (SSTr2) overexpression onto the cell membrane of these tumors open the way for a peptide receptor radionuclide therapy (PRRT). Diagnosis with 68Ga-Dota octreotide and therapy with 90Y/177Lu Dota-octreotide is currently possible within experimental protocols or as compassionate use. ***Materials and Methods:*** From October 2009 to October 2021 we enrolled meningioma patients highly positive to 68Ga-dotatoc PET and in radiological recurrence after standard therapies. They were treated with 90Y-dotatoc (dosage of 1.1 or 5.5GBq ) or with 177Lu-dotatate (dosage of 3.7 or 5.5GBq ) according to clinical status, in a mean 4 cycles. ***Results:*** Of 42 patients treated, 5 received 90Y-Dotatoc with a cumulative activity of 11.1GBq and 37 patients 177Lu Dotatate with a cumulative activity of 22GBq. Overall disease control rate (DCR) was 57% with better outcomes for younger age and moderate disease burden. In a median follow up of 63 months, mPFS was 16 months and mOS was 36 months. A re-challenge 177Lu-dotatate was carried out in 6 patients with a median injected activity of 13 GBq in mean 5 cycles. In a 75.8 months follow up we demonstrated a mPFS of 6.5 months and a mOS 17 months. PRRT was well tollerated as favored by personalized radiopharmaceutical dosages; only one patient discontinuing treatment due to G3 platelet toxicity. In the 6 re-challenged patients we had a rapidly transient G2 toxicity on neutrophils in one patient. ***Conclusion:*** PRRT in patients with advanced meningiomas overexpressing SSTr2 receptor was well tolerated, showed a 57% DCR and has a potential re-challenge option. The therapy efficacy can improve if applied at earlier stage. Due to the very low toxicity, further studies to explore possible association with other treatment are warranted.

## EP-0614

### 64CuCl2treatment: preliminary data on recurrent glioblastoma patients

***D. Stanimirovic***[1], *D. Milakovic*[1], *J. Mijatovic*[1], *I. Rakita*[1], *G. Vuleta*[1], *M. Basile*[2], *S. Valentini*[2];
[1]*University Clinical Center of the Republic of Srpska, Banja Luka, BOSNIA AND HERZEGOVINA,* [2]*A.C.O.M.-Advanced Center Oncology Macerata-S.R.L., Montecosaro (MC), ITALY.*

***Aim/Introduction:*** Glioblastoma (GBM) is one of the most prevalent and aggressive malignant brain tumors in adult patients, usually with poor prognosis and low survival rates. Despite multimodality treatment efforts in the past two decades, the overall survival has not significantly increased and the disease relapse is inevitable. $^{64}CuCl_2$ is an innovative theragnostic agent and this study aimed to determine the maximum tolerated dose (MTD) based on dose-limiting toxicity (DLT) and the preliminary efficacy of $^{64}CuCl_2$ treatment. ***Materials and Methods:*** Adult patients belonging to the class of recurrent/progressive GBM after standard treatments (surgery, radiotherapy, chemotherapy) have been recruited. All patients performed a $^{64}CuCl_2$ PET/CT scan for treatment selection. The therapy consisted of 7 doses administered once a week. Six patients received escalated doses in stage 1 (3+3 scheme), according to smoothed modified Fibonacci sequence, and were evaluated to determine the DLT/MTD and biodistribution by analysing PET/CT scans at different time points (1h, 4h, 24h, 48h). Patients included in stage 2 have received fixed doses and 5 patients were evaluated for response to treatment by MRI assessment according to RANO criteria. ***Results:*** Stage 1 evaluation has shown that $^{64}CuCl_2$ uptake increases up to 4h post-injection and decreases thereafter in the liver, followed by kidney and L2-L4 regions. However, no treatment related toxicities were registered associated to liver/kidney and red marrow distribution. 20 Adverse Events were detected and 4 SAE occurred not correlated to drug administration. No DLT occurred and the positive safety profile allowed to select the highest dose tested in stage 1 to proceed with the stage 2. Data cut-off was performed after 5 patients have been included in stage 2. Treatment response evaluation, in term of anti-tumor activity of $^{64}CuCl_2$ measured by MRI, showed that more than 50% of patients resulted as responders (stable disease,

partial or complete response) to $^{64}CuCl_2$ treatment. ***Conclusion:*** These preliminary data have demonstrated a favourable dosage scheme for $^{64}CuCl_2$ treatment of recurrent GBM patients both from a safety and an efficacy point of view, encouraging the development of this radiopharmaceutical.

## EP-0615

### Substantiation of an individual therapeutic dose of 153Sm-oxabiphor for the treatment of bone metastases

***G. Grushka***[1], *L. Stadnyk*[2], *V. Bobrova*[2];
[1]*Kharkiv National Medical University, Kharkiv, UKRAINE,* [2]*Grigorev Institute for Medical Radiology and Oncology, Kharkiv, UKRAINE.*

***Aim/Introduction:*** The majority of recommendations for the management of radionuclide therapy pain bone metastases do not provide individual dosimetric planning for patients. Individualized activity allows to optimize the radionuclide bone therapy (RBT) and prevents hematological toxicity. Aim of the investigation was optimization of the intravenous dose of $^{153}Sm$-oxabiphor for limitation of the red bone marrow absorbed dose (RBMAD) up to about 2 Gy. ***Materials and Methods:*** 26 patients with painful bone metastases received 39 courses of RBT. The average value of administered activities of $^{153}Sm$ was 2630.0 ± 970.0 MBq. Using the external body radiometry the coefficient of retention of $^{153}Sm$ in bone tissues ($K_{ret}$) for all patients was determined using the external body dosimetry which was carried out not less than 3 times during three-four days: the first - 0,5 hour after the first injection. Coefficients of variability of the volume of trabecular bone of the $L_2$-$L_4$ vertebra ($K_{L2-L4}$) for each patient were calculated using CT-exams. Estimation of cumulative activity in bone tissues and RBMAD and their correlation with the values of individual $K_{ret}$ and $K_{L2-L4}$ was performed. ***Results:*** RBMAD is associated with the individual pharmacokinetics of $^{153}Sm$-oxabiphor and the anatomical features of patients. The obtained data during the first course of RBT allowed to take into account the peculiarities of the distribution of radiopharmaceutical in the skeleton and red bone marrow for each patient separately and analysed the dependence of the RBMAD from the product of the assigned optimal specific activity ($A_{spec}$), $K_{ret}$ and $K_{L2-L4}$ for each patient. The correlation coefficient between these parameters was R2 = 0.96. The RBMAD was determined with the calculation of the values of the individual $K_{ret}$ and $K_{L2-L4}$ during the first course of the radionuclide therapy. The RBMAD ranged from 0.45 to 3.56 Gy and averaged (1.49 ± 0.89) Gy. In most cases (83%), the RBMAD did not exceed the allowable limit of 2 Gy. This was found the analytical correlation for the estimation of the value of optimal specific activity ($A_{spec}$) by $^{153}Sm$ for the following RBT courses with the value of the limit of RBMAD - 2000 mGy. ***Conclusion:*** The prognostic assessment of the RBMAD at the first course of the radionuclide bone therapy allows optimize the individual activity of $^{153}Sm$-oxabiphor for next courses of the RBT and prevents hematological toxicity. This can make the significant contribution to improving the effectiveness of bone metastases treatment.

## C: Therapy Clinical Study -> C2 Non-Oncological Treatments -> C21 Non-Oncological Treatments (including Thyroid Benign)

## EP-0616

### Radiosynoviorthesis of debilitating joints in haemophilia and rheumatoid arthritis : a local South East Asian hospital experience

***K. Loke***[1], *W. Tay*[1], *L. T. Cheng*[2], *C. Ng*[1], *H. Low*[1];
[1]*Singapore General Hospital, Singapore, SINGAPORE,* [2]*National University Hospital Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** Aim/Introduction: RSO is an efficacious treatment in symptomatic haemophilia and rheumatoid arthritis patients who are not well controlled with systemic or local targeted treatments. RSO is well tolerated and effective especially in patients who are treated in the early disease course with mild to moderate joint destruction[1,2]. ***Materials and Methods:***The Department of Nuclear Medicine and Molecular Imaging, Singapore General Hospital has been treating patients with RSO since 2013. To assess treatment response, clinical assessment of joint swelling, synovial thickening and symptomatology by way of pain score using VAS was used. ***Results:***Steadily increasing procedure numbers are possibly due to increased clinician and patient awareness. Since then, an annual average of 3-4 RSO procedures are performed. From 2018 to 2023, 24 RSO have been performed (11 knee, 11 ankles, 1 elbow and 1 wrist joint).Almost all patients reported an improvement of joint swelling/stiffness and/or pain reduction as early as 2-4 weeks following RSO of target joint. The duration of symptom control was from 6 to 20 months. Several patients reported symptom improvement allowing resumption of daily activities or work. Interestingly, it was noted that 2 patients experienced good response to initial target joint injections and returned to the clinic requesting for RSO of other affected joints. ***Conclusion:*** RSO is an uncommon well-tolerated and effective intraarticular nuclear medicine procedure for haemophilia and rheumatoid arthritis patients with debilitating joint symptoms[3]. An increasing number of patients with debilitating joints were treated within our department especially within the last 5 years from 2018 to 2022. RSO in these patients has been noted to improve patients' symptoms and in some patients, allowed them to return to previous functional status and regain employment. ***References:*** References:1. ## EP-0617

### The Impact Role of High Specific activity of Radioactive Iodine 131I in Hyperthyroidism Response Rate

***M. Al Rowaily***[1], *M. Al-Qahtani*[2];
[1]*KFSHRC & Alfaisal University, Riyadh, SAUDI ARABIA,* [2]*KFSHRC, Riyadh, SAUDI ARABIA.*

***Aim/Introduction:*** The mechanism of action of RAI is physiological. Iodine is the precursor of thyroxine. The radioactive form of iodine is taken up by iodide transporter of the thyroid the same way as natural iodine and is similarly processed. The beta particle destroys the follicular cell, gradually leading to volume reduction and control of the thyrotoxicosis however high specific activity is mandatory to achieve high response rate. ***Materials and Methods:*** In our study the choice made to use high dose of Iodine-131in purpose to achieve high cure rate. during year 2002-2010 (538) patients were treated with a response rate range from 70%-80% and 20%-30% needed a second dose of 131I-RAI who achieved a cure after second dose. in 2010-2011 response rate was low about 50%, more than 20 patients (40-50%) needed second dose of therapy. ***Results:*** After investigating and searching for the causes to this drop, we found that all these patients have been received high dose of Iodine-131 post calibration in other ward low specific activity. Shelf life usually 3 weeks 5 days before calibration and Two-weeks post calibration. A new role was stablished in our department after that no 131-Iodine should be given post calibration for Graves patient. A year after only one patient didn't respond to the therapy and after investigation found that the patient prescribed dose was 15 mCi who has received16.2 mCi using a 25 mCi capsule 5 days post calibration administered by new employee. Since that time more than 90% the response rate. ***Conclusion:*** High specific activity of I-131 is very crucial therefore always use pre-calibration Doses. Patient preparation ensures efficacy of RAI and reduces the potential complications. Important issues like the consent procedure, pregnancy and timing of medication.

## EP-0618

### Plasma Volume Deficit estimation using Cr-51 labelled RBC in Acute Pancreatitis Patients

***N. Kumar***, *S. Ballal, M. P. Yadav, M. Tripathi, C. Bal;*
*All India Institute of Medical Sciences, New Delhi, India, New Delhi, INDIA.*

***Aim/Introduction:*** Acute pancreatitis (AP) is the glandular parenchymatous inflammation of retroperitoneal organ that may involve multiple organ dysfunction if not treated, which may lead to death. Hypovolemia is the major complication that that may occur secondary to vomiting, reduced oral intake, third space extravasation, respiratory losses and diaphoresis. Therefore, patient's hydration is required to resolve the hypovolemia. Thus, early fluid therapy is the cornerstone of the treatment of acute pancreatitis and is universally recommended. There is a lack of consensus and proper guidance regarding the amount of fluid deficit in AP patients. The present work was aimed to estimate plasma volume (PV) deficit using Cr-51 labelled RBC in acute pancreatitis (AP) patients thereby establishing its clinical utility and also enabling institution of definitive therapeutic regimens early on, as treatment protocols differ widely depending on etiology of the abdominal pain and fever. ***Materials and Methods:*** Approximately 15-20 ml of blood was withdrawn from the patient and added to a sterile multi-injection bottle containing 4-5 ml of ACD solution. In-vitro labelling of RBC's was performed with approx. 100µCi of Cr-51 sodium chromate at room temperature. 10mL of tagged red blood cell (RBC) suspension mixture was reinjected intravenously as such and the remaining tagged RBC suspension was used to determine standard samples such as A, B and C. All counting samples were made in total volume of 4mL. Again, approx. 20 mL of blood was withdrawn from a different vein at 20-25min post-injection that was used to make other standard samples such as D, E and F. Counting was done with well counter (Biodex Atomlab 950 thyroid uptake system with optional well counter) in Cr-51 window. Background subtracted counting values were used to determine red cell volume. ***Results:*** Twenty six (17 men; 9 women) AP patients with mean age 41.23±15.38 years were screened and admitted within 72 hours of the onset of AP. The median ideal PV at equilibrium was 2905 mL, range (1883-3916 mL). The median intravascular PV deficit was 1568 ml. There was significant reduction in median ideal PV of 2905 mL to estimated median PV of 1587 mL with P value = 0.0002. ***Conclusion:*** All patients were revived by replacing the deficit volume with fluids and were recovered. Hence, the recovery of the patient validated our PV estimation results.

## EP-0619

### Urinary Excretion Rate of I-131 During Treatment of Benign Thyroid Disease

***U. Beguš***[1], *P. Tomše*[2], *K. Bajuk Studen*[2], *E. Pirnat*[2], *S. Gaberšček*[2], *K. Zaletel*[2];
[1]*Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA,* [2]*Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** The use of radioactive iodine (I-131) is an effective treatment for benign thyroid disease. It selectively destroys hyperfunctioning thyroid tissue by emission of beta radiation, and simultaneously emits gamma radiation. However, during treatment, the significant excretion of the administered activity in the urine poses a radiation risk to personnel and the environment. Therefore, appropriate radiation safety protocols must be followed when treating patients, especially those wearing diapers. Since there is little literature on the urinary excretion rate of I-131 in patients treated for benign thyroid disease, we aimed to investigate this issue. ***Materials and Methods:*** We performed a study in hospitalized patients with hyperthyroidism due to thyroid autonomy or Graves' disease. Urine samples were collected 2 and 4 hours after oral administration of the I-131 capsule and at the time of patient discharge from the hospital (24, 48, or 72 hours after administration). The time and volume of urine collection were recorded, and 0.05 ml of each urine sample was diluted with 0.95 ml of saline. We measured the count rate (cps) in the diluted samples with a gamma counter, and the accuracy of the sample activity (MBq) was obtained by calibrating the gamma counter beforehand, namely by measuring 6 samples of an I-131 solution with known activity. Linear fitting provided a calibration factor to calculate the percentage of excreted activity in each urine sample. ***Results:*** We collected urine samples from 34 patients (8 men, 26 women) aged 26 to 82 years (mean age, 62.5±13.2 years) who were administered a median dose of 890 MBq (730-1095 MBq). The median volume of urine samples collected was 200 ml (20-540 ml). A linear fit across gamma count measurements yielded a relation of activity = 2.46 * counts with 41% efficiency. Urine samples collected 2 and 4 hours after therapy showed substantial excretion of administered I-131 (7.9±3.6% (1.9-16.5%) and 7.3±4.6% (0.2-16.4%), respectively), whereas excretion 24, 48 and 72 hours after administration was low (1.08±0.51%, 0.85±0.90%, and 0.18±0.14%, respectively). Paired t-test showed significant

differences between samples collected 2 or 4 hours after therapy and at discharge (p<0.001), but not between the first two samples collected (p=0.46). ***Conclusion:*** Our finding that urinary I-131 excretion is high immediately after administration and decreases significantly after only 24 hours may improve patient care by providing more accurate radiation safety guidelines. These will contribute to lower radiation exposure to themselves and those around them.

## EP-0620

### Quality of life after radioisotope synoviorthesis in patients with chronic inflammatory diseases refractory to conventional treatments.

***J. Venero Chaparro***, *M. Sánchez Torrente, M. Gallego Márquez, F. Garí Martínez, D. Becerra García, M. Martínez-Valle Torres; Hospital Clínico San Cecilio, Granada, SPAIN.*

***Aim/Introduction:*** The objective is to describe our experience after radioisotope synoviorthesis (RSO) as the local treatment of choice in patients with chronic arthritis and synovitis of large and medium-sized joints, who have not responded to first-line treatments. In addition, to analyse the effectiveness of the treatment at one year and to assess its impact on quality of life. ***Materials and Methods:*** This is an observational, descriptive, cross-sectional study in which 22 RSOs performed in our centre between 2017 and 2023 were assessed. Twenty knees were injected with 185MBq of Ytrium Citrate (Y-90) and two elbows with 111MBq of Rhenium (Re-186). In both procedures the injection was performed inside the joint space and was guided by sonography, after administration of intra-articular anaesthetic in order to avoid movements during the injection that could interfere with the correct procedure. Finally, corticosteroids were administered to reduce post-therapy inflammation.Once the radioisotope is injected, the beta emission generated will irradiate the inflamed synovium, causing fibrosis and obliteration of the pain receptors of the synovial membrane, resulting in clinical improvement. To evaluate the clinical response, all patients were given a questionnaire before the procedure, 3 months and 1 year after treatment. The three variables analysed were: 1. Reduction of pain through the visual analogue scale (VAS), considering an adequate response if it decreased more than 25% in relation to the initial VAS; 2. Improvement of the activity of the disease, determined by increased joint mobility and decreased inflammation; 3. Improvement of the quality of life with decreased first-line analgesics. ***Results:*** All patients showed improvement in all three variables analysed. 1. Pain intensity was reduced by 63.7% at 3 months and by 65.3% at 1 year after treatment. 2. The decrease in disease activity was 73.7% at 3 months and 77.2% at 1 year after the procedure. 3. At one year post procedure, 72.1% of patients showed significant improvement in their quality of life. ***Conclusion:*** Radiosynoviorthesis is a useful and safe therapeutic alternative in patients with chronic arthritis and synovitis, resulting in a significant improvement in quality of life and reduction of inflammation parameters.

## EP-0621

### The most important problems of supervision over a patient qualified for knee synovectomy based on 10 years single-centre experience

***M. Wlodarczyk***, *Z. Adamczewski; Nuclear Medicine Department, Central Clinical Hospital, Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Radioisotope synovectomy (RS) is a recognized method used in the treatment of joint effusions in the course of diseases such as rheumatoid arthritis (RA), psoriatic arthritis, juvenile idiopathic arthritis, pigmented villonodular synovitis or degenerative joint disease. Exudative changes in the course of these diseases are often accompanied by secondary synovial hyperplasia. Radioactive colloid particles administered intra-articularly during RS are phagocytosed by synoviocytes leading to coagulative necrosis, fibrosis and involution of synovial hyperplasia. The effectiveness of this type of therapy depends to a large extent on the initial diagnosis. In the case of RA, it can be up to 80%. ***Materials and Methods:*** The Nuclear Medicine Department of the Medical University of Łódź (NMD) has extensive experience in performing radiosynovectomy of the knee joints. Over the last 10 years, 885 procedures of this type have been performed in 643 patients, mainly (36%) with RA. In most patients (N=465, 53%), the procedure was performed once. The rest of patients received the isotope 2-6 times over several years (N=420, 47%). The group treated multiple times was diverse. It included both patients in whom the procedure was repeated due to the ineffectiveness of the previous attempt, as well as those in whom the repetition was due to the desire to prolong the positive effect of the therapy. ***Results:*** In the majority of single-treated patients, there was no feedback on the effectiveness of therapy. Post-treatment follow-up was conducted by clinicians and rarely reported to NMD. In returning patients this assessment was mainly based on indicators such as pain reduction, swelling reduction or improvement in joint mobility. The most important was the overall improvement subjectively felt by the patient. Finally, among all procedures with information about the effectiveness, improvement was noted in about 80% of cases. ***Conclusion:*** In order to objectively assess the effectiveness of isotopic treatment, the procedure is now extended to include ultrasonographic measurements of the thickness of synovial folds and the amount of effusion in the joint during the qualification visit for the synovectomy. The control of clinical and ultrasound effects is scheduled 3-6 months after the RS, during an additional follow-up visits in NMD. This way of proceeding will ensure an objective evaluation of treatment effects, it will make it independent of the influx of information from clinicians, and in the case of qualifying new patients, it will enable the introduction of personalized rules of conduct.

## EP-0622

### Treatment of Hidradenitis suppurativa (HS) - A pilot study : Can Nuclear Medicine therapy be the answer?

***P. Gupta***, *K. K. Verma, R. Kumar; AIIMS, New Delhi, INDIA.*

***Aim/Introduction:*** Hidradenitis suppurativa (HS) is a dermatological condition characterized by inflamed and swollen lumps which are purulent and painful. As it usually occurs in underarms and groin region, it significantly affects the everyday activities. It is believed to be caused by hair follicles being obstructed, with the nearby apocrine sweat glands being strongly implicated in this obstruction. Antibiotics, immunosuppressive medication, laser therapy or surgery may help in partial improvement of symptoms. However, no definite cure is known and the present available options offer partial help with chances of recurrence. In this pilot study, we tried to explore if Nuclear Medicine therapy beholds the answer to the treatment of HS.The aim of the study was to determine if Nuclear Medicine therapy with radioactive patches can be used for treatment of Hidradenitis suppurativa (HS). ***Materials and Methods:*** A prospective pilot study was conducted with two patients (M/F:1/1) aged 32 yrs and 48 yrs. Written informed consent was obtained from both patients. Both patients had clinically confirmed HS lesions on underarms. The lesions were characterized by swelling, pus discharge and

severe pain at the lesion site affecting the daily activities of both the patients. Antibiotics of anti-infective tetracyclines class were started in both patients to reduce purulence and suppuration. After the initial baseline laboratory investigations were done, radioactive patches of Rhenium-188 were custom made according to shape of the lesions, sealed and applied locally over the lesions. A total of 45-50 Gy radiation dose was superficially delivered to the lesions in five fractions. Patients were followed up at 2 weeks, 6 weeks and 12 weeks. ***Results:*** Initial radiation induced dermatitis and inflammation was noted at the lesion site at 2 weeks in both the patients which gradually healed. At 6 weeks, inflammation was absent and there was partial improvement at the lesion sites with decreased swelling and pain. There was no pus discharge at the lesion sites. At 12 weeks, all the symptoms had subsided. Swelling, pain and pus discharge had completely subsided with significant improvement in the quality of life of patients. There was complete flattening of the lesions though some hypopigmentation was noted at the treated lesion sites. Routine laboratory examinations at the follow ups did not reveal any toxicity. ***Conclusion:*** Nuclear Medicine therapy using radioactive patches can be an effective option for treatment of Hidradenitis suppurativa (HS).

## EP-0623

### Percutaneous Microwave thermoablation (PMWT) for dominant benign thyroid nodules(BTN): a two years single centre experience

***B. Criscuoli***[1], *C. Manni*[1], *G. Follacchio*[1], *F. Salvatori*[2], *C. Mincarelli*[2], *S. Alborino*[2], *F. Capoccetti*[1];
[1]*Nuclear Medicine Unit, Macerata General Hospital, AST Macerata, ITALY,* [2]*Interventional Radiology Unit, Macerata General Hospital, AST Macerata, ITALY.*

***Aim/Introduction:*** Image-guided thermal-ablation(LTA; RFA) are well established therapy options in selected BTN.PMWT is a mini-invasive technique recently applied in thyroid disease;purpose is to demonstrate effectiveness of PMWT in treatment of BTN,and its application inside a thyroid pathways in a nuclear medicine unit. ***Materials and Methods:*** From May 2021,95 patients (66F,29 M, Aged 29-84,Mean 59,2)with BTN symptomatic/in growing,non eligible to surgery were enrolled. Inclusion criteria:solid nodule≥ 20%,diameter ≥ 2 cm,2 FNA cytology confirmed as benign(TIR2 sec ITCCS 2014).Baseline were performed ECG,ENT consults,where necessary anesthesiologic too,laboratory assessment(fT3,fT4,TSH,TPOAb,TgAb, calcitonin,blood count,clotting indexes).Additionally 52/95 pts done Thyroid-scintiscan with $^{99}$mTc-Pertecnetate(35 cold;11hot;6 non focal findings).Single-session of US-guided PMWTA was carry-out under local anesthesia through microwave-antenna,delivering 10-15 W in 10-15 minutes,depends on the BTN volume;in 2 cases,due to the high baseline volume,procedure was repeated in 6 months. Nuclear medicine physician effects anamnestic/thyroid physical examination,rating symptomatology with a Compressive Score(CS on a 10 cm visual-analog scale),Aesthetic Score (AS from 1-no palpable-to4 palpable-visible in all positions).US thyroid was performed to record Volume of BTN-target (VnT),baseline and scheduled after procedure at 1, 6, 12 months,in selected patients also at 18 months. Additionally volume reduction rate %(VRR) was calculated. Considering the baseline VnT,we divided in 2Groups: Group A >10 mL n°43 pts;Group B < 10 mL n°52 pts).Success rate fixed in a volume reduction ≥ 50%. ***Results:*** No peri-procedural major complications were observed. 4/95 with hot-nodules after procedure showed laboratoristic transient increase of thyroid hormone levels,1/4 develop 10 days after PMWT atrial fibrillation pharmacologically reverted;2/95 skin burn;1/95 transient lowering of voice. Clinically was registered CS mean score from 3,9 (baseline) to 1,8 and 0,95 (6 and 12 months respectively),AS from 3,2 (baseline) to 2 (6 and 12 months). Baseline mean VnT of 14,8 mL(range 77-1,2 mL) and 12 months post-procedure mean VnT of 5,8 mL (range 32,9-0,39 mL). In Group A the mean VRR at 1,6,12 months was respectively 45,5 %, 58,8 %, 63,8 %. In Group B the mean VRR at 1,6,12 months was respectively 49,3 %, 55,4 %, 61,9 %.The success rate was in Group A 89%,and 83 % in Group B.Neither a significant re-growth occurred in this middle-term evaluation, confirmed at 18 months control. ***Conclusion:*** From our results,PMWT is an effective option in selected BTN, demonstrated an high-successful rate as nodule shrinking,safe,well-tollerated and low complication rate,with a satisfactory clinical-response. No significant difference dividing patients by volume in 2 groups,assuming a spread potential inside decision making into thyroid pathways.

### SPECT Imaging Predictors of Social Anxiety Disorder Treatment Response: A New Way Forward

***S. Rezaei****, E. Gharepapagh;*
*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Precision psychiatry aims is to accurately predict treatment response. Here, we tested pre-treatment patient characteristics and functional imaging markers to predict treatment response accuracy in patients with social anxiety disorders (SAD). ***Materials and Methods:*** The selective serotonin reuptake inhibitor (SSRI) escitalopram or placebo was administered for 9 weeks to 40 SAD patients (mean SD age 32.1 ± 8.2 years, 20 women). The Clinical Global Impression Improvement scale was used to define treatment responders (CGI-I ≤ 2). Imaging with single photon emission computed tomography (SPECT) was conducted before and after treatment. Based on pre-treatment neuroimages, support vector machines (SVMs) were used to separate responders from non-responders. SVM models were tested using leave-one-subject-out cross-validation. ***Results:*** High accuracy was achieved by classifying treatment responders from non-responders using a linear SVM. Higher post-treatment perfusion was observed in responders compared to non-responders, particularly in those treated with SSRIs. ***Conclusion:*** Based on these results, psychiatric symptoms of clinical recovery are consistent with functional brain perfusion imaging findings on an individual basis.

## EP-0625

### Feasibility of an 123I-Ioflupane single photon emission tomography attenuation correction method with a deep convolutional neural network

***Y. Sayawaki***[1], *T. Ueda*[1], *T. Tomimatsu*[1], *R. Nagaoka*[1], *K. Yamasita*[1], *S. Ito*[2];
[1]*Graduate school of Health Sciences, Kumamoto University, 4-24-1 Kuhonji Chuo-ku,Kumamoto-shi, Kumamoto-ken, JAPAN,* [2]*Faculty of Life Sciences, Kumamoto University, 4-24-1 Kuhonji Chuo-ku,Kumamoto-shi, Kumamoto-ken, JAPAN.*

***Aim/Introduction:*** An attenuation correction (AC) is essential for 123I-FP-CIT single photon emission computed tomography (SPECT) for analysis and quantification of striatal. The CT based attenuation correction (CTAC) method have been used for 123I-FP-CIT SPECT. However, the use of CT scans increases radiation exposure to patients. Therefore, an AC method without radiation exposure and CT scan is required for clinical study. We developed a direct attenuation correction method (DAC) for brain positron emission tomography images without using MR images or CT images by using a deep convolutional neural network (DCNN). This method can be applied to 123I-FP-CIT SPECT without radiation exposure.The purpose of this study was to confirm the feasibility of the 123I-FP-CIT SPECT DAC by using DCCNN. ***Materials and Methods:*** Thirty patients who underwent 123I-FP-CIT SPECT/CT were used for training and testing for DCNN. A U-net architecture was used for generating DAC images and both CT attenuation correction (CTAC) and non-AC images were trained to predict DAC images. Images of 15 patients were used as training images, the images of remaining 15 patients data were used as examination set for accuracy evaluation of DAC images. The accuracy of DAC image was compared with the original CTAC image. ***Results:*** The normalized mean absolute error (NMSE) and structural similarity (SSIM) between the DAC and CTAC images were 0.31%±0.13%, and 0.96±0.0014, respectively. The DAC images were approximately equal to CTAC images. The SSIM with the DAC method was 0.96, suggestive of almost no differences between the DAC and CTAC images. Based on these results, the precision of NMSE and SSIM with the direct method is considered to have been very high, with good consistency between the two methods, encouraging their application in attenuation correction. ***Conclusion:*** Using a DNN, the 123I-FP-CIT DAC method that do not involve radiation exposure, were developed. The DAC images were similar to images corrected by CTAC, suggesting the clinical usefulness of this method. ***References:*** Development of attenuation correction methods using deep learning in brain-perfusion single-photon emission computed tomography:Taisuke Murata et al.MR-based synthetic CT generation using a deep convolutional neural network method:Xiao Han

## EP-0626

### Prognostic value of right ventricular dysfunction in chronic heart failure patients

***A. Mishkina****, T. Atabekov, S. Sazonova, S. Popov, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Gated blood pool SPECT(GBPS) is a well-established method for the assessment of right ventricle (RV) function due to its high accuracy and reproducibility[1]. Although recent studies proved that RV dysfunction is a predictor of adverse cardiac events in chronic heart failure (CHF) patients, the data regarding the role of RV dysfunction in cardiac resynchronization therapy (CRT) candidates is limited. The aim of this study was to evaluated RV function dynamic after CRT and prognostic value of RV dysfunction in CRT response. ***Materials and Methods:*** Patients with CHF eligible for CRT were included in this study. All patients underwent GBPS before and 6 months after CRT. The following RV indices were analyzed: end diastolic (EDV), end systolic (ESV) volumes, ejection fraction (EF), global and RV free wall phase standard deviation,degree(deg.) (PSD), phase entropy,% (PE), RV phase histogram bandwidth,deg. (PHBW), interventricular dyssynchrony, deg. (IVD), peak ejection rate (PER), peak filling rate (PFR), mean filling rate for one-third of diastole (MFR/3). Moreover before and six months after CRT implantation all patients underwent transthoracic echocardiography for assessment of left ventricle(LV) ESV, LV EDV, LV EF. ***Results:*** This study included 73 patients with CHF referred for CRT (males - 65%; mean age - 57±11 years; 38% - ischemic HF). Thirty patients had baseline RV dysfunction (RV ejection fraction<45% assessed by GBPS). Patients with RV dysfunction more common had atrial fibrillation, higher RV systolic pressure, higher RV_EDV, lower RV_PFR and higher RV dyssynchrony. RV contractility decreased from baseline to 6-month follow-up in all group of patients: RV_EF 54(IQR 41-56)% to 41(33-50)%, p=0.02; RV_SV 86(70.5 - 113)ml to 71.5(58.5 - 88) ml, and IVD 25(15.5 - 37.5)deg. to 21.5(11 - 26.5)deg, p=0.047. RV_EF changes after 6-month follow-up correlated suboptimal with baseline indices: QRS duration (r=-0.43,p=0.0019), RV systolic pressure (r=0.53,p=0.012), RV_ESV (r=0.48,p=0.0009), RV_PE (r=0.3,p=0.04), RV_MFR3 (r=-0.42,p=0.005), IVD (r=0.53,p=0.0002). According to the linear multivariate regression analysis (R2=0.82, p=0.004), significant predictors of LV_ESV changes after CRT implantation were: atrial fibrillation (p=0.0008), age (p=0.0005), RV_SV (p=0.001), RV_MFR/3 (p=0.0016), RV_PER (p=0.008), RV_PE (p=0.029). ***Conclusion:*** GBPS is useful for RV dysfunction assessment in patients with CHF. CRT implantation associated with the decreasing of RV_EF, RV_SV, IVD. The improvement of LV_ESV at 6 months after CRT is associated with atrial fibrillation, age, baseline RV_SV, RV_MFR/3, RV_PER, RV_PE. ***References:*** 1. Lebedev DI, Popov SV, Mishkina AI et al. Effect of right ventricular myocardial contractility on the response to cardiac resynchronization therapy. Kardiologiia. 2018;58(2).P:19-24. DOI:10.18087/cardio.2436

## EP-0627

### Comparing myocardium perfusion imaging features between 3D and 2D general-purpose SPECT/CT systems

***T. Noponen***[1]*, L. Kääriä*[2]*, R. Hirvilammi*[2]*, M. Hakulinen*[3]*, M. Seppänen*[2]*;*
[1]*Department of Clinical Physiology and Nuclear Medicine and Department of Medical Physics, Turku University Hospital, Turku, FINLAND,* [2]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [3]*Diagnostic Imaging Center, Kuopio University Hospital, Kuopio, FINLAND.*

***Aim/Introduction:*** In SPECT/CT myocardium perfusion imaging (MPI), a high contrast for ischemic defects and uniformity in normally perfused myocardium are desired features. A novel 3D digital SPECT/CT system may provide an increased contrast for a defect detection with respect to traditional 2D SPECT/CT systems. Capabilities of 3D digital SPECT/CT system for MPI were compared with the 2D SPECT/CT systems employing left ventricle phantoms. ***Materials and Methods:*** Two custom-designed 3D-printed left-ventricle phantoms were utilized. Both phantoms had realistic dimensions of human male anatomy, other modeling uniform myocardial perfusion without defects and other having three defects. Two cube-shaped defects had 10x10x10 mm dimensions, one located in an anterior cardiac wall and other on the lateral side of the apex. A large 20-mm height defect was located in an inferior cardiac wall. The phantoms having $^{99m}$Tc activity concentration ($c_A$) of 0,080 MBq/ml were inserted in a plastic container (20x35x45 cm, $c_A$ = 0,002 MBq/ml) modelling upper torso. The phantoms were imaged using three modern general-purpose SPECT/CT systems: 2D analog NaI, 2D digital CZT and novel 3D digital CZT system. Standard clinical acquisition and reconstruction protocols were used with 2D systems having 22-min SPECT imaging time and with 3D digital system 9-min. The acquisition was repeated with 3D system using 16-min imaging

time. The images of 2D systems were reconstructed using CT attenuation (CTAC) and resolution recovery corrections and 3D system using a Bayesian penalized-likelihood iterative algorithm with CTAC and median root prior regularization. Background regions and three defects were segmented in CT guidance using a modern commercial nuclear medicine analysing software. Defect contrast ((background-defect)/background) and uniformity (sd/mean) of background activity distribution were calculated. The defects were also visually interpreted using a polar plot. ***Results:*** 3D digital system had 77.4% contrast for large and 23.0-26.5% for small defects. The background uniformity ranged between 14.8-16.1% for the images of 3D system. 2D systems had 57.7-61.7% contrast for large and 8.6-15.2% for small defects and uniformity ranging between 10.3-11.0%. With the 16-min imaging time the background uniformity in 3D system decreased to 14.1%. With 3D system the small defects could be visually detected in a polar plot whereas with 2D systems they were not reliable detectable. ***Conclusion:*** 3D digital SPECT/CT system detects myocardial defects with clearly better contrast than 2D systems in MPI. However, also image non-uniformities are larger with 3D compared to 2D systems. Non-uniformities could be decreased by increasing an acquisition time.

## EP-0628

### Use of SPECT-CT In The Combined SLNB Technique and Node Labeling with 125i Seeds in Breast Cancer Patients Treated with Neoadjuvant Chemotherapy.

***M. Pérez Avila***[1], *M. Caballero Vivanco*[1], *F. González Asid*[1], *E. Córdoba Cañete*[1], *R. Sánchez Sánchez*[2];
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [2]*Hospital Universitario Virgen de las Nieves, Maracena, Granada, SPAIN.*

***Aim/Introduction:*** Selective sentinel lymph node biopsy (SLNB) is the procedure of choice for axillary staging of breast cancer, and allows the selection of patients in whom axillary lymphadenectomy does not provide any additional benefit. Currently, the performance of SLNB after neoadjuvant chemotherapy is accepted in patients with negative axilla at diagnosis, but in patients with positive axilla its application has limitations. Different lymph node markers have been proposed to guarantee their intraoperative identification and removal in axillary surgery. I125 seed labeling is a suitable procedure for intraoperative localization of biopsied positive lymph nodes in combination with SLNB and improves post-treatment axillary staging. The aim of our job is to present our protocol for carrying out the combined technique of SLNB and lymph node labeling with 125I seeds. ***Materials and Methods:*** 125I seed labeling of the biopsied positive axillary node is performed before starting neoadjuvant chemotherapy treatment. After treatment, the day before surgery, 74-111 MBq of 99mTc-albumin nanocolloid were injected periareolarly and then lymphoscintigraphy was performed until the sentinel node was visualized. The visualized node(s) was identified as sentinel node(s), especially if they are connected to a lymphatic channel, and once confirmed, their location on the skin was marked with the gamma radiation detector probe (99mTc energy window: 140 ± 10% keV). Next, SPECT/CT fusion images were acquired, which provide anatomical correlation of the SLNs and make it possible to check whether they coincide with the seed-labelled node, so this information helped to plan the surgery. ***Results:*** Of the 50 N1 patients with SRI-125 (GM) marking, 44 pre-QtNeo and 6 post-QtNeo, GM was identified in 97.2%: 23 negative, 26 positive. SLNB was performed in 45 and was identified in 93.3%: 26 negative, 16 positive. In 1 case the SRI-125 was not placed correctly and SLN was not located due to non-migration. In 61.9% of the patients, the GM was among the SLN(s) identified at surgery. In 5 patients, with non-coincident SLN and GM, the pathological result of the SLN was negative and the LM was positive. Axillary lymphadenectomy was performed in 53.8% of the patients. ***Conclusion:*** The addition of the SPECT/CT study to the lymphoscintigraphy is of special interest in patients with axillary labeling with I125 seeds, it allows to see coincidence with sentinel node and improves the surgical approach.

## EP-0629

### PSF correction and Tc-99m quantitative performance of a disruptive CZT multiple-head SPECT-CT

***A. Seret***[1], *C. Bernard*[2];
[1]*UNIVERSITY OF LIEGE, Liege, BELGIUM,*
[2]*CHU of LIEGE, Liege, BELGIUM.*

***Aim/Introduction:*** A methodology developed for a comparison of NaI SPECT-CT [1] was used to analyze the quantitative potentialities of a CZT multiple-head SPECT-CT. ***Materials and Methods:*** Phantoms: NEMA NU-2 1994 scatter, 9.4-cm (L) and 20-cm (XL) diameter cylinder. The last one was also converted in a contrast phantom (TOM) with two cold and hot rods inserts while leaving a uniform compartment. They were filled with 730-860 (360 for L) MBq of Tc99m and concentration was identical in all radioactive part. Acquisitions: Veriton 200, Focus mode, 4 orbits, 100 (800 for L) Mcounts, 2.46-mm pixels, WEHS collimator, factory default energy windows. Reconstructions: OSEM, CT-based attenuation, resolution recovery, optional scatter correction (SC) with dual-energy window, additional PSF recovery so-called quantitative (PSFRq) or display (PSFRd), OSEM iterations x subset number (ITER) from 40 to 240. Processing: NEMA NU-2 1994 methodology was followed to get the residual fraction (RF) in air, water and Teflon inserts of NEMA phantom. Cylindrical ROIs of about 35% rod height and rod full (FROI) or half (HROI) physical diameter (d) were drawn on the CT images of TOM together with a large cylindrical ROI in the uniform part. Mean ROI count per pixel (C) was computed and also standard deviation (SD) in the large ROI. Recovery coefficient (RC) was computed as $C_{rod}/C_{uniform}$ for hot rods and $1-C_{rod}/C_{uniform}$ for cold rods. Coefficient of variation (COV) in the uniform part was $SD/C_{uniform}$. Calibration factor (CF) were obtained from L and XL phantom using large cylindrical ROIs and applied to C of TOM uniform part and NEMA radioactive area. ***Results:*** RF decreased when ITER increased, was 5.5-10% without SC and 0-2% with SC. RC increased with ITER and rod diameter. For cold rods, a plateau was reached for d≥20mm at (FROI/HROI): 56/68%, 79/95% (SC), 57/70% (PSFRq), 80/97% (PSFRq+SC), 79/89% (PSFRd). Up to 10mm hot rods, RC increase was steep and then RC fluctuated with a maximum at d=20mm (FROI/HROI): 47/74%, 51/88% (SC), 49/77% (PSFRq), 52/88% (PSFRq+SC), 91/209% (PSFRd). COV increased almost linearly with ITER: 4.7-6.8%, 5.9-8.6% (SC), 5.1-7.3% (PSFRq), 6.3-9.3% (SC+PSFRq), 11.6-16.1% (PSFRd). Quantification error (SC and SC+PSFRq) depended moderately on the phantom and ROI size used to obtain CF and was in the range [-2.5,3.4]% for TOM and [-5.4,2.9]% for NEMA. ***Conclusion:*** SC or PSFRq increased contrasts but moderately for hot rods. SC or PSFR increased COV. PSFd should be restricted to visualization purpose. ***References:*** [1] EJNMMI Research 2012, 2:45.

## EP-0630

### Energy window narrowing or classical dual-energy window substraction for scatter correction in a CZT multiple-head SPECT-CT

***A. Seret***[1], *C. Bernard*[2];
[1]*UNIVERSITY OF LIEGE, Liege, BELGIUM,*
[2]*CHU of LIEGE, Liege, BELGIUM.*

***Aim/Introduction:*** A methodology developed for a previous comparison of SPECT-CT [1] was used to analyze scatter removal in a CZT multiple-head SPECT-CT. ***Materials and Methods:*** Phantoms: NEMA NU-2 1994 scatter (770 MBq) and 20-cm diameter cylinder (950 MBq) with cold and hot rods inserts and a uniform compartment (identical concentration in all radioactive part). Acquisitions: StarGuide, focus mode, 4 orbits, 100 Mcounts, 2.46-mm pixels, standard tungsten collimator, list-mode files. Reconstructions: OSEM, CT-based attenuation, resolution recovery, 6, 10, 15, 20% wide main peak energy window (EW), optional dual-energy window scatter correction (DEW) with 20% main and 10% secondary scatter energy windows, OSEM iterations x subset number (ITER) from 40 to 200. Processing: NEMA NU-2 1994 methodology was followed to get the residual fraction (RF) in air (A), water (W) and Teflon (T) inserts of NEMA phantom. Cylindrical ROIs of about 35% rod height and rod full (FROI) or half (HROI) physical diameter (d) were drawn on the CT images of contrast phantom together with a large cylindrical ROI in the uniform part. Mean ROI count per pixel (C) was computed and also standard deviation (SD) in the large ROI. Recovery coefficient (RC) was computed as $C_{rod}/C_{uniform}$ for hot rods and $1-C_{rod}/C_{uniform}$ for cold rods. Coefficient of variation (COV) in the uniform part was $SD/C_{uniform}$. ***Results:*** Reported values are for ITER200 and for d=20mm in contrast phantom. RF decreased when ITER increased down to (A/W/T) 1/9/2.2% (EW20) and 1.8/0.6/0.001 (DEW). Additional RF results for the other energy window will be added. RC increased with ITER. For cold rods, RC increased with d reaching a plateau for d≥20mm at (FROI/HROI): 68/87% (EW20), 70/85% (EW15), 73/87% (EW10), 74/89% (EW6),81/93% (DEW). Smallest hot rods were not visible for d≤13mm with DEW. RC was below 10% for d=4mm and all EW and fluctuated for the other rods (6-20mm) with a maximum (FROI/HROI) at d=20mm: 51/74% (EW20), 52/77% (EW15), 54/81% (EW10), 55/84% (EW6), 8/31% (DEW). $C_{uniform}$ was 89% (EW15), 76% (EW10), 59% (EW6), 63% (DEW) of its value for EW20. COV increased almost linearly with ITER and reached 10.3% (EM20), 10.8% (EM15), 11.7% (EM10), 13.5% (EM6), 12.9% (DEW) at ITER200. ***Conclusion:*** This study questions the use of the classical wide energy windows and scatter correction methods for this SPECT systems fitted with CZT detectors.

## EP-0631

### Small feature quantification in SPECT/CT - a focus on mandibular condyles

***S. De Schepper***[1,2], *O. Lenssen*[3], *G. Gnanasegaran*[4], *T. Van den Wyngaert*[1,2], *J. C. Dickson*[5];
[1]*Department of Nuclear Medicine, Antwerp University Hospital, Edegem, BELGIUM,* [2]*Faculty of Medicine and Health Sciences (MICA—IPPON), University of Antwerp, Wilrijk, BELGIUM,* [3]*Department of Oral and Maxillofacial Surgery, ZNA Middelheim, Antwerp, BELGIUM,* [4]*Department of Nuclear Medicine, Royal Free London NHS, London, UNITED KINGDOM,* [5]*Institute of Nuclear Medicine, University College of London Hospitals NHS Foundation Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** Unicondylar hyperplasia (UCH) causes facial asymmetry, and bone scintigraphy is the standard to assess growth and guide treatment. However, reconstruction and analysis techniques are heterogeneous, producing conflicting results. Absolute quantification using SPECT/CT may offer a solution, yet, concerns exist regarding its limited spatial resolution and associated partial volume effects (PVE), hampering its use in smaller features below 2cm, such as the condyles. Partial volume correction (PVC) may overcome these limitations using recovery coefficients (RC), typically derived from a NEMA IQ phantom. We aimed to determine the impact of PVE in UCH using the NEMA IQ phantom and hypothesized that disease-specific anthropomorphic phantoms could provide superior results. ***Materials and Methods:*** Anthropomorphic phantoms were created using patient CT data and consisted of two spheres enclosed within a background volume simulating bone (with an $HK_2O_4P$ solution to mimic trabecular bone density). One phantom modeled normal anatomy (both spheres: Ø 8mm) and one UCH (left: Ø 8mm, right: Ø 13mm). Phantoms were filled with a clinically relevant spheres-to-background ratio of 120kBq/mL:40kBq/mL of activity ($^{99m}$Tc). The impact of the PVE was assessed using clinically relevant acquisition protocols of the phantoms with/without resolution modeling (RM) reconstructions. Next, we compared RCs derived from NEMA phantom data and our anthropomorphic phantom to perform PVC and assess the quantitative accuracy. ***Results:*** The PVE was significant for the anthropomorphic phantom's 8mm and 13mm spheres, with a recovery of 47% and 71% of the true activity, respectively. Without the application of RM recovery significantly worsened to 29% and 44%, respectively. However, using RM leads to an overestimated recovered activity in the background volume from 86% to 126%. Using the NEMA phantom-derived RC of 26% for the 8mm spheres and 48% for 13mm resulted in an overestimation of true activity by 81% and 61% for the 8mm and 13mm spheres, respectively. The dependency of RCs on sphere position in the NEMA phantom could explain this observation, as we observed varying RCs for 8mm between 26% to 46% depending on sphere positions. Interestingly, using our anthropomorphic phantoms, applying the RC derived from the UCH phantom to the symmetric phantom, showed significant improvements in the deviations from the true activity concentration in left and right condyle: -2.6% and +2.5% (with RM) and +1.1% and -11.7% (without RM), respectively. ***Conclusion:*** Absolute quantification on SPECT/CT of small features benefits from anthropomorphic phantoms to improve the recovered activity, with potential clinical relevance in UCH.

## EP-0632

### Reduction of the acquisition time and improvement of the dopaminergic imaging quality with CZT gamma camera. Comparison with conventional gamma cameras.

***S. Asadurova***, *C. Lorenzo-Bosquet, S. Aguade, A. García-Burillo;*
*Hospital Universitari Vall d´Hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** Validate a 50% reduction in dopaminergic imaging acquisition time without affecting the visual or semiquantitative analysis of the studies. Comparison with conventional gamma cameras. ***Materials and Methods:*** 25 consecutive studies performed with each gamma camera are compared, analyzing parameters of: acquisition (matrix, zoom, pixel size, total counts, maximum counts/pixel), visual analysis (definition, contrast, resolution) and quantitative using DaTQUANT™ (SBR: Striatal Binding Ratio). All patients were injected with 185 MBq 123I-FP-CIT, with image acquisition 3 hours post injection. The conventional acquisition protocol uses LEHR collimators, 128x128 matrix, with 1.45 zoom and 3.3 mm pixel for G2, and 1.5 and 2.95 mm for G3. The G1 consists of 12 CZT detectors (CZT crystal thickness 7.25 mm, energy range 40-279 keV) in a circular arrangement, ME/LEHR collimator, 2.46 mm pixel size, with

adjustable zoom and matrix.The acquisition time is 30 minutes for G2 and G3, and 15 minutes for G1. It has been reconstructed with FBP and Metz 0.3/15 for the conventional ones, and Q.Clear, Butterworth 0.9/5 for the CZT, all without attenuation correction. The visual analysis was performed by a resident physician and two experts. ***Results:*** The average number of total counts in the entire detection field was 2,522,556 for G3, 2,152,531 for G2, and 1,124,763 for G1. The average number of maximum counts/pixel was 41 for G3, 73 for G2 and 85 for G1. Visual analysis shows greater contrast, definition and resolution in G1 images compared to conventional ones. No inter-observer differences have been found in the assessment of definition, contrast and resolution between the images from all the gamma cameras. In quantification, no significant differences in SBR values were observed between the different gamma cameras. ***Conclusion:*** The CZT gamma camera allows a significant reduction in acquisition time and better image quality, without affecting visual interpretation or quantification.

## EP-0633

### The Art of Juggling: On the Influence of Sphere Positioning on Recovery Coefficients Determined Using an IEC-NEMA Phantom

***J. Leube***[1], *J. Gustafsson*[2], *M. Lassmann*[1], *M. Salas Ramirez*[1], *J. Tran-Gia*[1];
[1]*University Hospital Würzburg, Würzburg, GERMANY,* [2]*Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** The NEMA IEC PET Body Phantom ("NEMA Phantom") with sphere inserts represents the go-to method for recovery assessment and partial volume correction in PET/CT and SPECT/CT imaging. Aiming at a reliable harmonization between imaging sites, this work investigates the influence of the sphere positioning on sphere-based recovery coefficients (RC). ***Materials and Methods:*** An in silico model of a NEMA Phantom was created based on sphere centers, attenuation map and detector trajectory of a clinical SPECT/CT measurement. Simulations for all 720 possible permutations of the sphere positioning were performed for two sets of spheres (standard NEMA Phantom with diameters 10-37 mm ["NEMA_PET"] and adapted SPECT NEMA Phantom with diameters 13-60 mm ["NEMA_SPECT"]) using the SIMIND [1] Monte Carlo program. Reconstructions were performed using OSEM without (CASToR [2], AC, SC, 5 iterations, 10 subsets, "OSEM") and with PSF modelling (STIR [3], AC, SC, 20 iterations, 10 subsets, "OSEM_PSF"). Recovery Coefficients (RC) were calculated as the ratio of SPECT-based activity (nominal contour) to known sphere activity. A fit of the recovery curve as function of the volume V was performed: $f\_RC(V)=1/(1+(\beta/V)^{\gamma})$. ***Results:*** In general, OSEM resulted in lower RCs than OSEM_PSF (NEMA_PET: 0.09/0.41 [10mm] - 0.60/0.89 [37mm], NEMA_SPECT: 0.10/0.57 [13mm] - 0.72/1.00 [60mm] for OSEM/OSEM_PSF). Furthermore, a strong dependence of the sphere positioning on RC was found, where again, OSEM_PSF outperform OSEM (maximum RC variation with respect to the mean [(maximum-minimum)/mean], NEMA_PET: 97%/48% [10mm] - 15%/7% [37mm], NEMA_SPECT: 110%/60% [13mm] - 10%/7% [60mm] for OSEM/OSEM_PSF). For OSEM, a strong dependence of RC on the distance between sphere and detector was found, with the largest RCs when positioning the sphere at the top of the phantom (smallest possible distance between sphere and detector). For OSEM_PSF, RC mainly depends on the volumes of the two adjacent spheres. Thus, the adjacency of the largest spheres resulted in smaller RCs. The sphere positioning also influenced the fit parameters and thus also a potential partial volume correction (mean±standard deviation; NEMA_PET: β=(12.6±0.9)ml, γ=0.66±0.05/ β=(0.67±0.12)ml, γ=0.82±0.13; NEMA_SPECT: β=(15.2±0.6)ml, γ=0.59±0.04/ β=(0.70±0.22) ml, γ=0.71±0.12). ***Conclusion:*** Our study shows that sphere positioning has a considerable influence on recovery coefficients obtained in NEMA Phantom measurements. This applies to both the standard NEMA Phantom (diameters 10-37 mm) and a NEMA phantom adapted for SPECT imaging (diameters 13-60 mm). ***References:*** [1] Ljungberg et al., Comput Meth Prog Bio, 1989(29) [2] Merlin et al., Phys Med Biol, 2018(63) [3] Thielemans et al., Phys Med Biol, 2012(57)

## EP-0634

### Objective Assessment of Gamma Camera's Intrinsic Resolution

***P. Trindev***[1], *M. Dimcheva*[2];
[1]*Retired, 1233 Sofia, BULGARIA,* [2]*Department of Nuclear Medicine, Sofia Cancer Center, Sofia, BULGARIA.*

***Aim/Introduction:*** This study aimed to design a new test pattern that would provide a more accurate estimate of intrinsic resolution.There are three main parameters of the detector field of the gamma camera - sensitivity, linearity, and intrinsic resolution. Sensitivity and linearity are software supported online in acceptable limits across the entire detector field. In time, methods have been developed for a sufficiently accurate assessment of sensitivity and linearity to objectively verify the values declared by the manufacturer in a datasheet. The situation is different in the third parameter - intrinsic resolution. The problem lies in the fact that intrinsic resolution varies across the entire detector field. Therefore, the recommended objective method (1) for assessing intrinsic resolution is based on the average estimate of many 30 mm bins, with the assessment result greater than the value declared in the datasheet. ***Materials and Methods:*** We have developed a new phantom, further referred to as TP-phantom, which consists of 2 parts - a slit phantom and an irradiation source. The slit phantom consists of 2 lead plates 33x110x5 mm each, which are fixed stationary with 2 additional aluminum tiles. The slit width between the two lead plates can be adjusted down to a size 10 пъти по-малък от измерваната стойност. The desired slit width is established with a gamma radiation transparent insert - for example, cardboard with corresponding thickness. The irradiation source is a vial with Tc-99m solution encapsulated in a lead container. At the bottom of the container, a hole with a diameter of 25 mm is cut to irradiate the slit. ***Results:*** Easy access to any point of the detector field allows us to determine exactly the extreme points of the intrinsic resolution - on a PMT and between 2 PMTs, respectively. A method of evaluating intrinsic resolution by measurement at constant support points is proposed. This approach allows us to objectively verify the value of intrinsic resolution in the datasheet during acceptance testing as well as to track the status in subsequent testing. ***Conclusion:*** The TP-phantom provides the following advantages: access literally to any point of the UFOV; adjustable slit width; adjustable count rate (below 20 kcps); short time to collect reliable information; zero radiation hazard for staff. ***References:*** 1. National Electrical Manufacturers Association. NEMA NU 1. (2018) Performance measurement of scintillation cameras. Rosslyn,VA: NEMA. 6-10

## EP-0635

### Calibration Factor and Recovery Coefficients for Lu-177 in a ring-shaped CZT gammacamera

***A. Garcia***, *A. Seoane;*
*Vall d'Hebron Hospital Campus, Barcelona, SPAIN.*

***Aim/Introduction:*** Targeted radionuclide therapies with Lu-177 isotope have experienced a great increase during last years due to well-established treatments in neuroendocrine tumours, and new prostate-specific membrane antigen labelled with Lu-177. The possibility to calculate the absorbed dose to tumour and organs for every patient based on imaging, allows to make individual dose prescriptions.The recently developed family of gammacameras based on cadmium-zinc-telluride (CZT) detectors arranged in a ring reduce the time needed to acquire SPECT.We determined the Calibration Factor (CF) and Recovery Coefficients (RCs) for the General Electric Starguide gammacamera (CZT), and compared to values obtained in the Anger-type camera GE Discovery NM670 (NaI crystal based detectors, MEGP collimator). ***Materials and Methods:*** The CF was determined by acquiring a SPECT of a cylindrical phantom filled with Lu-177. Images were acquired for the 208 keV emission peak, with an energy window of ±6% for the Starguide during 600 s, and ±10% for the Discovery during 1125 s (90 projections, 45 s/projection). CFs were obtained by measuring the counts per second divided by the activity within a spherical volume of diameter 15 cm.To measure the RCs, a NEMA/IEC Body Phantom was filled with a sphere-to-background activity ratio of 27:1. RCs were obtained by measuring the cps divided by the activity in the spheres defined by a threshold. SPECTs were corrected for scatter, attenuation and detector resolution. The algorithms used for reconstruction were Q.Clear for the Starguide and OSEM for the Discovery, both with 10 subsets and 4 to 50 iterations, with and without a Butterworth Filter (BWF) (critical frequency = 0.4; power = 10) applied. ***Results:*** Mean CFs with BWF were 79.4 and 21.6 cps/MBq for the Starguide and Discovery respectively. No differences were found without BWF applied. CFs were stable with the number of iterations, with maximum deviations of 1.9% for Starguide and 0.8% for Discovery. The RCs increased with iterations from 4 to 20, remaining stable after this value. Table shows the RCs for 20 iterations. Values for Starguide camera compared to Discovery for diameters > 2 cm were on average 9% and 14% lower with and without BWF applied respectively. ***Conclusion:*** Lu-177 Calibration Factor for the Starguide CZT camera was almost 4 times greater than for the Discovery. This allows a considerable reduction in the clinical imaging time.The Recovery Coefficients were found to be slightly lower in the Starguide camera and remained stable for N≥20 iterations.

## EP-0636

### Reducing scan time for post-therapy [131I]NaI SPECT/CT scans and [99mTc]Tc-HDP bone scintigraphy SPECT

***T. Ball***, *K. Sabanayagam, H. McMeekin, A. Haroon, M. Vadrucci, J. Buscombe, E. Nowosinska, M. Krishnamurthy;*
*Barts Health NHS Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** SPECT/CT scans post [$^{131}$I]NaI administration for thyroid ablation therapy are performed to assess radiopharmaceutical uptake and guide future treatment. Two- or three-bed SPECT images are often acquired with unacceptably long scan durations for patient comfort and departmental throughput. It was aimed to assess whether scan times could be reduced using third-party SPECT reconstruction software while maintaining acceptable image quality. [$^{99m}$Tc]Tc-HDP is administered to patients in order to visualise bone uptake. A reduction in scan time would allow for improved departmental throughput and patient comfort, or a reduced injected activity. These scans will be assessed using the same method as per the [$^{131}$I]NaI scans. ***Materials and Methods:*** Poisson resampling was used to simulate scan durations 30% and 50% that of the original. OSEM reconstruction was applied with 5i15ss, CTAC, MC scatter correction, Gaussian resolution recovery, and a 0.9cm FWHM Gaussian post-filter. Another reconstruction applied advanced MC collimator modelling for I-131. These reconstructions and the current reconstruction performed on the acquisition station were presented, randomised and de-identified, to three NM consultants for scoring on a scale of 1-5 for diagnostic confidence. At the time of presenting this method will also have been applied to [$^{99m}$Tc]Tc-HDP bone scintigraphy SPECT scans using a reconstruction with identical parameters but 16 subsets. 10 patient studies were included for the [131I]NaI post-therapy scans and by the time of publication a further 10 will be included for [$^{99m}$Tc]Tc-HDP acquisitions. ***Results:*** Two-tailed T-tests of the average score for each reconstruction compared with the current reconstruction showed no statistically significant differences ($p > 0.05$) apart from one ($p = 0.003$), where MC collimator modelling was applied to full count data. The average scores for the current reconstruction, third-party 30%, third-party 50%, and third-party 100% were 3.19 (SD 0.48), 3.22 (SD 0.52), 3.42 (SD 0.48), and 3.55 (SD 0.39). The MC collimator modelling offered no significant benefits in diagnostic confidence for the reduced count data. Early results of the same type for reconstructed [$^{99m}$Tc]Tc-HDP scans indicate similarly that reducing acquisition time by 50% would not reduce clinical confidence in patient scans, for the final report further data will be acquired. ***Conclusion:*** These data support scanning at 50% or even 30% of the current acquisition time using the third-party reconstruction software for [$^{131}$I]NaI scans. ***References:*** Sohlberg, A. O., & Kajaste, M. T. (2011). Fast Monte Carlo-simulator with full collimator and detector response modelling for SPECT. Annals of Nuclear Medicine.

### The earlier 18F-FDG and 68Ga-DOTA-FAPI-04 dual-tracer total-body PET/CT scan timing: a feasibility study

***Z. Zheng***, *Y. He, W. Mao, H. Yu, H. Wu, P. Hu, H. Shi;*
*Zhongshan hospital, fudan university, Shanghai, CHINA.*

***Aim/Introduction:*** To investigate the feasibility of 2-[$^{18}$F]-fluoro-2-deoxy-D-glucose-fibroblast activation protein inhibitors (FDG-FAPI) dual-tracer positron emission tomography/computed tomography (PET/CT) earlier imaging. ***Materials and Methods:*** Thirty-seven patients who underwent FDG-FAPI dual tracer imaging with $^{18}$F-FDG (0.37MBq/kg) and $^{68}$Ga-FAPI-04 (0.925MBq/kg) were enrolled retrospectively; among them, 11 patients were confirmed by pathological examination. Another 11 patients who underwent 60-min dynamic $^{68}$Ga-FAPI-04 scans were selected accordingly for matching with the pathological results. The image of the FDG-FAPI group was reconstructed at 34-39min and 50-60min, named $PET_{G34-39}$ and $PET_{G50-60}$, respectively. The image of the $^{68}$Ga-FAPI-04 group was reconstructed at 34-39min and named $PET_{FAPI}$. The image quality was evaluated by objective analysis. Objective analysis indicators of PET image quality included the mean of standardized uptake value (SUVmean) of the liver, standard deviation (SD) and

signal-to-noise ratio (SNR). The background SUVmean, lesion SUVmean and lesion-to-background ratios (LBRs) were compared between $PET_{G34-39}$, $PET_{G50-60}$ and $PET_{FAPI}$. To determine the lesions detectability at $PET_{G34-39}$, $PET_{G50-60}$ served as the reference. ***Results:*** Most normal organs were significantly higher on $PET_{G34-39}$ than on $PET_{FAPI}$. Liver SNR on $PET_{G34-39}$ (18.36±7.43) was lower than that on $PET_{G50-60}$ (21.64±8.74) and $PET_{FAPI}$ (21.65±5.18), but the differences were not significant (P=0.07, P=0.06, respectively). Liver SUVmean on $PET_{G34-39}$ was significantly higher than that on $PET_{FAPI}$ (1.97±0.82 vs 1.32±0.54, P=0.03), but was similar with $PET_{G50-60}$ (1.97±0.82 vs 1.93±0.88, P=0.95). Although the LBRs on $PET_{G34-39}$ were higher than that on $PET_{G50-60}$ and $PET_{FAPI}$, there were no statistically difference among them (all P>0.05). The SUVmean of metastases on $PET_{G34-39}$ were higher than that on $PET_{G50-60}$ (lymph nodes metastases: 7.05±2.36 vs 6.05±2.11, P<0.001; distant metastases: 8.10±3.32 vs 7.12±2.89, P=0.005). $PET_{G34-39}$ and $PET_{G50-60}$ were comparable with lesions detectability. The SUVmean of distant metastases on $PET_{G34-39}$ was significantly higher than that on $PET_{FAPI}$ (8.10±3.32 vs 4.14±2.80, P=0.008), but there was no statistically significant difference in LBRs. The SUVmean and LBRs of primary tumours and metastatic lymph nodes were not statistically different between that on $PET_{G34-39}$ and $PET_{FAPI}$. ***Conclusion:*** Dual-tracer (FDG-FAPI) PET at 34-min could provide sufficient information to meet the needs of clinical diagnosis and demonstrate better compatibility and feasibility with clinical practice.

## EP-0638

### Clinical evaluation of a head motion correction algorithm on PET/CT system

***W. Yang***[1], *F. Kang*[1], *Z. Xie*[1], *G. Li*[1], *K. Guo*[1], *C. Xi*[2], *H. Liu*[2], *Y. Li*[2], *C. Sun*[2], *E. M. Revilla*[2], *Y. Zhao*[2], *D. Zhang*[2], *L. Shi*[2], *H. Yi*[2], *Y. Zhao*[2], *Y. Lu*[2], *J. Wang*[1];
[1]*Department of Nuclear Medicine, Xijing hospital, Xi'an, CHINA,* [2]*United Imaging Healthcare, Shanghai, CHINA.*

***Aim/Introduction:*** In brain PET imaging, head motion (HM) is a major limitation that reduces image resolution and generates artefacts. In clinical settings, accurate quantification is crucial in treatment planning, diagnosis and response evaluation. Thus, modern PET scanners with higher spatial resolution are now being developed, e.g., sub 3-mm in full-width-half-maximum and even minor HM may cause resolution loss. Recently, a data-driven head motion correction (HMC) algorithm, which is a statistics-based HMC method that automatically detects HM using centroid-of-distribution (COD) without parameter tuning, is provided for the PET/CT system. The aim of this work is to evaluate this vendor-provided HMC algorithm and to reveal the head motion prevalence among short clinical $^{18}$F-FDG scans. To the best of our knowledge, this is the first study that applied an HMC algorithm to a relatively large clinical cohort. ***Materials and Methods:*** Single-bed, 3-min brain $^{18}$F-FDG scans (N=392) were retrospectively analyzed. CT scan was conducted prior to PET for attenuation correction. For each study, an in-house CT segmentation algorithm was used to segment the brain into 116 regions of interests (ROIs). A binary gray-matter (GM) mask was also generated. The intersection between the GM mask and 116 ROIs were used to generate the refined 116 ROIs. By merging all the refined ROIs into 11 regions based on the AAL definition, final 11 GM ROIs were generated. Furthermore, results were divided into two categories: small and large motion, where SUV change smaller/larger than 5% at frontal lobe after HMC was used as the criteria for grouping. ***Results:*** Quantitative results of SUV change at different GM ROIs showed that 38 of the participants experienced large HM and yielded 10.9±8.9% SUV increase after HMC while the rest showed insignificant uptake increase (0.1±1.3%). For large GM regions, SUV increase in frontal and temporal regions were 12.9±8.3% and 10.0±8.1%, respectively. Conversely, small GM regions like caudate and amygdala yielded 22.9±13.7% and 19.9±20.8% increase in uptake, respectively. Overall, the magnitude of motion in the large motion category (5.6±3.7 mm, 2-3 min post injection) was greater than it in the small motion (1.3±1 mm). ***Conclusion:*** We evaluated the efficacy of a vendor-provided HMC algorithm using short clinical $^{18}$F-FDG studies for a PET/CT system. The evaluation study revealed that approximately 12% of the clinical brain studies experienced large magnitude head motion that require correction. The HMC algorithm effectively corrected for HM and regarded sufficient for clinical brain $^{18}$F-FDG studies.

## EP-0639

### 18F-FDG PET/CT for evaluation of metastases in non-small cell lung cancer on the efficacy of immunotherapy

***Y. Feng****, P. Wang, Y. Chen, W. Dai;*
*Department of Nuclear Medicine, The First College of Clinical Medical Science, China Three Gorges University, Yichang city, CHINA.*

***Aim/Introduction:*** Aim This study aimed to investigate the relationship between metabolic parameters and metastases and the efficacy of ICIs treatment for advanced non-small cell lung cancer (NSCLC). ***Materials and Methods:*** 34 advanced NSCLC patients who received $^{18}$F-fluorodeoxyglucose positron emission tomography/computed tomography ($^{18}$F-FDG PET/CT) before ICIs treatment were retrospectively included in this study. All patients were divided into two groups, the clinical benefit (CB) group and the no-clinical benefit (no-CB) group and the clinical information, survival, and glucose metabolic parameters were evaluated. ***Results:*** 24 patients were in the CB group, and 10 patients were in the no-CB group. There was a significant difference between the CB group and the no-CB group in TNM stages, metabolic tumor volume of primary lesion (MTV-P, P=0.003), metabolic tumor volume of lymph node metastasis (MTV-LN, P=0.023), total lesion glycolysis of lymph node metastasis (TLG-LN, P=0.023), metabolic tumor volume of whole-body (MTVwb, P=0.005) and total lesion glycolysis of whole-body (TLGwb, P=0.015). For patient outcomes, the independent prognostic factor associated with PFS were TNM IV stage (HR=0.14, 95%CI 0.04 ~0.53, P=0.00), TLG-P>7.512 (HR=0.11, 95% CI 0.03 ~0.50, P=0.11), TLG-LN>61.06 (HR=0.12, 95% CI 0.03 ~0.45, P=0.00). But there was not any independent prognostic factor associated with OS. ***Conclusion:*** High MTV and TLG predicted poor clinical benefit and a large burden of metastatic lymph nodes predicted short PFS in advanced NSCLC with ICI treatment in advanced NSCLC patients.

## EP-0640

### PET imaging and quantification of small animals using a clinical SiPM-based camera

***C. Desmonts***[1,2], *C. Lasnon*[3,2], *C. Jaudet*[3], *N. Aide*[2];
[1]*Caen University Hospital, Caen, FRANCE,* [2]*Normandy University, UNICAEN, INSERM 1086 ANTICIPE, Caen, FRANCE,* [3]*Comprehensive Cancer Centre F. Baclesse, Caen, FRANCE.*

***Aim/Introduction:*** Small-animal PET imaging is an important tool in preclinical oncology. This study evaluated the ability of a clinical SiPM-PET camera to image several rats simultaneously and to perform quantification data analysis. ***Materials and Methods:*** Intrinsic spatial resolution was measured using 18F

line sources, and image quality was assessed using a NEMA NU 4-2018 phantom. Quantification was evaluated using a fillable micro-hollow sphere phantom containing 4 spheres of different sizes (ranging from 3.95 to 7.86 mm). Recovery coefficients were computed for the maximum (Amax) and the mean (A50) pixel values measured on a 50% isocontour drawn on each sphere. Measurements were performed first with the phantom placed in the centre of the field of view and then in the off-centre position with the presence of three scattering sources to simulate the acquisition of four animals simultaneously. Quantification accuracy was finally validated using four 3D-printed phantoms mimicking rats with four subcutaneous tumours each. All experiments were performed for both 18F and 68Ga radionuclides. ***Results:*** Radial spatial resolutions measured using the PSF reconstruction algorithm were 1.95 mm and 1.75 mm for centred and off-centred acquisitions, respectively. Spill-overs in air and water and uniformity computed with the NEMA phantom centred in the FOV were 0.05, 0.1 and 5.55% for 18F and 0.08, 0.12 and 2.81% for 68Ga, respectively. Recovery coefficients calculated with the 18F-filled micro-hollow sphere phantom for each sphere varied from 0.51 to 1.43 for Amax and from 0.40 to 1.01 for A50. These values decreased from 0.28 to 0.92 for Amax and from 0.22 to 0.66 for A50 for 68Ga acquisition. The results were not significantly different when imaging phantoms in the off-centre position with 3 scattering sources. Measurements performed with the four 3D-printed phantoms showed a good correlation between theoretical and measured activity in simulated tumours, with $r^2$ values of 0.99 and 0.97 obtained for 18F and 68Ga, respectively. ***Conclusion:*** We found that the clinical SiPM-based PET system was close to that obtained with a dedicated small-animal PET device. This study showed the ability of such a system to image four rats simultaneously and to perform quantification analysis for radionuclides commonly used in oncology.

## EP-0641

### Value of 2-[18F]FDG-PET/CT in detecting immune-related adverse events in patients with malignant melanoma or non-small cell lung cancer: a systematic scoping review

***S. Nadaraja***[1], *J. Helsing*[1], *M. Bezhad*[1], *L. H. Land*[2], *C. H. B. Ruhlmann*[2], *O. Gerke*[1,3], *M. G. Hildebrandt*[1,3,4];
[1]*Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK,* [2]*Department of Oncology, Odense University Hospital, Odense C, DENMARK,* [3]*Department of Clinical Research, University of Southern Denmark, Odense C, DENMARK,* [4]*Centre for Personalized Response Monitoring in Oncology (PREMIO), Odense University Hospital, Odense C, DENMARK.*

***Aim/Introduction:*** The aim of this systematic scoping review was to outline 2-[18F]FDG-PET/CT-reported prevalence of immune-related adverse events (irAEs) and evaluate the diagnostic accuracy of 2-[18F]FDG-PET/CT in identifying irAEs in patients with metastatic malignant melanoma or non-small cell lung cancer (NSCLC), receiving treatment with immune checkpoint inhibitors (ICIs). ***Materials and Methods:*** A comprehensive literature search was performed on April 11, 2023, using Medline (PubMed), Embase, and Scopus databases without time restriction. After applying inclusion/exclusion criteria and abstract/full-text review, seven articles with 478 patients with malignant melanoma and two articles with 155 patients with NSCLC were included in the analysis. The reference standard was irAE, corroborated clinically, biochemically, histologically, or on other imaging modalities. This work was conducted according to PRISMA guidelines for scoping reviews. ***Results:*** Malignant melanoma: Five studies reported the sensitivity of 2-[18F]FDG-PET/CT, while two reported the prevalence of irAEs detected only by 2-[18F]FDG-PET/CT (without other verification of irAEs).[1-7] The clinically reported prevalence of irAEs was 14-18% for thyroiditis and 29% for colitis. The sensitivity of FDG-PET/CT was 100% for thyroiditis and 49% for colitis, and the sensitivity for a sarcoid reaction in mediastinal lymph nodes, lungs, and skin was 100%, 43%, and 29%, respectively. In another study, sensitivity and specificity were 100% and 49% for irAEs relating to bowel, 100% and 96% for lung, and 89% and 81% for thyroid. [7] Lung cancer: The prevalence of 2-[18F]FDG-PET/CT detected irAEs included midgut/hindgut inflammation (36%), gastritis (21%), pneumonitis (18%), and thyroiditis (15%).[8] A sensitivity of 60% has been demonstrated for thyroiditis.[9] ***Conclusion:*** Studies suggest that 2-[18F]FDG-PET/CT is a valuable, non-invasive tool for detection of adverse events to anticancer treatment with ICIs. This allows for swift and relevant clinical management of irAEs for the benefit of patients. Prospective studies exploring the clinical impact are needed to determine the role and optimal timing of FDG-PET/CT in identifying irAEs. ***References:*** 1.Melin A, et al.Cancers.2022. 2.Lang N, et al.Immunotherapy.2019. 3.Frelau A, et al.Cancer Immunol Immunther.2021. 4.de Filette J, et al.J Clin Endocrinol Metab.2016. 5.Tirumani SH, et al.Cancer Immunol Res.2015. 6.Iravani A, et al.Eur J Nucl Med Mol Imaging.2020.7.Hribernik N, et al.Eur J Nucl Med Mol Imaging.2022 8.Humbert O, et al.Eur J Nucl Med Mol Imaging.2022. 8.Eshghi N, et al.J Nucl Med Technol.2018.

## EP-0642

### Quantitative consistency assessment along the axial field of view of a total-body PET scanner

***X. Meng***[1], *Y. Wu*[2], *F. Wang*[1], *Y. Song*[1], *R. Wu*[2], *N. Li*[1], *Z. Yang*[1];
[1]*Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Shanghai United Imaging Healthcare, Shanghai, CHINA.*

***Aim/Introduction:*** Total-body PET scanners (TB-PET) extend the axial field of view (AFOV) and add a new dimension to the detector structure. Obvious image quality inconsistency has been noticed between the central and peripheral parts of the scanner. This study aims to assess the quantitative consistency along the AFOV of a TB-PET. ***Materials and Methods:*** The TB-PET studied contains 8 detector units that span 1.94 m. The quantification process was conducted based on the EARL recommendation. However, the phantoms were placed across the AFOV, including the 8 centers of each unit and the 8 joints between adjecent units. The NEMA IQ phantoms was acquired at each position for 10 min, and the relative change of the activity during the acquisition period was contorlled within ±10%. Three positron emitters including $^{18}$F, $^{68}$Gas and $^{89}$Zr was used in this study. The image was reconstructed using 3 iterations, 20 subsets, point spread function (PSF) enabled, and no Gaussain filter. The results were quantified with a custom software called BCH_EARL, and the recovery coefficients (RC) including $RC_{mean}$, $RC_{max}$, and $RC_{peak}$, were obtained for each hot sphere at each position with each positron emitter. ***Results:*** The $RC_{mean}$ and $RC_{max}$ for the larger spheres fluctuated very little along the axial direction, while those for the smaller spheres fluctuated obviously. Take $^{18}$F for example, the $RC_{mean}$ for the 37 mm large sphere fell into the narrow range between 0.88 and 0.93, while the $RC_{mean}$ for the 10 mm small sphere fell from 1.13 by the edge of the detector to 0.71 around the center of the AFOV. $RC_{max}$ demonstrated a similar trend. The quantitative discrepancy is due to the elevated noise level at the edge of the detector, which excerts a stronger effect on the smaller spheres. However, the trend for $RC_{peak}$ was somewhat different, and the larger spheres were more prone to fluctuation. The minimum $RC_{peak}$ of the 37

mm sphere was 0.78 which is around the edge of the detector. This is due to the fact that the edge of the larger spheres are more affected by the PSF effect compared to the smaller spheres. $^{68}$Gas and $^{89}$Zr showed the similar trends. ***Conclusion:*** Although the quantitative performance along the axial direction of the AFOV of TB-PET is consistent, fluctuations exist, especially on the peripheral part of the AFOV. Precuations should be taken in the imaging of the head and the feet in clinical applications.

## EP-0643

### 68Ga-Pentixafor in Squamous Cell Carcinoma of the head and neck, a pilot study

***B. Hadebe***[1], *L. Harry*[1], *L. Gabela*[1], *S. Masikane*[1], *M. Patel*[1], *P. Bipath*[1], *N. Cebekhulu*[1], *N. E. Nyakale*[2], *C. Aldous*[1], *M. M. Sathekge*[3], *M. Voster*[1];
[1]*University of KwaZulu Natal, Durban, SOUTH AFRICA,* [2]*Sefako Makgatho Health Sciences University, Pretoria, SOUTH AFRICA,* [3]*University of Pretoria, Durban, SOUTH AFRICA.*

***Aim/Introduction:*** Head and neck squamous cell carcinoma (HNSCC) is common [1] and its incidence is increasing, particularly in HIV-infected individuals who present with more aggressive disease [2]. Despite aggressive treatment, the prognosis remains poor due to resistance to chemoradiation therapy [3]. So far, studies report very low tracer avidity in HNSCC [4]. This study investigated the diagnostic performance of CXCR4-directed imaging of squamous cell carcinoma of the head and neck with PET/CT using the radiolabelled chemokine ligand $^{68}$Ga-Pentixafor. ***Materials and Methods:*** Twenty-one (21) patients with head and neck SCC underwent [$^{68}$Ga]-Pentixafor-PET/CT. In 14/21 patients, 2-[$^{18}$F]fluoro-2-deoxy-D-glucose ($^{18}$F-FDG), performed within 1 month of the [$^{68}$Ga]-Pentixafor-PET/CT and immunohistochemistry served as standard of reference. All primary lesions were visually rated as Pentixafor and FDG positive or negative, qualitative assessment of the images was performed using the 5 point Likert scale. For both tracers, SUVmax, SUVmean of the primary lesions as well as tumor to muscle ratio (TMR), tumor to liver (TBR), was documented and correlated with HIV, HPV and survival. ***Results:*** Twenty one (21) patients, 16 males and 5 females aged 35 - 73 years (mean 52 ± 10)with primarily diagnosed (n=16) or pre-treated (n=5) SCC of the oral cavity (n=10), oropharynx (n=8), nasopharynx (n=2) and unknown primary (n=1) underwent $^{68}$Ga-Pentixafor-PET/CT. [$^{68}$Ga] Pentixafor-PET/CT was visually positive in 18/21 patients cases with a sensitivity of 86%, however [$^{18}$F]FDG PET demonstrated higher $SUV_{max}$ in all patients compared to [$^{68}$Ga]Pentixafor PET. The $SUV_{max}$ and $SUV_{mean}$ were 5,8 ± 2.6 and 3± 1.6 and $TBR_{max}$ was 2,36 ± 1.4 for [$^{68}$Ga]Pentixafor. The $SUV_{max}$ and $SUV_{mean}$ were 16 ± 6.7 and 9.3 ± 4.1 and $TBR_{max}$ 4.9 ± 2.3 for [$^{18}$F]FDG. Fourteen percent (14%) 3/21 of the patients were HIV positive, there was higher accumulation of both $^{68}$Ga]Pentixafor and FDG in HIV positive patients. Also, nasopharyngeal cancer demonstrated more intense tracer accumulation than oropharyngeal and oral cavity malignancies. ***Conclusion:*** Our data shows that PET/CT imaging the CXCR4 chemokine receptor with [$^{68}$Ga]Pentixafor is in SCC of the oral cavity, oropharynx and nasopharynyx is feasible but less avid than [$^{18}$F]FDG and can be considered complementary to [$^{18}$F]FDG-PET/CT. Of note, CXCR4 expression seems to be higher in nasopharyngeal SCC, followed by oropharynx and low in oral cavity SCC, however this should be confirmed in a larger sample. $^{68}$Ga-Pentixafor is limited by accumulation in the tonsils and reactive nodes in the neck which may complicate image interpretation in head and neck malignancies.

## EP-0644

### The asymmetry of tau deposition and its correlation with cerebral metabolic asymmetry in Alzheimer's disease

***H. Lin****, p. wu, c. zuo;*
*Deparment of Nuclear Medicine / PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** The correlation between tau deposition and metabolism has been observed in Alzheimer's disease (AD), but the asymmetry of tau deposition and its correlation with metabolic asymmetry have not been roundly studied in AD. To analyze the asymmetry of tau deposition in AD and investigate its correlation with cerebral metabolic asymmetry. ***Materials and Methods:*** 142 patients with AD who underwent $^{18}$F-FDG PET and $^{18}$F-Florzolotau PET imaging at the same period were retrospectively enrolled. Standardized uptake value ratios (SUVRs) were obtained from $^{18}$F-FDG and $^{18}$F-Florzolotau positron emission tomography (PET) images of all participants, and the asymmetry indices (AIs) of metabolism and tau deposition were calculated according to the SUVRs. AD group was divided into left/right-dominant or bilateral symmetric hypometabolism (AD-L/AD-R or AD-BI), or left/right-dominant or bilateral symmetric tau deposition (tau-L/tau-R or tau-BI) when more than half of the AIs of the 20 pairs of regions of interest (ROIs) closely related to AD were < -2SD, > 2SD, or between ± 1SD. Clinical differences among metabolic or tau deposition subgroups in AD were compared, and the correlation between asymmetry of tau deposition and metabolic asymmetry in bilateral cerebral hemispheres of 20 pairs of ROIs were analyzed. ***Results:*** In 142 AD patients, the proportion of AD-L, AD-R and AD-BI were 26.1%, 14.8% and 16.2%, and tau-L, tau-R and tau-BI were 22.5%, 23.9% and 4.9% respectively. In clinical, asymmetric hypometabolic patients had younger age of onset, and poorer cognitive function than symmetric hypometabolic patients, but theses was no significant difference in tau subgroups. The asymmetry of tau deposition was negatively correlated with the metabolic asymmetry in the following 16 pairs of ROIs: Frontal_Sup, Frontal_Sup_Orb, Frontal_Mid, Frontal_Mid_Orb, Frontal_Inf_Oper, Frontal_Inf_Tri, Frontal_Inf_Orb, Frontal_Sup_Medial, Frontal_Mid_Orb, Parietal_Sup, Angular, Precuneus, Temporal_Sup, Temporal_Mid, Temporal_Pole_Mid, Temporal_Inf ($r=-0.639\sim-0.192$, $P < 0.05$). That is, with the tau deposition in bilateral hemispheres increased, the reduction of metabolism became more significant in AD. But there was no significant correlation between $^{18}$F-FDG and tau deposition in the other 4 ROIs: Parietal_Inf, Temporal_Pole_Sup, Hippocampus and Cingulum_Post ($P > 0.05$). ***Conclusion:*** There is a negative correlation of asymmetry between tau deposition and cerebral glucose metabolism AD, but the metabolic asymmetry may also be influenced by other factors.

## EP-0645

### Characterizing the 5-Ring GE Discovery MI PET/CT Scanner Using AAPM TG-126 and Compare these Results with the NEMA NU 2-2012 Results

***R. Almazrou***[1], *S. Alanazi*[1], *M. Alrabiah*[2], *R. Al-Fakhranee*[1], *O. Mawlawi*[3];
[1]*King Faisal Specialist Hospital and Research center, Riyadh, SAUDI ARABIA,* [2]*GE HealthCare, Riyadh, SAUDI ARABIA,* [3]*University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** To report on the performance characteristics of two 5-ring GE Discovery MI PET/CT systems using the AAPM TG-126 report (1) and compare these results to NEMA NU 2-2012

(2) where applicable. ***Materials and Methods:*** TG-126 testing and NEMA NU 2-2012 were performed on two GE discovery MI 5-Rings. Tests performed included spatial resolution, PET/CT image-registration accuracy, sensitivity, count rate performance, accuracy of corrections, image contrast, scatter/attenuation correction and image uniformity. All acquired data was analysed using scanner console or free software tools as described by TG-126 and NU 2-2012. ***Results:*** Both scanners gave similar TG-126 and NEMA results. The FWHM of radial/tangential/axial spatial resolution measurements using the filtered back projection algorithm were 5.1/5.0/5.8 mm, 5.7/5.7/8.4 mm and 7.4/5.2/8.0 mm at 1, 10, and 20 cm from the centre of the FOV, respectively. For NEMA testing, these values were 4.5/4.2/5.2 mm, 5.5/4.5/6.9 mm, and 7.5/4.9/7.0 mm. Image-registration accuracy between PET and CT using clinical protocol showed excellent results with values < 1 mm. Sensitivity using TG-126 was 18.4 cps/kBq while for NEMA the value was 19.7 cps/kBq. The peak noise-equivalent counting rate is not comparable between TG-126 and NEMA NU-2 due to differences in phantoms and methods used to measure and calculate this parameter. TG-126 results were 2174 kcps at 63.1 kBq/ml while NEMA results were 273 kcps at 22.7 kBq/ml. The accuracy of corrections for count losses for TG-126 were expressed in SUV values for the range of activity concentration between 0.26 KBq/cc and 76.5 KBq/cc and found to be 1.1 g/ml and 0.9 g/ml, respectively. Image contrast and scatter/attenuation correction using the TG-126 method gave acceptable results. Image uniformity assessment resulted in values within the recommended + 5% limits. ***Conclusion:*** To our knowledge this is the first study that reports on PET system characterization using the AAPM TG-126 report. These results show that PET scanner testing using TG-126 is reproducible and has similar results to NEMA NU 2-2012 tests where applicable. Due to the lack of manufacturer PET scanner performance characterization using TG-126, we hope these results start to form the basis by which these systems can be compared to one another. ***References:*** (1) Mawlawi OR, Jordan DW, Halama JR, Schmidtlein CR, Wooten WW. ## EP-0646

### Clinical solution to minimize mis-registration artifacts in PET/CT

***T. Pan****;*
*The University of Texas, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Misregistration between CT and PET can impact PET/CT image quality and is due to mismatch of temporal resolution between CT (< 1 second) and PET (averaged over many cycles of respiration). Most misregistration issues occur in the chest and/or abdomen regions. We implemented a measure to minimize misregistration on a network of 9 PET/CT scanners from two vendors including a total body (TB) PET/CT scanner by fusing a repeat short CT scan not bounded by the fixed PET bed positions over the misregistration area to a whole body (WB) CT for attenuation correction (AC) of the PET data and for minimum CT radiation to the patient. ***Materials and Methods:*** The minimum coverage of repeat CT, set by the vendors, ranges from 21.6 to 104 cm for one bed of PET scan in our 9 PET/CT scanners, and is much larger than the misregistration area ~14 cm observed over the lower lungs and upper abdomen in our patient population. A decision to repeat a limited CT only on the misregistration area is made at the last bed of PET acquisition when a misregistration between CT and PET is observed. The repeat CT, which can overlay in part with two beds, and the WB CT are sent to a server shared by the 9 PET/CT scanners to fuse the repeat CT with the WB CT to the requesting PET/CT scanner for AC of the WB or TB PET. This step is to ensure the fused CT can be used for AC. The turn-around time between sending and receiving data for AC is < 2 min, shorter than the time between patients for PET/CT. ***Results:*** The proposed measure is effective for reduction of misregistration but at a cost of a limited repeat CT over the misregistered area to the patient, which is about 5% of PET/CT radiation dose. The scan coverage of this approach can be prescribed on the scout or topogram rather than by pencil and paper for a scan coverage tied to the starting and ending positions of the PET beds set by the vendors. ***Conclusion:*** We have developed an effective solution to minimize misregistration between CT and PET on our 9 PET/CT scanners of two vendors including a TB PET/CT scanner.

## EP-0647

### Physical and Clinical Optimization of Acquisition Durations on a Digital BGO High Sensitivity PET-CT System

***Q. Maronnier****, M. Terroir, T. Cassou-Mounat, A. Latgé, J. S. Texier, L. Vija, F. Courbon, O. Caselles;*
*Oncopole Claudius Regaud, Toulouse, FRANCE.*

***Aim/Introduction:*** During the past decade, new PET-CT systems emerged with performances that could change clinical practice. A system coupling a significantly increased sensitivity and an extended field of view (FOV) was evaluated. Its characteristics could allow optimized acquisition protocol to reduce exam duration while maintaining equivalent image quality with no impact on the quantitation of PET images. In this study, we evaluated the impact of reduced acquisition times on phantom and on patient. ***Materials and Methods:*** The study was performed on the Omni Legend PET-CT system (General Electric Healthcare, Waukesha, WI USA) using Bayesian penalized likelihood reconstruction algorithm, optimized according to the image statistics. First, we evaluated the quantitative impact of reduced acquisition durations (2-min/FOV, 1.5-min/FOV, 1-min/FOV, 0.5-min/FOV) based on the EARL optimization procedure, its acceptance criteria and our clinical practice (2MBq/kg and protocol). Secondly, we applied the same parameters to four clinical cases of 18F-FDG PET-CT to assess the impact of acquisition times reduction on patient data. The images obtained were blindly analyzed by four nuclear medicine physicians using 5-levels scale for four clinical criteria (Likert scale). The images were judged clinically acceptable if the score was strictly above 2 for each criterion, this threshold corresponding to a non-degradation of clinical information. Additionally, based on clinical results, we applied Precision Deep Learning (PDL), a deep learning software simulating Time-Of-Flight information on PET images, and evaluated its impact on the clinical criteria. ***Results:*** Physical analysis performed on phantoms showed that the EARL2 criteria were fulfilled for all acquisition durations studied except 0.5-min/FOV. The analysis of clinical data was consistent with phantom results, as only the shortest acquisition time failed to meet the criteria. However, based on the differences in scoring, we opted for 1.5-min/FOV in order to maintain the quality of clinical images. Finally, by applying PDL on the 1-min/FOV duration, we observed Likert scale scoring on par with 1.5-min/FOV without PDL. ***Conclusion:*** It is possible to reduce acquisition duration to 1.5-min/FOV for 18F-FDG PET-CT exams without affecting the overall quality of images. Furthermore, the results obtained with PDL suggest that a reduction to 1-min/FOV would be acceptable. Currently, in our center, all 18F-FDG PET-CT acquisitions are performed using 1.5-min/FOV. Regarding these results, we are now considering reducing the acquisition time even further to 1-min/FOV once we ensured PDL doesn't alter images.

## EP-0648

### Quantitative Evaluation of Low-dose Whole-body Indirect Patlak Parametric Imaging with Deep Progressive Reconstruction

***Q. Ye***[1], *C. Xi*[1], *H. Dai*[1], *H. Zeng*[1], *Y. Zhao*[1], *G. Li*[2], *F. Kang*[2], *J. Wang*[2], *Y. Lv*[1], *Y. Lu*[1];
[1]*United Imaging Healthcare, Shanghai, CHINA,* [2]*Xijing Hospital, Xi'an, CHINA.*

***Aim/Introduction:*** For PET scanners with short axial field of view (AFOV), whole-body Patlak parametric imaging requires multi-pass multi-bed acquisition protocols. This practice leads to discontinuous data collection with relatively short-time acquisition for each bed position within one pass, which results in high image noise in the subsequent parametric images via post-reconstruction Patlak fitting. Direct Patlak parametric imaging directly reconstructs the kinetic parameters from PET raw data, which helps to reduce the image noise but requires higher computation burden and more complex algorithm design than the indirect method, i.e., post-reconstruction fitting. Here, we proposed a whole-body indirect Patlak method with an aid of a deep learning-based reconstruction algorithm, i.e., deep progressive reconstruction (DPR), to provide denoised parametric images without introducing extra computation cost. We compared the proposed method with the indirect Patlak method using PMOD. ***Materials and Methods:*** Whole-body dynamic $^{18}$F-FDG (6.4-9.5 mCi) scans were performed on four participants (3/1 M/F, 57-67 yrs, 53-75 kg) from Xijing Hospital (Xi'an, China). Each 0-60 min post-injection scan was composed of a 10-min single-bed acquisition centered at the cardiac region, followed by a multi-pass acquisition (5 pass×4 bed×90 sec and 1 pass×4 bed×300 sec). Image-derived input function was generated from the descending aorta. Low-dose data were simulated by down-sampling the listmode data of the multi-pass acquisition. The proposed method was applied to generate parametric images at full, 1/2, and 1/3 dose levels. Indirect Patlak fitting with PMOD at full dose was used as the reference. Regions of interest (ROI) including thalamus, cerebellum, myocardium, liver, and lesions (N = 32) were drawn manually. Coefficient of variance (CoV) at liver and contrast-to-noise ratio (CNR) of lesions were calculated. ***Results:*** Correlation analysis of $K_i$ values for all the ROIs and all the participants was performed. Comparing to the PMOD results, the proposed method showed high correlation with $R^2$ of 0.9943, 0.9913, and 0.9909 at full, 1/2, and 1/3 dose levels, respectively. The liver $K_i$ CoV increased with the dose decreased and showed comparable results at 1/3 dose with the PMOD results at full dose. The lesion $K_i$ CNR values were 25.4±19.3, 22.2±15.1, and 19.8±12.3 at full, 1/2, and 1/3 dose, respectively, while the full-dose PMOD yielded 18.8±13.1 in lesion CNR. ***Conclusion:*** Without extra computation cost, the proposed method was demonstrated quantitatively accurate and showed similar performance in noise reduction and contrast recovery at 1/3 dose as compared with the conventional indirect method at full dose.

## EP-0649

### Deep learning-based method for the reconstruction of high-quality 3D PET image from low-dose data

***R. Guo***[1,2], *J. Wang*[3], *Y. Miao*[1,2], *S. Xue*[4], *Y. Zhang*[1,2], *K. Shi*[4], *B. Li*[1,2], *G. Zheng*[3];
[1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Ruijin Center, Shanghai, CHINA,* [3]*Institute of Medical Robotics, School of Biomedical Engineering, Shanghai Jiao Tong University, Shanghai, China, Shanghai, CHINA,* [4]*Department of Nuclear Medicine, University of Bern, Switzerland, Bern, SWITZERLAND.*

***Aim/Introduction:*** Deep learning models have shown great potential in reconstruction of full-dose PET image from low-dose ones. However, most methods only focus on the reconstruction of a single view and ignore the 3D characteristics of PET image. We aim to reconstruct the high-quality 3D PET image on three views by a deep learning-based spatial fusion method and evaluate the generalization of this method on different scanners and traces. ***Materials and Methods:*** The study was performed on 456 participants scanned on 3 different PET scanners with 2 different tracers. We proposed a spatial fusion model to reconstruct the high-quality 3D PET image based on three views and compared the qualitative and quantitative results with the state-of-the-art methods of 2D and 3D. The quantitative metrics were NRMSE, PSNR, SSIM. The qualitative results were assessed by two nuclear medicine physicians independently and they were asked to use a 5-point grading scheme for visual image quality assessment. Furthermore, we also evaluated the generalization of this method on different PET scanners and tracers. ***Results:*** The results reconstructed by our method showed the significant NRMSE improvement of low-dose PET image, compared with 2D C-Gan and 3D-Unet (Table1). All pair-wise tests had P values <0.0001. Additional results of PSNR and SSIM showed the same tendency as the NRMSE results. The clinical evaluation scores of two nuclear medicine physicians had high agreement that our method perform the best results on three views (Axial: 4.2 from our method vs. 3.8 from C-Gan and 3.7 from 3D-Unet; Sagittal: 4.2 from our method vs. 2.9 from C-Gan and 4.0 from 3D-Unet; Coronal: 4.1 from our method vs. 3.0 from C-Gan and 3.8 from 3D-Unet). For the generalization evaluation, the performance of our method also exhibited the NRMSE improvement of low-dose PET image on different PET scanners and tracers with different dose reduction factors (DRF) from 4 to 100 (Table2). ***Conclusion:*** The method we proposed can reconstruct the high-quality 3D PET image on three views and have great generalization on different scanners and traces.

### Diffuse high uptake of 68Ga-FAPI in both kidneys helps with diagnosis of kidney diseases

***X. Zhong***[1], *J. Cheng*[2], *M. Su*[2], *W. Zhang*[3];
[1]*Nuclear Medicine Department and Biomedical Big Data Center, West China Hospital of Sichuan University, Chengdu, CHINA,* [2]*Nuclear Medicine Department, West China Hospital of Sichuan University, Chengdu, CHINA,* [3]*Biomedical Big Data Center, West China Hospital of Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Gallium-68 labeled fibroblast activation protein inhibitor ($^{68}$Ga-FAPI) is a promising novel imaging agent beyond tumor disease. The aim of this study is to investigate the relationship between diffuse increased uptake of $^{68}$Ga-FAPI in kidneys and glomerular filtration rate (GFR), and its diagnostic ability for kidney diseases. ***Materials and Methods:*** We conducted a retrospective study from February 2022 to September 2022, analyzing images from participants who underwent whole-body or abdominal $^{68}$Ga-FAPI PET/CT examinations. The relationship between tracer uptakes, quantified by maximum standardized uptake value (SUVmax) and mean standardized uptake value (SUVmean), and GFR was analyzed using Pearson correlation analysis. The diagnostic performance of $^{68}$Ga-FAPI PET/CT for renal diseases was evaluated by receiver operating characteristic (ROC) curve and the area under the curve (AUC). Optimal SUVmax threshold for diagnosing kidney disease was determined using the percentile method recommended by the American Clinical

and Laboratory Standardization Institute (CLSI). ***Results:*** A total of 121 images of 99 patients (median age, 59 years [interquartile range: 23 - 83 years]; 82 men) were included. Pearson correlation analysis showed an inverse association between renal SUVmax and SUVmean with GFR, with $R^2$ values of 0.233 and 0.226, respectively. The AUC of SUVmax for diagnosing renal disease was 0.961. The sensitivity, specificity, and accuracy of SUVmax > 2.15 for diagnosing kidney disease were 90.48% (19/21), 73.91% (17/23), and 81.82% (36/44), respectively. ***Conclusion:*** The concentration of $^{68}$Ga-FAPI in renal parenchyma is inversely associated with GFR and shows great potential for the diagnosis of kidney diseases.

## EP-0651

### Designing a 1-mm Resolution Brain-Dedicated PET System with a Hemispherical Detector Arrangement

***T. Yamaya***[1], *E. Yoshida*[1], *G. Akamatsu*[1], *K. Narita*[2,1], *H. Tashima*[1], *Y. Iwao*[1], *M. Takahashi*[1];
[1]*National Institutes for Quantum Science and Technology (QST), Chiba, JAPAN,* [2]*Chiba University, Chiba, JAPAN.*

***Aim/Introduction:*** Due to the strong demand for PET diagnosis of dementia, the development of brain-dedicated PET systems is drawing attention worldwide. Even for amyloid PET, high spatial resolution is needed for quantitative diagnosis by separating cortical amyloid from non-specific accumulations in white matter. For brain tumour treatment, higher spatial resolution is required for more accurate identification of a tumour invasion area. In practice, not only high spatial resolution but also high sensitivity and low cost are desired, and we have proven that a hemispherical detector arrangement can achieve higher sensitivity with a smaller number of detectors than a conventional cylindrical geometry [1]. In addition, a smaller detector ring leads to better spatial resolution by eliminating a photon non-collinearly effect, which determines the theoretical resolution limit of about 2 mm for whole-body PET and of about 1 mm for brain-dedicated PET. Therefore, our aim in this work was to design a practical brain-dedicated PET system that will achieve the theoretical limit of 1-mm resolution. ***Materials and Methods:*** The proposed 1-mm resolution brain PET consists of two component technologies. The first one is the hemispherical detector arrangement, which can balance the sensitivity and the costs and minimize the photon non-collinearly effect. The second one is our original crosshair light-sharing (CLS) detector, which enables both time-of-flight (TOF) and depth-of-interaction (DOI) measurements. The hemispherical arrangement of the CLS detectors, on a ring diameter of 28 cm, was simulated by Geant4, and spatial resolution to be expected was assessed. ***Results:*** Using a module detector with 4.2 mm pitch lutetium fine silicate (LFS) crystals (10 mm long) and 229 ps TOF resolution, we developed the first prototype system, which demonstrated 2.2 mm rod separation. For better spatial resolution, the CLS detector with 1.5 mm pitch and 15 mm long lutetium-gadolinium orthosilicate (LGSO) crystals was developed, and 3-layer DOI discrimination and 293 ps TOF resolution were achieved. The simulation in which the CLS detectors formed the hemispherical geometry showed that 0.75 mm rods were separated with a valley-to-peak ratio of 0.684. In addition, reconstructed images of a simulated Hoffman phantom and a BigBrain phantom showed high contrast between the gray and white matters. ***Conclusion:*** A feasibility of the 1-mm resolution brain-dedicated PET system was numerically shown with the combination of the CLS detector and its hemispherical arrangement, both of which have been experimentally proven. ***References:*** [1] Takahashi M et al EJNMMI Phys 9 69 (2022)

## EP-0652

### 68Ga -FAPI PET/CT Improves Detection Rates of Gastrointestinal Mucinous Adenocarcinoma or Signet Ring Cell Carcinoma: A Comparative Study with 18F-FDG

***Y. Sun****;*
*Fudan University, Shanghai Cancer center, Shanghai, CHINA.*

***Aim/Introduction:*** Purpose: The aim of this study was to investigate the diagnostic value of Gallium 68 ($^{68}$Ga) labeled fibroblast activation protein inhibitor (FAPI) PET/CT in gastric and colorectal mucinous adenocarcinoma (MAC) and signet ring cell carcinoma (SRCC) by comparing it with $^{18}$F-FDG PET/CT. ***Materials and Methods:*** $^{68}$Ga-FAPI PET/CT was performed in patients with inconclusive findings by conventional imaging. The detection rate, the SUVmax and tumor-to-background ratio (TBR) of $^{18}$F-FDG and $^{68}$Ga-FAPI PET/CT were evaluated and compared. ***Results:*** Fifty-seven patients were enrolled. When compared with $^{18}$F-FDG, $^{68}$Ga-FAPI showed a superior detection rate for primary tumors (100% vs 80%) and the SUVmax was significantly higher ($8.9 \pm 3.7$ vs $5.3 \pm 3.3$, $p = 0.035$). In the patient-based analysis, all patients with metastatic peritoneum were FAPI-positive (40/40, 100% detection rate), whereas only fourteen were also FDG-positive (14/40, 35%). In the lesion-based analysis, $^{68}$Ga-FAPI showed better sensitivity and specificity in peritoneal metastases than $^{18}$F-FDG (sensitivity 89.16% vs 53.61%, $p < 0.001$; specificity 82.30% vs 59.29%, $p = 0.001$). Additionally, peritoneal lesions showed intense $^{68}$Ga-FAPI uptake ($6.8 \pm 2.4$ vs $3.6 \pm 2.5$, $p < 0.001$). The TBRs were higher for $^{68}$Ga-FAPI in all the recurrent anastomotic stoma, involved lymph nodes, bone and visceral metastases ($p < 0.001$). Additionally, immunofluorescence staining demonstrated that metastatic lesions had high FAP expression and low Glut-1 expression, corresponding with paired PET/CT. ***Conclusion:*** $^{68}$Ga-FAPI PET/CT was superior to $^{18}$F-FDG in the detection of both primary and metastatic tumors in patients with gastrointestinal MAC/SRCC, particularly in patients with peritoneal metastases.

## EP-0653

### Effect of Radiopharmaceutical Extravasation on the Accuracy of SUV Estimation in PET/CT

***I. Znamenskiy***[1,2,3], *V. Volkov*[2,3], *A. Kondakov*[1,2], *M. Beregov*[3], *D. Mosin*[1,2];
[1]*Petrovsky National Research Centre of Surgery, Moscow, RUSSIAN FEDERATION,* [2]*Pirogov Russian National Research Medical University, Moscow, RUSSIAN FEDERATION,* [3]*Federal center of brain research and neurotechnologies, Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The evaluation of a patient's clinical case and staging in PET studies partially relies on the calculation of standardized uptake value (SUV). This value can be altered by an incomplete injection of the prescribed dose or its leakage into soft tissues (also known as extravasation) [1]. Extravasation should also be monitored in myocardial blood flow quantification, i.e. with Rb-82 chloride. Our goal was to estimate the importance of extravasation for SUV quantification in the choice of further treatment tactics. ***Materials and Methods:*** This is an ongoing study. To date, 7 patients with visible extravasation were retrospectively enrolled. Extravasation radioactivity was calculated in VOI by multiplying scanner-measured activity by its volume defined by an isocontour with a 5% cut-off of maximum value. As a reference, we used the mean intact liver parenchyma SUV measured in a 50 ml VOI. For the patients with metastatic lesions, the most active lesion was included in analysis. ***Results:*** Of the 7 PET/CT studies 6 had extravasation radioactivity of 1% or less of

the total injected dose. One patient had the measured activity at the extravasation site equal to 5% of the injected dose. Normal tissue and lesions demonstrated extravasation corrected SUVmax, SUVmean, and SUVpeak values that were inversely proportional to the % change in injected dose. This naturally follows from the SUV calculation procedure, which allows us to establish the following relation: SUV increases in 1(1-x) times for x % extravasation of the injected dose. Percent change in SUV ranged from 0 to 5%. ***Conclusion:*** In the majority of patients even visible extravasation usually accounts for less than 1% of the injected dose and therefore leads to SUV alterations of approximately less than 1%, which is consistent with previously published data [2]. However, a non-linear relationship between extravasation activity and SUV results in a disproportionate increase of SUV on higher degrees of extravasation, which could be of critical importance for both diagnostic PET and evaluation of response to therapy. Automated methods for dose correction would be simple and clinically valuable. ***References:*** 1. H. Nathan, Z. Jun, R. Robert, H. Deborah, K. Michael, Impact of FDG extravasation on SUV measurements in clinical PET/CT. Should we routinely scan the injection site? Journal of Nuclear Medicine 47, 115P (2006) 2. Kiser JW. The decision to reimage following extravasation in diagnostic nuclear medicine. Front. Nucl. Med. 3:1171918. (2023)

## EP-0654

### Last generation digital PET: comparison of the performances of 5 vs. 6 rings systems and optimization of the overlap value

***M. Bernardini***[1], *T. Mbaye*[1], *M. Alqabandi*[2], *F. Hyafil*[1]; [1]*Hôpital Européen Georges Pompidou (HEGP), Paris, FRANCE,* [2]*Nuclear Medicine Department, Faculty of Medicine, Kuwait University, Kuwait City, KUWAIT.*

***Aim/Introduction:*** Novel 5-rings (5R) and 6-rings (6R) PET systems offer longer detector coverages and increased sensitivity. The objectives of this study were: 1. to evaluate the impact of extending the field-of-view (FOV) from 25cm to 30cm on performance tests; 2. to identify the best overlap value for the 6R-system. ***Materials and Methods:*** A digital PET system of 25cm-FOV was installed initially and then upgraded to 30cm-FOV. Performance tests were realized on both systems following the NEMA-NU-2-2018 procedures. The impact of overlap on image quality and quantification was tested for 0.9%, 28%, 35%, 42% and 50% overlap values and compared to a single FOV acquisition. For analysis of image quality, hot contrast recovery coefficient (HCRC), recovery coefficient (RC) and background variability (BV) were measured on the NEMA-IQ phantom acquired with clinical parameters. For measurement of spatial resolution (SR), FWHM were assessed using the triple-line phantom. ***Results:*** On NEMA-NU-2-2018 tests, SR values were found similar for 5R and 6R systems (3.80mm and 3.77mm for 1cm radial FWHM, respectively). NEMA-NU-2-2018 HCRC and BV values were similar on both systems (mean difference of 1.9 and -1 points of %, respectively). Average sensitivity and equivalent noise count rate (NECR) were, however, much higher on the 6R system (62 % and 67%, respectively). In clinical conditions, HCRC and RC coefficients for 28%, 35%, 42% and 50% overlap values were similar but lower than 1FOV (up to -10.2 and -4.0 points of %, respectively), except for the smallest sphere for which overlaps did improve results, and with the same extent for 35% and 42% overlaps (12.5 and 9 points of % respectively). For all overlaps, the improvement in BV compared to 1FOV was small (< 3 points of %). SR values with Q.Clear reconstructions were similar to 1FOV (2.2 mm) for all overlaps, except for 0.9% (3.5 mm). With VPFX-S reconstructions, SR values were similar to 1FOV, but significantly higher than with Q.Clear (7.0 mm). ***Conclusion:*** Our study demonstrates that image quality and quantification are similar with the 6R and 5R-PET systems. Yet, in addition to the longer FOV, the percentage of overlap on the 6R-PET may be reduced from 42% to 35% without significant loss in detectability, noise, spatial resolution or absolute quantification translating into faster whole-body PET acquisitions. The dramatic increase in sensitivity observed on the 6R-system paves the way for improved image quality and quantification for low-count or short-time-frame PET acquisitions.

## EP-0655

### Influence of the CT-Energy on the Attenuation Correction of the PET/CT and the Impact on Small Bone Lesions

***A. Haslauer***, *E. Solari, J. Brosch-Lenz, W. Weber, S. G. Nekolla; Klinikum rechts der Isar, Technical University Munich, Munich, GERMANY.*

***Aim/Introduction:*** For the reconstruction of PET data in multimodal PET/CT systems, an attenuation map (μ-Map) is created from CT images. Therefore, the photon energy from the 120kV CT is extrapolated into 511keV. Photons with lower energy are attenuated stronger in dense material (e.g. cortical bones) than higher energy photons, which leads to our assumption that bones will have a higher HU-value and thickness in the CT. This higher bone thickness will presumably have an impact on the activity measured in small bone lesions. ***Materials and Methods:*** To evaluate the effect of the CT energy, pig bones and a reference abdomen phantom (QRM) were measured in a clinical PET/CT (Vision, Siemens) and a high-energy industrial CT (Fraunhofer Institut, Inline CT, HEITEC PTS). Additionally, the bones were scanned with tubes of 7mm diameter filled with FDG (4.4MBq/mL +/- 0.4 MBq/mL activity). The PET was performed with the e7 tools (Siemens, Knoxville), the PET data was evaluated with Siemens TrueD. This measurement setup was positioned in a larger, water filled container, with 6 tubes in bones and 5 tubes in water. ***Results:*** A measurement of the bones in the clinical CT at 120kV compared with the industrial CT of 450kV gives a difference in the thickness of the bones of 1.7mm as mean value, which is a deviation of 6%. Extrapolated to the μ-Map, the thickness difference changes to 25% (SD = 20%) compared to the HE-CT. A line integral through the bones showed that the industrial CT is on average 13% thinner than the clinical CT and 11% thinner than the μ-Map. The energy extrapolation was performed with the bilinear conversion [1]. The maximum activity in the tubes in water showed an average of 3.0MBq/mL (SD = 0.3MBq/mL). This is 9.5% smaller than the average maximum activity in the tubes in bone (mean = 3.3MBq/mL, SD = 0.2MBq/mL). ***Conclusion:*** The results of the bone thickness and associated line profile proof our assumption that the conversion of CT images to μ-Map contain an error that stems not only from linear attenuation coefficients but also from cortical bone thickness. These measurements showed that lesions around cortical bones are overcorrected. ***References:*** [1] Carney, J.P.J., Townsend, D.W. Method for transforming CT images for attenuation correction in PET/CT imaging. Medical Physics 33,4 (2006)

## EP-0656

### PET digitization chain for Monte Carlo simulation in GATE

***J. Salvadori***[1], *A. Merlet*[2], *B. Presles*[3], *A. Etxebeste*[4], *J. Vrigneaud*[3], *D. Sarrut*[4];
[1]*Institut de cancérologie Strasbourg Europe (ICANS), Strasbourg, FRANCE,* [2]*Imagerie et Vision artificielle, ImViA EA 7535, Dijon, FRANCE,* [3]*Institut de Chimie Moléculaire de l'Université de Bourgogne (ICMUB), UMR CNRS 6302, University of Burgundy, Dijon, FRANCE,* [4]*Universitée de Lyon, CREATIS; CNRS UMR5220; Inserm U1044; INSA-Lyon; Universitée Lyon 1; Centre Leon Bérard., Lyon, FRANCE.*

***Aim/Introduction:*** We proposed a comprehensive method for accurately modeling a PET imaging system using Monte Carlo simulation. Accurate Monte Carlo modeling involves implementing a complex analytical signal processing chain, called Digitizer, to closely reproduce the different counts rates of the real system. The Digitizer shapes the signal, determines the timestamp and the position of the interactions, models the timing resolution, the energy resolution, the saturation effects of the detectors, and implements the pulse-processing logic for selecting and coupling single events into coincidences. ***Materials and Methods:*** The proposed method includes 1) modeling the Digitizer as closely as possible to the detection chain of a real system and incorporating all freely available or manufacturer-provided parameters, 2) estimating of remaining parameters (such as background noise level, detection efficiency, dead time, and pile-up) through a two-steps optimization process and 3) validating the estimated parameters with experimental data. The method was applied and validated using experimental data from the NEMA protocol count rates test for three state-of-the-art SiPM TOF-PET : Philips Vereos (digital SiPM), GE Discovery MI 4-ring and Siemens Biograph Vision 600 (analog SiPM). ***Results:*** For all three PET systems, results showed that the relative absolute differences between simulated and experimental data for Single, Prompt, True, Scatter, Random and NEC rates were less than 2 %, 3 %, 5.1 %, 6.7 %, 2.5 % and 10.8 % on clinical activity range (< 10 kBq/mL) and less than 2 %, 3 %, 12 %, 13 %, 2.5 % and 23 % up to the activity of the $NECR_{peak}$. ***Conclusion:*** Overall, the proposed Digitizer optimization method was able to accurately reproduce the counts and NEC rates of three of the latest generation SiPM-based TOF-PET imaging systems.

## EP-0657

### Sensitivity comparison of non-TOF and TOF PET/CT

***L. Carnegie-Peake****, J. Dickson, S. McQuaid;*
*University College London Hospital, London, UNITED KINGDOM.*

***Aim/Introduction:*** Commercial scanners are available using detectors both with and without time-of-flight (TOF) capabilities. To compensate for the lack of TOF information, non-TOF PET scanners must be more sensitive. The aim of this work was therefore to determine the fundamental sensitivity requirements of a non-TOF system to obtain equivalent contrast and noise properties to that obtained with a TOF system. ***Materials and Methods:*** The NEMA image quality phantom with 6 fillable spherical inserts (volume range: 0.6 - 32 ml) containing F-18 with a sphere to background activity concentration ratio of 12 was scanned on a Siemens Vision 600 (TOF resolution 240 ps) and list mode data were acquired. The data were reconstructed using TOF and non-TOF image reconstruction algorithms. First, reconstruction parameters were selected such that the degree of convergence between the contrast recovery curves (CRC) of the TOF and non-TOF reconstruction methods were matched. The RMSE was evaluated between the CRCs of a standard OSEM TOF reconstruction (4 iterations, 5 subsets) and multiple non-TOF image reconstructions (Iteration number range: 4 to 30). The reconstruction with the minimum RMSE was used as the reference non-TOF reconstruction in the remainder of the work. Second, to obtain equivalent noise in the datasets, the list mode data used in the TOF reconstruction were downsampled. The SNR was evaluated for the six spheres using these downsampled TOF datasets and for the previously determined reference non-TOF reconstruction. The RMSE was evaluated between the TOF and non-TOF SNR curves. The relative sensitivity increase required by a non-TOF system to match the SNR performance of a TOF reconstruction was determined based on the downsampled dataset with the minimum RMSE. ***Results:*** The CRC of a non-TOF image reconstruction with 15 iterations matched the CRC of a standard TOF image reconstruction with 4 iterations (both with 5 subsets). Good agreement of the SNR properties between this non-TOF reference reconstruction was identified when the TOF data was downsampled to 35%. This corresponds to a relative sensitivity increase requirement of 2.9 for a non-TOF system, compared to a TOF system with a timing resolution of 240 ps. ***Conclusion:*** Non-TOF scanners are required to be significantly more sensitive to compete with the good SNR provided by TOF systems. However, non-TOF systems have the ability to match both the contrast and SNR of images obtained from a TOF system if the PET detector sensitivity is sufficiently high.

## EP-0658

### Development and Validation of a Monte Carlo Simulation Workflow for a Total-Body PET Scanner

***C. Pommranz***[1,2], *E. Elmoujarkach*[3], *J. Cabello*[4], *W. Lan*[5], *M. Rafecas*[3], *J. Mannheim*[1,6], *P. Linder*[5], *A. Santangelo*[2], *C. la Fougère*[5,6], *B. Pichler*[1,6], *F. Schmidt*[1,5];
[1]*Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard Karls University Tuebingen, Tuebingen, GERMANY,* [2]*Institute for Astronomy and Astrophysics, Eberhard Karls University Tuebingen, Tuebingen, GERMANY,* [3]*Institute of Medical Engineering, University of Lübeck, Lübeck, GERMANY,* [4]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [5]*Department of Nuclear Medicine and Clinical Molecular Imaging, University hospital Tuebingen, Tuebingen, GERMANY,* [6]*Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tuebingen, Tuebingen, GERMANY.*

***Aim/Introduction:*** The latest generation of total-body PET scanners feature high sensitivity and a long axial field of view that enable novel clinical applications. Monte Carlo simulation studies potentially help understanding and characterizing these scanners as well as to optimizing scan protocols due to repeatability and known ground truth information. The purpose of this study was to develop and validate an end-to-end Monte Carlo simulation workflow for a total-body PET scanner, ranging from modeling physical properties of events and their detection to producing tomographic images. ***Materials and Methods:*** The Geant4 Application for Emission Tomography (GATE) was used together with a proprietary scanner-specific digitizer and coincidence sorter to determine list-mode event data. Image reconstruction was performed using the same vendor proprietary software that is used for the emission data of the real scanner. Normalization correction was performed using a normalization matrix from the real scanner with a calibration factor adapted for simulation. Phantom simulation studies including image quality,

quantification and sensitivity assessment were performed and validated against measurements. Patient-like simulations with the XCAT phantom were enabled by implementing voxelized synthetic μ-maps in the workflow. ***Results:*** Activity concentrations determined for three different phantoms were found to agree with the simulation ground truth with differences below 1%. For a simulation of the image quality phantom (4:1 sphere to background ratio, 5.5 kBq/ml background activity), contrast recovery coefficients were found to be 87.3% and 85.5% (37 mm sphere), 83.5% and 82.4% (28 mm sphere), 79.0% and 77.7% (22 mm sphere), 74.4% and 74.6% (17 mm sphere), 69.2% and 67.9% (13 mm sphere), and 55.5% and 64.3% (10 mm sphere) for the simulation and measurement [1], respectively. The lung residual error was 4.7% for the simulation and 4.8% for the measurement. Sensitivity profiles for different acceptance angles showed a good correlation with experimental data. Preliminary results from a 20s short simulation of the XCAT phantom indicate its potential as a surrogate for real patient scans. ***Conclusion:*** A workflow based on GATE and proprietary image reconstruction software is proposed for precise Monte Carlo simulations of a total-body PET scanner. Future work will include a full NEMA based validation of the simulation workflow. The simulation workflow can be used to generate training and validation datasets, including simulation of ground truth information for machine learning algorithms (e.g., validation of motion correction algorithms), and to investigate scenarios impractical for patients (e.g., varying applied dose). ***References:*** [1] Prenosil et al., 2022

## EP-0659

### Can SUVmax be used to predict the development of anatomical correspondence in bone uptakes detected by 18F-PSMA-1007-PET/CT?

***L. Eklund****, M. Anttinen, J. Vanhatalo, S. Malaspina, T. Noponen, J. Kemppainen, P. Boström, M. Seppänen, O. Ettala;*
*University of Turku, Turku, FINLAND.*

***Aim/Introduction:*** To improve the diagnostic accuracy in detecting local and metastatic prostate cancer (PCa), various radioligands have been developed. Unlike the FDA approved $^{Ga}$68-PSMA-11 and $^{18}$F-PSMA-DCFPyl, $^{18}$F-PSMA-1007 is eliminated via the hepatobiliary route, which represents an advantage in local staging and restaging of PCa. However, a limitation of $^{18}$F-PSMA-1007 is the higher incidence of non-specific bone uptakes. The objective of this study was to describe how many bone uptakes without anatomical correspondence detected by $^{18}$F-PSMA-1007-PET/CT developed correspondence during follow-up and investigate if baseline SUVmax values can predict this development. ***Materials and Methods:*** This retrospective study analyzed data from two prospective, registered trials, the PROSTAGE study (NCT03537391) and the ADTPSMA2 study (NCT03876912), which recruited treatment-naïve high-risk or metastatic PCa subjects. Subjects with at least one uptake without correspondence in the baseline $^{18}$F-PSMA-1007 PET/CT were included. To determine the development of anatomical correspondence during follow-up, either whole body contrast-enhanced CT or $^{18}$F-PSMA-1007 PET/CT were used. Baseline SUVmax values in bone uptakes were compared between those that developed correspondence and those that didn't. AUC, sensitivity, and specificity were calculated for SUVmax in predicting the development of anatomical correspondence. ***Results:*** At baseline in 70 subjects, $^{18}$F-PSMA-1007 PET/CT identified a total of 714 bone uptakes. Of these, 470 (65.8%) were with anatomical correspondence, and 244 (34.2%) were without. Out of the uptakes without correspondence, 219 had at least one follow-up image. Median (IQR) follow-up time was 13 (12; 35) months, during which 82 (37.4%) uptakes developed anatomical correspondence. The median (IQR) SUVmax in the baseline $^{18}$F-PSMA-1007-PET/CT were 10.3 (6.18; 14.63) and 5.6 (4.2; 8.5) for lesions that did and did not develop anatomical correspondence, respectively. Wilcoxon two-sample test showed a statistically significant difference between groups ($p<0.0001$). In predicting the development of correspondence, baseline SUVmax ROC analysis achieved AUC of 0.725. The highest sum for sensitivity and specificity was achieved at SUVmax 7.5, where sensitivity and specificity reached 0.71 and 0.69, respectively. At SUVmax 4.0 sensitivity and specificity were 0.96 and 0.18, respectively. ***Conclusion:*** This study showed that a notable number of the PSMA uptakes without anatomical correspondence developed correspondence, suggesting a metastatic nature. Baseline SUVmax values in those lesions were significantly higher compared to those that did not develop correspondence. However, due to its unsatisfactory performance in terms of sensitivity and specificity, baseline SUVmax in $^{18}$F-PSMA-1007-PET/CT bone uptakes seems to be of limited clinical utility in predicting the development of correspondence.

## EP-0660

### Measurement of NECR in a Long Axial Field of View Scanner using a Custom Humanoid Phantom covering the Full Axial Field

***S. Holm****, J. V. *Henriksen, T. L. Andersen, F. L. Andersen;*
*Rigshospitalet, Copenhagen University Hospital, Copenhagen, DENMARK.*

***Aim/Introduction:*** Recent developments in PET provided scanners with large axial field of view (LAFOV) >1 meter, having markedly increased sensitivity over systems with 15-25cm AFOV. We examined a LAFOV system with length 106cm. Assessment using NEMA NU-2-2018 standard showed peak noise equivalent countrate (NECR) value 1.92 Mcps@25 kBq/mL for full ring acceptance. However, the NEMA phantom (70cm) is too short to reflect clinical use. Here we aim to characterize the system NECR using a humanoid phantom, covering the full FOV and reaching from activity beyond system electronic capacity down to background by intrinsic radiation from LSO-detectors. This information is relevant for decisions on system use both for fast studies with high activity and studies with ultralow activity/dose over prolonged time. ***Materials and Methods:*** A phantom was composed of independent compartments with varying concentrations of FDG and a total volume of 37 liters (total weight 53 kg). Brain: Hoffman phantom. Heart, lungs and liver: home-made thorax phantom. Abdomen: two NEMA IQ phantoms (with hot/cold spheres). Bladder: small bottle included in the lower NEMA IQ. Legs: 2L bottles. With background in thorax and abdomen phantoms =1.00, concentrations were: brain, myocardium, "hot spheres" (4.0), liver (2.0), heart ventricle (1.0), legs (0.5) and bladder (~50). The phantom contained a total of 2244 MBq at scan start. Five minute scans were performed for 30 h, at intervals 20 min until 8 hours, 30 min until 12 hours, then 60 min. Global NECR was calculated from measured prompts and delayed randoms. ***Results:*** Peak NECR for the body phantom was 1.02 Mcps@17.3 kBq/mL. This value (like in NEMA measurements) seems determined by a coincidence bottleneck rather than detector deadtime or (random) correction effects. At the break point, the NECR curve is already very flat, but clinical use with standard activity (3 MBq/kg) is not compromised. However, the slope of the NECR curve is

reduced to 47% of maximum and radiation protection concerns may warrant the use of lower activity. In this phantom, reduction from 3 MBq/kg to 0.3 MBq/kg is compensated by an increase in time by a factor 7. Only below 0.01 kBq/mL, random corrections from background will influence quality. The peak point likely will shift with patient size; a phantom extension to mimic obesity is considered. ***Conclusion:*** The 106 cm LAFOV system is well suited to patient studies in the normal range of injected activities with wide possibilities for balancing activity versus time.

## EP-0661

### Feasibility study of Sub-minute acquisition with deep-learning reconstruction using 18F-FAPI Total-body PET/CT

***E. Liu***, *L. Jiang;*
*Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, CHINA.*

***Aim/Introduction:*** FAPI PET/CT has demonstrated promising outcomes in the detection and restaging of various cancer types, showcasing superior image contrast and tumor-background ratio.This is beneficial for reducing the tracer injection doses and shortening the acquisition time, especially with the long axial field-of-view (LAFOV) PET/CT scanners and deep-learning-based reconstruction algorithms. This study aimed to evaluate the feasibility of $^{18}$F-FAPI-04 total-body PET/CT sub-minute acquisition combined with deep-learning reconstruction (DLR). ***Materials and Methods:*** Fourteen restaging patients (2 females, 12 males; mean age, 59.0 years; range, 34 - 78 years) with different types of malignant tumors were included in the study. All patients underwent a 300-second list-mode $^{18}$F-FAPI-04 total-body PET/CT (1.85 MBq/kg). The entire dataset was divided into groups of durations of 10, 20, 30, 60, 120, and 180-second. PET images were reconstructed using ordered subset expectation maximization (OSEM) with a Gaussian smoothing filter (3 mm) and DLR. A region of interest (ROI) with a round circle (2D mode) and a diameter of 1 cm was selected in the right posterior lobe of the liver , ascending aorta (bronchial bifurcation), and bilaterally in the gluteal muscle (the upper edge of the acetabulum). The SUVmax, SUVmean, and standard deviation (SD) were recorded for each ROI. Considering the 300-second OSEM reconstruction image as a standard, a 5-point Likert scale and semi-quantitative analysis were used to compare the effects of OSEM and DLR on image quality, detection rate, and uptake value of primary and metastatic lesions at different acquisition durations. ***Results:*** Fourteen patients with recurrence were identified, with nine primary and eleven metastatic lesions. The signal-to-noise ratio (SNR) of the liver, ascending aorta, and gluteal muscle in images acquired for 10, 20, and 30 seconds of OSEM reconstruction were lower compared to images reconstructed with 300-second OSEM reconstruction ($P<0.01$). The visual image quality scores of images and SNR acquired for 10, 20, 30, and 60 seconds were significantly improved with DLR compared to OSEM reconstruction ($P < 0.01$). No significant difference was observed in the SNR of the liver, the ascending aorta, and the gluteal muscle, SUVmax of primary and metastatic lesions between the 20 and 30-second DLR and 300-second OSEM reconstruction images ($P>0.05$). ***Conclusion:*** DLR can significantly improve the image quality of $^{18}$F-FAPI-04 total-body PET/CT with ultrafast acquisition. Compared with 300-second OSEM reconstruction, the 20 and 30-second DLR image quality and tumor (primary and metastatic lesions) quantitative evaluation are comparable.

## EP-0662

### Effect of time-of-flight capabilities on noise in clinical PET-CT

***S. McQuaid***, *L. Carnegie-Peake, J. C. Dickson;*
*Institute of Nuclear Medicine, London, UNITED KINGDOM.*

***Aim/Introduction:*** PET systems with different time-of-flight (ToF) capabilities and crystal sensitivities are commercially available. The aim of this work was to assess the impact of ToF on noise in a variety of patient study types, and therefore to determine the relative gain in crystal sensitivity needed to overcome a lack of ToF capabilities in each study type. ***Materials and Methods:*** Ten datasets acquired in listmode on a Siemens Vision 600 (ToF resolution: 240ps) were used for this study: 3 paediatric FDG studies, 4 brain FDG studies and 3 Rb-82 cardiac studies. Each dataset was reconstructed with and without ToF, and reduced-count ToF datasets were reconstructed by using 80, 60, 40 and 20 % of the original listmode data. All ToF reconstructions used OSEM with PSF modelling, with 4 iterations and 5 subsets. The non-ToF dataset reconstructions used 15 iterations to produce equivalent convergence (as previously determined from phantom data), but all other parameters were matched. Noise was compared between reconstructions for each patient through evaluation of the standard deviation (SD) of counts within volumes-of-interest (VOIs). The downsampled ToF dataset with matched noise to the non-ToF data was determined and used as an estimate of the effective sensitivity gain introduced by the ToF capabilities. ***Results:*** Liver VOIs in FDG wholebody data demonstrated higher noise in non-ToF datasets, with VOI SDs on average 60% higher (47-82%) compared to the non-ToF datasets. Noise was matched when the ToF datasets were downsampled to on average 29% (range 22-32%) of the full counts, indicating a factor effective sensitivity increase of over 3 produced by the ToF capability. Other VOIs exhibited similar results: small FDG hotspot VOIs in the wholebody data required ToF downsampling to 31% on average (range 27-34%) to match non-ToF SDs, brain VOIs matched at 24% (range 20-33%) downsampling and Rb-82 myocardial VOIs matched at 38% (range 27-44%) downsampling. These are equivalent to factor increases in effective sensitivity of 3.5, 3.3, 4.1 and 2.6 for each of the VOIs/scan types respectively. ***Conclusion:*** Although variations between patients and between study types were seen, the use of ToF produced substantial gains in effective sensitivity for all study types, with noise being matched to non-ToF reconstructions with 20-40% of the counts. Systems without ToF capabilities therefore need at least a 3-fold increase in sensitivity to produce images with equivalent noise to that of a 240-ps resolution ToF system with the same axial field-of-view.

## D: Technical Studies -> D1 Instrumentation -> D13 PET/MR

## EP-0663

### Development of a low-cost protocol using standard equipment for the constant infusion administration of [18F]FDG in PET-MR

***A. Cripps***[1], *J. Taylor*[1,2], *M. Singleton*[1], *D. Selvarajah*[1,2], *G. Armitage*[1], *A. Scott*[1];
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM,* [2]*University of Sheffield, Sheffield, UNITED KINGDOM.*

***Aim/Introduction:*** PET-MR research study required the constant infusion of [$^{18}$F]FDG at a slow rate (36mL/hr) for 1 hour to a patient on the PET-MR scan bed. The administered activity was patient weight-dependent, expected to be an average of 300MBq/patient. There was no appropriate method in the literature, and no pieces of equipment available to us that could meet the needs of the study, so we have developed a low-cost protocol using a standard infusion pump to perform constant infusion of PET tracers in the MR environment. This method aimed to keep the radiation dose to staff and the patient as low as reasonably practicable, to minimise radiation contamination risk, and to maintain MR safety. ***Materials and Methods:*** It was decided to eliminate the need for MR-shielding of equipment, by hosting much of the set-up in an adjacent room that contained a hatch into the scan room. A drip stand was used to hold a burette with two inputs, one of which was attached to a saline bag, and the other was used as a port to inject [$^{18}$F]FDG into. The [$^{18}$F]FDG and saline were mixed in the burette. The burette output port was connected to a volumetric infusion pump, which was attached to 6.75m of extension lines, passing through the hatch into the scan room, and terminating at the patient bed, where they could be connected to a cannula. The only significant cost was attributed to custom lead shielding that clamped onto the drip stand to surround the burette. Radiation doses were calculated manually and using computed dose simulation software. Doses were considered for the whole body, skin/extremity, and eye dose for all aspects of the routine work, as well as several reasonably foreseeable incidents. ***Results:*** The developed protocol met the specification, with radiation and MR safety accounted for. The total cost of the project was less than £400, which is significantly less than the cost of an MR-compatible infusion pump. The projected radiation doses to staff were 0.036mSv/procedure for routine external whole-body and eye dose, and 6.3mSv/procedure for external skin/extremity dose. The greatest reasonably foreseeable incident dose was 28.5mSv to the skin/extremities, if [$^{18}$F]FDG was ejected from the line. These results added justification to the ongoing classification of the staff concerned. ***Conclusion:*** We have successfully developed a low-cost protocol for the slow infusion of [$^{18}$F]FDG in the PET-MR environment, that considers both radiation and MR safety.

## EP-0664

### Addressing PET Attenuation Correction Challenges for the ACR Accreditation of a Simultaneous PET/MR Scanner

***H. Kulkarni***[1], *A. Samuels*[1], *T. Faasse*[1], *V. Sridhar*[2], *L. Hu*[2], *J. Botti*[1]; [1]*BAMF Health, Grand Rapids, MI, UNITED STATES OF AMERICA,* [2]*UIH America, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Integrating both PET and MRI modalities into a single scanner with simultaneous acquisition has several advantages in various clinical applications but is met with unique challenges for implementation with the highest quality standards. The uPMR 790 PET/MR combines the SiPM-based HD TOF 32-cm-axial-field-of-view PET with a 3T MRI. This advanced technology needs standardized quality assurance. The American College of Radiology (ACR) accreditation ensures clinically relevant and standardized image quality measurement using phantom testing. Although PET/CT imaging utilizes CT-based PET-attenuation correction, the MR-generated maps cannot be used for accurate attenuation correction in PET/MR, causing potential bias of molecular imaging parameters like SUV. We describe the quality assurance of the PET/MR scanner based on ACR testing guidelines for MRI and PET, along with unique solutions to intrinsic imaging-related challenges. ***Materials and Methods:*** The ACR-PET-Phantom was used to perform adequate F-18-PET testing. The phantom was filled with F-18, and SUVs in the background, and the radioactivity-filled regions were assayed. Best practices included measurement of the residual syringe activity, scanner cross-calibration, and clock synchronization. Specific μ-maps registering ACR phantom images for attenuation and scatter correction were generated and used. Standardized phantom fixation and positioning ensured the correct alignment of μ-maps in relation to PET. PET images were reconstructed per ACR parameters. The ACR-MRI-Phantom was scanned using recommended MRI sequences. Axial T1W images were obtained as follows: TR= 4500, 5.0mm-slice-thickness with 5.00mm-gap, 480x480-matrix. Axial T2W images were obtained as follows: TR=2000, 5.0-mm-slice-thickness with 5.00mm-gap, 384x 384-matrix. Additionally, all site coils (Body, Integrated Spine, Large and Medium Flex, Knee, Shoulder, Breast, and Head Coils) were tested with T1W acquisitions as follows: TR=300, TE=20, 5.0mm-slice-thickness with 5.00mm-gap, and 384x384-matrix. ***Results:*** PET imaging of the ACR phantom registered with the specific μ-maps showed the background SUVmean of 0.93 and SUVmax of 1.91-2.75, both within the recommended ACR limits. Uniformity and noise were evaluated qualitatively through inspection of reconstructed tomographic sections by a certified medical physicist and were found to be within acceptable limits. All ACR MRI phantom sequences produced a relative SNR of 1.0 (100%), acceptable according to ACR guidelines on all coils and sequences. ***Conclusion:*** The performance measurements of the uPMR 790 PET/MR system are comparable with other state-of-the-art PET/CT systems using unique solutions created to address challenges pertaining intrinsically to the imaging modality, and these can be extended for use in other clinical systems. ***References:*** ACR guidance documents for nuclear medicine/PET and MRI accreditation.

### Coincidence distribution in 2-layer hemispheric PET geometries

***K. Scheiff****, A. Pashazadeh, C. Hoeschen;*
*Otto-von-Guericke-University Magdeburg, Magdeburg, GERMANY.*

***Aim/Introduction:*** Positron Emission Tomography (PET) is used for diagnostic and research purposes of a wide range of brain diseases, requiring high resolution of about 1mm. To achieve such resolution, brain-dedicated geometries have been proposed and prototyped in recent years.[1] Many of these PET-systems use (hemi-)spherical geometries to minimize the scanner's radius and reach a desired resolution.[2] Like most PET-systems, brain-dedicated geometries commonly utilize detectors with pixelated crystals. However, over the last decade, detectors using monolithic crystals have achieved intrinsic resolutions comparable to pixelated ones.[3] Since the intrinsic resolution of monolithic crystals is related to their thickness, a second layer of detectors can be added to achieve the same total-crystal-depth as that

used in pixelated detectors and to close gaps in the positioning of the first layer. By having pixelated crystals on the inner layer and monolithic detectors on the outer layer, time-of-flight resolution and depth-of-interaction resolution can be achieved, respectively. The ratio of coincidences on each layer and interlayer-coincidences provides information on the impact of the abilities on the image quality. ***Materials and Methods:*** The simulation study was conducted using GATE. We simulated 2-layer hemispheric PET-geometries with detectors, employing pixelated crystals on the inner and monolithic crystals on the outer layer. The geometries were simulated for BGO, LSO and LYSO crystals and activities between 0.1MBq and 100MBq. An in-house coincidence sorter provides the number of coincidences, with singles either on the inner layer, outer layer or one on each layer. ***Results:*** The coincidence distribution regarding the layers is presented. For all materials, interlayer-coincidences dominate, with an average percentage between 55.2% (BGO) and 58.9% (LSO). The second highest fraction of coincidences were inner-layer-coincidences, with an average between 36.3% (BGO) and 29.4% (LYSO). The smallest contribution to total coincidences was observed for outer-layer-coincidences, ranging from 8.4% (BGO) and 16.6% (LYSO) in average. ***Conclusion:*** More than 50% of the coincidences in 2-layer geometries are interlayer-coincidences. Outer-layer-coincidences contribution is highly material dependent. The impact of special abilities of different detector types is therefore limited. The interlayer-coincidences effect on the resolution needs further investigation. ***References:*** [1] Ciprian Catana, Development of Dedicated Brain PET Imaging Devices: Recent Advances and Future Perspectives,J.Nucl.Med.2019Aug.;60(8):1044-1052. ### MC Simulator Framework for Monolithic Scintillator Based PET and SPECT

***J. Peter****, L. P. Clemens;*
*German Cancer Research Center, Heidelberg, GERMANY.*

***Aim/Introduction:*** A fully integrated Monte Carlo (MC) simulation (and reconstruction) framework tailored for monolithic scintillator-based PET and SPECT imaging systems is proposed in order to investigate particular aspects of system design and imaging realization. ***Materials and Methods:*** The framework integrates dedicated simulators for positron and high-energy photon propagation within heterogeneous phantoms as represented by arbitrary integration of multi-parametric polygonal surface meshes (PSMs) and point/cell clouds. Phantom, source and parameter management for all involved physical entities is compatible with the multimodal simulation and reconstruction framework Musiré, [1], it is however extended by time/space probabilistic parameter modeling. Scintillation crystals can be defined either as arbitrary PSMs in free space or constrained to (cylindrical, orbital) scanner geometry, including phoswich capabilities, and can be fitted with digital sensors, e.g. Silicon photomultiplers, that include diverse primary and correlated noise models. Low energy scintillation light distributions within the crystals are modeled using an integrated dedicated simulator yielding light fluences on the crystal surfaces. From those, photoelectric interaction sites are estimated employing various approaches from inline statistical fluence moment estimation to unsupervised machine learning approaches using Gaussian mixture models. For subsequent image reconstruction, estimated interaction sites can be preserved as point clouds to enable novel image reconstruction strategies or, to be compatible with existing reconstruction software, can be discretized into virtual binning planes. This new framework, when integrated into the Musiré ecosystem, supports automatic distribution and parallel execution of simulation requests in a multimodal context. It also extends that ecosystem by adding simulator and reconstructor pipelines. ***Results:*** The monolithic scintillator kernel allows for the investigation of detection, energy, timing, and position information for a variety of crystal and sensor arrangements. One exemplary field of application is the study of extended axial field-of-view (total body) PET systems. A simulation study was executed to assess and to improve spatial resolution and partial volume homogeneity, which can be impaired by parallax effects of oblique lines-of-responses in conventional voxelized block detector systems (e.g. Siemens Biograph Quadra Vision), through modified monolithic detector implementation. ***Conclusion:*** Physically exact MC simulation in nuclear imaging not only remains, but increasingly becomes a more and more prolific research tool helping to advance the current state-of-the-art. ***References:*** [1] Peter, J. "Musiré: multimodal simulation and reconstruction framework for the radiological imaging sciences" RSTA, 379(2021).

## EP-0668

### The Situation of Nuclear Medicine in China: A Report of the First Official Nationwide Survey in 2021

***H. Zhang****[1], J. Zheng[2], N. Hu[1], Y. Liu[1], H. Jing[1], L. Huo[1];*
*[1]Peking Union Medical College Hospital, Beijing, CHINA, [2]Department of Radiology, University of Cambridge, Cambridge, UNITED KINGDOM.*

***Aim/Introduction:*** National Nuclear Medicine Quality Control Center of China conducted the first official survey to investigate the nationwide situation of nuclear medicine in 2021. The survey aimed to unveil the current nuclear medicine situation and its quality control in China. These results are the foundation for the establishment of the quality control management system. ***Materials and Methods:*** The web-based survey was conducted and the data was collected via the National Clinical Improvement System of China from June 31 to August 31, 2021. Significant deviations from the reported data were checked and corrected with phone confirmation. ***Results:*** A total of 808 institutes across 30 provinces responded to the national survey. For human resources, there are 4460 nuclear medicine physicians (1.6 to 10.3 per million population among provinces), 3077 technicians (0.8 to 7.7), and 339 physicists (0.1 to 0.9). There are 887 single-photon imaging instruments, including 354 (40%) SPECT, and 365 PET instruments, including 314 (86%) PET/CT. There are on average 1.0 SPECT and 0.4 PET per million population. 600 (74%) institutes perform SPECT examinations and 302 (37%) perform PET examinations. 60% of SPECT scans are bone scintigraphy. 97% of PET scans use an $^{18}$F-FDG tracer. Furthermore, 551 (68%) institutes provide radionuclide therapy services but only 280 (35%) have admission rooms. Among the 808 institutes, the top three radionuclide therapies are $^{131}$I-targeted therapy for hyperthyroidism with 546 (68%) institutes, $^{89}$Sr-targeted therapy for bone metastasis with 400 (50%) institutes and $^{131}$I-targeted therapy for differentiated thyroid cancer with 286 (35%) institutes. Finally, for the frequency

of equipment quality control per year, there are about 67 times (ranging from 7 to 172) self-inspections within the department for SPECT instruments and 111 times (ranging from 9 to 278) for PET instruments on average in each province. There are about 4 failures (ranging from 2 to 6) of SPECT and 5 failures (ranging from 2 to 12) of PET on average per year in each province. There are 408 institutes (of 600 SPECT institutes) performing quality control of SPECT radiopharmaceuticals, 216 (of 302) for PET and 373 (of 551) for radionuclide therapy. ***Conclusion:*** There are high heterogeneities in geographical distributions of human resources and equipment, and in common types of SPECT scintigraphy, PET tracer usage and radionuclide therapy. The average quality control frequency of SPECT complies with the government regulation with a lack of government regulations for quality control of PET and radionuclide therapy.

### Monte Carlo performance with impact of different crystal materials on sensitivity characteristic of preclinical PET scanner

***Z. Karimi***[1], *P. Sheikhzadeh*[2], *M. Ay*[3];
[1]*Faculty of Physics, University of Isfahan, Isfahan, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment Institute (AMTEI), Tehran University of Medical Sciences (TUMS), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Nowadays, significant technological advances have been made in design of small animal PET scanners that improved image quality and quantitative accuracy such as development of new scintillation materials. New our developed dedicated small animal scanner was manufactured based on Silicon Photomultipliers (SiPMs) with LYSO crystals. However, it is necessary to choose the appropriate crystal that can improve the scanner's performance or provide a cost-effective scanner. The aim of this research is to develop an accurate Monte Carlo simulation model of this scanner, and outcome simulating an impact of scintillation material on absolute sensitivity characteristic to find the optimum material. ***Materials and Methods:*** The animal PET scanner was simulated via (GATE), the Geant4 Application for Tomographic Emission with eight different scintillation materials (CeBr3, GLuGAG, LaBr3, LFS, LSO, LYSO, LuAP, LuYAP). The Absolute sensitivity was calculated following the guidelines of National Electrical Manufactures Association (NEMA) NU-4 2008 standard, therefore a point source with activity of 11.1 kBq was simulated at center of FOV. It emitted mono-energetic back-to-back 511 keV photons with time running of 70 seconds then replace it via step of 5 mm along the axial FOV (50.3 mm). Two classes of energy window (250-650 keV and 400-700 keV) were also selected. The obtained results were compared together to find optimum crystal for the animal PET configuration. ***Results:*** The highest absolute sensitivity at CFOV was 3.35% for LuAP material at energy window of 250-650 keV and 2.53% at energy window of 400-700 keV. LFS, LYSO and LuYAP had absolute sensitivity of 2.96%, 2.80% and 2.55% respectively after LuAP with energy window of 250-650 keV and also 2.24%, 2.06% and 1.80% at energy window of 400-700 keV. These values are appropriate for manufacturing preclinical PET scanner with high sensitivity in comparison to other materials such as LSO, GLuGAG, LaBr3 and CeBr3. ***Conclusion:*** After our analysis, we determined that the sensitivity could be enhanced by utilizing LuAP scintillator material. This choice would result in high-performance capabilities and is well-suited for preclinical molecular imaging-based research. Additionally, utilizing GLuGAG as a low-cost design further supports this conclusion. ***References:*** Ghabrial, A., Franklin, D., & Zaidi, H. . A Monte Carlo simulation study of the impact of novel scintillation crystals on performance characteristics of PET scanners. Physica Medica, 2018. 50, 37-45.

## EP-0670

### Determination of the Kernel with which to Smooth the CT for Air Fraction Correction in Lung PET/CT Studies

***F. Leek***[1,2], *C. Anderson*[3], *A. P. Robinson*[2,4,5], *R. M. Moss*[1], *B. F. Hutton*[1], *K. Thielemans*[1];
[1]*University College London, London, UNITED KINGDOM,* [2]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [3]*University College London Hospital NHS Foundation Trust, London, UNITED KINGDOM,* [4]*The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM,* [5]*University of Manchester, Manchester, UNITED KINGDOM.*

***Aim/Introduction:*** Voxel-wise air fractions (AF) determined from the CT can be used to correct for variable air content in lung PET/CT [1]. However, resolution mismatch between PET and CT can cause artefacts in the AF-corrected image. We compare methodologies for determining the optimal kernel to smooth the CT when PET images are reconstructed with iterative reconstruction methods. ***Materials and Methods:*** Noiseless simulations and non-TOF MLEM reconstructions were performed. An idiopathic pulmonary fibrosis (IPF) patient-realistic digital phantom was constructed. The optimal smoothing was determined in six VOIs within the lungs via i) the point-source insertion-and-subtraction method, $h_{pts}$; ii) AF-correction with varyingly smoothed CT to achieve the lowest RMSE with respect to the ground truth AF-corrected VOI, $h_{AFC}$; iii) smoothing a ground truth image to match the reconstruction within the VOI, $h_{PVC}$. Optimal kernels were used for AFC and VOI RMSE was calculated. A non-uniform AF-corrected lung (cold sphere walls) prohibits the application of $h_{AFC}$ to measured data; only the $h_{PVC}$ method was considered. A modified thorax phantom (spherical inserts in each lung) was acquired on two clinical scanners. Ground truth images were constructed from CT and known activity concentrations. The WMSE in a single VOI, the physical diameter of the spheres (0-4 voxel dilations), determined the optimal kernel. The largest VOI was used to determine the RMSE. ***Results:*** Simulations: for iterative reconstruction, optimal kernel FWHM was dependent on iteration number (i) and VOI position. At 1000i, a kernel FWHM range still existed (7.01-10.6mm), depending on method and VOI position. Despite this, the range of the RMSE of the AF-corrected reconstructed VOIs was 4.46-10.3%. Measured: the range of $h_{PVC}$ FWHMs for varying VOI diameters was 8.75-9.55mm. VOI RMSE ranged between 5.61-9.10% of the unAF-corrected ground truth. ***Conclusion:*** All three kernel determination methods on simulated data produce roughly equivalent AF-corrected RMSE, suggesting that AF-corrected quantification is not very sensitive to the smoothing applied to the CT. This provides confidence in the $h_{PVC}$ method and a single VOI approach to determining a global kernel for AFC on measured data. The small range of $h_{PVC}$ FWHMs obtained for varying VOI sizes on the measured data suggests that kernel width is not very dependent on VOI size. The low RMSE indicates that $h_{PVC}$ has the potential to be utilised to determine the appropriate kernel for AFC on clinical scanners for application to patient PET/CT lung scans. ***References:*** [1] Lambrou et al., EJNMMI, 38, 2011.

### Is It Reliable to Use NMQC-Toolkit as a Self-QC Software for Nuclear Medicine Departments?

***N. KODALOGLU***[1], *G. Vural*[2], *N. C. Gülaldi*[3];
[1]*University of Health Sciences, Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Department of Radiation Oncology, ANKARA, TÜRKIYE,* [2]*University of Health Sciences, Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Department of Nuclear Medicine, ANKARA, TÜRKIYE,* [3]*University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, ANKARA, TÜRKIYE.*

***Aim/Introduction:*** IAEA (International Atomic Energy Agency) (1), NEMA (National Electrical Manufacturers Association)(2), EANM (European Association of Nuclear Medicine)(3), have different guidelines for analysing routine quality control and quality assurance testing of gamma camera and SPECT systems. However, since many countries lack experienced personnel, independent analysis software is needed to evaluate the QC test images to take action. Nuclear Medicine Quality Control (NMQC) Toolkit (4) is a QC image processing and analysis software developed under the auspices of IAEA. We want to investigate whether this program is feasible and reliable for those nuclear medicine departments that have independent evidence of the quality control decision of their gamma camera units. ***Materials and Methods:*** In this study, we analyzed the images of the planar (intrinsic flood field) uniformity, tomographic resolution etc. tests of the SPECT-CT system (Mediso AnyScan SC, SPECT/CT Hungary) in 2 different time period and compared them to the vendor's results. The results of the analysis of the software are presented in Table 1. The pass criterion for NEMA NU-1 (2) or IAEA HHS-6 (1) testing is between 3.5-5% (upper limit: 5%). Ultra-high-performance threshold levels for differential Central Field of Volume (CFOV), differential Useful Field of Volume (UFOV), integral CFOV, integral UFOV are 1.4%, 1.9%, 1.9%, 2.4%, respectively.) ***Results:*** As can be seen from Table 1, all QC test results after the calibrations were within acceptable limits or below the threshold defined by NEMA and IAEA guidelines. ***Conclusion:*** The NMQC-toolkit is a user-friendly tool to adapt to the daily routine. It doesn't take time to install the software, get used to the interface, and access the software's results to decide when to take action to respond to an unacceptable result. It can be used as a self-QC software for the nuclear medicine departments who owe different kind of SPECT devices and want to collect and store their QC data with the same and independent software. ***References:*** 1. ## EP-0672

### The Role of SPECT/CT NEMA NU2 Calibration in Quantitative Imaging

***I. Irimescu***[1,2], *R. Maaz*[1], *A. Lazar*[1], *M. Mutuleanu*[1,3], *C. Petroiu*[1], *M. Mihailescu*[2], *M. Gherghe*[1,3];
[1]*Institute of Oncology „Professor Doctor Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*Applied Sciences Doctoral School, Politehnica University, Bucharest, ROMANIA,* [3]*„Carol Davila" University of Medicine and Pharmacy, Bucharest, ROMANIA.*

***Aim/Introduction:*** Quantification is one of the major benefits of molecular imaging. Compared to PET/CT, the "gold standard" for absolute quantification, quantitative SPECT/CT imaging allows the usage of a wider range of radiopharmaceuticals and applications. Performing acquisitions using SPECT/CT systems that meet the requirements of periodic quality control tests and are properly calibrated according to NEMA/IAEA/AAPM international guidelines is essential for obtaining accurate quantitative results. ***Materials and Methods:*** In our study, we used SPECT/CT acquisitions of a cylindrical homogeneous phantom and a NEMA NU2 phantom on two Discovery 670 DR SPECT/CT systems (GE Healthcare), equipped with low energy - high resolution collimators, to evaluate the operational mode and the quality of the obtained images. Six spherical inserts (10, 13, 17, 22, 28, and 37 mm in diameter) were filled with Tc99m-pertechnetate, with an activity concentration 8.5 times higher than the concentration of the phantom background. The following tests were performed: volumetric sensitivity of the SPECT/CT system (according to NEMA No. 1: 2018), accuracy of activity recovery, image noise evaluation and deviation from the total activity. For these tests, we used a cylindrical phantom of known volume, containing radioactive solution, performing acquisitions according to the NEMA protocol, with 120 projections per 360 degrees (60 degrees per detector). Quantitative SPECT reconstructions for the obtained test images were done with the dedicated software module, using the Ordered Subset Expectation Maximization (OSEM) algorithm. ***Results:*** Our results showed that the best quantitative reconstruction algorithm can be obtained for 10 iterations with 4 subsets, because this algorithm conveys into less noise, and its accuracy is higher than 95%, finding a balance between quantitative accuracy and visual analysis of the obtained images. The activity concentration recovery in the insert with diameter > 24 mm was satisfactory (variation of less than 5%). Following the tests, no results were obtained for one of the equipment according to the acceptance criteria recommended by the manufacturer and the international guidelines, and corrective actions and recalibrations were required. ***Conclusion:*** The set of images used for diagnostic purposes is made with a limited number of iterations and with post-filtering. For quantitative accuracy, the reconstruction includes correction for patient motion, attenuation, scatter, and collimator blur. For more accurate quantitative results, the number of iterations should be increased and post-filtering avoided. The resulting image is quantitatively more accurate, but also noisier and less suitable for viewing.

## EP-0673

### Stability of Brain PET/CT Image Quantification for Imaging with a VR Headset

***L. Raes***[1,2], *S. Bourgeois*[1], *A. Bracke*[1], *T. De Haan*[1], *H. Everaert*[1,2];
[1]*Universitair Ziekenhuis Brussel, Brussels, BELGIUM,*
[2]*Vrije Universiteit Brussel, Brussels, BELGIUM.*

***Aim/Introduction:*** Acquiring SPECT/CT or PET/CT images in patients suffering from claustrophobia can be challenging due to long acquisition times and camera design. This often results in degradation of imaging quality. Virtual Reality (VR) headsets have been successfully used in the emergency department to reduce anxiety and could potentially offer a solution to address this issue in nuclear medicine, hereby obliterating the need for pharmacological sedation. ***Materials and Methods:*** A clinical PET/CT system (FOV 16.2 cm) was used to acquire a 720s PET scan of a Hoffman 3D brain phantom filled with ~23kBq/mL [$^{18}$F]-FDG. Scan data were reconstructed using various reconstruction settings and were compared to baseline (clinically used reconstruction settings). Recovery Coefficient (RC) and Grey Matter (GM) to White Matter (WM) ratio (GMWMr) were calculated for the whole brain, as well as for the Frontal- (FL), Parietal- (PL) and Occipital Lobes (OL). Contours were delineated on the phantoms without VR headset mounted, to which the phantoms with VR

headset were registered using rigid transformations. ***Results:*** No significant systematic discrepancies in the RC of multiple regions and GMWMr were observed between images with and without VR headset. RCs of the regions as reconstructed without Point Spread Function (PSF), resp. without and with VR headset mounted, were as follows: $RC_{GM}$=[0.73-0.75], $RC_{GM-FL}$=[0.81-0.82], $RC_{GM-OL}$=[0.78-0.79], $RC_{GM-PL}$=[0.73-0.72], $RC_{WM}$=[0.38-0.39], $RC_{WM-FL}$=[0.45-0.47], $RC_{WM-OL}$=[0.42-0.44], $RC_{WM-PL}$=[0.42-0.41], leading to a GMWMr between [1.73-1.93]. For reconstructions with PSF, the following RCs were obtained: $RC_{GM}$=[0.77-0.78], $RC_{GM-FL}$=[0.84-0.86], $RC_{GM-OL}$=[0.82-0.82], $RC_{GM-PL}$=[0.75-0.74], $RC_{WM}$=[0.36-0.37], $RC_{WM-FL}$=[0.42-0.44], $RC_{WM-OL}$=[0.40-0.42], $RC_{WM-PL}$=[0.41-0.40], leading to a GMWMr between [1.85-2.13]. No visual differences were present in the PET image, although some streak artefacts were present in the CT image at the level of the battery pack. The attenuation map of that image was less subject to artefacts: [0.02-0.02]/mm vs [134-176] $HU_{Avg}$ for a sphere VOI close to the battery pack within the plastic discs, respectively without and with VR headset mounted. ***Conclusion:*** The impact on PET imaging is limited. We conclude that a VR headset can be used during PET/CT imaging. ***References:*** Rousseaux F, Panda R, Toussaint C, Bicego A, Niimi M, Faymonville ME, Nyssen AS, Laureys S, Gosseries O, Vanhaudenhuyse A. ### Parametric imaging of P-glycoprotein function at the blood-brain barrier using KE,brain-maps generated from dynamic [11C]metoclopramide PET data in rodents, monkeys, and humans

***L. Breuil***[1,2], *M. El Bialil*[3], *D. Vodovar*[1], *S. Marie*[1], *S. Auvity*[1,2], *S. Goutal*[1], *S. Rodrigo*[1], *M. Bauer*[3], *O. Langer*[3,4], *N. Tournier*[1];
[1]*1.BioMaps, Laboratoire d'Imagerie Biomédicale Multimodale Paris-Saclay,Inserm, CNRS, CEA, Université Paris-Saclay, Orsay, France, Orsay, FRANCE,* [2]*2. Inserm UMR-S1144, University of Paris Cité, 75006 Paris, France., Paris, FRANCE,* [3]*3.Department of Clinical Pharmacology, Medical University of Vienna, 1090 Vienna, Austria., Vienna, AUSTRIA,* [4]*4.Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Austria., Vienna, AUSTRIA.*

***Aim/Introduction:*** The P-glycoprotein (P-gp) is the most studied efflux transporter expressed at the blood-brain barrier (BBB). Kinetic modeling of PET imaging data using the radiolabeled substrate [11C]metoclopramide showed the importance of P-gp-mediated brain-to-blood efflux ("$k_2$-effect") in promoting the elimination of solutes from the brain. Taking advantage of this property, the elimination slope from the brain ($K_{E,brain}$, $min^{-1}$), which can be directly calculated from dynamic PET images without arterial blood sampling, was evaluated as an outcome parameter to describe P-gp-mediated efflux function at the BBB in several species. ***Materials and Methods:*** The $K_{E,brain}$ parameter was obtained from linear regression of Log-transformed time-activity curves (TACs) obtained in rats, monkeys, and humans. The $K_{E,brain}$ values obtained in the baseline situation were compared with values obtained after complete P-gp inhibition using tariquidar in rats (n=4) and monkeys (n=4) and after partial inhibition using cyclosporin A in humans (n=10), (unpaired Student's t-test). Full kinetic modeling using the 1-tissue compartment model in monkeys enabled a comparison of the sensitivity of $K_{E,brain}$ versus the total volume of distribution ($V_T$), influx ($K_1$), and efflux ($k_2$) rate constants obtained in the same individuals. Finally, $K_{E,brain}$-maps were generated in each species using the PXMOD module of the PMOD software. ***Results:*** The linear part of the Log-transformed brain TACs used to calculate $K_{E,brain}$ was 10-30 min in rats, 15-60 min in baboons, and 20-60 min in humans. P-gp inhibition significantly decreased $K_{E,brain}$ values rats by 39±12% in rats, 32±6% in monkeys, and 37±22% in humans. In monkeys, complete P-gp inhibition was associated 101±12% increase in $V_T$, a 28±14% increase in $K_1$ and a 36±9% decrease in $k_2$. Visual analysis of $K_{E,brain}$-maps displayed an evident decrease in $K_{E,brain}$ in brain of all tested species, although the calculation of parametric images was associated with a loss in spatial resolution. ***Conclusion:*** The $K_{E,brain}$ of [11C]metoclopramide provides a simple outcome parameter to describe the P-gp function in the brain. This method takes advantage of the particular pharmacokinetic properties of [11C]metoclopramide (absence of brain radiometabolites and fast plasma clearance). The sensitivity of $K_{E,brain}$ to detect change in P-gp function reflects the "$k_2$-effect" but is not as sensitive as $V_T$, which estimation requires arterial blood sampling. $K_{E,brain}$ decreases when P-gp function decreases whereas $K_1$ and $V_T$ increase. $K_{E,brain}$-maps therefore provide an intuitive representation of the P-gp activity. $K_{E,brain}$-mapping may not be suitable in rodents but may be useful for voxel-wise analysis in monkeys and humans.

## EP-0675

### Coupling between Cortical Thickness and Glucose Metabolism in the Human Brain: a PET/MRI study

***Q. Huang***[1], *Y. Yang*[2], *N. Qi*[2], *S. Ren*[1], *J. Wang*[1], *Y. Guan*[1], *J. Zhao*[2], *F. Xie*[1];
[1]*Department of Nuclear Medicine & PET center Huashan Hospital Fudan University, Shanghai, CHINA,* [2]*Department of Nuclear Medicine, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** The human brain is an intricately organized system where structure and function of different regions work together to accomplish complex tasks. Disruption of this balance has been implicated in neurological and psychiatric disorders. This study investigated the coupling between cortical thickness (CTh) and glucose metabolism using $^{18}$F-FDG PET/MRI. ***Materials and Methods:*** 138 subjects who performed brain 18F-FDG PET/MRI were retrospectively recruited. The subjects were divided into two age groups: middle adult (MA, 41 male and 28 female, mean age: 42.33±5.25 years) and old adult (OA, 41 male and 28 female, mean age: 60.19±4.88 years) group. All subjects were clinically evaluated and confirmed by whole-body PET/MRI with no brain disorders. The CTh and FDG uptake values were calculated using SPM12 (http://www.fil.ion.ucl.ac.uk/spm) and CAT12 (http://www.neuro.uni-jena.de/cat/). The Spearman-rank correlation coefficient was calculated between the FDG uptakes and CTh values of the series of regions for each subject to explore the structural and functional coupling (S-F coupling) at regional level. And the association between S-F coupling and age was calculated to explore the physiological effects of the S-F coupling. The structural connectivity (SC) based on CTh and functional connectivity (FC) based on glucose metabolism were constructed by calculating

Spearman-rank correlation coefficients between CTh or FDG uptake values of each pair of brain regions in an inter-subject manner. To explore the structural and functional connective coupling (SC-FC coupling), the correlations between the SC and FC matrix were calculated for each group, that is, each row in SC matrix was correlated via Spearman-rank with the same region's row in the FC matrix. ***Results:*** In regional level, 97.83% of subjects exhibited significant negative correlation between regional CTh and FDG uptake across the whole brain ($p<0.05$ with FDR correction), and the S-F coupling was negatively associated with age ($r = -0.35$, $p<0.001$), suggesting a larger discordancy between brain structure and function with aging. While in connective level, SC-FC coupling was almost entirely positive, with more regions in OA exhibiting significant FC-FC coupling than in MA group. SC-FC coupled regions in MA mainly related to visual and sensorimotor functions, while SC-FC coupled regions in OA covered the whole range of functions from primary to high level. ***Conclusion:*** The human brain CTh and glucose metabolism were coupled from regional to connective level, and this coupling could reflect the aging progress. These findings may have implications for the diagnosis and treatment of neurological and psychiatric disorders.

## EP-0676

### Spinal Cord imaging by [11C]PIB PET/MRI: evaluation of drawing methods and reference region use in myelin uptake quantification of Healthy Volunteers and Multiple Sclerosis Patients

***L. Zorante de Lucena***, *M. Sales Pitombeira, K. Repiso Campanholo, C. Alberto Buchpiguel, D. de Paula Faria; Centro de Medicina Nuclear do Hospital da Clínicas da Faculdade de Medicina da USP (CMN-HC-FMUSP), São Paulo, BRAZIL.*

***Aim/Introduction:*** Multiple sclerosis (MS) is a neurodegenerative disease subdivided in Progressive MS (PMS) and Relapsing-Remitting MS (RRMS), affecting Spinal Cord (SC) in 90% of patients, mainly at the cervical level. PET imaging studies of SC are scarce and challenging, due to the low dimensions, movement's artefacts, and lack of methods to define the Volume of Interests (VOIs) and myelin content. PET/MRI enables the interplay between pathophysiology and morphology of the SC in vivo, contributing to understanding MS pathology. This study aims to evaluate different VOI drawing methods and quantification of cervical SC [$^{11}$C]PIB PET/MRI images in patients with MS. ***Materials and Methods:*** The [$^{11}$C]PIB PET and T1-weighted 3T-MRI of 10 healthy volunteers (HV) were evaluated using four VOIs drawing methods, in a semiautomatic and automatic form on sagittal and axial plane. Hence, [$^{11}$C]PIB PET and T1-weighted 3T MRI of 49 MS and 19 HV were assessed using semiautomatic VOI on axial plane and sphere VOI on a neck muscle. The Cervical SC VOIs were based on the anatomical level of the C1/C2, C3 and C4 vertebrae. The results are presented in SUV (Standardized Uptake Value) and SUVr (SUV ratio), with the muscle as reference tissue. The variables evaluated were the [$^{11}$C]PIB PET uptake of the last 20 minutes, considering p-value < 0.05. ***Results:*** No differences were found between the VOI drawings, therefore, the drawing choice can be based on the analyst preference and the time-consuming, considering that VOIs drawing on axial plane takes 1/4 hours, whereas on sagittal plane 30/60 minutes, using automatic and semiautomatic methods respectively. [$^{11}$C]PIB SUV was significantly lower in PMS SC at: C3 level, compared to HV (p=0.02); C4 level, compared to HV (p=0.04) and RRMS (p=0.03). The [$^{11}$C]PIB SUVr in patients with PMS was significantly lower compared to: HV and RRMS at C1/C2 (p=0.24; p=0.028); C3 (p=0.31; p=0.033) and C4 levels (p=0.01; p=0.005). Our results demonstrate that SUVr, using a neck muscle as reference, was more sensitive to differentiate SC myelin content in the PMS group. ***Conclusion:*** We got similar results in the four VOIs drawings strategies, allowing the analyst to choose based on preference and time availability. Regarding the myelin uptake, the SUVr was more sensitive to show Cervical SC myelin content differences in the PMS group in all spinal cord segments evaluated. Thus, SUV ratio using the neck muscle as reference region can be suited to evaluate cervical SC myelin uptake.

## EP-0677

### Quantification of Neuroinflammation using [18F]DPA714 PET in individuals with Long COVID

***S. Golla***[1], *D. Visser*[1], *S. C. J. Verfaillie*[2], *E. M. Coomans*[1], *R. M. Rikken*[1], *E. van de Giessen*[1], *M. E. den Hollander*[1], *M. Yaqub*[1], *A. Verveen*[2], *F. M. van Berckel*[1], *N. Tolboom*[9], *R. Boellaard*[1]; [1]*Department of Radiology & Nuclear Medicine, Amsterdam Neuroscience, Vrije Universiteit Amsterdam, Amsterdam, NETHERLANDS,* [2]*Department of Medical Psychology, Amsterdam University Medical Centers, University of Amsterdam, Amsterdam Public Health Research Institute, Amsterdam, NETHERLANDS,* [3]*Institute of Neurology and Healthcare Engineering, University College London, London, UNITED KINGDOM,* [4]*Department of Intensive Care & Laboratory of Experimental Intensive Care and Anesthesiology (L·E·I·C·A), University of Amsterdam, Amsterdam UMC, Amsterdam, NETHERLANDS,* [5]*Pulmonary Medicine, OLVG, Amsterdam, NETHERLANDS,* [6]*Department of Anaesthesiology, Amsterdam Neuroscience, Vrije Universiteit Amsterdam, Amsterdam UMC, Amsterdam, NETHERLANDS,* [7]*School of Chemistry, The University of Sydney, Sydney, AUSTRALIA,* [8]*Department of Internal Medicine, University of Amsterdam, Amsterdam UMC, Amsterdam, NETHERLANDS,* [9]*Department of Radiology & Nuclear Medicine, University Medical Centre Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** 'Long COVID', occurs in a significant number of individuals after a COVID-19 virus infection. Previous histopathology studies have indicated severe neuroinflammatory responses in COVID-19 patients. Positron emission tomography with [$^{18}$F]DPA714 can be used to study in vivo neuroinflammation. Quantification of in vivo kinetics of [$^{18}$F]DPA714, however, requires identification of optimal kinetic parameter(s). Earlier studies showed that distribution volume ($V_T$) is affected by the rate of influx of the tracer from blood ($K_1$), suggesting $V_T$ to be unreliable. Moreover, $K_1$ appears to be highly variable, possibly due to inter-region/subject variations in the extraction fraction, maybe due to the binding to endothelium of blood vessels in the brain observed with [$^{18}$F]DPA714. The aim of the current study was to identify a suitable kinetic parameter to assess the (specific) signal in post-COVID individuals. ***Materials and Methods:*** For this study, 23 post-COVID individuals (18 high affinity binders (HAB), 5 mixed-affinity binders (MAB)) with persistent and severe complaints and, 3 post-COVID individuals (3 HABs) without substantial complaints were included. All subjects underwent a 60 min dynamic PET acquisition using [$^{18}$F] DPA714 with arterial sampling. Regions of interests were defined using PVElab and Hammers template. A plasma input reversible two tissue compartmental model with blood volume correction was applied to obtain micro/macro-parameters. Associations of $V_T$ and binding potential ($BP_{ND} = k_3/k_4$) with $K_1$ were evaluated. Inter-region/subject non-displaceable distribution volume ($V_{ND} = K_1/k_2$) were assessed. Pseudo distribution volume ratio ($DVR_{WhBr}$) was estimated by correcting $V_T$ with $V_{ND}$ of whole brain grey

matter. Additionally, differences between the HABs and MABs using different micro/macro-parameters for different regions of interest were explored. Linear regression and t-tests were performed to evaluate the associations and significance ($p<0.01$) between different parameters. ***Results:*** Significant association between $V_T$ and $K_1$ ($r = 0.57$) was observed for all subjects (even when segregated into different subject groups). Inter-region/subject differences for $V_{ND}$ were observed, though, inter-regional differences seem to be minimal compared to inter-subject differences. No significant differences between MABs and HABs was observed for $V_{ND}$ of whole brain grey matter. Significant differences for whole brain grey matter between MABs and HABs with $K_1$, $k_3$, $V_T$, $BP_{ND}$ and $DVR_{WhBr}$ were observed. ***Conclusion:*** $V_T$ does not seem to be a suitable parameter for quantification of [$^{18}$F]DPA714 binding due to its strong association with $K_1$. We propose either the use of $BP_{ND}$ or $DVR_{WhBr}$ for quantification of [$^{18}$F]DPA714 in individuals with (Long)COVID.

## EP-0678

### Florbetaben PET quantification strongly agrees with histopathological confirmation of amyloid-beta load and visual reads.

***S. Bullich***[1], *J. Koikkalainen*[2], *A. Jovalekic*[1], *N. Roé-Vellvé*[1], *G. D. Kolinger*[1], *N. Koglin*[1], *A. W. Stephens*[1], *L. Thurfjell*[2];
[1]*Life Molecular Imaging GmbH, Berlin, GERMANY,*
[2]*Combinostics Oy, Tampere, FINLAND.*

***Aim/Introduction:*** Positron emission tomography (PET) with florbetaben is an established tool for detecting amyloid-beta deposition in the brain either by visual inspection or quantitation. Several software packages have been developed allowing continuous measurement of amyloid-beta burden. This work assessed the performance of florbetaben PET quantification using cPET against post-mortem histopathological confirmation, the comparison against visual examination, and its capacity to detect subtle longitudinal amyloid-beta deposition. ***Materials and Methods:*** This analysis used florbetaben PET images from previous clinical trials (n=673). PET scans were quantified with cPET (Combinostics Oy) using either the PET-only pipeline (PET-pipeline) or structural MRI (MRI-pipeline) to obtain standardized uptake value ratios (SUVR) with the whole cerebellum as reference region and centiloids (CL). The optimum cutoffs for amyloid-beta load classification were derived using receiver operator characteristic curve analysis using histopathology as the standard of truth (Bielschowsky silver staining in combination with immunohistochemistry) (n=90). The percentage of agreement between quantification and majority visual assessment from 5 independent blinded readers was also compared using the derived cutoffs (n=386). Amyloid-beta deposition over time was assessed in a group of mild cognitively impaired subjects (n=41) that underwent at least a one-year follow-up scan. ***Results:*** The optimal SUVR cutoffs to classify amyloid-beta positive and negative scans were 1.13 (26.9 CL) (MRI-pipeline), 1.11 (35.5 CL) (PET-pipeline). The mean sensitivity, specificity, and accuracy were 96.3%, 96.2%, and 96.3% (MRI-pipeline), and 90.7%, 100.0%, and 94.4% (PET-pipeline). The percentage of agreement between binary quantitative assessment and visual read was 92.8% (MRI-pipeline) and 94.8% (PET-pipeline). In those subjects where the five independent blinded readers assessed the scans by consensus, the agreement was 98.2% (MRI-pipeline) and 98.8% (PET-pipeline). In a subset of amyloid-beta negative elderly cognitively normal subjects, 95% of the subjects had SUVR values below 1.1 (22.9 CL)( MRI-pipeline) and 1.0 (17.1 CL) (PET-pipeline). Both pipelines detected statistically significant differences in amyloid-beta deposition over time between negative and positive subjects at baseline. ***Conclusion:*** cPET quantification exhibits a high sensitivity and specificity to detect amyloid-beta load and excellent agreement with visual assessment. The results suggest that quantification obtained from cPET can be used for continuous measurement of amyloid-beta burden and to assess amyloid-beta change over time.

## EP-0679

### Attenuation correction of cardiac PET with end-expiratory CT and average CT

***K. Sander***[1], *T. Pan*[2], *A. Roby*[1];
[1]*University of Texas Medical School, Houston, TX, UNITED STATES OF AMERICA,* [2]*University of Texas at M. D. Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Misregistration between PET and CT data can compromise attenuation correction (AC) and quantification of cardiac perfusion on $^{82}$Rb PET scan. Although average CT (ACT) is effective for AC of cardiac PET, it can suffer from irregular respiration (IR) due to acquisitions of 1 to 2 breathing cycles of cine CT data. New end-expiratory (EE) CT can be extracted from the same cine CT data for ACT via data-driven gating. The aim is to compare ACT and EECT in AC of cardiac perfusion $^{82}$Rb PET. ***Materials and Methods:*** 35 patients were scanned for cardiac perfusion at rest and stress with $^{82}$Rb on a GE DMI-20cm PET/CT scanner totaling 70 acquisitions. The protocol consists of 5.7s free-breathing low-dose cine CT scans every 2cm followed by PET rest and stress. ACT was averaged from cine CT images and EECT was derived from cine CT images with the largest CT numbers in the lung regions or the largest expansion of the body contour outside the lung regions. Both ACT and EECT were derived from the same cine CT data. Registration between PET and ACT or EECT were performed manually. Comparisons were made between ACT and EECT maximum activity (μCi/cc), myocardial blood flow (MBF) (cc/min/gm), and the size of relative perfusion defect, defined as percent of the left ventricle less than 60% of the maximum activity. ***Results:*** IR impacted ACT in 14 patients (28 acquisitions) and EECT in 4 patients (8 acquisitions). The maximum activities in the myocardium for ACT and EECT were 4.42±1.10 and 4.52±1.13 μCi/cc, respectively, and statistically different ($p < 0.0001$). The difference of quartile MBF was not significantly different by paired t-test at rest (septal p=0.55, anterior p=0.14, lateral p=0.15, inferior p=0.18) or stress (septal p=0.53, anterior p=0.13, lateral p=0.46, inferior p=0.14), respectively. Of the ACT acquisitions impacted by IR, EECT decreased the relative perfusion defect in 16 of 28 (57%). ***Conclusion:*** Overall, EECT was less impacted by IR than ACT. EECT renders higher maximum activity than ACT in the myocardium. Switching from ACT to EECT did not impact quartile MBF. Relative defect size was decreased for acquisitions impacted by IR. For IR compromised ACT, EECT is an additional option for cardiac PET AC. ***References:*** Pan T, Thomas MA, Luo D. Data-driven gated (DDG) CT: An automated respiratory gating method to enable DDG PET/CT. Med Phys, 3/2022. e-Pub 3/2022. PMID: 35324002.

## EP-0680

### "Enhancing Quantitative and Qualitative Analysis in Transthyretin Amyloid Cardiomyopathy Imaging: Preliminary Results from the iTAC IAEA Project"

***P. Knoll***[1], *L. Torres Aroche*[2], *F. Mut*[3], *G. Grossmann*[4], *S. Orbala*[5], *G. Agu*[6], *S. Mirzaei*[6], *I. de Souza Baptista*[4], *D. Paez*[1], *A. Brink*[1], *M. Ljungberg*[7];
[1]*IAEA, Vienna, AUSTRIA,* [2]*Nuclear medicine department, Centis, La Habana, CUBA,* [3]*Servicio Medicina Nuclear, Hospital Italiano, Montevideo, URUGUAY,* [4]*Hospital Moinhos de Vento, Porto Alegre, BRAZIL,* [5]*Brigham and Women's Hospital, Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [6]*Department of Nuclear Medicine, Klinik Ottakring, Vienna, AUSTRIA,* [7]*Lund University Skane University Hospital, Lund, SWEDEN.*

***Aim/Introduction:*** The growing significance of 99mTc-PYP SPECT and SPECT/CT imaging in assessing the severity of transthyretin (TTR) cardiac amyloidosis necessitates accurate quantification and high-quality images. This study aims to establish and evaluate procedures to ensure accurate clinical evaluation metrics, such as, activity concentration and SUV and to attain optimal image quality for detection. These preliminary evaluations are part of the newly started iTAC IAEA coordinated research project. ***Materials and Methods:*** We utilized a cardiac insert within a cylindrical Jaszczak phantom to simulate realistic clinical examination conditions. A comprehensive assessment of image processing parameters (iterations and subsets) was conducted to optimize activity uptake recovery in the heart wall. The Activity Calibration Factor (ACF) was assessed following well-established procedures using a homogenous activity in a cylinder phantom. Image quality parameters, such as Signal-to-Noise Ratio (SNR), image-noise levels (RMS) together with an estimate of the wall thickness were computed and analyzed. We employed clinical OS-EM reconstruction method together with a Monte-Carlo-based software for image reconstruction and activity quantification; 3D image segmentation, curve fitting and complementary image/data processing techniques were used. ***Results:*** Our optimization approach identified 100 updates (10 iterations, 10 subsets) as the optimal parameter set for OS-EM reconstruction and from this recovering over 97% of the maximum uptake under clinical conditions. The ACF for the evaluated system was approximately 78.6 cps/MBq. Relative differences between estimated and measured activity in the myocardial wall were 7.9% and 11.3% in air and water environments, respectively. SNR values met the Rose criteria (SNR > 5) for adequate detectability when using 100 updates. Initial SPECT and SPECT-CT studies of patient revealed activity concentration values and cavity-to-myocardium ratios that varied depending on disease severity. Qualitative image quality assessment deemed the patient data-sets acceptable. ***Conclusion:*** We propose and implemented a novel methodology for optimizing quantitative and qualitative analyses in transthyretin amyloid cardiomyopathy studies. Initial evaluations with phantoms and real patients show good results in terms of accuracy and feasibility. Further evaluations are warranted to assess the methodology's performance across a broader range of clinical conditions. ***References:*** Ren C., Ren J., Tian Z., et al. ## EP-0681

### A novel assisted workflow created to obtain cardiac semiquantitative indexes from 99mTc-DPD-scintigraphy and to correlate them with different etiologies of transthyretin-related cardiac amyloidosis.

***S. E. Prisco***[1], *S. Mattoni*[1], *A. Paccagnella*[2], *F. Mattana*[3], *M. F. Morrone*[4,5], *G. Della Gala*[4], *M. Sguazzotti*[6], *S. Longhi*[6], *G. Saturi*[6], *S. Fanti*[1,7], *N. Galiè*[6], *L. Strigari*[4], *R. Bonfiglioli*[7];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Unit, AUSL Romagna, Cesena, ITALY,* [3], *IEO European Institute of Oncology IRCSS, Milano, ITALY,* [4]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Specialization School in Medical Physics, University of Bologna, Bologna, ITALY,* [6]*Cardiovascular Department, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [7]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** Semi-quantitative analysis of Technetium-99metastable-3,3-diphospono-1,2-propanodicarboxylic acid (99mTc-DPD) bone scintigraphy is promising in diagnosing cardiac amyloidosis but prone to processing errors and time consuming. As previously demonstrated in another study, the Geometric Mean image (GMi) can be used to perform a more efficient semi-quantitative analysis than standard method (reported as Classic Method (CM)). Based on these results, we implemented a novel assisted workflow (referred to AW) designed to further enhance the evaluation of semi-quantitative indexes, such as Heart Whole Body ratio (H/WBr), Heart retention (Hr) and Whole Body retention (WBr) on the GMi, and compared it to CM. In addition, we investigated the capability of the indexes thus obtained to differentiate the etiology (mutated vs wild-type) in cardiac transthyretin-related amyloidosis (cATTR) patients. ***Materials and Methods:*** 154 patients with cATTR confirmed diagnosis were retrospectively enrolled. Firstly, a random subset of 30 patients were extracted to compare CM and AW. The H/WBr, Hr and WBr, were calculated extracting counts by WB, kidneys, bladder and heart on early and late planar image scans and applying the background, scan-time and decay corrections, using GMi both with CM and AW. The comparison between CM and AW was executed with Pearson's correlation and Bland Altman analysis. Subsequently, the selected semi-quantitative indexes were measured with AW in the entire enrolled patients cohort. H/WBr, Hr and WBr and several clinical variables (age, sex, interventricular septum, left ventricular ejection fraction) were used to implement three different models, Least Absolute Shrinkage and Selection Operator (LASSO), Random Forest (RF) and Neural Network (NN) to predict two etiologies, ATTR mutated (ATTRm) and ATTR wild-type (ATTRwt). Receiver operating characteristic (ROC) curves and area under the curve (AUC) were calculated. ***Results:*** The AW and CM resulted highly correlated for Hr, WBr and H/WBr, (Pearson's linear correlation coefficient= 0.98, R=1). The Bland-Altman analysis between CM and AW within the assisted workflow showed the H/WBr bias of 0.12% [CI: 0.04%;0.19%], the Hr bias of 0.07% [CI: 0.01%;0.13%] and the WBr bias of -0.50% [CI: -1.22%;0.22%]. The three models, LASSO and NN had good performance in predicting different etiologies with AUC values of 87.3% and 73.6%, respectively. The RF model showed a performance with AUC of 55.8%. ***Conclusion:*** The GMi developed in the assisted workflow (AW) was both highly correlated and more efficient than CM. The use of Hr calculated with AW in LASSO, RF and NN allowed to obtain good prediction performances for cATTR etiology.

## EP-0682

### Long-term prognostic value of automated measurements in nuclear cardiology: Comparisons with the expert reading scoring

***G. Angelidis****, V. Valotassiou, I. Tsougos, C. Tzavara, S. Giannakou, D. Psimadas, E. Theodorou, A. Ziaka, C. Ziangas, J. Skoularigis, F. Triposkiadis, P. Georgoulias;*
*University of Thessaly, Larissa, GREECE.*

***Aim/Introduction:*** Automated methods for the analysis of myocardial perfusion studies have been incorporated into the clinical practice, given their advantage to exclude the subjective character of interpretation. However, computer-based assessment is currently used only as an adjunct to visual interpretation, and there is only scarce data regarding the incremental value of the corresponding automated measurements. In the present study, using three widely available software packages [Emory Cardiac Toolbox (ECTb), Myovation (MYO), Quantitative Perfusion SPECT (QPS)], we aim to evaluate the role of automated measurements of summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS) as long-term prognostic markers

of morbidity and mortality, in comparison to the prognostic value of expert reading. ***Materials and Methods:*** The study was conducted at the Nuclear Medicine Laboratory of the University of Thessaly, Larissa, Greece. 378 consecutive patients with known or suspected coronary artery disease were enrolled in the study, as they did not meet any of the exclusion criteria. All participants were referred to our laboratory for the performance of stress/rest myocardial perfusion single photon emission computed tomography. Stress testing was performed according to the Bruce protocol, while patients with contraindication or inability to achieve a satisfactory exercise level underwent pharmacologic testing, with or without low-level exercise. Scintigraphic studies were carried out using a dual-headed camera, without attenuation-scatter correction. Follow-up data was recorded after phone contacts, as well as through review of the patients' hospital records. All-cause death, cardiovascular death and non-fatal myocardial infarction were considered as hard events, while stroke, revascularization and hospitalization (due to unstable angina, heart failure or resuscitated cardiac arrest) as soft events. ***Results:*** The prognostic ability of SSS, SRS, and SDS was compared between the three software packages and the expert reading. It was found that ECTb-derived SSS had significantly lower prognostic ability in comparison to expert scoring ($p<0.001$), while expert scoring of SSS had also significantly greater prognostic ability in comparison to MYO- and QPS-derived measurements ($p<0.001$ for both comparisons). Moreover, expert scoring of SDS was associated with greater prognostic ability compared to all software packages ($p<0.001$ for all comparisons). Similarly, automated SRS values were associated with lower prognostic ability in comparison to expert scoring. ***Conclusion:*** Despite the useful contribution of automated analyses in the interpretation of myocardial perfusion studies, expert reading should continue to have a crucial role, not only in clinical decision making, but also in the assessment of prognosis.

## EP-0683

### Centiloid Calibration of a Commercial Amyloid Quantitation Software for different Fluorine-18 Radiotracers

***R. Fahmi***;
*Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Variability in amyloid-beta (Aβ) PET quantification using standardized-uptake-value-ratio (SUVr) makes it challenging to compare amyloid-PET acquired with different tracers and/or processed using different methods. The centiloid (CL) method was proposed by Klunk et al. [1] to standardize measures of Aβ burden from PET images using a standard processing method. Our aim is to calibrate a commercial PET-only amyloid quantification method, henceforth referred to as 'syngo-Aβ', to the centiloid scale for florbetapir (FBP), florbetaben (FBB), and flutemetamol (FLUTE) radiotracers. ***Materials and Methods:*** Calibration PET images and their corresponding SUVr and CL reference data were obtained from the GAAIN website. For each tracer, level-2 calibration analysis prescribed in [1] was performed to generate direct syngo-Aβ SUVr-to-CL transformations. A global cortical SUVr value was calculated using six tracer-specific cortical regions in reference to the whole cerebellum, as implemented in syngo-Aβ software. Results corresponding to other reference regions and to standard cortical regions from the GAAIN project were also generated but are not reported here. For validation purposes, we downloaded two independent datasets (N=162 florbetapir and N=118 florbetaben) from the ADNI study and compared the generated CL values against the ones calculated using ADNI CL pipeline [2]. ***Results:*** The transformation equations derived using the calibration images, from GAAIN, fulfilled the acceptance criteria, with strong agreement and little bias between syngo-Aβ CL values and those computed and published using the standard method [1], with $R^2$=0.97 (FBP), $R^2$=0.98 (FBB), and $R^2$=0.95 (FLUTE). The syngo-Aβ SUVr-to-CL transformations were: CL=173.26×SUVr - 174.63 (FBP); CL=181.31×SUVr - 175.90 (FBB); and CL=120.73×SUVr - 116.81 (FLUTE). The independent validation demonstrated strong agreements between syngo-Aβ and ADNI CL values with the following regressions and $R^2$ values: $^{syngo}CL=1.044\times {}^{ADNI}CL - 0.712$; $R^2$ = 0.97 (FBP) and $^{syngo}CL=1.095\times {}^{ADNI}CL - 7.241$; $R^2$ = 0.98 (FBB). ***Conclusion:*** We have successfully calibrated a commercially available amyloid quantification software to the centiloid scale for the three commercially available amyloid tracers. Validation on two independent datasets showed strong agreement with the ADNI calibration pipeline for FBP and FBB. Validation results for FLUTE will be added.***References:*** [1] Klunk W et al. Alzheimer's & Dementia (2015) [2] S. Kolibash et al., 'Centiloid Level-2 Analysis of [18F]Florbetaben (FBB) and [18F]Florbetapir (FBP) PET Image Data using the ADNI Pipeline', https://ida.loni.usc.edu/.

## EP-0684

### Comparison of MR arterial spin labelling regional Cerebral Blood Flood estimates to early amyloid PET measurements

***J. Anton Rodriguez***[1,2], *J. C. Matthews*[3], *L. A. Scott*[3], *J. J. McFadden*[3], *B. R. Dickie*[2], *K. Herholz*[3], *L. M. Parkes*[3];
[1]*The Christie NHS Foundation Trust and University of Manchester, Manchester, UNITED KINGDOM,* [2]*Division of Informatics, Imaging and Data Sciences, MAHSC, University of Manchester, Manchester, UNITED KINGDOM,* [3]*Division of Psychology, Communication and Human Neuroscience , Faculty of Biology, Medicine and Health-University of Manchester, Manchester, UNITED KINGDOM.*

***Aim/Introduction:*** [$^{15}$O]water PET is the gold standard measurement of regional cerebral blood flow, $rCBF_{water}$ (mL/min/dL). However, it is only available in a few sites as it requires on-site [$^{15}$O]water production and full-kinetic analysis. Early amyloid-PET has been proposed as a surrogate for relative rCBF [1], $rCBF_{Amy}$(kBq/ml). The non-invasive MRI technique arterial-spin-labelling (ASL) can also measure $rCBF_{ASL}$(mL/min/dL). Previous reports show that although there is a good correlation between $rCBF_{ASL}$ and $rCBF_{water}$, there are quantitative differences resulting in underestimations within subcortical regions with ASL [2]. We compare $rCBF_{ASL}$ and $rCBF_{Amy}$ measurements in a cohort of cognitively normal and MCI elderly participants. ***Materials and Methods:*** Twenty-two participants, 70(60-80) years old (mean(range)), 13 cognitively normal/9 mild cognitive impairment, were scanned using a GE SIGNA PET/MR. $rCBF_{Amy}$ corresponded to summed images 20s-80s post-arrival of tracer in the brain following the injection of ~185MBq of [18F]flutemetamol. Enhanced-ASL with pCASL labelling and 3D spiral FSE acquisition was acquired with six post-labelling delays and processed to obtain voxel-wise $CBF_{ASL}$ and arterial-transit-time (ATT) maps using a single-blood compartmental model [3]. Voxel-wise $M_0$ calibration was employed. For each patient, tissue $T_1$ and $T_2^*$ maps were available. FreeSurfer brain segmentation on each participant's T1wMPRAGE was used to estimate median values for 13 brain regions in all available maps ($rCBF_{ASL}$, $rCBF_{Amy}$, ATT, $T_1$ and $T_2^*$). Regression models were used to compare $rCBF_{ASL}$ and $rCBF_{Amy}$ to assess the dependency of the gradient and intercept on the region and the covariates ATT, $T_1$ and $T_2^*$.

Parameters to scale the $rCBF_{Amy}$ values across all participants were included in the model. Statistical testing (F-tests) was conducted to assess the significance of model parameters. ***Results:*** There was a statistically significant positive intercept (p=0.016; range 24-40 mL/min/dL), also dependent on $T_2^*$ (p=0.003). The gradient was statistically different from zero (p=0.000) and was dependent on both $T_2^*$ (p=0.003) and region (p=0.012). There was no dependency of the intercept or gradient on $T_1$ or ATT. The relative differences in the gradients between regions and the relative mean values of $rCBF_{ASL}$ and $rCBF_{Amy}$ across regions agreed well with values previously reported using $rCBF_{water}$ [2]. ***Conclusion:*** This work supports the previous findings of quantitative regionally dependent differences between ASL and PET measurements of $rCBF_{water}$[2]. It also suggests that these differences are partially due to $T_2/T_2^*$ differences between tissues, with further corrections required to make ASL rCBF measurements accurate. ***References:*** [1]Anton-Rodriguez et al., EANM2020-meeting-Vienna,OP-1001; [2]Fahlström et al., Diagnostic,11(5):821-2020 [3]Parkes and Tofts, MRM,48(1):27-2002

### A ROI-based Quantitative Pipeline for [18]F-FDG PET Metabolism and pCASL Perfusion Joint Analysis: Validation on [18]F-FDG PET Data

***V. Cerina***[1], *E. De Bernardi*[2], *C. Crivellaro*[3], *S. Morzenti*[4], *F. E. Pozzi*[1], *L. Jonghi Lavarini*[2], *V. Bigiogera*[2], *R. M. Moresco*[2], *G. Basso*[2,5]; [1]*PhD program in Neuroscience, Department of Medicine and Surgery, University of Milano Bicocca, Milano, ITALY,* [2]*Department of Medicine and Surgery, University of Milano Bicocca, Milano, ITALY,* [3]*Nuclear Medicine, Fondazione IRCCS San Gerardo dei Tintori, Monza, ITALY,* [4]*Medical Physics, Fondazione IRCCS San Gerardo dei Tintori, Monza, ITALY,* [5]*Neuroradiology, Fondazione IRCCS San Gerardo dei Tintori, Monza, ITALY.*

***Aim/Introduction:*** In neurodegenerative dementias the study of brain metabolism, provided by [18]F-FDG PET, can be integrated with brain perfusion by means of pseudo-Continuous Arterial Spin Labelling MR sequences (pCASL). Aim of this study is to validate, on PET images relying on normative data, a region-based pipeline constructed to be independently applied to PET and pCASL data to jointly analyse metabolism and perfusion. ***Materials and Methods:*** Thirty-six MCI patients and 107 healthy-controls PET images were considered. Pre-processing included MNI normalization, Grey Matter segmentation through mean Tissue Probability Map, partial volume error (PVE) correction and smoothing. Sixteen ROIs were derived from AAL3 atlas and SUV ratios (SUVr) normalized on cerebellum activity were extracted. For each ROI, SUVr mean and standard deviation in healthy controls were computed. Patient SUVr values falling outside (σ, 1.5σ, 2σ) normality range were considered hypometabolic. Results were compared to: 1) visual analysis (supported by CortexID-Suite); 2) two different SPM statistical analyses (SPM-A: voxel-size 2x2x2 $mm^3$, smoothing Gaussian Kernel FWHM 8x8x8 $mm^3$; SPM-B: voxel-size 1x1x1 $mm^3$, PVE correction). This analysis was conducted for each ROI separately. Agreement among methods was assessed with accuracy, sensitivity, specificity and Cohen's κ. ***Results:*** By using visual analysis as reference, the (σ, 1.5σ, 2σ) normality ranges obtained, on average on the 16 ROIs, accuracy (76, 78, 76)%, sensitivity (84, 67, 47)%, specificity (69, 85, 94)%, and κ (49, 60, 60) %, respectively. With SPM-A as reference, accuracy (71, 79, 83) %, sensitivity (89, 75, 59)%, specificity (63, 80, 93)%, and κ (42, 58, 67)% were obtained. With SPB-B as reference, accuracy (76, 77, 73)%, sensitivity (79, 64, 46) %, specificity (71, 88, 97)%, and κ (51, 54, 47)% were obtained. SPM-A (SPM-B) compared to visual analysis obtained 79(75)% accuracy, 60(76)% sensitivity, 92(75)% specificity, 57(51)% κ. SPM-B compared to SPM-A obtained 79% accuracy, 94% sensitivity, 72% specificity, 58% κ. ***Conclusion:*** The proposed region-based analysis pipeline with the 1.5σ normality range showed a good agreement with reference methods, in line with intra reference methods agreement levels. It can be therefore considered as a promising tool for future PET-pCASL joint analyses. ***References:*** Festari C. et al., Alzheimer's Dement, 2022; Yan L. et al., NeuroImage Clin, 2017; Musiek E.S. et al., Alzheimer's Dement., 2013; Guedj E. et al., J. ## EP-0686

### Method evaluation for quantification of cerebral blood flow for [15O]-water PET/CT, a segmentation comparison between using ASPECTS method for simplified quantification to a 3D-volume based arterial atlas

***A. Eriksson****, J. Patrick Connelly, A. Gul Sherwani, L. Gridset, K. Angell, L. Gyland Mikalsen, C. Stokke, M. Stavrinou; Oslo Universityhospital, Oslo, NORWAY.*

***Aim/Introduction:*** [15O]-water PET/CT is the gold standard to quantify cerebral blood flow (CBF). In order to extract the vascular brain areas an anatomical arterial atlas and dedicated software is needed. However, if a subject cannot undergo MRI, or is in an acute situations a fast method for simplified quantification would be preferable. In this study a CT-based semi-manual segmentation method based on pc-ASPECTS (Alberta Stroke Programme Early CT Score) including posterior circulation has been used for quantification, and compared to an arterial atlas. ***Materials and Methods:*** Six subjects with suspected Moyamoya disease were included for a cross-evaluation of the two methods. Each subject underwent two dynamic [15O]-water PET/CT acquisition with a continuous arterial sampling, pre- and post-vasodilator (acetazolamide 1g IV). For the ASPECTS, segmentations were performed in four axial levels from base to vertex on CT or T1-weighted MRI, divided into 20 bilateral territories [1]. The arterial method is a 3D atlas, which include 32 territories [2]. The arterial atlas was then used for automatic segmentation based of an isometric T1-weighted MRI. To obtain quantitative CBF values, kinetic modelling with the same set of parameters was performed for both methods of segmentations using a commercial software. Relative differences were calculated between the pre- and post-vasodilator acquisitions, and results for corresponding regions for the two segmentation methods compared. ***Results:*** For smaller regions such as the lentiform nucleus, thalamus and caudate there is good agreement the values from ASPECTS and the arterial atlas. For larger territories such as frontal or parietal portions of the MCA (middle cerebral artery) the majority of values from the ASPECTS method shows greater variability from the arterial atlas values. ***Conclusion:*** In this study only the relative difference for CBF between pre- and post-vasodialator was used as a control parameter, since the segmentations were in focus. Since the ASPECTS model is only based on slices at four levels it is therefore sensitive to local variations due to noise or pathology. In contrast, the arterial atlas is volume based and will often contain both normal and pathological regions, yielding an averaged CBF. In conclusion, the results from this small subject sample supports that the ASPECTS based segmentation method may be more representative for smaller pathological regions and could potentially be expanded for more CT or MRI slices for better brain coverage. ***References:*** [1] Barber et al.,Lancet 2000; 355: 1670-74 [2] Liu, CF. et al., Scientific Data 2023; 10:74

### Comparison of Results Analysis for Isotopic Determination of Plasma Volume: a Prospective Study

***M. Ragot***, *R. Charmelot, P. Orhon, B. Berton, A. Revy, M. Tempier, S. Levesque;*
*Centre Jean Perrin, Clermont-Ferrand, FRANCE.*

***Aim/Introduction:*** Determination of blood volumes, including plasma volume (PV), is central for the diagnosis of polycythaemia. According to the 1980 ICSH recommendation, the gold standard (GS) for PV is the use of $^{125}$I labelled human serum albumin ($^{125}$I-HSA), with 3 plasma samples (10-20-30 min after injection) and extrapolation of results to the time of injection ($t_0$). There is however no consensus in clinical practice. This study was conducted to compare various methods, to determine the optimum method: minimum samples for equivalent results to GS. ***Materials and Methods:*** Patients with suspected polycythaemia were enrolled from September 2021 until December 2022. Patients were injected with 1.8 kBq/kg of $^{125}$I-HSA. Based on the dilution technique, PV is calculated from the quotient of the administered dose and the $^{125}$I-HSA concentration (average or linear extrapolation at $t_0$), deducted from the amount of activity present in the plasma samples taken 10, 20, 30 and 40 minutes after injection. The data was analysed on Excel and R. Five methods (2, 3 or 4 samples, with or without extrapolation) were compared to the GS, with Student test (paired measures, $\alpha = 0.05$) to conclude on statistical difference and Bland-Altman plots to analyse agreement. ***Results:*** 75 patients were included: 63 men and 12 women, with an average age and BMI of 59 years and 28 kg/m$^2$. Although extrapolation is described in GS, it has limitations: it can overestimate PV if the last samples show higher concentrations than the first one, leading to the exclusion of five patients from our analysis. When results are extrapolated to $t_0$, there is no statistically significant difference when adding a sample at 40 min. However, extrapolating from only two samples (10-20 min) leads to substantial unpredictable random error. The alternative is to use average values, which overestimates the PV by neglecting the loss of $^{125}$I-HSA from the plasma. The method M2, based on average concentrations of only 2 samples (10-20 min), leads to an average systemic error of +0.08L (+3%). Using a fixed correction factor instead of extrapolation will prevent this phenomenon and remove the systemic error. When a correction factor of 3% is applied to the PV obtained with M2, results are not statistically different from GS. ***Conclusion:*** Switching from a 3 dots extrapolation to an average 2 dots analysis integrating a corrective factor concluded to statistically equivalent results, allowing for a less time-consuming procedure for patients and personal.

## EP-0688

### Discordance between 90Y PET/CT(MR)-estimated activity and dose calibrator measured administered activity: an international patient study in SIRT with resin and glass microspheres

***T. Carlier***[1], *S. Gnesin*[2], *J. Mikell*[3], *M. Conti*[4], *J. Prior*[5], *C. Bailly*[1], *M. Pérez Lago*[6], *Y. Dewaraja*[7], *T. Lima*[6];
[1]*University Hospital of Nantes, Nantes, FRANCE,* [2]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Department of Radiation Oncology, University of Michigan, Saint Louis, MI, UNITED STATES OF AMERICA,* [4]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc, Knoxville, TN, UNITED STATES OF AMERICA,* [5]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [6]*Department of Radiology and Nuclear Medicine, Luzerner Kantonsspital and Faculty of Health Sciences and Medicine, University of Lucerne, Luzern, SWITZERLAND,* [7]*Division of Nuclear Medicine, Department of Radiology, University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Permanent implantation of $^{90}$Y-loaded microspheres is routinely applied in selective internal radiotherapy of primary and secondary liver tumours. $^{90}$Y-PET is the reference post-therapy imaging modality that is used to evaluate absorbed dose for efficacy and toxicity assessment. A recent study showed that manufacturer-declared vial activities were substantially overestimated/underestimated for glass (Gm) and resin microspheres (Rm) respectively. The main aim of this work is to confirm the above discrepancies observed for vials, using patient data. We also evaluate how the discrepancies are impacted by using two different background scaling (BS) methods for the single scatter simulation (SSS) with different PET systems. ***Materials and Methods:*** Patients (Gm: 60, Rm: 11) were enrolled retrospectively from 4 different institutions (CHUV Lausanne, Switzerland; University of Michigan, USA; Luzern Kantonsspital, Switzerland and Nantes Hospital, France). $^{90}$Y-PET images were acquired and reconstructed using 4 different systems (Vision 600 and 450, Biograph mCT and mMR), following the local procedures. Residuals after therapeutic injection were measured using either a survey-meter or by PET imaging. Sixty patients were imaged using a PET/CT (with time-of-flight, TOF) and 11 (all Gm) with the PET/MR (without TOF). The PET measured activity ($A_{PET}$) was assessed in a volume encompassing the liver (CT/MR-based segmentation) expanded by 1cm to account for resolution and motion spill-out effects. The ratio $A_{PET}/A_M$ was subsequently calculated for each patient where $A_M$ was the injected activity as measured by the dose calibrator corrected for residual and lung shunt. Two different methods of SSS BS were considered: tail fitting (TFBS) and absolute (ABS). Comparison used a Wilcoxon signed-ranked test. ***Results:*** The mean $A_{PET/CT}/A_M$ (respectively, $A_{PET/MR}/A_M$) for Gm was significantly different using TFBS (0.84±0.07 resp. 0.69±0.12) vs ABS (0.91±0.06 resp. 0.80±0.07). The mean $A_{PET/CT}/A_M$ for Rm was also significantly different using TFBS (1.15±0.09) vs ABS (1.29±0.12). While unpaired, a significant difference between PET/CT and PET/MR was highlighted. The mean LSF was 1.8±1.1% and the mean residual fraction was 2.5±3.4% for Gm and 5.6±3.0% for Rm, hence the expected uncertainty in these values is unlikely to substantially impact the observed discrepancies. ***Conclusion:*** We confirmed in patients the discrepancies previously reported with vials. TFBS BS should be avoided when estimating the scatter component. A significant difference between PET/CT and PET/MR was also reported highlighting the importance of the field-of-view diameter and the potential benefit of TOF availability.

## EP-0689

### Using Different Dichotomisation Methods for Lesion Dissemination to Predict Survival Outcomes in Lymphoma Patients

***X. Wong***[1], *L. Yong*[1], *Y. Chen*[2,3], *S. Liu*[1,3], *K. Lue*[1];
[1]*Tzu Chi University of Science and Technology, Hualien, TAIWAN,* [2]*Tzu Chi University, Hualien, TAIWAN,* [3]*Hualien Tzu Chi Hospital, Hualien, TAIWAN.*

***Aim/Introduction:*** The lesion dissemination feature, the largest distance between two lesions (Dmax), measured using $^{18}$F-FDG PET, can be useful in determining the prognosis of patients with lymphoma. A cut-off point for Dmax is commonly used to stratify patients into good or poor prognoses. However, the cut-off may vary depending on the dichotomisation method used. This study investigated whether various methods of dichotomising Dmax influenced survival prediction in patients with lymphoma. ***Materials and Methods:*** Ninety patients diagnosed with lymphoma who underwent baseline $^{18}$F-FDG PET were retrospectively enrolled. All the patients had at least two detectable lesions. $^{18}$F-FDG-avid lesions were contoured using a standardised uptake value threshold above 4.0. The centroid of each lesion was identified, and the distances between all pairs of lesions were computed in three-dimensional coordinates. The maximum distance (Dmax) was calculated for each patient. The standardised Dmax (SDmax) was normalised to the body surface area of the patient. The cut-off points for the dissemination features (Dmax and SDmax) were determined using the Youden index of receiver operating characteristic analysis, X-tile bioinformatics software (Yale University, New Haven, USA), and the Cut-off Finder web application (Charite, Berlin, Germany). The respective prognostic effects on survival outcome prediction were compared using the Cox hazard regression, Kaplan-Meier analysis, and log-rank tests. All images were analysed using the LIFEx software (LITO, Orsay, France) and the ACCURATE tool (VUmc, Amsterdam, Netherlands). ***Results:*** The median (interquartile range) Dmax and SDmax values were 0.269 m (0.155-0.526 m) and 0.169 $m^{-1}$ (0.089-0.327 $m^{-1}$), respectively. The cut-off values for Dmax in predicting progression-free survival (PFS) and overall survival (OS) ranged from 0.191 m to 0.587 m and 0.227 to 0.590 m, respectively. The cut-off values for SDmax in predicting PFS and OS ranged from 0.116 $m^{-1}$ to 0.183 $m^{-1}$ and 0.156 $m^{-1}$ to 0.327 $m^{-1}$, respectively. All dichotomisations significantly predicted PFS and OS, except for one that was based on a mixture of two Gaussian distributions in the OS. Patients were stratified into distinct prognostic groups based on survival curves. The Harrell's concordance index for predictive performance ranged from 0.588 to 0.631 (hazard ratio, 1.924-4.066) and 0.603 to 0.623 (hazard ratio, 2.648-2.778) for PFS and OS, respectively. ***Conclusion:*** Although the cut-off points varied using different dichotomisation methods, Dmax and SDmax could remain predictive values for survival in lymphoma patients. A consistent method to determine dissemination feature cut-off should be considered when defining the threshold.

## EP-0690

### Evaluation of Image Quality and Quantification with Various Scan Times on 64 Copper PET/CT Imaging: Phantom and Clinical study

***F. Sadeghi***[1], *A. Monsef*[2], *P. Sheikhzadeh*[1,3];
[1]*Department of Medical Physics and Biomedical Engineering ,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Radiation Oncology, University of Minnesota Medical School, Minneapolis, MN, UNITED STATES OF AMERICA,* [3]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Recently, there is a growing trend in utilizing copper isotopes as radiopharmaceuticals for positron emission tomography (PET) imaging. The aim of this work was to evaluate 64-copper PET/CT image quality and quantitative parameters using ordered subset expectation maximization (OSEM) method with reduced scan times for different activity concentrations and lesion sizes. ***Materials and Methods:*** NEMA phantom with lesion to background ratios of 4:1 and 8:1, as well as patients who were administered with 64-copper. We conducted OSEM reconstruction using varying time intervals, ranging from 1⁄2 to 1⁄32 of the original duration in the phantom study and 30s, 60s, 90s ,120s and original scan time (180s) in clinical study. We evaluated images in the terms of signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), recovery coefficient (CR) and background variability. In clinical data, we measured the noise and SNR in the liver. ***Results:*** As the acquisition time was decreased, there was an increase in BV, as well as, a reduction in quantitative parameters. The BV for OSEM with 1⁄2 and 1⁄4 of original time at LBR 4:1 and only 1⁄2 of original time at LBR 8:1 were within the acceptable noise range(<5%). In this acceptable noise level, for all lesions and both LBRs, CNR satisfied the Rose criteria in image detectability (CNR>5). The CNR decreased by 3.6% at LBR 4:1, when the scan time was reduced to half, while at LBR 8:1, the reduction was 21.2%. The decrease of SNR for smallest sphere in 1⁄2 of standard acquisition time was 33.2% at LBR 4:1 and 42.2% at LBR 8:1 compared to full acquisition time. There is no specific relationship between changes in scan time and the RC. The RC of a sphere with diameters of 22 mm on 1⁄2, 1⁄4 and 1⁄8 of the original scan time were reduced by 0.7%, 0.4% and 1.6% compare to original scan time, respectively. In clinical study, only images at 120s and 180s had noise in acceptable level. We reported 7.1% decrease in SNR in liver when the scan time was reduced to 120 seconds. ***Conclusion:*** In larger lesions, it is possible to further reduction of the scan time with preserving the lesion detectability, while the SNR and CNR in smaller lesions are more susceptible to degradation with reduced time. Whole-body PET/CT scan used 64-copper can reduce the acquisition duration to 120s for each bed position without compromising the image quality.

## EP-0691

### Cluster Analysis in Binary Classification of Amyloid PET/MR Imaging with/without-Partial Volume Effect Correction

***E. Balci***[1], *U. O. Akdemir*[1], *M. A. Topcuoglu*[2], *E. Saka*[2], *L. O. Atay*[1];
[1]*Gazi University Medical Faculty Department of Nuclear Medicine, ANKARA, TÜRKIYE,* [2]*Hacettepe University, Faculty of Medicine, Department of Neurology, ANKARA, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study is to investigate the binary classification (positive or negative) of amyloid PET images using unsupervised clustering algorithms: k-means, partitioning around medoids (PAM), and agglomerative nesting (AGNES), and the contribution of partial volume effect correction (PVEC) to the discriminative power of the classification. ***Materials and Methods:*** PET/MR imaging (3D T1-MR, [18F]-Flutemetamol) was performed on a total of forty-nine patients diagnosed with subjective cognitive decline (SCD, n=11), amnestic mild cognitive impairment (aMCI, n=17), and Alzheimer's disease (AD, n=21). Volume of interest (VOI) of the sixty-eight cortical regions of the brain were determined by performing parcellation on T1-MR images using FreeSurfer. The PET images were applied the extended Müller-Gärtner PVEC method with PetSurfer. The standardized uptake value ratio (SUVr) values of the regions were obtained for with/without-PVEC. SUVr

values of the VOIs in sixty-eight cortical regions were used as inputs in cluster algorithms. k-means, PAM, and AGNES cluster algorithms were performed using R software. PET images were classified as positive or negative by two experienced nuclear medicine experts, and this classification was used as a reference to compare the results of clustering algorithms. ***Results:*** In the visual evaluation of [18F]-Flutemetamol PET images, the SCD group was found to be negative, except for one patient in the MCI group, which was positive, and the AD group was positive. In the classification performed without applying PVEC, similar results were obtained with k-means (accuracy: 82%, sensitivity: 100%, specificity: 57%), PAM (accuracy: 88%, sensitivity: 100%, specificity: 67%), and AGNES (accuracy: 78%, sensitivity: 100%, specificity: 52%) algorithms. However, after applying PVEC, the results of the k-means (accuracy: 90%, sensitivity: 100%, specificity: 71%), PAM (accuracy: 90%, sensitivity: 100%, specificity: 71%), and AGNES (accuracy: 98%, sensitivity: 100%, specificity: 92%) algorithms increased positively. ***Conclusion:*** The k-means, PAM, and AGNES cluster algorithms used in the study are valuable tools for classifying [18F]-Flutemetamol PET images due to their ability to classify without the need for a training set and their repeatability using standard packages in R software. Sensitivity was 100% for all algorithms with/without- PVEC. Applying PVEC to the images improves specificity and classification accuracy but accuracy and specificity values were not at the desired level except for AGNES. The AGNES algorithm provides highly accurate results in classifying [18F]-Flutemetamol PET images with-PVEC.

## EP-0692

### Improving Efficiency of Simultaneous Dual-Tracer PET Imaging

***Z. Li***[1], *V. Shah*[2], *S. L. M. Viol*[3], *P. van Snick*[1], *G. Luurtsema*[1], *R. H. J. A. Slart*[1], *A. Lammertsma*[1], *C. Tsoumpas*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Molecular Imaging, Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [3]*Department of Radiology and Nuclear medicine, Amsterdam University Medical Center, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Simultaneous imaging of two PET tracers would reduce overall scanning time and provide molecular information in exactly the same physiological condition. However, separating signals from different PET tracers is difficult as all coincidence photons have the same energy. One possibility of separating signals is to utilise differences in half-life between two tracers. The purpose of this study was to explore the feasibility of pre-processing techniques, in combination with differences in half-life, to achieve rapid separation without compromising image quality, as well as to evaluate the impact of both acquisition time and frame duration on image quality. ***Materials and Methods:*** A NEMA IQ phantom filled with [$^{18}$F]fluorodeoxyglucose ([$^{18}$F]FDG) in the spheres and [$^{15}$O]water in the background compartment was scanned at the centre of the FOV for 20min using an LAFOV PET/CT scanner. A 4D extended cardiac-torso (XCAT) phantom was generated by selecting six organs, containing [$^{11}$C]choline and [$^{18}$F]FDG and simulating a 20min acquisition. In addition, to evaluate the possibility to reduce scan duration, image data were reprocessed for different acquisition times (120, 300, 450, 600 and 1200s) and frame durations (10 and 5s) for both phantoms. A linearization method was applied to the conventional half-life method [1]. Subsequently, several estimators and optimization methods were adjusted and implemented for separation of individual tracer concentrations. Resulting images were evaluated using the pixel-wise normalized root mean square error (NRMSE) and the pixel-wise multiscale structural similarity (MS-SSIM). ***Results:*** Application of the pre-processing linearization method resulted in a reduction in computation time by a factor of 3 to 13 compared with the conventional half-life method. For both phantoms, the image quality did not significantly improve for acquisition times above 600s. (MS-SSIM: 1 and 0.998, NRMSE: 0 and 0.025 for NEMA IQ and XCAT phantoms, respectively, when comparing 600 and 1200s images). Frame duration had a negligible effect on separation performance, with both phantoms exhibiting MS-SSIM higher than 0.9994 and NRMSE lower than 0.015 when comparing frame durations of 5 and 10s. ***Conclusion:*** This preliminary study demonstrates that using a pre-processing linearization method significantly improves computation time without loss of image quality. Furthermore, both overall acquisition times longer than 600s and shorter frame durations may not be necessary to obtain optimal image quality for both phantoms. The pre-processing linearization method should now be tested in real dual tracer patient studies. ***References:*** [1] Figueiras et al. Mol Imaging Biol. 2011;13(3):500-510.

## EP-0693

### Patlak graphical analysis: Net Influx Rate (Ki) obtained with a fully-automated Multiparametric PET Suite versus traditional Regional Plot

***A. Capotosti***[1], *R. Moretti*[1], *M. De Summa*[2], *S. Taralli*[1], *E. Perrone*[1,3], *M. L. Calcagni*[1,3], *L. Indovina*[1];
[1]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [2]*Medipass S.p.a. Servizio Integrativo PET/CT - Radiofarmacia, TracerGLab, Fondazione Policlinico Universitario A.Gemelli IRCCS, Rome, ITALY,* [3]*Università Cattolica del Sacro Cuore, Rome, ITALY.*

***Aim/Introduction:*** Patlak model is a graphical analysis technique that can be applied to PET images to estimate dynamic processes. This type of analysis is usually performed offline using the mean values of the signal present in the volumes of interest (VOIs) by setting up a'regional'Patlak. Today, with the introduction of the fully automated Multiparametric PET Suite feature, all the information required for Patlak analysis is included in the PET acquisition protocol, allowing image series to be expressed in terms of glucose consumption. The aim of this study is to compare the net influx rate ($K_i$) derived from a fully-automated multiparametric PET suite to the one obtained with the traditional Patlak regional plot. ***Materials and Methods:*** Four patients with small-cell lung cancer who underwent dynamic 18F-FDG PET were evaluated. Patients were injected on the bed at the same time as the PET acquisition started (entire exam lasting about 71 minutes). First 6 minutes were acquired as a static single-bed over the cardiac region, while remaining 65 minutes were acquired over whole-body in continuos bed motion. These two acquisitions were used to generate parametric images of the $K_i$. VOIs were defined over the descending thoracic aorta of each patient and over target lesions (n=19) on the full dynamic PET reconstructions. Regional $K_i$ on the full dynamic PET reconstructions by standard regional Patlak plot analysis using Image Derived Input Function (0-70min) and tissue response (40-70min) curves from VOIs was obtained. The same VOIs were placed on parametric images derived from the dedicated suite and net Ki values were obtained. Net $K_i$ values obtained with the traditional Patlak regional plot were compared to the ones obtained from multiparametric PET suite. ***Results:*** Mean percentage difference between $K_i$s obtained with regional Patlak and voxel-based ones was found to be -7% ± 13%. Linear

regression plot showed a slope of 0.75 and intercept value of 0.004 with a good correlation ($R^2$=0.95). The Passing-Bablok regression for comparison between regional $K_i$ and $K_i$ from parametric imaging showed a slope of 0.78 and intercept value of 0.0001 ($R^2$=0.98). ***Conclusion:*** The introduction of the fully-automated Multiparametric PET Suite guaranties an accurate measurement of the $K_i$ related to the metabolic rate of glucose in tissue and to local glucose consumption. This preliminary work showed a good correlation between $K_i$ from regional Patlak analysis and $K_i$ obtained from multiparametric imaging.

## EP-0694

### PET imaging with somatostatin analogue (SomaKitTOC®) for assessment of neuroendocrine tumors: unknown physiological uptake, patient in/dependent? Experience feedback

***C. Provost***[1], *C. Schmitt*[1], *J. Fouque*[1], *O. Madar*[1], *L. Champion*[2];
[1]*Institut Curie, Radiopharmacology department, Saint Cloud, FRANCE,* [2]*Institut Curie, Nuclear Medicine departement, Saint Cloud, FRANCE.*

***Aim/Introduction:*** Radiopharmaceuticals somatostatin analogues are used for neuroendocrine tumours, which are characterized by an overexpression of somatostatin receptors in more than 80% of subtypes 2 and 5. In our institute, we have used [$^{68}$Ga]Ga-edotreotide (SomaKit TOC®) for positron emission tomography (PET) imaging since 4 years. Physicians have described some misunderstood physiological uptakes in the stomach, pancreas and liver. The purpose of this study is to find some explanation of these uncommon physiological uptakes. For this, we investigate on quality control of the radiopharmaceutical and $^{68}$Ge/$^{68}$Ga generator used. ***Materials and Methods:*** Fifty-seven radiopharmaceutical preparations were analysed, from 2019 to 2021. Quality control consisted in two radio-thin-layer chromatographies to determine the percentage of free $^{68}$Ga and $^{68}$Ga colloids. Respectively 41 and 16 preparations were carried out with, GalliaPharm®/E&Z and Galliad®/ Ire ELiT generators. The final activities were ranging from 426 to 1090 MBq. One hundred and five patients were injected for PET imaging, 78 patients had 1 PET-scan, 17 had 2 scans, 6 had 3 scans and 4 had 4 scans. ***Results:*** Radiochemical purity (RCP) mean was 98 ± 1.33 %, with the percentage of free $^{68}$Ga ranging from 0.05 to 1.92% and the percentage of $^{68}$Ga colloids ranging from 0.03 to 3.41%. No significate difference was observed between percentage of free $^{68}$Ga and $^{68}$Ga colloids and between RCP and brand of generator. Uptake evaluation of stomach, liver and pancreas on patients PET scans do not show difference when preparations had a percentage of $^{68}$Ga colloids > 2% or/and free $^{68}$Ga > 1%. ***Conclusion:*** No matter which generator was used, there was no difference for the quality control of the preparation. The percentage of free $^{68}$Ga and $^{68}$Ga colloids do not seem to have an impact on the physiological uptakes in stomach, liver or pancreas. Regardless of the generator used, there is no difference in the quality control of the preparation and the interpretation of images. Physiological uptakes could be explain by patient treatments or hormone levels. Regarding our cohort of patients, those parameters need to be investigate. ***References:*** 1. Johnbeck CB, et al. PET tracers for somatostatin receptor imaging of neuroendocrine tumors: current status and review of the literature. Future Oncol. 2014 Nov;10(14):2259-77. 2. Al-Ibraheem A, et al. Focal uptake of 68Ga-DOTATOC in the pancreas: pathological or physiological correlate in patients with neuroendocrine tumours? Eur J Nucl Med Mol Imaging. 2011 Nov;38(11):2005-13.

## EP-0695

### A fuzzy C-mean segmentation technique to estimate methodological uncertainties on time-activity curves in dynamic quantitative positron emission tomography studies

***P. Laporte***[1], *J. Carrier*[1,2,3];
[1]*Département de Physique, Faculté des Arts et Sciences, Université de Montréal, Montréal, QC, CANADA,* [2]*Institut de Génie Biomédical, Faculté de Médecine, Université de Montréal, Montréal, QC, CANADA,* [3]*Département de radiologie, radio-oncologie et médecine nucléaire, Faculté de Médecine, Université de Montréal, Montréal, QC, CANADA.*

***Aim/Introduction:*** Dynamic positron emission tomography (PET) acquisitions can be used to compute time-activity curves (TACs) for an imaged subject, from a selected region of interest (ROI). These curves can then be used to extract pharmacokinetic parameters. To obtain a relevant ROI, a segmentation technique must be used. The obtained ROI depends on the segmentation scheme, as well as the timeframe(s) used as reference. This latter part introduces a significant variation in the ROI, which can then lead to varying values for the pharmacokinetic parameters. Since many clinical trials use a small number of test subjects, it is relevant to assess the methodological impacts pertaining to the selection of the ROI. ***Materials and Methods:*** Using a home-made dynamic phantom, PET acquisitions have been obtained, using FDG. This phantom is a simple three-compartment device, for which the analytical model can be derived. Using a Fuzzy C-mean (FCM) segmentation technique, more specifically the SpectaQle algorithm [1], a rough ROI can be obtained. Using statistical sampling on the voxels' probability of belonging to the ROI, an uncertainty has been estimated for the TAC. From there, using a nested sampling algorithm, the pharmacokinetic parameters of the analytical model are obtained. All the numerical analysis were conducted using Python3.8. ***Results:*** The obtained TACs with error bars show a higher degree of statistical overlap compared to TACs obtained from a segmentation on a single timeframe. The obtained pharmacokinetic parameters show a larger range of values, but are more reproducible. ***Conclusion:*** The advantage of this whole process is to allow the analysis of TACs from a single patient, as would be the case in the context of clinical care. With the emergence of new radiopharmaceutical compounds, this will yield greater medical confidence in the administration of specific drugs to patients. :This segmentation method with the proposed methodology to obtain a time-activity curve with error bars lead to safer statistical analyses of dynamic quantitative PET acquisitions. This helps in making the scientific endeavour more reproducible, transparent, and honest. ***References:*** Lapuyade-Lahorgue, J. et al. SPEQTACLE : An automated generalized fuzzy C-means algorithm for tumor delineation in PET. Med. Phys. 42 (10).

### Influence of normal database sample size on the development of new statistical image analysis software for bone SPECT imaging

***Y. Yakushiji***[1], *K. Miwa*[2], *K. Wagatsuma*[1,3], *S. Fukuda*[1], *T. Yamao*[2], *Y. Kamitaka*[3], *N. Miyaji*[2], *T. Hasegawa*[1];
[1]*Kitasato University Graduate School of Medical Sciences, Kanagawa-ken, JAPAN,* [2]*Fukushima Medical University, Fukushima-ken, JAPAN,* [3]*Tokyo Metropolitan Institute of Gerontology, Tokyo-to, JAPAN.*

***Aim/Introduction:*** Bone metastasis is currently diagnosed based on standardized uptake values (SUV) derived from bone single photon emission computed tomography (SPECT) images; however, they vary according to patient size or lesion location.

We focused on Z-scores calculated using an anatomical statistical method as a new quantitative index for bone SPECT images. We developed a new statistical image analysis software for bone SPECT imaging that inputs projection data and CT images, automatically reconstructs and corrects scatter and attenuation, normalizes and anatomically standardizes between reconstructed SPECT and CT images, and analyzes anatomical statistics. Z-scores were substantially affected by the size of the normal database (NBD). The statistical image analysis software for brain SPECT required data from at least 15 normal persons to create the NDB. The amount of data in the NDB required to calculate Z-scores for bone SPECT imaging is unclear. The present study aimed to validate the impact of NDB size on bone SPECT imaging. ***Materials and Methods:*** Twenty-two patients with (n = 3) and without (n = 19) bone metastasis were assessed by 99mTc-MDP pelvic SPECT imaging using a Symbia Intevo (Siemens Healthineers) under clinical conditions. We created NDB-16 (n = 16) and NDB-8 (n = 8) comprising persons without bone metastasis and compared them. We quantified the means and standard deviations (SD) of pixels at five points in the pelvis, then calculated the SD/mean to determine the accuracy of the NDB. We calculated Z-scores from the ilium and lumbar regions in three persons each with and without bone metastasis, and from lesions in three patients with bone metastasis. ***Results:*** The median SD/mean values were 17.2 and 13.8 for NDB-16 and NDB-8, respectively and did not significantly differ (p = 0.31, Mann-Whitney tests). The median Z-scores were 1.92 and 1.86 for NDB-16 and NDB-8, respectively, and 1.05 and 1.39 for NDB-16 and NDB-8 in patients with and without metastasis, respectively. The median Z-scores in metastatic lesions were 17.81 and 30.67 for NDB-16 and NDB-8, respectively. ***Conclusion:*** We created a small NDB (n < 10) using statistical image analysis software for bone SPECT imaging. The Z-scores were < 2.0 and > 2.0 in normal regions and metastatic lesions. Z-scores might be a novel quantitative index for bone SPECT imaging.

## EP-0697

### The Management of Diabetic Patients During the Positron Emission Tomography Examination: the Experience of Sahloul University Hospital

***A. Ben Naceur***, *A. Toumi, N. Ayachi, K. Chatti;*
*Sahloul University Hospital, Sousse, TUNISIA.*

***Aim/Introduction:*** Positron Emission Tomography (PET) marked with $^{18}$F-2-fluoro-2-deoxy-D- glucose ($^{18}$F-FDG ) is a functional imaging technique of notable sensitivity and specificity. However, high blood glucose levels might decrease the sensitivity of PET due to a low absorbance of $^{18}$FDG. Our goal is to study the follow-up of the preparation of diabetic patients for the PET examination to establish a management protocol for them. ***Materials and Methods:*** This is a descriptive prospective study consisting of monitoring the preparation of diabetic patients for the PET scan taking into account antidiabetic treatments, blood sugar levels, tolerance to fasting, risk of hypoglycemia and/or hyperglycemia, glycemic profile in previous PET scans, weight, etc. Then, we analyzed the feasibility of the examination in order to establish a common protocol to guarantee the minimum number of canceled examinations. Our study has been underway for two months now in the nuclear medicine department of Sahloul university hospital in Tunisia. ***Results:*** The study has been conducted on 33 diabetic patients, 27 with non-insulin-dependent diabetes and 6 with insulin-dependent diabetes. As part of the optimization of FDG doses in PET aiming to scan the maximum number of patients, we injected 4 patients at a time between 10:30 a.m. and 12:00 p.m. These patients have been fasting since 5 a.m, while 29 patients have been fasting since the night before the examination, and they were injected at a time between 7:45 a.m. and 9:30 a.m. On the examination day, 27 patients (81.8%) had a fasting blood sugar inferior to 2 g/dl, and 6 patients (18.2%) had a fasting blood sugar superior to 2 g/dl which counter-indicates the performance of the examination. These patients were injected with 4 IU of regular insulin and their blood sugar levels were monitored every hour for 4 hours. 2 of the 6 patients had a blood sugar level inferior to 2 g/dl 4 hours post-injection, while 4 patients (66.66%) did not experience an improvement in their blood glucose levels leading to the cancellation of their appointments. In conclusion, 4 examinations among the 33 (12.12%) were postponed due to uncontrolled diabetes. ***Conclusion:*** According to our study, a rigorous preparation of the patient is essential to limit the glycemic imbalances leading to the delay of the examination. The percentage of patients whose examination was postponed (12.12%) could be reduced with further management. The study continues to determine the most effective mode of preparation.

## EP-0698

### Towards AI application with automatic subtraction to improve parathyroid adenomas detection

***O. Boukhennoufa***[1], *L. Comas*[2,3], *E. Lajeune*[1], *C. Ungureanu*[2], *M. Soualhi*[1], *J. Nicod*[1], *N. Zerhouni*[1], *H. Boulahdour*[2,3];
[1]*Université de Franche-Comté, SUPMICROTECH, CNRS, institut FEMTO-ST, Besançon, FRANCE,* [2]*Service de Médecine Nucléaire, CHU Besançon, Besançon, FRANCE,* [3]*Université de Franche-Comté, LNIT, F-25000, Besançon, FRANCE.*

***Aim/Introduction:*** Nuclear medicine parathyroid imaging is an efficient diagnostic procedure to detect parathyroid adenomas. With dual tracer imaging system, addition of a processing layer of collected images can lead to efficient detection and localization of hyperfunctioning parathyroids. The processing is a subtraction between normalized $^{99m}$Tc-MIBI and the $^{123}$I images after defining the best factor of subtraction which is actually performed fastidiously. Also, the normalization is calculated after determining the region of interest (ROI), automatically or manually by physicians. This study aims to automatically find an adaptive optimal subtraction image for physicians towards AI applications. ***Materials and Methods:*** A total of 42 patients (5 men; mean age 63.8 years, range 28-91 years) were retrospectively included. After two injections of radioactive products, $^{99m}$Tc-MIBI and $^{123}$I, static LEHR and PINHOLE images were collected. In these acquisitions, three examinations were excluded from the study due to the absence of thyroid uptake preventing the determination of the ROI which is a crucial step for the normalization of $^{99m}$Tc-MIBI and $^{123}$I images. The proposed methodology starts by determining the thyroid ROI with an optimal threshold, which is 50% of the maximum pixel value in the thyroid area (40 lines in the center of the image). Then, the ROIs obtained from each patient of the $^{99m}$Tc-MIBI and $^{123}$I images are normalized so that the thyroid activity is comparable on the two images, allowing an optimal adaptive subtraction image for each patient. After simulation of subtraction with weight factors ranging from 0 to 2, the sum of pixels inside ROI is stored. Thus, optimal weight is obtained by the first positive derivative. Finally, the subtraction activity is the difference between the normalized $^{99m}$Tc-MIBI and $^{123}$I images with the adaptive normalization factor multiplied by the optimal threshold. ***Results:*** First, the 39 pinhole images were subtracted manually by the physician. Then, the manual subtraction was

compared to the proposed automatic one. The performance comparison between these two approaches was by calculating the correlation coefficient in the thyroid ROI of each subtracted image. The obtained correlation coefficients are promising with a mean value of 0.935. ***Conclusion:*** The developed algorithm allows automatic generation of an adaptive optimal subtraction of the static images. This method is fast and can be used for diagnostics by physicians and towards AI applications. ***References:*** Petranović Ovčariček, Petra, et al. "The EANM practice guidelines for parathyroid imaging." European journal of nuclear medicine and molecular imaging 48 (2021): 2801-2822.

## EP-0699

### Evaluation of PaIRe PET/CT segmentation software as cancerous lesion contouring tool in fully-automated annotation workflows for image-based research studies

***D. Abler***[1], *M. Jreige*[2], *O. Michielin*[1,3], *N. Schaefer*[2], *J. O. Prior*[2], *A. Depeursinge*[4,2], *M. A. Cuendet*[1,5,6], *P. Blanc Durand*[7];
[1]*Department of Oncology, Precision Oncology Center, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Nuclear Medicine and Molecular Imaging Department, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Department of Oncology, Geneva University Hospital and University of Geneva, Geneva, SWITZERLAND,* [4]*Institute of Informatics, School of Management, University of Applied Sciences Western Switzerland, Sierre, SWITZERLAND,* [5]*Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, SWITZERLAND,* [6]*Department of Physiology and Biophysics, Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA,* [7]*Nuclear Medicine Department, Henri-Mondor University Hospital, Créteil, FRANCE.*

***Aim/Introduction:*** Assistive automatic segmentation tools for clinical applications frequently prioritize detection of 'suspicious' regions of interest (ROIs), thereby accepting many false positives. While these can be discarded by expert review, fully-automated annotation is important for large-scale retrospective research[1]. This study assesses the PaIRe PET/CT segmentation software[2] and its potential role in such settings. ***Materials and Methods:*** Tumour ROIs in 20 whole-body PET/CT images of 10 metastatic melanoma patients at baseline and after treatment with Immune-Checkpoint-Inhibitors were contoured by a nuclear medicine expert aware of all clinical and follow-up information to obtain a ground-truth (GT) segmentation. For these images, PaIRe (version 0.2.1) yielded: (a) contours of suspicious ROIs, and (b) maps indicating each voxel's likelihood of being pathological. Agreement between GT and PaIRe contours was investigated at the voxel and lesion level. For each ROI, the number of True Positive (TP), False Positive (FP) and False Negative (FN) voxels was established. PaIRe ROIs sharing at least one voxel with GT were considered TP lesions. To investigate alternative operating points, PaIRe's sensitivity-recall curve was computed by assessing contours resulting from varying decision thresholds. ***Results:*** The GT dataset contained 98 malignant lesions across 19 PET/CT scans with average total metabolic tumour volume (TMTV) of 33.9cm$^3$ per patient (1 scan not evaluable). PAIRE, using default settings, identified an average TMTV of 125.1cm$^3$ and 399 ROIs. Of these, 92 TP and 307 FP (6 FN), corresponding to a (precision, recall) by lesion (PRL) of (0.23, 0.94) and by voxel (PRV) of (0.23, 0.84). Decision thresholds between 0.01 and 0.99 yielded PRLs between (0.06, 1.00) and (0.69, 0.70), and PRVs between (0.08, 0.98) and (0.88, 0.22), respectively. The highest average dice index (0.75) for corresponding ROIs was achieved at a decision threshold of 0.6 with PRL of (0.53, 0.85) and PRV of (0.70, 0.67). ***Conclusion:*** While PaIRe achieved almost perfect recall for cancerous lesion detection, any alternative operating point with acceptable recall (e.g., >0.8) resulted in large FP/TP ratios, possibly exacerbated by the presence of immunotherapy-induced pseudo-progression in this cohort. Further processing steps for removing FP (non-pathological, pathological but non-cancerous) lesions/voxels are thus required for automated workflows. Overall, PaIRe's voxel precision exceeded lesion detection precision, while the opposite applied to recall. Consequently, the optimal choice will depend on the specific research use case. ***References:*** [1] D. Abler et al. JCO Clinical Cancer Informatics. 2023; in-press. [2] A. Van Der Gucht et al. Médecine Nucléaire. 2021;45(4):192.

## EP-0700

### Pituitary Gland: Do We Really See It?

***A. Macula***[1,2], *L. Airo*[3], *S. Colombo Serra*[2], *M. Ali*[4], *S. Papa*[4], *G. Valbusa*[2], *A. Bifone*[1], *P. Gandolfo*[4];
[1]*Università di Torino, Torino, ITALY,* [2]*Bracco Imaging S.p.a., Milano, ITALY,* [3]*Università di Milano, Milano, ITALY,* [4]*Centro Diagnostico Italiano, Milano, ITALY.*

***Aim/Introduction:*** The pituitary gland is an endocrine organ that releases several hormones, including prolactin and growth hormones, along with pituitary hormones such as follicle-stimulating hormone, luteinizing hormone, thyroid-stimulating hormone, and adrenocorticotropic hormone. Oncological evaluation of cerebral parenchyma is not usually investigated by [18F]FDG-PET/CT imaging. However, during clinical practice, an anomalous uptake has been noticed on the hypophysis of many patients without sellar symptoms. The aim of this work is to analyze this phenomenon and its possible correlation with some clinical parameters. ***Materials and Methods:*** Scans from eighty-one patients who underwent [18F]FDG-PET/CT from 03/2018 to 01/2023 at our center (Centro Diagnostico Italiano, Milan, Italy) were selected by a qualitative analysis which compares the pituitary uptake with the mediastinal uptake. Inclusion criteria were: (a) cancer patients, (b) patients with at least two acquisitions, (c) [18F]FDG-PET/CT performed according to standard execution modalities, (d) whole body acquisitions starting from vertex, (e) patients without any pituitary biochemical examination or radiological evidence of pituitary adenoma. For each patient, clinical attributes of interest were automatically extracted from the clinical reports, by filtering reason for study, conclusions, and findings fields through keywords. An incidence count analysis was conducted by linking the presence/absence of hypophysis uptake with the type of therapy (chemio, radio, immuno, none), primary tumor (breast, lungs, others), setting (staging, follow up), result of the investigation (positive or not), status of the disease (progression or not). ***Results:*** The qualitative analysis showed focal uptake (> mediastinal) of the pituitary gland on forty-four patients (54%) while thirty-seven patients (46%) were considered negative. The preliminary incident count analysis did not show any evident connection between anomalous hypophysis uptake and any of the considered parameters. ***Conclusion:*** The finding of pituitary uptake in [18F]FDG-PET/CT is a very rare occurrence (0.07-0.8% [1]). However, in patients with a known tumor, especially in those with lung or breast cancer, the incidental pituitary uptake should be furthered investigated, although it could have functional or flogistic significance. For this reason, we designed a more structured retrospective study to: - Expand the dataset to investigate the possible correlation between the positive hypophysis cases and the primary tumor or the secondary lesions; - Perform a semi-quantitative analysis by eventually establishing a cut-off

to systematically classify the positive/negative cases; - Exclude any concomitant pathology of endocrine/non-endocrine nature which can have an impact on hypophysis uptake. ***References:*** 1. Iglesias, P., https://doi.org/10.1016/j.ejim.2019.08.008

## EP-0701

### A statistical method to adapt a normal range for thyroid uptake measurements following replacement of a gamma camera

***A. Gemmell***[1,2,3], *C. Brown*[1,2], *S. Ray*[3], *S. Small*[1,2];
[1]*Nuclear Medicine, Gartnavel General Hospital, Glasgow, UNITED KINGDOM,* [2]*Department of Clinical Physics & Bioengineering, Glasgow, UNITED KINGDOM,* [3]*School of Mathematics & Statistics, University of Glasgow, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** Semi-quantitative $^{99m}$Tc-Pertechnetate thyroid uptake measurements on a gamma camera provide useful diagnostic information for patients with hyperthyroidism. Guidelines suggest that centres should determine a local normal range due to geographical variations in normal thyroid measurements [1]. When a camera is replaced, previously established normal ranges may no longer be valid due to variations in camera performance [2]. This study uses a statistical batch harmonisation approach [3] to adapt an existing normal range to a new camera. ***Materials and Methods:*** Thyroid uptake measurements were gathered retrospectively for camera A (112 cases) and its replacement camera B (287 cases). The full dataset were harmonised using Location-Scale harmonisation [4]. The normal range for camera A (0.5% - 3.5%) was adjusted based on the resultant model to create a normal range for camera B. Repeated testing using random samples of the dataset was performed to determine minimum required sample size for accurate harmonisation. ***Results:*** Harmonisation of the full dataset improved distribution of the measurements between the two cameras from p=0.052 to p=0.988. Normal range was adjusted from 0.5% - 3.5% to a new range of 0.44% - 4.49%. Variations in potential normal ranges reduced with increasing sample size. Improvements were minimal with sample sizes > 100, where mean p=0.926 and mean adjusted normal range was 0.45% - 4.46%. ***Conclusion:*** The batch harmonisation method adjusts the distributions of thyroid uptake measurements from two gamma cameras, making them statistically more alike. Applying the adjustment to an existing normal range can correct for differences in camera performance. A downside is harmonisation can only be applied after sufficient data has been acquired on the new camera. Facilitating earlier harmonisation, smaller sample sizes may be used but with greater uncertainties - an iterative process of adaptation as more data is acquired may be appropriate. ***References:*** 1. ## EP-0702

### EImpact of using different SUV thresholds for delineating human brown adipose tissue volume with 18F-FDG PET-CT

***Y. Garcia-Rivero***, *E. Rodríguez García, S. Beltrán Arenas, M. Pérez Gómez, C. Rodríguez García, Á. García Rodriguez, M. Ruiz Molina, G. Sánchez-Delgado;*
*Hospital Virgen De Las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** Brown adipose tissue (BAT) has emerged as a promising target for treating obesity and metabolic diseases since its discovery in human adults in the early 21st century. Despite extensive research, many fundamental questions about BAT remain unanswered. One of the main knowledge gaps concerns the uncertainty surrounding the amount of BAT that adult humans possess. Various SUV thresholds have been employed in 18F-FDG PET-CT scans to evaluate BAT volume, which is the most commonly used technique. This study aims to determine the impact of different SUV thresholds on BAT volume quantification. ***Materials and Methods:*** The ACTIBATE study recruited 135 young, healthy adults (45 men, 90 women; 22.0±2.1 years old; 24.9±4.7 kg/m2) to assess their BAT using a static 18F-FDG PET-CT scan. Participants were exposed to a 2-hour personalized cold exposure while wearing cooling vests connected to a temperature-controlled water circulation system. The individual shivering threshold was considered to individualize the cold exposure. A bolus of ~185 MBq 18F-FDG was administered 1 hour after starting the cold (1 hour before the PET-CT). PET-CT images were acquired from the atlas vertebrae to the mid-chest. A range of radiodensity (-190 / -10 Hounsfield Units) was first applied to focus on adipose tissue, followed by three different SUV thresholds (1.5, 2, and individualized: 1.2*(lean body mass/body mass)). BAT volume, SUVmean, and SUVpeak were then calculated for each SUV threshold. ***Results:*** The mean BAT volume was 70.5±58.8 ml when using the individualized SUV threshold, 73.7±63.7 ml when using the 1.5 SUV threshold, and 99.5±79.7 ml when using the 2 SUV threshold, with all values differing significantly (all P<0.003). SUVmean was also impacted by the SUV threshold (Individualized SUV threshold: 3.8±2.0; 2 SUV threshold: 3.7±2.0; 1.5 SUV threshold: 3.3±1.5; all P<0.15). In contrast, SUVpeak was similar when using the Individualized SUV threshold (11.4±8.3) and 2 SUV threshold (11.4±8.4) (P=0.594) but differed when using the 1.5 SUV threshold (11.5±8.2) (all P<0.01). ***Conclusion:*** The use of different SUV thresholds significantly affects the quantification of BAT volume and activity in humans. Therefore, determining the most appropriate SUV threshold and standardizing it across studies is urgently needed.

## EP-0703

### Parametric Images And KEi Index In A Small Kidneys Clearance Function Assessment

***K. Filipczak***, *P. Cichocki, J. Kusmierek, A. Plachcinska, Z. Adamczewski;*
*Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Parametric images of clearance function are the result of processing data from Dynamic Renal Scintigraphy (DRS). Visualized clearance parameter can be presented also in the form of clearance efficiency classes, which allows visual assessment of the clearance function. This study presents a method for visual assessing of kidney function, which allows to compare results between patients, compare studies of the same patient, as well as assess clearance function of small kidney. ***Materials and Methods:*** Results of DRS of healthy volunteers (26

- 66 y/o, average 50 y/o, without urinary tract diseases or other diseases that could impair kidney function) were processed to define clearance function classes. Subsequently, 15 patients, whose one kidney appears relatively small and for which a standard way of assessment of the clearance function was problematic, was examined with a new method. Scintigraphy data were obtained using the standard DRS protocol, (60 images 20s, 128x128 matrix, 111MBq $^{99m}$Tc-EC). The gamma camera detector was in a position that includes the heart area. Clearance parametric images were generated and KEi (kidney efficiency index) was determined. KEi index and its standard deviations were used to define ranges of values characterizing the clearance function as: normal (very high, high), impaired (reduced or trace) and lack of active renal parenchyma. According to defined ranges, a color map was created for the parametric images. ***Results:*** Small kidney clearance was assessed using parametric images and a dedicated clearance color map. ***Conclusion:*** Parametric images with colormap of classified clearance function allows an easy visual assessment of a single kidney clearance function. The method appears very useful in assessment of small kidney function and also in comparison of results within the same patient and between patients. ***References:*** DOI 10.5603/NMR.2020.0025

## EP-0704

### Standardized Uptake Values for SPECT-CT in Normal Lumbar Spine, using xSPECT Quant Bone Reconstruction

***A. Duarte***, *D. Calado, N. do Canto, M. Correia, A. Figueiredo, S. Matos, B. Martins, C. Pinto, V. Sousa;*
*Hospital da Luz, Lisboa, PORTUGAL.*

***Aim/Introduction:*** Diphosphonates, such as HMDP (hydroxymethylene diphosphonate) labeled with $^{99m}$Tc are used to perform bone scintigraphy. The hybrid techniques such as SPECT-CT are helpful in diagnosis of bone pathology. Hybrid images of SPECT and CT create attenuation correction maps that are used for quantitative analyses through the standardized uptake value (SUV). In clinical practice, the use of SPECT-CT can significantly increase the diagnostic value of bone scintigraphy, by displaying sites of higher osteoblastic activity and perhaps sites warranting directed treatment. xSPECT Bone® is a new reconstruction algorithm for hybrid bone imaging. CT-based tissue segmentation is incorporated into the reconstruction to provide SPECT images with better bone definition.In this study, we aimed to determine standard SUV values of [99mTc] Tc-HMDP uptake in normal lumbar vertebrae, using SPECT-CT images reconstructed with xSPECT Bone®. ***Materials and Methods:*** We conducted a retrospective study between June 2020 and March 2023, with 173 patients undergoing SPECT-CT using [99mTc] Tc-HMDP. From those, only 31 patients (11 men and 20 women) complied with the inclusion criteria: adults (21 at 66 years) and have all the measures required for quantification (height; weight; dose activity; time of injection; residual dose). The median: age 40 years, weight 70 kg, and height 167 cm. We analyzed 140 normal lumbar vertebrae and obtained the maximum SUV Body Weight ($SUV_{BWmax}$) for each one. We studied the relationship of $SUV_{BWmax}$ values with age, height and weight of the patients. ***Results:*** Mean $SUV_{BW\ max}$ values were calculated for each of the lumbar vertebrae: L1 (12,10 ± 2,36), L2 (12,13 ± 2,43), L3 (12,08 ± 2,33), L4 (12,02 ± 2,33) e L5 (11,87 ± 2.04). There was no significant correlation of the mean $SUV_{BW\ max}$ value for the lumbar spine, with age, weight and height ($p = 0.160$; $p = 0.871$; $p = 0.453$). ***Conclusion:*** Using the new reconstruction algorithm xSPECT Bone®, it was possible to quantify standard SUV values for the lumbar spine. In this study there was no significant association of $SUV_{BWmax}$ values with age, weight and height, although it is necessary to carry out future studies with larger samples to study the impact of biometric parameters and age in $SUV_{BWmax}$ values. ***References:*** Qi, N., Meng, Q., You, Z., Chen, H., et al. Standardized uptake values of 99mTc-MDP in normal vertebrae assessed using quantitative SPECT/CT for differentiation diagnosis of benign and malignant bone lesions. ## EP-0705

### Relationship of 18F-FDG PET/CT metabolic parameters reduction during neoadjuvant chemotherapy to complete cytoreduction and pathologic response in primarily inoperable high-grade serous ovarian cancer.

***L. Sancho Rodriguez***[1], *L. Sánchez Lorenzo*[1], *F. Boria Alegre*[1], *T. Iscar Galán*[1], *L. García Belaustegui*[1], *V. Carrasco Rubio*[1], *C. Beorlegui Arteta*[2], *M. Romera Caballo*[3], *V. Betech Anta*[3], *M. García Velloso*[3];
[1]*Clinica Universidad De Navarra, Madrid, SPAIN,* [2]*Departamento de Salud. Gobierno de Navarra. Pamplona., Pamplona, SPAIN,* [3]*Clinica Universidad De Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** To evaluate the usefulness of reduction of $^{18}$F-FDG-PET/CT metabolic parameters after neoadjuvant chemotherapy(NACT) as predictors of complete cytoreduction and NACT response, in patients with advanced FIGO stage(III/IV) high-grade serous ovarian cancer(HGSC). ***Materials and Methods:*** Retrospective review of prospectively collected data from primarily inoperable HGSC patients who underwent $^{18}$F-FDG-PET/CT before(PETpre) and after NACT(PETpost). Reduction of CA-125 levels after NACT, pathological chemotherapy response score(CRS1-no response, CRS2-partial response and CRS3-complete response) and cytoreduction(R0-complete vs. R1-incomplete) were used to evaluate NACT response. $^{18}$F-FDG-PET/CT parameters were obtained by means of the segmentation of the supradiaphragmatic disease and the different abdominal areas (primary tumor, peritoneal carcinomatosis and infradiaphragmatic lymph nodes) using Syngo. via (Version VB60A Siemens), with automatic thresholding at 30% of SUVmax. The metabolic parameters studied were: metabolically active tumor volume (MTV) and total lesion glycolysis (TLG), for each segmented region and for the entire disease. The variation for all these parameters between PETpre and PETpost were calculated. The presence of ascites with pathological uptake of $^{18}$F-FDG (SUVmax ascites > SUVmean blood pool) was evaluated. Variables were described by mean (SD) or median (IQR) depending if data followed normal distribution. The relationship between quantitative variables were assessed by Spearman correlation coefficient (rho), and between quantitative and binary variables by logistic regression and ROC analysis. ***Results:*** Seventeen patients were included, with a mean age of 63.6 years (range: 37-78); most patients (94.1%) received three cycles of NACT. Only two patients (11.8%) presented R1, eight (47.1%) complete response (CRS 3) and only one did none response (CRS1). All patients associating pathological uptake in ascites on PETpre (n=13, 76.5%) normalized on PETpost. The reduction of CA-125 was moderately correlated to the reduction of the total TLG value (rho: 0.535; p=0,027), the total infradiaphragmatic disease MTV (rho: 0.577; p=0,015) and TLG (rho: 0.597; p=0,011) values and the total peritoneal disease MTV (rho: 0.609; p=0,012) and TLG (rho: 0.609; p=0,014) values. No significant relationship was detected among metabolic variables and cytoreduction; only variation of peritoneal MTV and total

infradiaphragmatic disease showed a p-value <0.200. No variables were found to be associated to CRS. ***Conclusion:*** Despite the small sample size, this study identifies some metabolic parameters of $^{18}$F-FDG-PET/CT whose variations could predict cytoreduction and NACT response in patients with FIGO stage III-IV HGSC. ***References:*** Eur J Nucl Med Mol Imaging (2018) 45:1224-1232. Annals of Nuclear Medicine (2020) 34:128-135. CJ Gynecol Oncol. 2022 May;33(3):e28. Cancer Res Treat. 2020:52(4):1211-1218. Gynecologic Oncology 140 (2016) 29-35.

## EP-0706

### Is there any metabolic parameter of staging 18F-FDG-PET/CT related to the therapeutic strategy performed (primary cytoreduction vs. neoadjuvant chemotherapy and interval cytoreduction) in patients with high-grade serous ovarian cancer?

***L. Sancho Rodriguez***[1], *L. Sánchez Lorenzo*[1], *F. Boria Alegre*[1], *T. Iscar Galán*[1], *L. García Belaustegui*[1], *E. eguillenv@unav.es*[1], *V. Carrasco Rubio*[1], *C. Beorlegui Arteta*[2], *M. Romera Caballo*[3], *V. Betech Anta*[3], *M. García Velloso*[3];
[1]*Clinica Universidad De Navarra, Madrid, SPAIN,* [2]*Departamento De Salud. Gobierno De Navarra, Madrid, SPAIN,* [3]*Clinica Universidad De Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** To analyze if there is any metabolic parameter of the staging $^{18}$F-FDG-PET/CT related to the therapeutic strategy performed [primary cytoreduction vs. neoadjuvant chemotherapy(NACT) and interval cytoreduction] in patients with high-grade serous ovarian cancer(HGSC). ***Materials and Methods:*** Retrospective review of prospectively collected data from patients with HGSC who underwent a staging $^{18}$F-FDG-PET/CT before defining the therapeutic strategy to be performed: A(primary cytoreduction) or B(NACT and interval cytoreduction). $^{18}$F-FDG-PET/CT parameters were obtained by means of the segmentation of the supradiaphragmatic disease and the different abdominal areas (primary tumor, peritoneal carcinomatosis and infradiaphragmatic lymph nodes) using Syngo.via(Version_VB60A_Siemens), with automatic thresholding at 30% of SUVmax. The metabolic parameters studied were: metabolically active tumor volume(MTV) and total lesion glycolysis(TLG), for each segmented region and for the entire disease. The presence of ascites with pathological uptake of $^{18}$F-FDG (SUVmax ascites>SUVmean blood pool) was evaluated. Clinical data as age, basal CA-125(U/mL), complete or incomplete cytoreduction were also collected. The dependent variable was the therapeutic strategy performed. Data were described by median(IQR) and frequency(%). Chi-square and Mann-Whitney U tests were used to compare groups and ROC analysis to dichotomize continuous variables. The predictors of the therapeutic strategy performed were analyzed using multiple logistic regression analysis. ***Results:*** 42 patients were included, 25 in group A (primary cytoreduction) and 17 in group B (NACT and interval cytoreduction). Both groups were similar in relation to age (61 years (56-66) in group A vs. 65 years (58-71) in group B; p = 0,155), median basal CA-125 (667 U/mL (143-1113) vs 840 U/mL (299-1778); p =0.289), and frequency of complete cytoreduction (68 vs 87.5%; p=0.102). Group A display significantly less ascites with pathological uptake (32 vs 76.5%; p=0.005), smaller MTV and TLG values for supradiaphragmatic disease (0 (0-0) vs 8.7 (3.9-55.0)) and (0 (0-0) vs 25.5 (11.4-132.0)), respectively, both p<0.001) and smaller MTV and TLG values for infradiaphragmatic disease, (208.2 (35.04-411.56) vs 455.9 (152.9-683.9) p=0.028) and (502.2 (194.3-1460.8) vs 2082 (999.3-2935.2) p=0.032), respectively, than group B. Both, ascites with pathological uptake (OR=0.197 (0.045-0.865); p=0.031) and MTV value >286 for infradiaphragmatic disease (OR=0.225 (0.052-0.954); p=0.044) were independent predictors of the therapeutic strategy (Sensitivity=64.7% and specificity=92%). ***Conclusion:*** This study, despite its small sample size, identifies very useful 18F-FDG PET/CT biomarkers for deciding the therapeutic strategy in patients with HGSC. ***References:*** Eur J Nucl Med Mol Imaging(2018)45:1224-1232. Annals of Nuclear Medicine(2020 34:128-135. J Gynecol Oncol. 2022 May;33(3):e28. Cancer Res Treat. 2020:52(4):1211-1218.

## EP-0707

### Quantification parameters of 99mTc-MDP single-photon emission computed tomography/computed tomography in the diagnosis of active condylar hyperplasia.

***M. Umar***, *D. Khan, S. Sagar, S. Ahmad Shamim, R. Kumar; Aiims, Delhi, INDIA.*

***Aim/Introduction:*** 99mTc-MDP SPECT/CT has a significant role in the identification of active condylar hyperplasia. The aim of our study is to assess the quantification parameters of 99mTc-MDP single-photon emission computed tomography/computed tomography (SPECT/CT) for the diagnosis of active condylar hyperplasia (CH) and studies based on this concept is scarce in the literature. ***Materials and Methods:*** 30 patients who underwent 99mTc-MDP bone scan (with regional SPECT/CT) were retrospectively enrolled in the diagnosis of active CH. Images were evaluated by 2 nuclear medicine physicians in consensus.ROI was drawn around the bilateral condyles, radioactive counts were measured per region of interest, and the respective percentages were calculated. The anteroposterior and transverse dimensions of the normal and abnormal sides were measured on CT. A cutoff difference percentage score above which can be confidently reported as active CH was also calculated. The DPS was calculated by taking the abnormal and normal side counts, and then calculating extra percentage uptake on the abnormal side. ***Results:*** The mean age of the patients was 20.84 ± 5.15 years, with 22 males and 8 females. SPECT/CT was positive in 56% (17/30), while the rest of the 13 patients had negative scans. We calculated the uptake percentage of the positive scans (abnormal side counts/total counts x100) and found mean uptake as 58% on the abnormal side. Also calculated quantitative parameter for the differentiation of disease from the normal side: difference percentage score (DPS) (abnormal side counts-normal side counts/normal side counts x100). Average difference percentage of the 17 patients was found to be 63 %. Size of the condyles as measured on the CT showed, a mean AP of 0.945 ± 0.36cm and TR of 1.785± 0.18 cm at the abnormal side compared to the normal side mean AP of 0.705 ± 0.14cm and TR of 1.745± 0.27 cm respectively. A significant difference in anteroposterior CT measurements (p=0.05) of the abnormal and normal sides of the condylar hyperplasia was noted. Both groups had no significant difference (p=1.00) in transverse measurements. ***Conclusion:*** Quantitative parameters of 99m Tc-MDP SPECT /CT like percentage counts and DPS give an insight into the correct prediction and diagnosis of active CH. Also, abnormal anteroposterior CT measurement of active CH is the best CT parameter for differentiation. Larger studies are needed to establish absolute values for the same and will therefore help as an objective tool to assess condylar hyperplasia in 99m Tc-MDP SPECT /CT. ***References:*** doi: 10.1097/MNM.0000000000000607.

## EP-0708

### Normalizing SUV values by lean body mass effectively reflect patient weigt and body composition variations improving SUVmax values determination in 18F-FDG PET-CT imaging.

***A. Hurtado de Mendoza***, *M. Yaryes, C. Soza-Ried, H. Amaral; Positronmed, Santiago, CHILE.*

***Aim/Introduction:*** This study aims to compare the SUV max, signal-to-noise ratio (SNR) and tumour-to-background ratio (TBR) values between SUV normalized by body weight and lean body mass in patients undergoing $F^{18}$-FDG PET/CT imaging and to determine whether body mass index (BMI) affects SNR. This parameter is particularly relevant in oncologic patients since their body weight suffers significant fluctuations during treatment. ***Materials and Methods:*** A total of 45 patients who underwent $F^{18}$-FDG PET/CT imaging were included in this retrospective study. Nuclear medicine physicians with over ten years of experience determined and evaluated SUV values. The tumoral lesion with the highest uptake was chosen in each patient to compare SUV max, SNR and TBR values using SUV normalize by weight and SUV normalize by lean body mass. We categorized the sample into normal weight (BMI ≤ 24.9), overweight (BMI 25-29.9), and obese (BMI ≥ 30) to analyze the effect of BMI on SUVmax, TBR and SNR. The results were analyzed by non-parametric statistical tests and considered significant when p-values < 0.05. ***Results:*** Comparison analysis between SUV normalization by body weight and LBM showed that normalization by LBM reduced variability and decreased overestimation of SUVmax values compared to SUV normalization by body weight. There were no statistically significant differences in SUVmax and TBR values between the three BMI categories. In contrast, BMI significantly affected SNR values, showing less noise in the normal BMI group. ***Conclusion:*** Our findings suggest that LBM normalization is the preferable approach to normalizing SUV values in PET/CT imaging due to less variability and overestimation of SUVmax values than body weight normalization. An appropriate SUV normalization method can effectively account for patient weight and body composition variations, less impacting SUV values determination and interpretation. However, the study did not identify an optimal SUV normalization method for each BMI category, emphasizing the necessity for additional research in this area.

## EP-0709

### Current status and new trends in technetium-99m described through a patent analysis (2000-2022)

***M. Riondato***[1], *D. Rigamonti*[2], *P. Martini*[3], *C. Cittanti*[3], *A. Boschi*[3], *L. Uccelli*[3];
[1]*University Policlinic Hospital of Genoa, Genoa, ITALY,* [2]*European and Italian Patent Attorney, Milan, ITALY,* [3]*University of Ferrara, Ferrara, ITALY.*

***Aim/Introduction:*** During the last 60 years, Nuclear Medicine has undergone many changes, but the discipline demonstrated to evolve rapidly following the considerable advances in several scientific fields, such as molecular biology, chemistry and radiochemistry. PET seems to better take the advantage of this opportunity and the recent achievements in the use of radiopharmaceuticals labelled with positron emitters hardly affected the field of SPECT. in this context there are some uncertainties as to what will be the role of technetium-99m in the next future. The main goal of the study was to identify key areas of development by examining patent data from the past 20 years, highlighting innovation trends and market predictions for the coming years. ***Materials and Methods:*** QUESTEL's ORBIT Intelligence® system was used for the collection of technetium inventions disclosed in patents and patent applications in more than 96 countries, in the period 2000-2022. Patent documents underwent to cleaning processes using the software and manually by the authors, addressing the required information and identifying trends and topics of interest. ***Results:*** The keywords "+99MTC+" or "TECHNETIUM" were identified as the search query that best retrieves technetium-related patents. 2768 patent documents were analyzed. Each item was referred to a single patent family, filed in various countries to protect a single invention. After several cleaning processes a total of 221 patent documents, regularly granted and pertinent to technetium, were retrospectively analyzed to identify the major areas of discovery and developments in the last 20 years. The criteria were based on the current major lines of innovation, including novel modalities for supporting technetium-99m availability (39 patents), labelling methods (21), expanded use or reformulation of established radiopharmaceuticals (19), new radiotracers (65, as candidates with the ambition to become radiopharmaceuticals) and molecular carrier which might be used as the building block for developing new probes (41). Other patents (36) were not matching with the previous groups. In eastern economies, such as China and other emerging markets, patent applications are on the rise, while those in developed western countries are stagnating, with some exceptions for the USA. ***Conclusion:*** The place of SPECT imaging using $^{99m}$Tc-radiopharmaceuticals is still solid. The result of this study is an impulse that fuels the rediscovery of technetium-99m, an unique radionuclide within the scenario of Nuclear Medical imaging for its ideal nuclear properties, availability and the easy preparation radiopharmaceuticals.

## EP-0710

### Building a Normative Database for [18F]-FDG imaging: Insights from a Japanese Screening Cohort

***S. Gutschmayer***[1], *T. Beyer*[1], *Z. Chen*[2], *T. Junichi*[3], *S. Kinuya*[2], *L. Shiyam Sundar*[1], *S. Takeda*[3], *H. Wakabayashi*[2];
[1]*Quantitative Imaging and Medical Physics (QIMP) Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, JAPAN,* [3]*PET Center, Kanazawa Advanced Medical Center, Kanazawa, JAPAN.*

***Aim/Introduction:*** Whole-body and total-body [$^{18}$F]-FDG-PET enable insights into the global physiology of the human body by assessing glucose metabolism. However, to interpret metabolic aberrations across organs, a normative inter-organ mapping of tracer uptake is needed. A key confounder of glucose uptake resembles subject ethnicity. This study aims to report the first insights from two healthy control groups of different ethnicity used to establish normative [$^{18}$F]-FDG-PET template images. ***Materials and Methods:*** To date, 15 healthy subjects of Japanese ethnicity (13M/2F, 71±11 kg, 2 scans with 1-y apart) and 19 healthy subjects of European ethnicity (10M/9F, 76±17 kg, 1 scan) underwent whole-body [$^{18}$F]-FDG -PET/CT imaging. A normative template PET/CT image pair was first established for each scan/cohort by a process that starts by overlapping and averaging all CT images within a cohort to an initial template image. Using diffeomorphic co-registration, all CT images are aligned iteratively to the initial template. The resulting warp fields are applied to the corresponding PET images. The aligned CT and PET images are averaged in each iteration, acting as the following iteration template. Once the template CT image is deemed sharp enough (determined within the frequency domain), the

process is stopped, resulting in a cohort-specific, normative PET/CT template image. A normative SUV and an SUV variance image are also created for each cohort. This study ascertains voxel- and organ-wise intensity and SUV differences between the Japanese and European cohorts for five automatically delineated [1] organs, the skeleton, subcutaneous fat and muscle. ***Results:*** The volume, maximum and mean SUV change of selected tissues between the two scans of the Japanese cohort was below 8.5%, 15%, and 2.2%, respectively. Subcutaneous fat and liver showed the highest volume change of 6% and 8%. Volume and mean SUV were up to 90% and 93% higher in the European cohort, with a noticeably higher peak SUV in the liver, muscle and subcutaneous fat. Maximum voxel SUV variance was also significantly higher in the European cohort (45) than in both Japanese (10, 13). ***Conclusion:*** This study presents a viable approach to building a normative [$^{18}$F]-FDG-PET/CT template for assessing voxel-based aberrations of incoming study subjects. The significant voxel-wise intensity and SUV differences found between the Japanese and European cohorts suggest that additional high-quality, healthy control studies are needed to investigate further key confounders.

**Validation for dual-gate motion correction techniques using ECG gating and data-driven respiratory motion correction for cardiac PET: A pilot study**

***K. Takanami***[1], *H. Odagiri*[2], *H. Watabe*[3], *H. Kodama*[4], *H. Kawakami*[5], *A. Katsuki*[5], *N. Uetake*[5], *K. Takase*[1];
[1]*Tohoku University Hospital, Sendai, JAPAN,* [2]*Department of Diagnostic Image Analysis, Tohoku University Graduate School of Medicine, Sendai, JAPAN,* [3]*Division of Radiation Protection and Safety Control, Cyclotron and Radioisotope Center, Sendai, JAPAN,* [4]*Department of Radiology, Tohoku University Hospital, Sendai, JAPAN,* [5]*GE Healthcare Japan, Tokyo, JAPAN.*

***Aim/Introduction:*** We aim to validate the clinical feasibility of the dual motion correction techniques using ECG gating and data-driven respiratory motion correction for cardiac PET. ***Materials and Methods:*** This study included the five patients who underwent cardiac PET under overnight fasting condition using F18-FDG for the evaluation of cardiac sarcoidosis. One hour after the intravenous injection of 3.7 MBq/kg BW of FDG, 30-minute emission scans were acquired using Discovery MI PET/CT scanner (GE HealthCare) while ECG was acquired with body surface electrodes. All PET data were reconstructed under 4 conditions: "without motion correction", "with 3-segment ECG-gating", "with data-driven respiratory motion correction (DDMC)", and "with both gating (DDMC+ECG-gating)". Especially, "DDMC" and "DDMC+ECG-gating" were performed using PET reconstruction software (PET toolbox, GE HealthCare). A boundary box was set at lower chest and upper abdomen including the whole heart. A 2-second ultra-fast frame reconstruction was executed from a list data, and respiratory motion was estimated using a volume inside the boundary box by 3D image-based registration. The reference for registration was set to the frame at 30 seconds. The ratio of the accumulation of FDG in the left ventricular (LV) wall compared to those in the liver or blood pool, and the metabolic tumor volume (MTV) of the accumulation in the whole left ventricular wall with the threshold of SUV of the blood pool (MTV-LV) were compared among the 4 conditions using Wilcoxson's signed rank test. $P<0.05$ was set at statistical significance. ***Results:*** The average and range of the MTV-LV for "without motion correction", "ECG-gating", "DDMC", and "DDMC+ECG-gating" were 173.1 ml(48.5-264.0), 162.8 ml (39.9-236.0), 156.2 ml (45.8-229.0), and 120.4 ml (29.9-210.0) ,respectively. There was statistically significant difference in MTV-LV only between "DDMC+ECG-gating" and "without motion correction"($p < 0.05$). Meanwhile, there was no statistically difference among the ratio of the accumulation of the LV wall compared to the liver or blood pool. ***Conclusion:*** The dual motion correction techniques using ECG gating and DDMC for cardiac PET may reduce blurring of myocardial accumulation associated with respiration and heartbeat, allowing more accurate assessment of the distribution of myocardial accumulation.

### EP-0712

**Determining the optimal reconstruction algorithm for FDG brain PET/CT images in BGO-based Whole body PET scanner**

***M. Asami***[1], *M. Ay*[1], *S. Farzanehfar*[2], *P. Ghafarian*[3], *P. Sheikhzadeh*[2];
[1]*Department of Medical Physics and Biomedical Engineering ,Tehran University of Medical Sciences, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** In this study, we aimed to evaluate and compare image quality parameters in order to obtain the optimal reconstruction algorithm for PET brain imaging. To achieve this goal, we optimized the number of iterations and subsets in the OSEM algorithm, as well as the amount of noise control factor (beta parameter) in the BPL algorithm. ***Materials and Methods:*** A Carlson phantom, a two-slice Hoffman phantom and a point source were used and scanned by a five ring BGO-based PET/CT scanner. The obtained images were reconstructed with iterations"2-4-8-14-20" and subset "1-6-12" and beta "50 to 500" by steps of 50 and in addition a reconstruction with the default scanner algorithm (12 iterations and 12 subsets) were done. Then, the spillover ratio, Recovery coefficient (RC), point source FWHM and peak-to-valley ratio were measured. also 10 clinicaly Brain FDG PET/CT study were reconstructed with the same algorithms and the ratio of putamen and caudate to the background(BG) was calculated to validate the phantom results. ***Results:*** The highest RC in the largest sphere (22.3 mm) corresponds to beta "50 to 150" and iteration-subset 12/20, which is 3% more than iteration-subset 12/12 which is the recommended value by scanner manufacturer in the best case. The lowest spillover ratio in the largest sphere (17.9 mm) is related to beta "50 and 100" and iteration-subset 12/20, which is 17% less than the recommended value as well. The lowest FWHM value obtained is related to beta "50 to 500" (3.36-3.41 mm), versus 4.1 mm for 12/12. The highest value of peak-to-valley ratio in the line profile drawn in the Hoffmann phantom is related to beta (50 to 150) and iteration-subset of 12/20 . Also, the evaluation of clinical images shows that the highest ratio of putamen/BG and caudate/BG is in beta "50 and 100" and It/sb of 12/20. ***Conclusion:*** On average, BPL produces better resolution and RC than OSEM. The best resolution is related to beta 50. Gibbs artifacts can be

seen in the reconstructed images with beta 50 and 100, since the difference in the values obtained between betas 50 and 150 is minor, therefore BPL reconstruction with beta 150 can be considered as the optimal reconstruction algorithm in brain PET images in five ring BGO-based PET/CT scanners.

## EP-0713

### Faster time-of-flight performance reduces effect of misregistration on myocardial uptake scores in cardiac PET-CT

***M. Hylle***[1], *N. A. Bebbington*[2], *M. R. Pedersen*[3], *H. D. Zacho*[1];
[1]*Aalborg University Hospital, Aalborg, DENMARK,*
[2]*Siemens Healthcare A/S, Aarhus, DENMARK,*
[3]*Lillebaelt Hospital, Vejle, DENMARK.*

***Aim/Introduction:*** PET-CT misregistration is common in cardiac examinations, due to differences in respiratory position between PET and CT acquisitions. However, misregistration artifacts are reduced with time-of-flight (TOF) reconstruction, as described by Conti (2011) with a study using a lutetium-oxyorthosilicate/photomultiplier (LSO/PMT)-based system (1). Yet, development of silicon photomultiplier (SiPM)/LSO-based systems has since dramatically advanced TOF performance. The aim of this study was to assess the impact of PET-CT misregistration on myocardial uptake scores, and to determine whether improved TOF performance reduces the effect of misregistration on myocardial uptake scores. ***Materials and Methods:*** An air-filled cylindrical phantom with water-filled cardiac insert was scanned with surrounding fat layers to simulate a patient chest. The insert was filled with ~75MBq [F-18]FDG, and scanned for 30 minutes on LSO/PMT-based (540ps timing resolution) and LSO/SiPM-based (249ps timing resolution) PET-CT systems. Four new registration matrices were created with CT offsets of 5 and 10 pixels in inferior and posterior directions. PET reconstructions were made for the original registration matrix and the four misregistered matrices, using TOF together with point-spread-function (PSF) modelling, and with PSF-only (without TOF). Total uptake scores were calculated in Corridor 4DM. Percentage myocardial uptake values for misregistered reconstructions were subtracted from corresponding values without misregistration, providing the Percentage Reduction in Uptake through Misregistration (PRUM) value. The absolute percentage reduction in PRUM with TOF was determined by calculating $PRUM_{PSF}$ - $PRUM_{PSF+TOF}$, and values for PRUM reduction with TOF were compared between PET-CT systems. ***Results:*** For the LSO/PMT system, PRUM values for PSF-only reconstructions were 5.7%, 4.5%, 9.6% and 13.7%, for 5 pixels inferior, 5 pixels posterior, 10 pixels inferior and 10 pixels posterior, respectively. Reductions in PRUM with the addition of TOF were 0.4%, 3.2%, 0.0% and 7.0%. For the LSO/SiPM system, PRUM values for PSF-only reconstructions were 5.5%, 7.8%, 10.2% and 15.2%. Corresponding reductions in PRUM with TOF were 3.1%, 3.4%, 4.2% and 5.5%. This demonstrated a greater mean reduction in PRUM with TOF for the LSO/SiPM system (4.1%) compared with the LSO/PMT system (2.7%). ***Conclusion:*** Cardiac PET-CT misregistration provides images with apparently reduced tracer intensity in affected walls, thereby artefactually reducing myocardial uptake scores. However, this effect is reduced with TOF reconstruction, and the faster timing resolution associated with LSO-SiPM systems reduces this effect even further. ***References:***
Conti M (2011) Why is TOF PET reconstruction a more robust method in the presence of inconsistent data? Phys Med Biol 56:155-168

## EP-0714

### Optimizing the Block Sequential Regularized Expectation Maximization (BSREM) Algorithm for 68Ga-PSMA PET-CT Imaging: Phantom and Clinical Study

***F. Sadeghi***[1,2], *P. Sheikhzadeh*[1,3], *N. Kasraie*[4], *S. Farzanehfar*[3], *M. Abbasi*[3], *Y. Salehi*[3], *M. Ay*[1,2];
[1]*Department of Medical Physics and Biomedical Engineering ,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Department of Radiology, UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The Block sequential regularized expectation maximization (BSREM) algorithm was created as a solution to address the issue of excessive noise. It involves a point spread function and noise penalization factor. This study aimed to identify the most effective noise penalization factor on 68Ga-PSMA imaging. ***Materials and Methods:*** We examined NEMA IQ phantom and 15 prostate cancer patients with injections of 68Ga-PSMA. Images were reconstructed using Ordered Subset Expectation Maximization (OSEM) and BSREM, with various β-values. Clinical lesions were classified into small and large size groups. We evaluated background variability (BV), contrast recovery (CR), signal-to-noise ratio (SNR), and lung residual error (LE) using phantom data, as well as Signal-to-Background Ratio (SBR) and contrast using clinical data. ***Results:*** There is not a significant difference on BV and SUVmax behavior in higher β-values. As the β increased from 100 to 200, BV decreased by 29.4%, while from 900 to 1000, BV decreased by 3.4%. there was a negative correlation between β-value and CR. Highest CR was attributable to BSREM with β-value of 100.RC of small lesions, resulting from BSREM with all β-values was less than 1. In contrast, in large lesions, RC from lower β-values was greater than 1. The relative differences of SNR was dependent on sphere size. As the β-value increased from 100 to 1000, the SNR also increased by 140.5%, 37.6% and 29.0% in the smallest, mid and largest spheres respectively. BSREM using all examined β-values, resulted in lower LE compared to OSEM. in clinical study, The mean SUVmax of small and large lesion size groups for $BSREM_{500}$ was 12.1 ± 2.4 and 25.0 ± 8.1 and the mean SUVmax for OSEM was 7.9 ± 3.2 and 21.8 ± 8.6 , respectively. The SBR and contrast increase with decreasing β-value, whereas an increase on β-value translates into an increase in SNR. The lowest SBR and contrast was related to the OSEM, irrespective of lesion size and β-value. When β-values decreased from 500 to 100, the SBR and contrast rose by 69.7% and 71.8% in small lesions and 35.6% and 33.0% in large lesions respectively. ***Conclusion:*** When the size of the lesion decreased, the ideal β-value also decreased. The findings of both studies indicated that a β-value of 400 was most suitable for reconstructing small lesions. However, for larger lesions, a β-value of 600 and 500 were recommended for the phantom and clinical studies, respectively.

## EP-0715

### Evaluation of advanced artificial intelligence-based PET image reconstruction (HYPER DPR) on brain PET/CT imaging

***K. Miwa***[1], *M. Watanabe*[2], *M. Ishiguro*[2], *T. Yamao*[1], *N. Miyaji*[1], *K. Hasegawa*[1], *A. Takenaka*[3], *Y. Inui*[3], *H. Toyama*[3];
[1]*Fukushima Medical University, Fukushima, JAPAN,*
[2]*Fujita Health University Hospital, Aichi, JAPAN,* [3]*Fujita Health University School of Medicine, Aichi, JAPAN.*

***Aim/Introduction:*** HYPER DPR (Deep Progressive Reconstruction) represents a cutting-edge artificial intelligence (AI) PET image reconstruction algorithm, recently introduced by United Imaging Healthcare for their PET scanners[1]. The present study aimed to validate the impact of HYPER DPR on the ability of brain [18F] F-FDG PET imaging. ***Materials and Methods:*** We used a uMI550 PET/CT system (United Imaging Healthcare) to acquire 30-min PET scans of Hoffman 3D Brain and cylindrical phantoms each containing 20 MBq of [18F]F-FDG at the starting acquisition. We reconstructed using OSEM+TOF, and HYPER DPR (postfilter; combined non-local means; Gaussian and Metz filters), and a 256 × 256 matrix. Gray-white contrast (%contrast) and recovery coefficients (RC) for grey and white matter were calculated from images generated by the Hoffman 3D Brain phantom, and image noise (CV) and uniformity (SD) were calculated from those generated by the cylindrical phantom according to the Japanese Society of Nuclear Medicine (JSNM) and the European Association of Nuclear Medicine (EANM) phantom test criteria. ***Results:*** The %contrast exhibited significant improvement when reconstructed using HYPER DPR (range of 72.9%-90.5%) compared to OSEM (63.1%). The RCs for grey ($RC_{GM}$) and white ($RC_{WM}$) matter were 0.79 and 0.27, respectively, for OSEM, and 0.82-0.88 and 0.24-0.26 for HYPER DPR. The %contrast, CV and SD of HYPER DPR for all conditions met the JSNM criteria (%contrast ≥ 55%, CV ≤15%, SD ≤ 0.0249). The HYPER DPR with Enhance2, which contains non-local mean and Metz filters as a postfiltering option, outperformed other evaluated reconstruction methods. ***Conclusion:*** Overall, our findings demonstrate that the HYPER DPR enhances image quality and quantitative accuracy when compared to OSEM-based reconstruction methods for diagnosing Alzheimer's disease using brain [18F]F-FDG PET images. HYPER DPR reduced noise, improved image contrast, and augmented PET image quantitation. ***References:*** 1) Lv Y, et al. Phys Med Biol. 2021;66(10):105016.

## EP-0716

### Impact of the 68Ga Source Model on Positron Range Simulations and 68Ga-specific PET Reconstructions

***P. Gavriilidis***[1,2,3], *A. Marinus*[4,1], *F. M. Mottaghy*[5,1,2], *T. W. Deller*[6], *F. P. Jansen*[6], *M. Koole*[3], *R. Wierts*[1,2];
[1]*Maastricht University Medical Center, Maastricht, NETHERLANDS,* [2]*Maastricht University, Maastricht, NETHERLANDS,* [3]*Katholieke Universiteit Leuven, Leuven, BELGIUM,* [4]*Eindhoven University of Technology, Eindhoven, NETHERLANDS,* [5]*RWTH University Hospital, Aachen, GERMANY,* [6]*GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The positron range (PR) distribution profile of a radionuclide can be obtained from Monte Carlo simulations. For those simulations, a point source is usually employed. However, in positron emission tomography (PET), the point source assumption is not accurate, as voxelated PET images are reconstructed. We investigate whether positron range correction (PRC) based on a cubic source, having the same size as the reconstructed PET voxels, is superior compared to a point source approach. ***Materials and Methods:*** Monte Carlo simulations were performed for both $^{18}F$ and $^{68}Ga$. A point source (diameter=0.001 mm) or cubic source (2.73x2.73x2.8 $mm^3$) of $^{18}F$ or $^{68}Ga$ was placed in the center a water based uniform phantom (20x20x20 $cm^3$). Each simulation generated 8.88 million positron emissions from which the PR distribution profile of the corresponding radionuclide was generated. Each profile was modeled as a spatially invariant Gaussian function of which the full width at half maximum (FWHM) was calculated. For each type of source, $^{68}Ga$-specific PRC was performed by adding/subtracting the respective $^{68}Ga/^{18}F$ FWHM to the Gaussian filter applied in the image space of the Hybrid-Space PET Point Spread Function (Hybrid PSF) [1]. $^{68}Ga$-specific Hybrid PSF ($^{68}Ga$-specific PSF) was applied to OSEM+PSF (2 iterations, 34 subsets) and Q.Clear (β=700) reconstructions which were compared to the non-corrected reconstructions. A line source and NEMA IQ phantom were imaged using $^{68}Ga$-PSMA. Spatial resolution (FWHM), average recovery coefficient (RC) and background coefficient of variation (COV) measurements were performed. ***Results:*** Although cubic sources showed wider PR distribution profiles than point sources for both $^{68}Ga$ (3.99 vs 3.53 mm) and $^{18}F$ (1.99 vs 0.71 mm), the calculated FWHM of the Gaussian filter applied in the $^{68}Ga$-specific PSF reconstruction was identical for both source types (difference < 0.01%). For the line phantom, $^{68}Ga$-specific PSF resulted in improvements in the transaxial and axial FWHM for both OSEM (14.7%, 12.7%) and Q.Clear (16.7%, 16.6%). Furthermore, RC values were improved by 10.6% for OSEM and 6.2% for Q.Clear. For OSEM the COV was reduced by 21.7% and for Q.Clear it was slightly increased by 1.5%. ***Conclusion:*** Although the source size was shown to affect the PR distribution profiles of $^{68}Ga$ and $^{18}F$, it did not affect the FWHM of the Gaussian filter used in $^{68}Ga$-specific PSF reconstruction. $^{68}Ga$-specific PSF improved the spatial resolution and RC as measured in phantoms. ***References:*** [1] T. ## EP-0717

### Transforming a low-count nuclear medicine image into a high-count image using Dynamic Stochastic Resonance

***A. Pandey****, S. Kumar, P. D. Sharma, C. Patel, R. Kumar;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Low-count nuclear medicine images are observed in routine nuclear medicine practice. However, it is always desired to have a high-count image because of better signal to noise ratio. Various methods are continuously being developed for further improvement of nuclear medicine images. In this study, we investigated the dynamic stochastic resonance (DSR) technique for transforming a low-count nuclear medicine image into a high-count image. DSR is a type of stochastic resonance in which a controlled amount of noise (in this case internal noise of the image) is added to the image itself, to improve the signal-to-noise ratio. DSR may be explained using motion dynamics of a particle oscillating in a bistable double-well system, in the presence of a weak periodic signal, and noise, the double well gets tilted back and forth asymmetrically following the equation: $x_{n+1} = x_n + \Delta t[ax_n - bx_n^3 + Signal + Noise]$. ***Materials and Methods:*** A phantom was filled with 99mTc, and a dynamic acquisition (256 X 256 image matrix, 30 seconds per frame for 10 minutes) was performed. The first frame of the study was considered as a low count image and the high-count image (of 10 minutes duration) was formed by summing all the frames of the study. At each value of Δt low-count image was transformed into 30 different high-count images (creating one image at each iteration). Twelve different values of Δt were used. The low-count image, DSR-transformed-high-count image and high-count image (of 10 minutes duration) were compared. ***Results:*** The DSR transformed image looks identical to the high-count image (of 10 minutes duration). At value of Δt =0.1,0.2,0.3, 0.5 and 2.5, after 30 iterations, although the DSR-transformed image looked equivalent to high-count image, the total counts in the DSR-transformed-high-count image was less than the high-count image. At value of Δt= 5.5, 7.0, 9.0, 10.5, 15.5, and 25.5, with increase in

number of iterations the DSR-transformed image (until the total counts reached was up to 18 million counts) progressively became equivalent to high-count image, with further increase in iteration the DSR-transformed image became very high contrast image and at 30th iterations all pixels got equally bright. ***Conclusion:*** A low-count nuclear medicine image can be transformed into a high-count image using DSR by adding a controlled amount of noise till the image counts becomes 18 million in 256 X 256 image.

### Role of dynamic stochastic resonance in enhancing the contrast between the abnormal and no-abnormal tau uptake on reconstructed tau (F-18 ML-104) PET images

***A. Pandey***[1], *J. Yadav*[2], *M. Tripathi*[1];
[1]*All India Institute of Medical Sciences, New Delhi, INDIA,*
[2]*All India Institute of Medical Sciences, Faridabad, INDIA.*

***Aim/Introduction:*** Nuclear medicine physicians look for the intensity difference between the abnormal and no-abnormal uptake of tau in cortex of brain tau PET images. Usually, the signal to noise ratio in PET images is very good. However, in many instances, the signal to noise ratio (here in this case, the contrast difference between the abnormal and no-abnormal uptake of tau) is not very obvious, and hence might lead to incorrect interpretation of tau PET images in patients with cognitive impairment. Thus, there is need for a post processing method that can improve the contrast for better interpretation of topography on F-18 ML-104 tau PET images. In this study we have investigated the role of dynamic stochastic resonance (DSR) in enhancing the contrast between the abnormal and no-abnormal tau uptake on reconstructed tau PET images. . ***Materials and Methods:*** Each image slice of Ten tau PET studies was processed using DSR technique. The number of iterations used were 2,5,10 and 20, these four enhanced images were visually compared with its input image. During the image review, nuclear medicine physician looked for contrast difference between abnormal and no-abnormal tau uptake region. The number of iterations at which enhanced image had better contrast between abnormal and no-abnormal uptake was labelled as the best image. ***Results:*** NM Physician labelled the DSR-enhanced image obtained at number of iterations = 2 as the best image. In DSR-enhanced image obtained at number of iterations = 2, NM Physician found two important characteristics: 1) difference between abnormal and no-abnormal tau uptake regions were obvious compared to its input image, and 2) size of the abnormal and no-abnormal tau uptake regions were comparable to its input image. In the remaining three sets of DSR-enhanced images, the difference between abnormal and no-abnormal tau uptake region was slightly less obvious and their size (abnormal and no-abnormal tau uptake region) was not so comparable to that of its input image. ***Conclusion:*** Application of DSR (number of iterations = 2) enhances the contrast between the abnormal and no-abnormal tau uptake on reconstructed tau (F-18 ML-104) PET images.

## EP-0719

### Comparative study of respiratory gating techniques on pulmonary 18F-FDG PET lesions

***A. BORGES TAVARES***[1], *R. Amblard*[1], *F. Hugonnet*[2], *B. Paulmier*[2], *N. Garnier*[1], *R. Villeneuve*[1], *V. Natal*[2], *F. Mocquot*[2], *M. Faraggi*[2], *B. Serrano*[1];
[1]*Centre Hospitalier Princesse Grace - Medical Physics Department, Monaco, MONACO,* [2]*Centre Hospitalier Princesse Grace - Nuclear Medicine Department, Monaco, MONACO.*

***Aim/Introduction:*** Pulmonary lesions affected by respiratory motion are commonly studied in PET/CT images with respiratory gating correction. Actually, several standard gating correction techniques are available as phase-based-gating (PBG), amplitude-based-gating (ABG) and elastic-motion-based-gating with (EMBG) and without device (EMBGWD). We aimed to compare these four gating methods on maximum standardized uptake value (SUVmax) and uptake volume (UV) measurements in a series of 28 patients with pulmonary lesions. ***Materials and Methods:*** This study was performed on a PET/CT, fitted with 26cm axial field of view and time of flight (TOF) with motion flow table option. We study 28 patients with 40 18F-FDG PET/CT pulmonary lesions classified by amplitude movement: 11 nodules with amplitude movement ≥ 0.7cm and 29 < 0.7cm. The nodules sizes varied between 0.4 to 89cc. The 18F-FDG activity injected to the patients was 2.5±0.9 MBq/kg, and a fixed table speed of 1.3mm/s was chosen in the thoracic region. Gated acquisitions were monitored with pressure sensor device (Anzai Medical Corporation). Parameters reconstructions were: 3 iterations, 5 subsets, gaussian filter (FWHM=3mm), matrix size 400x400 pixels, TrueX+TOF algorithm (ultraHD-PET). We studied 5 different PET reconstructions: standard acquisition without gating correction (WG) and respectively PBG, ABG, EMBG and EMBGWD corrections. The pulmonary nodules SUVmax of each gating correction was compared to the WG. UV for the five reconstructions was determined with a 30% threshold of SUVmax and compared to the WG acquisition. ***Results:*** In comparison to the SUVmax value obtained with WG, SUVmax increased significantly in all 40 lesions with PBG acquisitions ($\Delta_{SUVmax}$=17±22%, $p<10^{-6}$) and ABG acquisitions ($\Delta_{SUVmax}$=14±14%, $p<10^{-6}$), while average gain on SUVmax were moderate with EMBG acquisitions ($\Delta_{SUVmax}$=8±6%, $p<10^{-6}$) and EMBGWD ($\Delta_{SUVmax}$=8±5 %, $p<10^{-6}$). Compared to the UV obtained with WG, $\Delta_{UV}$ for nodules with amplitude movement ≥ 0.7cm decrease notably with PBG ($\Delta_{UV}$=-29±22%, $p<10^{-3}$) and ABG ($\Delta_{UV}$=-24±19%, $p<10^{-3}$) acquisitions and slightly with EMBGWD ($\Delta_{UV}$=-16±12%, $p<10^{-3}$) and EMBG ($\Delta_{UV}$=-16±13%, $p<10^{-3}$) acquisitions. For nodules with amplitude movement < 0.7cm, the $\Delta_{UV}$ difference was smaller for all acquisitions, respectively for EMBG ($\Delta_{UV}$=-9±26%, $p<10^{-3}$), ABG ($\Delta_{UV}$=-10±22%, $p<10^{-3}$), PBG ($\Delta_{UV}$=-10±23%, $p<10^{-3}$) and EMBGWD ($\Delta_{UV}$=-12±14%, $p<10^{-3}$). ***Conclusion:*** For all pulmonary nodules the gating acquisition corrections allows to increase the SUVmax measurement especially for the PBG (17%) and ABG (14%). The uptake volume decreases with all gating corrections and the major impact was for amplitude movement ≥ 0.7cm: $\Delta_{UV}$ up to -29, -24 and -16% for respectively PBG, ABG and EMBG with or without device.

## EP-0720

### Assessment of a new PET event-by-event image-based motion correction for brain imaging in amyloid and epilepsy on a multimodality PET-MR scanner

***J. Anton Rodriguez***[1,2], *K. Herholz*[3], *C. Oldfield*[1], *M. G. Spangler-Bickell*[4], *T. W. Deller*[4], *L. M. Parkes*[3], *J. C. Matthews*[3];
[1]*The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM,* [2]*Division of Informatics, Imaging and Data Sciences, MAHSC, University of Manchester, Manchester, UNITED KINGDOM,* [3]*Division of Psychology, Communication and Human Neuroscience , Faculty of Biology, Medicine and Health-University of Manchester, Manchester, UNITED KINGDOM,* [4]*GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** We used phantom and clinical brain datasets to assess a new image-based motion correction approach for brain imaging that corrects event-by-event

acquired list mode (LM) to obtain motion-free images using rigid-body transformations calculated from registrations of consecutive 2-sec framed reconstructions [1]. ***Materials and Methods:*** A Flangeless Esser-PET-phantom™ (contrast ratio of 4-1 hot-cylinders-inserts to background), taped to a wooden board, was scanned three times (10min, 6min, 6min), with the phantom moved in a heterogeneous manner (discrete, continuous, rotations and translations) during each session and with increasing magnitude of motion. Full-length and 2-minute frames were reconstructed. Quantitative analysis was performed using background image roughness (IR), background variability (BV) and contrast recovery of the inserts (CRC). Clinical data: 43 participants were injected with [$^{18}$F]flutemetamol (41/43) or [$^{18}$F]florbetaben (2/43), and three paediatric epilepsy [$^{18}$F] FDG scans were analysed (20 min scans). MR $T_1$-weighted 1-mm isotropic MPRAGE images, the MNI-Hammers' brain atlas and the PET data were co-registered to extract SUVs for different brain regions. Additionally, for amyloid scans, centiloid ROIs, both non-refined and grey-matter-refined, were used to calculate SUVR. All data were acquired on a GE SIGNA PET/MR (GE HealthCare, Waukesha, WI). Reconstructions were performed using GE-ListMode-of-fline-reconstruction (ImDuetto_v02.18) for non-motion-correction (noMC) and motion-correction (MC) with Q.Clear using β=250/250/100 (phantoms/amyloid/FDG). ***Results:*** Phantom acquisitions: MC images showed visual and CRC improvements for all inserts without any increase in the noise (BV and IR). For example, CRC-12mm full-scan length (acq1-acq2-acq3): 70.0% (motion-free); 51.4%-42.9%-32.8% (noMC); and 69.6%-66.7%-67.3% (MC). For the 2-min frame reconstructions, 5+3+3=11 overall, CRC-12mm was (68.8±2.5)% (average±std) (MC). Clinical data: Visual image quality improvements were observed for 5 amyloid and 2 FDG scans. The main observed difference with MC was the alignment of the PET and the MR-derived attenuation correction map (MRAC) for 29 scans with medium to high motion, including all three FDGs. Despite these differences, changes in SUVR for the amyloid scans were at most small (4-6% observed). For FDG scans, improvements in GM/WM ratio of up to 5% were observed within the temporal lobes. ***Conclusion:*** This deviceless brain motion correction approach retains precision and accuracy over the three independent phantom acquisitions with heterogeneous motion. Such corrections could be very valuable in patient groups that are likely to move during scan acquisition, such as patients with dementia and children. Despite a large number of scans with PET-MRAC mismatches, quantification improvements were modest for the particular applications we investigated. ***References:*** [1]Spangler-Bickell et al., JNM, 63(10):1604-1610,2022

## EP-0721

### Analysis of segmented single-photon emission computedtomography images acquired with and without a copper filter

***S. Kheruka****, N. Al Maymani, N. Al Makhmari, K. Al Riyami, R. Al Sukaiti, A. Jain, S. Usmani;*
*Department of Radiology & Nuclear Medicine, Sultan Qaboos Comprehensive Cancer Care and Research Center, Muscat, OMAN.*

***Aim/Introduction:*** Reliable measurement of photon flux attenuation in tissue is crucial for single-photon emission computed tomography (SPECT) to produce reconstructed images. Computed tomography (CT) scanners give attenuation correction data for SPECT as well as anatomical data for diagnostic reasons.As part of the segmentation process, an image is divided into regions with similar brightness, contrast, color, texture, and grey level. The use of image segmentation may be advantageous for analyzing medical images. We used a copper filter to remove the low-energy X-rays in the poly-energetic X-ray beam used in CT scans in order to calculate the appropriate attenuation factor. Images collected with and without filters were statistically evaluated using the segmentation technique to reduce human error. ***Materials and Methods:*** Axial images of the AAPM CT phantom with a 3 mm copper filter (low intensity) and without a copper filter (high intensity) were obtained using low-dose CT (140 kvp and 2.5 mA) of a SPECT/CT system (Hawkeye, GE Healthcare). Segmentation is accomplished using the Simulated Annealing Based Fuzzy C-means technique. For quantitative quality assessment, we employ the universal image quality index. The attenuation correction map of the filtered CT images was validated using a SPECT scan after the Jaszczak SPECT phantom was filled with 500 MBq of 99m Tc. Low-dose CT images were collected in order to account for attenuation during SPECT image reconstruction. Another set of CT images was collected after a 3 mm additional copper filter was added. Two sets of axial SPECT images were reconstructed using an attenuation map generated from the CT images collected both with and without a filter. ***Results:*** When we applied Simulated Annealing Based Fuzzy c-means segmentation to both CT images, the CT images with the filter improved significantly, and all six sections of the spheres in the Jaszczak SPECT phantom were clearly visible after using CT images with a 3 mm copper filter for attenuation correction. ***Conclusion:*** We found that hardening the X-ray beam with a 3 mm copper filter removes artifacts without reducing photon flow. Image quality increased with nearly no artifact, a frequent issue with poorly filtered X-ray beams. The 3.00 mm copper filter produces high-quality photos without bloom artifact. This research also indicated that image segmentation reduces human error in image analysis.

### Advantages and opportunities of using an open-source reconstruction platform for SPECT quantification

***S. Varzakis***[1]*, A. Denis-Bacelar*[2]*, D. Deidda*[2]*, J. Dickson*[3]*, S. McQuaid*[3]*, K. Thielemans*[1]*;*
[1]*University College London, London, UNITED KINGDOM,*
[2]*National Physical Laboratory, London, UNITED KINGDOM,*
[3]*University College London Hospital, London, UNITED KINGDOM.*

***Aim/Introduction:*** Molecular radiotherapy has grown significantly in the past decade. Dosimetry for these treatments has made absolute quantification for SPECT systems necessary. The proposed EARL Lu-177 quantitative SPECT accreditation scheme provides a method of assessing the quality of quantitation by characterizing the recovery of activity concentration in different sized volumes, which can be heavily affected by the reconstruction method, collimator design and detector positioning [1]. Most sites are limited by manufacturers' image reconstruction options. The aim of this project is to demonstrate the advantages of a "non-black box" open-source reconstruction platform (STIR [2]) allowing a variety of reconstruction options in SPECT quantification and image optimisation applicable to any system. ***Materials and Methods:*** Two Lu-177 phantoms were prepared according to EARL [3] requirements: a cylindrical uniform phantom and a NEMA IQ phantom. The projections were reconstructed in STIR with 2 subset OSEM, saving every 5 sub-iterations, correcting for attenuation and scatter. Permutations with and without PSF modelling (in 2D)

were investigated with and without incorporating a log-cosh prior and two different penalty strengths. Recovery coefficients (RC) were estimated for the 60mm sphere for all the tested algorithms, while noise was estimated by the standard deviation in a 40 mm region within the largest sphere. The algorithms were compared for noise and quality of convergence at 100 sub-iterations. ***Results:*** In the PSF reconstructions, ringing artefacts were visible within the two largest spheres. Application of the prior eliminated the artefact after 100 sub-iterations. Compared to OSEM applying PSF decreased the standard deviation from 6.22 to 3.54, while RC (60mm) was improved from 0.814±0.035 to 0.880±0.037. Applying the prior without PSF for penalty weightings of 0.1 (resp. 0.01), standard deviation was 1.07 (resp. 2.71) with the RC (60mm) hardly affected at 0.803±0.034 (resp. 0.812±0.034). The combination of PSF and prior provided the best results with standard deviation at 1.02 (resp. 3.16) while preserving the RC (60mm) at 0.871±0.037 (resp. 0.878±0.037) for a penalty strength of 0.1 (resp. 0.01). ***Conclusion:*** Appropriate use of priors allows noise suppression without compromising accuracy in SPECT quantification. STIR as an open-source reconstruction platform provides the benefit of customising and testing a variety of reconstruction techniques to optimise quantification in SPECT. ***References:*** [1] J. Dickson et al, EARL SPECT accreditation (DOI:10.1007/s00259-022-05924-4), [2] Fuster et al. ### Utility of delta radiomics for response evaluation in primary mediastinal large B-cell lymphoma

***F. Yousefirizi***[1], *C. Gowdy*[2], *I. Klyuzhin*[3], *K. Savage*[1], *C. Uribe*[1], *A. Rahmim*[3];
*[1]Bc Cancer, Vancouver, BC, CANADA, [2]BC Children's Hospital, Vancouver, BC, CANADA, [3]BC Cancer Research Institute, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Delta-radiomics is the analysis of alterations in radiomics features before and after an intervention. In this study, a cohort of patients with primary mediastinal large B-cell lymphoma (PMBCL) was examined to predict response to treatment. ***Materials and Methods:*** Baseline $^{18}$F-FDG PET scan and post-therapy scan after 6 cycles of R-CHOP chemotherapy were obtained for each of 30 patients. Patients were dichotomized as responders or non-responders depending on the Deauville criteria. Lesions were segmented using the PET-Edge algorithm in MIM. Radiomics features were extracted using the Pyradiomics package (3.0.1) from primary tumors on pre- and post-PET scans. Maximum and mean standardized uptake values (SUVmax and SUV mean), metabolic tumor volume (MTV), total lesion glycolysis (TLG), and the maximum diameter of the primary tumors were also calculated. After feature normalization (z-scores), we used the individual coefficient approximation for risk estimation (ICARE) model) [1]. ICARE mitigates the risk of biased estimation of feature importance in the case of limited training data. and reduces the risk of overfitting using a minimal learning approach, achieved by dropping highly correlated features (Pearson r>0.8). It evaluates each feature sign using an univariate approach (Cmin threshold) . Features are also normalized and multiplied by their sign. For precise classification, the ensemble (aggregated with median) of 1000 binary-weighted models with a random number of selected features (F) was trained, and each model was trained on a random sample of size of the training data drawn with replacement. The hyperparameters of the model (r, Cmin, and F) were optimized by random search and the best-selected sets were used for the ensemble model. To evaluate the model, we applied 10-fold cross-validation on 85% of the dataset and 15% of the dataset was used as test data. ***Results:*** Mean accuracy of the classifiers was (0.72±0.2) for sole ICARE and (0.77±0.19) for ensemble ICARE. Mean accuracy of the best model on the unseen test data was 0.68 for the sole ICARE and 0.75 for the ensemble of best ICARE models. The order of the predictive power of the radiomics features are Delta-Entropy, Delta-NGTDM strength, Delta-NGTDM coarseness, Delta-TLG, Delta-NGTDM contrast, Delta-NGTDM busyness, Delta-GLRLM RLN, Delta-GLRLM GLN, Delta-MTV, Delta-SUVmax, Delta-SUVmean and Delta-NGTDM complexity. ***Conclusion:*** We found that delta-radiomics enable the development of predictive biomarkers for disease response prediction in PMBCL. The ensemble ICARE binary-weighted model was found to perform well in classifying responder vs non-responder. ***References:*** [1] Rebaud et al. 2023. Springer Nature Switzerland.

## EP-0724

### Noninvasive diagnostic models based on CT scans for differentiating solitary pulmonary metastasis in colorectal cancer patients by artificial intelligence : a multicenter study

***D. Ma***;
*Department of Colorectal Surgery, Zhejiang Cancer Hospital, Hangzhou, CHINA.*

***Aim/Introduction:*** Indeterminate solitary pulmonary nodules are often encountered on CT scans, and diagnosis of solitary pulmonary metastasis (PM) is important for patients with colorectal cancer (CRC). We aim to build and validate proper noninvasive artificial intelligence diagnostic models based on routine chest CT for solitary PM in CRC patients. ***Materials and Methods:*** All patients (n=212) with pretreated solitary CRC PM on chest CT were reviewed in the local database in Zhejiang Cancer Hospital between 2012 and 2022, and randomly divided into the training or internal validation groups on 7: 3. A total of 185 patients with pretreated T1 stage primary lung cancer and 256 patients with benign solitary pulmonary nodules were randomly selected. Artificial intelligence models based on machine learning (Decision Tree, Extra Trees, Light GBM, Radom Forest, Support Vector Machine, XGBoost) and deep learning were built to classify the solitary pulmonary nodules as PM, benign lesion or primary lung cancer. External validation group included 44 CRC patients with solitary PM from two independent hospitals. ***Results:*** For classification between PM and benign solitary pulmonary nodule, the machine learning model based on support vector machine showed the best diagnostic ability, with a 0.995 area under the curve (AUC) in the internal validation, a 0.977 AUC in external validation. The deep learning model showed a 0.966 AUC in the internal validation, and 0.893 AUC in external validation. For classification between PM and lung cancer, the best machine learning model based on support vector machine showed a 0.991 AUC in internal validation and the deep learning model showed a 0.949 AUC. ***Conclusion:*** Non-contrast CT based radiomic analyses can be useful for noninvasively differentiating solitary PM and benign pulmonary nodule or primary T1 stage lung cancer which can aid clinical decision in CRC patients with indeterminate solitary pulmonary nodules detected by CT.

## EP-0725

### Bio-functional radiomics based machine learning for improving the accuracy of hypermetabolic lymph node metastasis in lung cancer

***C. Ren***;
*Shanghai Proton and Heavy Ion Center, Shanghai, CHINA.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT is one of the best methods for the staging of lung cancer, but there is still a problem of high false positive rates (FPR) in the diagnosis of high metabolic lymph node (LN) metastasis. Therefore, the aim of this study is to develop and validate a bio-functional radiomics based machine learning model to reduce the FPR of hypermetabolic LNs in lung cancer and improve the accuracy of LN staging. ***Materials and Methods:*** A total of 260 patients with lung cancer who underwent radical surgery from January 2019 to June 2022 were retrospectively analyzed, and randomly divided into the training (n=182) and validation (n=78) sets. The preoperative PET/CT images showed that the patients' mediastinum and hilar LNs were all positive (SUVmax≥2.5 or higher than the mediastinal background). Preoperative clinical factors, serum tumor markers, and PET, CT radiomic features were analyzed. Prediction models were developed using the least absolute shrinkage and selection operator (LASSO) regression analysis. The performance of the models was evaluated and compared by the area under receiver-operator characteristic curve (AUC), accuracy, FPR and DeLong test. Then, a nomogram was developed based on the model with the best predictive efficiency and clinical utility and was validated using the calibration plots. ***Results:*** In total, 151 LN positive (LN+) and 109 LN negative (LN-) patients with lung cancer were enrolled in this study. 3 independent prediction models were separately developed to differentiate LN+ from LN- using clinical factors-tumor markers, PET/CT radiomics, and their combination. The AUC of PET/CT for the diagnosis of LN metastasis in the training set was 0.83 (0.77-0.89), the accuracy was 75.27%, and the FPR was 14.10%. The DeLong test showed that the Combined Model composed of patient age, serum CEA, LN SUVmax and size, and radiomics signature had the highest efficiency in diagnosing LN metastasis, with AUCs of 0.90 (0.86-0.95) and 0.89 (0.82-0.96) in the training and validation sets, respectively, with an accuracy of 84.07% and 82.05%, and FPRs of 12.82% and 6.45%, respectively. Compared with PET/CT, the FPR of Combined Model decreased by 9.08%, and the AUC and accuracy increased by 8.43% and 11.69% ($p<0.05$), respectively. ***Conclusion:*** In this study, a machine learning model integrating clinical features, serum tumor marker levels, and PET/CT radiomics was constructed, which could reduce the FPR of hypermetabolic LNs, greatly improve the accuracy of mediastinal and hilar LN staging, assist clinical treatment decisions, and achieve precise treatment.

## EP-0726

### Multimodal Radiomic Analyses Allow IDH-Prediction in Glioma Patients at Initial Diagnosis

***L. Kaiser***[1], *S. Quach*[2], *A. J. Zounek*[1], *A. Zatcepin*[1], *A. Holzgreve*[1], *A. Bollenbacher*[1], *L. Bartos*[1], *V. Ruf*[3], *G. Böning*[1], *L. von Baumgarten*[2], *N. Thon*[2], *J. Herms*[3], *M. J. Riemenschneider*[4], *S. Stöcklein*[5], *M. Brendel*[1], *R. Rupprecht*[6], *J. Tonn*[2], *P. Bartenstein*[1], *S. Ziegler*[1], *N. L. Albert*[1];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Neurosurgery, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Center for Neuropathology and Prion Research, LMU Munich, Munich, GERMANY,* [4]*Department of Neuropathology, University Hospital Regensburg, Regensburg, GERMANY,* [5]*Department of Radiology, University Hospital, LMU Munich, Munich, GERMANY,* [6]*Department of Psychiatry and Psychotherapy, University of Regensburg, Regensburg, GERMANY.*

***Aim/Introduction:*** Gliomas are classified according to the new WHO classification based on their IDH mutation status. To predict this non-invasively at the time of initial diagnosis prior to any therapeutic intervention, we assessed the diagnostic value of multimodal radiomic analyses (FET-PET, TSPO-PET, and MRI) for identifying an IDH-wildtype glioma. ***Materials and Methods:*** 87 glioma patients who received TSPO-PET by [$^{18}$F]GE180, dynamic [$^{18}$F]FET-PET, and MRI examination at initial diagnosis were included. The following images were analyzed: 5-15 and 20-40 min p.i. FET-PET, 60-80 min p.i. TSPO-PET, T1-weighted MRI with contrast agent, and T2-weighted MRI. Static PET and MRI images were normalized to the background signal of the contralesional side (TBR). In addition, time-to-peak (TTP) and late slope ($Slope_{FET,15-40}$) images were extracted from dynamic FET-PET data. First, T2 volumes were applied to extract VOI-based radiomics from each modality. Furthermore, the tumor volumes segmented on each original modality were used to extract radiomic features. Multivariate analysis was performed with logistic regression and L1 regularization using nested cross-validation with 5 folds and 50 repeats in the outer loop to report reliable AUC values. ***Results:*** When T2 volumes were used for the extraction of radiomics in all modalities, only radiomics derived from TTP and $Slope_{FET,15-40}$ images showed high performance. The performance of all PET images was higher when radiomics were extracted from the tumor volumes segmented in each original modality, reaching AUC values above 0.8. Multimodal analyses further improved the performance reaching AUC values above 0.9. Parameters from $TBR_{GE180}$, $Slope_{FET,15-40}$ and TTP images showed the highest average LR-coefficients. ***Conclusion:*** Multimodal analyses of FET-PET, TSPO-PET and MRI showed a high performance for non-invasive IDH-prediction in newly diagnosed gliomas. Notably, the tumor segmentation method used for the extraction of radiomics seems to have a high impact on the performance of each modality, which needs to be considered in future studies.

***Aim/Introduction:*** This study aimed to evaluate the performance of radiomics and machine learning algorithms for Gleason Score (GS) prediction of primary prostate cancer (PCa) from $^{68}$Ga-PSMA-PET/CT images. ***Materials and Methods:*** Altogether,138 patients with PCa referred to the nuclear medicine department from December 2018 to March 2023, and undergoing $^{68}$Ga-PSMA-PET/CT for staging before giving any

medical treatment, were enrolled. All patients are grouped into two groups based on GS; above 4+3 as malignant and under 3+4 as benign. The tumor in the prostate bed was diagnosed and segmented from PET and CT images by an experienced nuclear medicine physician. Subsequently, 27 radiomic features including shape, first-order, GLCM, GLRLM, GLSZM, and GLDM were extracted from the volume of interest (VOI) of a local tumor on PET and CT images, separately. The features selected by mRMR and Recursive Feature Elimination (RFECV) with Cross-Validation. Nested cross-validation was applied with 3-fold cross-validation for the outer and inner loops. Five models were assessed, including support vector machine (SVM), Logistic regression, Random Forest, Decision Tree, and K-Neighbors. The best model of each outer loop was determined using the area under the curve (AUC) of the receiver operating characteristic (ROC curve. The performance of the models was evaluated based on the outer loop results. ***Results:*** The results of this study were split into two parts, CT alone and PET alone. All five models that were applied to predict Gleason grade were compared to each other using AUC Score. Firstly, logistic regression achieved the best results on CT images, in which mean AUC, sensitivity, and specificity were 0.80, 0.87, and 0.61, respectively. Secondly, K-Neighbors reached the best predictive performance on PET images, achieving a mean AUC Decision Tree 0.75, sensitivity of 0.72, and specificity of 0.76. ***Conclusion:*** The results of the present study demonstrate that radiomic models based on PET/CT images could be a promising non-invasive approach to predict pathological indices, such as GS in primary PCa.

## EP-0728

### The value of 18F-FDG PET/MR radiomics features in predicting the pathological classification of rhabdomyosarcoma in children

***Y. Xu****;*
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To explore the value of 18F-FDG PET/MR radiomics features in predicting the pathological classification of rhabdomyosarcoma in children. ***Materials and Methods:*** The clinical data and PET/MR imaging data of 125 children with pathologically confirmed rhabdomyosarcoma were collected. They were divided into two groups: embryonal rhabdomyosarcoma (ERMS) (n=75) and acinar rhabdomyosarcoma (ARMS) (n=50). Pathological and clinical diagnosis results serve as the gold standard for diagnosis. We used AK software to extract the most relevant imageomics features for tumor classification, and randomly divided the two groups of images into training set (70%) and test set (30%). The maximum correlation and minimum redundancy (mRMR) and minimum absolute shrinkage and selection operator (LASSO) methods were used to select features from 1800 features extracted from MR and PET, and finally eight best features were retained. Multivariate logistic regression analysis was performed using the radiomics characteristics and clinical variables to establish the prediction model. The receiver operating characteristic (ROC) analysis is used to evaluate the prediction model. ***Results:*** The established PET/MR radiomics features have good prediction efficiency for the recognition of ERMS and ARMS classification, and there are significant differences. The AUC of the training group and the validation group were 0.918 (95% CI: 0.783-0.979) and 0.856 (95% CI: 0.775 - 0.996), respectively. ***Conclusion:*** The prediction model of PET/MR radiomics features can be used as a promising and practical auxiliary method to predict the pathological classification of rhabdomyosarcoma in children. It can also provide objective basis for accurate clinical diagnosis and individualized treatment, and has important guiding significance for clinical treatment.

## EP-0729

### Correlating 68Ga-PSMA PET/CT Imaging Features with PSA Variation for Castration-Resistant Prostate Cancer Patients

***R. Eduardo***[1,2]*, J. Badel*[3]*, D. Sarrut*[1]*, E. Paquet*[3]*, A. Giraudet*[3]*;*
[1]*Creatis, Lyon, FRANCE,* [2]*Siemens Healthcare SAS, Paris, FRANCE,* [3]*Centre Léon Berard, Lyon, FRANCE.*

***Aim/Introduction:*** Prostate cancer is a major health concern worldwide, and the treatment of advanced prostate cancer is still challenging. Radiopharmaceutical therapy with $^{177}$Lu-PSMA has emerged as a promising approach to address this issue. PET/CT imaging is commonly used to determine the extent of disease and the correlation between PET/CT imaging features and serum PSA levels has been shown to predict treatment outcomes [1]. In this work, we analyzed some correlations between imaging features and PSA levels to highlight the importance of PET/CT imaging in predicting the response to $^{177}$Lu-PSMA therapy. ***Materials and Methods:*** We conducted a retrospective analysis of 45 male patients who received $^{177}$Lu-PSMA treatment, all patients had a 68Ga-PSMA PET/CT imaging. The images were pre-processed using a deep learning automatic segmentation (TotalSegmentator [2]); the physiological organs uptake, obtained by expanding $^{68}$Ga-PSMA-avid known OARs (liver, kidneys, spleen, stomach, pancreas ⋯), was set to zero to obtain one single whole-body tumor region (WBTR) encompassing all potential tumors without physiological uptake. For each patient, the biological PSA (initial and final) was retrieved, and we studied the correlation between the PET radiomics and the PSA values using Spearman's rank correlation, a Multi-Layer Perceptron with three hidden layers, and a Random Forest. We compared the results to a standard approach where the $WBTR_{standard}$ is obtained by a threshold set as the kidney's mean SUV. ***Results:*** A significant but weak correlation was found between the WBTR volume and the PSA variation. The correlation coefficient was -0.41 (p-value: 0.01), while for the standard approach it was -0.34 (p-value: 0.02). Moreover, we evaluated the predictive performance of MLP and Random Forest models for PSA variation. We obtained a mean absolute error of 163% for MLP and 563% for Random Forest. The standard approach had an error of 149% for MLP and 558% for Random Forest. ***Conclusion:*** This preliminary study only showed the presence of a weak correlation between the WBTR volume and the PSA variation. The use of simple statistics is not enough to establish a significant improvement. Further research through advanced machine learning techniques is necessary to explore the potential of this method. ***References:*** [1] Moazemi, May 2021, Annals of Translational Medicine[2] Wasserthal, 2022, arXiv

## EP-0730

### Prediction of pathological complete response in T-stage III rectal cancer using 18F-FDG PET texture features

***S. Woo****, J. Yang, H. Ju, K. Kim, A. Muath, S. Cho, U. Shin;*
*KIRAMS, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Rectal cancer is is known to have low chance to have pCR with combined multimodal therapy. Therefore, it is important to predict pCR to avoid treating insensitive patients. Several studies on the prediction of ractal cancer has been conducted based on the machine learning (ML) model using

radiomics feature extracted from anatomical image modality including MRI, and CT. In this study, the rectal cancer pCR prediction ML model was developed based using multimodal radiomics feature extracted from $^{18}$F-FDG PET/CT image. ***Materials and Methods:*** $^{18}$F-FDG PET/CT images were acquired from ractal cancer patients. Internal dataset (n=105) consisted of 21 pCR and 84 non-pCR patients. External dataset (n=30) comprised of 6 pCR and 24 non-pCR patients obtained from different institution. Total patients were diagnosed pathologic T-stage III rectal cancer. Textural analysis was conducted with extracted 23 of intensity and 32 of texture feature using LIFEx software. As a ML prediction model, RF was used, which were implemented by the Scikit-learn library in Python. To evaluate the performance of the prediction model, k-fold cross validation was applied. For quantitative evaluation of the model, the accuracy and ROC-AUC was calculated. ***Results:*** The estimation of pCR prediction model with extracted intensity and texture image features from PET/CT was proceeded. The internal validation of RF model accuracy and ROC-AUC were 0.916 and 0.969 with PET feature, 0.883 and 0.946 with CT features 0.898 and 0.961 with PET/CT feature. The internal test of RF model accuracy and ROC AUC were 0.720 and 0.720 using PET features, 0.600 and 0.600 using CT features, 0.600 and 0.600 using PET/CT features. The external test of RF model accuracy and ROC AUC were 0.492 and 0.492 with using PET features. The external test of RF model accuracy, precision, and ROC-AUC were 0.640 and 0.640 with using PET texture features. ***Conclusion:*** RF model estimation result using $^{18}$F-FDG PET image features was higher than using CT image features for predicting pCR in rectal cancer. RF model with $^{18}$F-FDG PET/CT image feature showed lower performance than RF model using $^{18}$F-FDG PET and CT separately. RF model to predict pCR with 32 of texture feature shows higher evaluation value than model construction with total of intensity and texture features from $^{18}$F-FDG PET. In order to improve external test results, it is necessary to consider the bacth effect in using multicenter data.

## EP-0731

### Reproducibility of CT radiomic features extracted from resampled images using various interpolation methods.

***G. Mehta***[1], *A. Tripathi*[1], *S. Panchal*[1,2], *U. B. Sherkhane*[1,3], *N. Purandare*[1,2], *S. Mithun*[1,2,3], *A. K. Jha*[1,2], *V. Rangarajan*[1,2];
[1]*Department of Nuclear Medicine and Molecular Imaging, Tata Memorial Hospital, Mumbai, INDIA,* [2]*Homi Bhabha National Institute (HBNI), Deemed University, Mumbai, INDIA,* [3]*Department of Radiation Oncology (Maastro), GROW School for Oncology and Reproduction, Maastricht University Medical Centre+, 6229 ET Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Role of radiomics based prediction models is increasing in oncology. However, the stability of radiomic features needs to be assessed before its utilization in prediction model development. There are mainly two causes of instability of these features i.e. 1) variability in imaging and image reconstruction and 2) variability in pre-processing steps. The aim of this study is to assess the stability of radiomic features due to variability in image pre-processing i.e. image interpolation. ***Materials and Methods:*** CT images of NSCLC case (n=35) were selected for this retrospective study and loaded onto the Philips IntelliSpace Discovery workstation. The delineation of tumour volume was performed by an experienced nuclear medicine physicist. The volume was contoured, named as GTVand saved as an RTSTRUCT file. The input CT had slice thickness of 2mm and pixel size -0.9707,0.9707. These files were loaded on the 3-D slicer image computing software for further processing. Here, the images were resampled to 1*1*1mm3 using three methods of interpolation, namely, linear, nearest neighbour, and bspline. For the original and resampled images, 1129 radiomic features were extracted. The features were analysed using the Intra class correlation (ICC3) method and the percentage of highly correlating features were obtained. We categorise the features based on the ICC values as, excellent: ICC ≥0.9, good: 0.9>ICC ≥0.75, moderate: 0.75>ICC≥0.5, and poor: ICC<0.5. ***Results:*** When all four sets were correlated, a total of 323/1129(28.6%) presented excellent reproducibility. 154/1129 (13.6%) features presented good reproducibility.281/1129 (24.8%) features showed moderate and 371/1129 (32.8%) showed poor reproducibility. On correlating just the resampled images ie., bspline, linear and nearest neighbour interpolation methods, the excellent features increased to 51%. 586/1129(51.9%) presented excellent reproducibility. 190/1129 (16.8%) features presented good reproducibility.171/1129 (15.1%) features showed moderate and 182/1129 (16.1%) showed poor reproducibility. On correlating two sets extracted by bspline and linear interpolation, 861/1129(76.2%)features presented excellent reproducibility. 183/1129 (16.2%) features presented good reproducibility.73/1129 (6.4%) features showed moderate and 85/1129 (7.5%) showed poor reproducibility. ***Conclusion:*** The reproducibility of CT radiomic features is highly influenced by the image resampling and methods of interpolation applied while image pre-processing. When the correlation is performed with original and resampled images the reproducibility is shown by 28% features only. In our study, the 3 methods applied show high reproducibility ie., >50% of features showed excellent correlation. The percentage increases to 76% when reproducibility of 2 methods is analysed (bspline and linear).

## EP-0732

### A Comparative Study on Radiomics Pipelines for Histological Classification of Non-Small Cell Lung Cancer through [18F]FDG PET/CT

***L. Wichert-Ana****, L. Alexandre-Santos, A. C. Trevisan, L. R. Suzuki, F. A. Pitella, O. Y. Fukumori, M. Kato, P. M. Azevedo-Marques, M. Koenigkam-Santos;*
*Ribeirão Preto Medical School - University of São Paulo, Ribeirao Preto, BRAZIL.*

***Aim/Introduction:*** In clinical oncology, a biopsy of neoplastic tissue and histopathological investigation are valuable diagnostic tools for investigating non-small cell lung cancer (NSCLC) cases. However, the gold standard analysis is limited by the possibility that the sample may not be representative of the entire tumour volume to be treated due to the spatial and temporal heterogeneity of the tumour. The number of times a biopsy can be performed, or the inability to perform the procedure depending on the patient's clinical condition due to the high risk of complications are other limitations observed that make this diagnostic evaluation unfeasible for identifying the histological features. Radiomics techniques can complement the therapy approach by highlighting portions of more significant histological heterogeneity, mainly when identification is made through increased local metabolic activity imaged with the [18F]FDG-PET-CT. This study aimed to assess the performance of different machine learning pipelines in classifying NSCLC cases through [18F]FDG-PET-CT images. ***Materials and Methods:*** We investigated 81 PET images of patients diagnosed with NSCLC of type adenocarcinoma (Adc) and squamous cell carcinoma (SCC), confirmed through histopathological assessment. A nuclear medicine physician manually segmented the images to extract

2082 radiomic features that could contribute to histological classification. We used three feature selection and dimensionality reduction methods (high correlation Spearman, ANOVA F-Score (ANOVA), Mutual Information (MI), and Principal Component Analysis (PCA)) along with six classification methods (Random Forest, Support Vector Machine, k-Nearest Neighbors, Gaussian Naïve Bayes, Decision Tree, and XGBoost) to build machine learning pipelines capable of differentiating between the two types of NSCLC. The model complexity and area under the curve (AUC) were used as metrics to assess the performance of the methods. ***Results:*** The eighteen classification pipelines assessed evidenced good performance through AUC values for XGBoost+ANOVA and MI (AUC > 0.9 for the test) and increased performance for the pipeline with PCA for dimensional reduction. ***Conclusion:*** The radiomic machine learning methods for classifying NSCLC cases have demonstrated accurate performance in distinguishing [18F]FDG-PET/CT images of Adc and SCC when implemented with feature selection methods ANOVA and MI. However, the performance was compromised for the PCA method.

## EP-0733

### Assessing PET andCMR radiomic featuresfor detectionof cardiac sarcoidosis

***N. Mushari***[1], *G. Soultanidis*[2], *L. Duff*[3], *M. G. Trivieri*[2,4], *Z. A. Fayad*[2], *P. M. Robson*[2], *C. Tsoumpas*[1,2,5];
[1]*Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, UNITED KINGDOM,* [2]*BioMedical Engineering and Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA,* [3]*Beatson Institute for Cancer Research, Glasgow, UNITED KINGDOM,* [4]*Cardiovascular Institute, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA,* [5]*Department of Nuclear Medicine and Molecular Imaging, University Medical Centre Groningen, University of Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Cardiac sarcoidosis (CS) is a granulomatous inflammatory disease which can be diagnosed with [$^{18}$F]-FDG PET. However, myocardium signal suppression, which is needed to improve the diagnostic accuracy of PET, does not work effectively for around 25% of patients and therefore it may result in false-positive findings. On the other hand, cardiovascular magnetic resonance (CMR) imaging is a non-specific tool for diagnosing CS but can detect scarring tissue that may indicate inactive CS. The independent use of visual data of PET and CMR imaging may fail to identify CS with high specificity. This study aimed to evaluate the specificity of PET and CMR radiomic features in differentiating CS from other diseases and in this particular case, post-covid (PC) patients. ***Materials and Methods:*** PET and CMR were treated separately in this work. For PET analysis, subjects were classified into PC (36 patients) and CS (40 patients). Two different regions of interests (ROI) were drawn manually; a hot region (segmentation A) and the entire left ventricle (segmentation B). Segmentation B is unlikely to be influenced by the experience of observers. For CMR analysis, there were 25 PC patients and 30 CS patients. The ROI was drawn manually in the entire left ventricle. The radiomic features were then extracted. To achieve the purpose of the study, two major methods were followed: one with the individual features by applying Mann-Whitney U tests and the other by testing machine learning (ML) classifiers for separating CS from PC patients. ***Results:*** The Mann-Whitney U tests and logistic regression were trained with individual features to build a collection of features. For PET analysis, maximum target-to-background ratio ($TBR_{max}$) showed very high area under the curve (AUC) and accuracy with small p-value (< 0.00053) among different segmentations (segmentation A: accuracy and AUC 1.00; segmentation B: accuracy 0.89 and AUC 0.95). Also, Energy showed promising results in segmentation B only. For MR analysis, Gray Level Run Length Matrix (glrlm)_Run Length Non-Uniformity showed good results with smallest error bars (accuracy 0.78 and AUC 91). Principal Component Analysis was used as another way to collect the best group of features with cumulative variance higher than 90%. ***Conclusion:*** Using of radiomic features may prove useful in identifying individuals without the disease. Some features showed promising results to differentiate between PC and CS. By automating the analysis of joint radiomic features, the patient management process can be accelerated and improved.

## EP-0734

### Role of Textural and Radiomic Analysis Parameters in Predicting Histopathological Parameters of the Tumour in Breast Cancer Patients.

***M. Ravina****, R. Kote, T. Lukose, R. K. Gupta, Y. Kashyap, D. Mohanty; All India Institute of Medical Sciences, Raipur, Raipur, INDIA.*

***Aim/Introduction:*** Texture and Radiomic analysis characterises the tumor!s phenotype and evaluates its microenvironment in quantitative terms. In case of breast cancer, histopathological parameters of the tumor are important prognostic factors. This study aims to investigate the role of textural and radiomic analysis parameters in predicting these prognostic factors. ***Materials and Methods:*** 156 Primary breast cancer patients underwent 18F FDG PET/CT on GE DISCOVERY MIDR PET/CT scanner for staging. The images were processed in commercially available textural analysis software. ROI (Region of interest) was drawn over the primary tumor with a 40% threshold and was processed further to derive 42 textural and radiomic parameters. These parameters were then compared with Histopathological factors like the type of tumor (Ductal vs Mucinous), molecular subtype (Triple-negative, Luminal A, Luminal B, HER 2 enriched, Luminal HER 2 positive), Modified Bloom Richardson Grade, Nuclear grade, Tubule differentiation and Mitotic rate of the tumor. ROC analysis was performed with a p value<0.05 for statistical significance using statistical analysis software. ***Results:*** A retrospective study of 156 primary breast cancer patients was done. In the case of histological type, seven patients had mucinous carcinoma, and 149 patients had ductal carcinoma. Fourteen textural analysis parameters turned out to be significant (AUC>0.7) in predicting the histological type. Among them, six parameters had AUC > 0.8, suggesting a better correlation. The cut off were also calculated for them -GLRLM_LGRE(0.0029), GLRLM_SRLGE(0.0027), GLRLM_LRLGE(0.004), GLZLM_LGZE(0.0027), GLZLM_SZLGE(0.0015), GLZLM_LZLGE(0.714). None of the textural and radiomic parameters were found to be significant for predicting molecular subtypes or hormone receptor status. 60 patients had Modified Bloom Richardson grade III tumors. Nine textural analysis parameters turned out to be significant for the grade of the tumor. They were SUVmin, SUVmean, SUVmax, SUVstd, GLRLM_HGRE, GLRLM_SRHGE, GLRLM_LRHGE, GLZLM_SZE, GLZLM_HGZE. The statistical analysis was also performed for the nuclear grade, tubule differentiation, and mitotic rate of the tumor. Three textural analysis parameters - GLCM_Contrast, NGLDM_Contrast, and GLZLM_SZE- were significant for predicting a higher grade of tubule differentiation, and only one parameter, GLZLM_SZE, was significant in predicting a higher mitotic rate in the tumor. However, the textural parameters could not predict the nuclear grade. ***Conclusion:*** Though textural analysis could not predict the

hormonal status and molecular subtype of the tumor, it could predict the tumor!s histologic type and grade noninvasively. A PET-based machine learning method can be made in the future, which may help predict various histopathological prognostic factors.

## EP-0735

### The Impact of Bayesian Penalized Likelihood (BPL) Reconstruction Algorithm With Various β-values on Radiomic Features Reproducibility: An [18F]FDG PET Phantom Study

***Z. Valibeiglou***[1], *J. Pirayesh Islamian*[1], *Y. Soleymani*[2], *P. Sheikhzadeh*[3,4];
[1]*Department of Medical Physics, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Neuroscience and Addiction Studies, School of Advanced Technologies in Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Department of Medical Physics and Biomedical Engineering, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The tumor heterogeneity assessment using various radiomics features has recently been considered increasingly in the PET imaging community. It is unclear how radiomics features are impacted by the PET imaging reconstruction focusing on noise correction. The purpose of this study was to determine the impact of different noise-controlling variables (β-values) on the robustness of various PET-derived radiomic characteristics using Bayesian penalized likelihood (BPL) image reconstruction algorithm. ***Materials and Methods:*** Six spheres with inner diameters of 37, 28, 22, 17, 13, and 10 mm that were filled with 18F-FDG solution, as the standard National Electrical Manufacturers Association (NEMA) image quality phantom, with a lesion-to-background ratio (LBR) of 4:1 were scanned and reconstructed using the BPL reconstruction algorithm with β-values of 50, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, and 700. Considering the LIFEx software default preprocessing settings, following segmentation, 130 radiomic characteristics (14 morphological, 60 intensity-histogram, and 56 textural features) were obtained from each of the spheres. The coefficient of variation (COV) was used for categorizing all the radiomics characteristics. The measures of COV<5%, 5%<COV<10%, 10%<COV<20%, and COV>20% were considered as very small, small, intermediate, and large variations, respectively. ***Results:*** Out of the total analyzed morphological features, 78.57% (11 features) exhibited very small variations, 14.28% (2 features) had small variations, and 7.14% (one feature) showed intermediate variations. No morphological feature was found to have a large variation by changing β-values. On the other hand, among intensity-histogram features, 26 (43.33%), 17 (28.33%), 11 (18.33%), and 6 (10%) had very small, small, intermediate, and large variations across different β-values, respectively. Furthermore, very small, small, intermediate, and large variations were seen for 12 (21.42%), 15 (26.78%), 16 (28.57%), and 13 (23.21%) textural features, respectively. No statistically significant differences in COV values were found by changing the inner diameter of spheres. ***Conclusion:*** It seems that PET-derived radiomics feature values are affected by changing noise-controlling variables. Considering the β-values, different groups of radiomic features showed differently with morphological and textural features the most and least robust features. Therefore, according to the PET multi-center research, radiomic features should be extracted and selected with more caution. Features that exhibit a very small or low COV may be considered as promising candidates for accurate tumor quantification.

## EP-0736

### Can We Predict Future Relapsed Lymph Nodes on Staging PET/CT for Pediatric Hodgkin's Lymphoma?

***N. C. M. Gülaldi***[1], *M. O. Kartal*[2];
[1]*University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Health Ministry of Türkiye Republic, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Our goal is to distinguish lymph nodes that may recur in the future within the staging phase PET/CT scans of pediatric lymphoma patients. We used textural features of the lymph nodes and compared them to those that later resurfaced. ***Materials and Methods:*** Staging phase PET/CT scans of 23 pediatric Hodgkin's lymphoma patients who had relapsed lymph node/nodes in their follow-up PET/CT scans were included into the study. Lymph nodes with complete metabolic response and preserve their state in their follow-up scans were segmented and analyzed with LifeX 7.3.1 texture analyzing software [1]. 97 lymph nodes which recurred and showed increased metabolic activity after chemotherapy in 23 patients on follow-up scans were also noted and retrospectively analyzed within the same PET/CT images to see any textural differences within these nodes to predict future failure to treatment response. VOI-based calculations were segmented over diseased lymph nodes and software applied a gray-level co-occurrence matrix (GLCM) to those images. ***Results:*** 23 variants of GLCM measurements were made through images. Most of the parameters did not fit into normal distributions. Hence, we used non-parametric Wilcoxon signed-rank test to compare lymph nodes with complete metabolic response and recurred ones. GLCM_joint maximum and GLCM_joint average (p=0.021), GLCM_Joint entropy Log2 and Log10 (p=0.04), GLCM_difference entropy (p=0.04) showed significant difference between the groups. However, other parameters related to GLCM values did not show any statistically significant difference. ***Conclusion:*** Entropy is a kind of texture feature to measure of the randomness or unpredictability of the distribution of pixel intensities in an image [2]. A higher entropy value indicates a more random and unpredictable texture. It suggests tumor heterogeneity and the presence of necrosis and hypoxia. We found entropy-related textural parameters of future-recuring lymph nodes were significantly differ from the lymph nodes with complete metabolic response. We believe if clinicians aware of these lymphatic groups with heterogeneous features at the beginning, it can be taken into consideration to implement more aggressive treatment at the very early phase of the disease. ***References:*** 1. **The XGBoost algorithm combined with 18F-FDG PET/CT imaging in the differentiation between benign and malignant thyroid incidentalomas**

***J. Di***[1], *X. Ma*[1], *Z. Ge*[1], *Q. Xie*[1], *D. Kong*[1], *S. Liu*[1], *S. Lin*[2], *J. Ma*[3], *H. Pei*[3], *Y. Zhong*[4], *W. Qu*[1], *X. Zheng*[1];
[1]*Department of Nuclear Medicine Department, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, CHINA,* [2]*School of Computer Science and Engineering, Sun Yat-sen University, Guangzhou, CHINA,* [3]*The MOE Key Laboratory for Intelligent Networks and Network Security, Xi'an, CHINA,* [4]*Department of Clinical Laboratory, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, CHINA.*

***Aim/Introduction:*** The detection rate of thyroid incidentalomas (TIs) based on $^{18}$F-FDG PET/CT has increased significantly, of which approximately 33.3% have been confirmed as malignant by the pathologist. However, it is still controversial in the differentiation between benign and malignant TIs by $^{18}$F-FDG PET/CT imaging with SUVmax greater than 2.5, which contributes to the reliance on ultrasonography to guide the follow-up treatment. We aimed to utilize the XGBoost algorithm to establish a new model for improving the ability of $^{18}$F-FDG PET/CT imaging in the differentiation between benign and malignant TIs. ***Materials and Methods:*** A total of 377 patients examined by $^{18}$F-FDG PET/CT in our institution from November 2022 to March 2023 were reviewed. There were 264 patients who were diagnosed or suspected of having non-thyroid cancer, of whom 45 had thyroid abnormalities detected by ultrasonography and pathological examinations. The semiautomatic segmentation of 3D-Slicer software (version 5.3.0) was used for the accurate contouring of the thyroid glands and TIs. The datasets were saved in CSV files and were used to train the XGBoost model. The sensitivity, specificity, F1-score, and AUC (area under the curve) of ROC charts were evaluated. ***Results:*** There were 39 patients (14.77%) who detected TIs in 264 patients diagnosed with or suspected of non-thyroid cancer. 13 male and 26 female cases with an average age of 62.51±13.36 were observed among TIs patients. The average $SUV_{max}$ in TIs patients (5.71±1.23) was significantly higher than those without TIs (1.08±0.77, $p<0.01$). It was noticed that 33 were benign and 6 were malignant (18.18%) in all TIs patients according to the pathological examination. All TIs patients obtained ultrasound and the XGBoost algorithm combined with $^{18}$F-FDG PET/CT imaging. For the ultrasound tests combined with $^{18}$F-FDG PET/CT imaging of TIs individuals, the sensitivity, specificity, and accuracy were 66.67%, 81.82%, and 79.49%, respectively. For the XGBoost algorithm combined with $^{18}$F-FDG PET/CT imaging of TIs individuals, we found that the AUC and F1-score were 0.94 and 0.48, respectively, as well as 100.00% and 35.29% sensitivity and specificity. The XGBoost algorithm combined with $^{18}$F-FDG PET/CT imaging significantly improved the sensitivity ($p<0.05$) and maximized the identification of all TIs, but the specificity of the algorithm model should be adjusted. ***Conclusion:*** The XGBoost algorithm combined with $^{18}$F-FDG PET/CT imaging will effectively improve the differentiation ability between benign and malignant TIs, which provides a new foundation for clinical diagnosis and therapy.

### EP-0738

**Image quantitative parameters using deep learning-based denoising of ultra-fast whole-body [18F]FDG PET/CT are comparable to standard acquisitions**

***L. C. Silva***[1], *C. S. Constantino*[1], *M. Silva*[1], *F. P. M. Oliveira*[1], *R. Vigário*[2], *D. C. Costa*[1];
[1]*Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*NOVA School of Science and Technology, Lisbon, PORTUGAL.*

***Aim/Introduction:*** This study aims to assess the feasibility of reducing the acquisition time of whole-body [$^{18}$F]FDG PET scans to 15s/AFOV through deep-learning-based denoising. ***Materials and Methods:*** 82 whole-body [$^{18}$F]FDG PET/CT scans of oncological patients were included in the training (57+10) and testing (15) of a 2.5D U-Net convolutional neural network. Mean squared error (MSE) was employed as the loss function for training. Images were acquired on the Philips Vereos Digital PET/CT. From the standard-duration (70s/AFOV) raw data, ultra-fast scans were simulated by cropping the data to 15s/AFOV and 30s/AFOV. Reconstruction was performed on-site using the manufacturer's OSEM algorithm and following EARL1 standards. MSE, intraclass correlation coefficient (ICC) and structural similarity index measure (SSIM) were used for a voxel-wise standardized uptake value (SUV) comparison between deep-learning-denoised images (DL) and reference images (70s/AFOV). Further quantitative analysis was performed in terms of signal-to-noise ratio (SNR = mean SUV/standard deviation) on the regions with "expected" uptake uniformity (liver and lungs). On a lesion basis, $SUV_{max}$ discrepancy was quantified. For benchmarking, Gaussian filter (GF) denoising was implemented and its width optimized through MSE minimization relatively to the reference images. ***Results:*** Voxel-wise ICC, SSIM and MSE between reference and DL-denoised images showed a statistically significant improvement relatively to the original (not denoised) 15s/AFOV and 30s/AFOV images and the GF-denoised images ($p<0.001$). Average ICC, SSIM and MSE for 15s/AFOV-based sets were of, respectively, 0.987, 0.950 and 0.009 [DL], against 0.980, 0.939 and 0.014 [GF] and 0.972, 0.923 and 0.019 [original]. For 30s/AFOV-based sets: 0.991, 0.967 and 0.006 [DL], against 0.989, 0.965 and 0.007 [GF] and 0.987, 0.959 and 0.009 [original]. Concerning SNR, the relative difference to 70s/AFOV was promising for DL denoising, displaying an improvement even regarding the reference images: +79.8±30.1% [DL] against -20.6±16.9% [GF] and -49.1±9.2% [original] for 15s/AFOV-based images in the liver, and +27.3±26.3% [DL] against -6.8±16.8% [GF] and -29.7±11.7% [original] for 30s/AFOV-based images in the liver. Similarly improved results were obtained for SNR in the lungs. For 55 identified lesions, $SUV_{max}$ relative difference to 70s/AFOV was of -14.8±17.9% [DL], -21.9±10.4% [GF] and -0.2±11.6% [original] for 15s/AFOV-based images and -6.8±11.7% [DL], -14.1±8.7% [GF] and -0.4±9.6% [original] for 30s/AFOV-based images. ***Conclusion:*** The implemented DL algorithm proved to be a viable denoising method for ultra-fast (15s/AFOV) whole-body [$^{18}$F]FDG PET scans, having achieved comparable quantitative parameters with 70s/AFOV. In addition, it outperformed optimized Gaussian filtering.

### EP-0739

**A pilot of study: Development of AI model to automatically segment the metastatic lesions on FDG-PET/CT in patients with differentiated thyroid carcer**

***Y. Li***[1], *K. Hirata*[1,2,3], *J. Takenaka*[1,2], *H. Endo*[1], *M. Tang*[1], *S. Watanabe*[1,2], *R. Kimura*[1,4], *K. Kudo*[1,3,4];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [3]*Global Center for Biomedical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, JAPAN,* [4]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.*

***Aim/Introduction:*** Thyroid cancer is one of the most common malignant tumors of the endocrine system. In recent years, the number of patients with differentiated thyroid cancer (DTC) has increased rapidly. Patients with poor prognosis are identified by measuring metabolic tumor volume with FDG-PET/CT. In order to solve the time-consuming and low reproducibility task of tumor segmentation by hand, the aim of this study was to create an AI model that can automatically segment metastatic lesions of DTC from FDG-PET/CT images. ***Materials and Methods:*** We retrospectively analyzed FDG PET/CT images of 112 patients who had DTC and showed FDG-avid before undergoing I-131 treatment at Hokkaido University Hospital from 2014 to 2022. In our study, a researcher segmented FDG-avidity metastatic lesion (SUV>3) on FDG-PET/CT using Metavol software, and the segmentation was confirmed by a nuclear medicine physician. Each case included 180 maximum intensity projection (MIP) images by projecting in 1° step. After taking the logarithm of the SUV, the images were resized to the resolution at 512x512, saved as PNG format. The PNG was augmented by using image rotation from -170° to 180° in 10° step. The 80 of 112 patients were selected, and of each patients, a total of 180 images were randomly picked up for training : validation : test-1 (internal test group) datasets = 7:1:1. The rest of 32 patients were used as test-2 (external test group) dataset. We trained a ResNet-50 model via Matlab. The training parameters were as follows: optimizer stochastic gradient descent with momentum (Momentum SGD), maximum training epochs 4, mini-batch size 192, initial learning rate 0.001, momentum 0.9, L2 regulation 0.05. ***Results:*** The mean Dice similarity coefficient (DSC) of the test-1 and test-2 were 0.54±0.17 (standard deviation) and 0.53±0.18, respectively. The AI-predicted tumor areas showed a significant correlation with the areas of annotation in test-1 (R=0.98) but a lower correlation with that in test-2 (R=0.68). For sub-analysis, we classified the patients into four groups according to the areas of tumor lesions: <100, 100-200, 200-1000, and >1000 pixels. DSC tended to be higher for larger tumors (The mean DSC of <100 pixels and >1000 pixels were 0.40±0.14 and 0.73±0.08). ***Conclusion:*** The results indicated that AI model could automatically segment the lesions of DTC in FDG-PET/CT images, although more data also necessary to improve the accuracy of AI model. The performance of segmentation was affected by the tumor size.

## EP-0740

### Predicting Sentinel Lymph Node Status by Using FDG-PET Imaging-Based Texture Analysis in Breast Cancer

***K. Saglam****, S. ASA, A. KİBAR, M. SAĞER, K. SÖNMEZOĞLU;*
*Istanbul Univercity-Cerrahpasa Cerrahpasa Medical Faculty, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Breast cancer is the most frequently diagnosed malignancy globally, with more than two million cases yearly [1]. FDG-PET imaging is performed to evaluate the extent of disease and tumor burden in the preoperative period. In many cases lymph node metastasis cannot be detected in FDG-PET imaging or axillary node biopsies; lymph node metastases are seen as a result of intraoperative sampling, and this guides the course of the operation(2). In this retrospective study, we aimed to evaluate FDG-PET imaging-based texture analysis applications in predicting the sentinel lymph node outcome and create machine learning models to predict sentinel node outcome using obtained parameters. ***Materials and Methods:*** FDG-PET scintigraphies of patients diagnosed with breast cancer were scanned. FDG-PET images of 412 patients who underwent intraoperative sentinel axillary node sampling were analyzed. Patients with no clinical node metastasis detected by preoperative USG and sentinel node biopsy and who weren't treated with chemotherapy or radiotherapy were selected. Patients with multiple lesions and lesion size >5 cm were excluded. According to the pathology results of intraoperative sentinel lymph node sampling, FDG-PET imaging of 58 patients, 27 positives and 31 negatives, was studied with LIFEX(https://www.lifexsoft.org/ index.php) imaging analysis. Parameters obtained from LifeX program were evaluated with WEKA. Parameters for decision tree algorithms in WEKA program were determined with WEKA-Attribute Evaluator. Predictability values were tested by decision tree algorithms such as RandomForest. Machine learning models evaluated prediction accuracy. In addition, SUVMax, SUVMean , lesion sizes, 5 other parameters detected by OneR, and 3 other parameters detected by attribute evaluator with WEKA were evaluated separately with T-test. ***Results:*** Intensity-Based_Minimum_Grey_Level is the most significant parameter among the studied parameters. (p-Value:0,0006913). Satisfactory results (75%-85% accuracy) were obtained on the efficiency of machine learning applications in predicting the data in the pool. ***Conclusion:*** Texture analysis-based machine learning methods may reduce the dependence on invasive interventions in the initial evaluation of breast cancer cases. In addition, it is thought that the accuracy values predicted by the machine will be more successful with the inclusion of data obtained with the standard imaging protocols and large patient groups in the study. ***References:*** 1. Chagpar,A.B.; Horowitz, Does lymph node status influence adjuvant therapy decision-making in women 70 years of age or older with clinically node negative hormone receptor positive breast cancer?

## EP-0741

### Construction of a prognostic risk score model with multimodal features of18F-FDG PET/CT images of non-small cell lung cancer byfeatures fusing

***X. Wang***[1,2]*, X. Li*[1,2]*, C. Cui*[1,2]*, Z. Wu*[1]*, Z. Wu*[3]*;*
*[1]Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, Shanxi, CHINA, [2]Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan, Shanxi, CHINA, [3]Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan,Shanxi, CHINA.*

***Aim/Introduction:*** Through a small multicenter dataset, we extracted radiomics features and deep learning features from PET/CT images of different modalities to construct machine learning models for feature fusion, obtained their prediction scores as input features, combined them with clinical information, and constructed a Cox proportional risk regression model as the prediction model for the risk of death scores of patients with non-small cell lung cancer, to provide support for clinical decisions such as early detection of patients and improvement of patient prognosis. ***Materials and Methods:*** In this study, we used the $^{18}$F-FDG PET/CT public dataset (98 cases) as the training set and our data as the validation set (41 cases). The 3D lesions were first outlined to extract the radiomics features, and then the ResNet50 and VGG16 networks were constructed by transfer learning to extract the deep learning features at the largest lesions of 2D PET and CT images. After feature selection by the Lasso method, RSF, XGBoost, GBM, Coxboost, SSVM, and Deepsurv survival analysis machine learning models were constructed to fuse high-dimensional features, respectively. The best performance

models were selected to output predictive values combined with clinical data (gender, age, smoking history, pathological staging, and TNM stage) to construct risk score prediction models by univariate and multifactor Cox analysis. ***Results:*** 139 patients were included in this study. Outcome events occurred in 43 (28 in the training set and 15 in the test set.) ROC analysis showed that the GBM model constructed using CT and PET radiomics features and deep learning features performed best. It was selected to fuse various types of features and output predictive values, and after univariate and multifactor Cox analysis by combining clinical features to select T-stage (HR=1.680), CT-radiomic-GBM predictive score (HR=2.759), PET-radiomic-GBM predictive score (HR=2.539), CT-ResNet50-GBM predictive score (HR=7.778), and PET-VGG16-GBM predictive score (HR=3.317) were selected as predictors to construct the Cox proportional risk model. The model performed well in the test set (AUC=0.738±0.072) and could bring more benefits for clinical decision-making compared with the traditional TNM staging model. ***Conclusion:*** By fusing high-dimensional features through machine learning models, deep learning features can effectively complement radiomics features to combine anatomical and metabolic information from PET/CT images with clinical data to predict the prognosis of patients with non-small cell lung cancer. The risk score model constructed in this study showed strong predictive ability compared to conventional TNM staging.

## EP-0742

### Section-Based Regional Recognition of FDG PET/CT Images with Machine Learning

***S. Asa****, A. Kibar, S. E. Biyiklioglu, M. T. Bodur, S. Sager, K. Sonmezoglu;*
*Istanbul University Cerrahpasa, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The use of machine learning algorithms in medical imaging is increasing daily. Machine learning applications can make it easier for physicians to make the right decisions by evaluating the images and reducing the workload. In our study, we aimed to assess the success of machine learning in determining which region the slice belongs to by using axial PET, CT, and PET/CT fusion images of patients who underwent FDG PET/CT. ***Materials and Methods:*** A total of 4672 cross-sections whole-body FDG PET/CT images of 6 patients in whom FDG had physiological distribution were included in the study. Axial PET, CT, and PET/CT fusion sections of the patients' whole-body PET/CT images were converted from DICOM to JPEG format. Areas were classified in separate folders: head, neck, thorax, abdomen, and pelvis. The orange program was used for image analysis(VGG-16) and classification. While the images of 3 of the six patients were used in training, the remaining three were used for testing. Random forest, linear regression, and Suppor vector machine algorithms were used for machine learning. ***Results:*** When PET, CT, and PET/CT fusion sections of patients with physiological distribution were evaluated with random forest, logistic regression, and Suppor vector machine models, the highest correct classification ratio (90.1%) was found in the logistic regression model of CT images (table 1). PET/CT and CT correct classification ratios were similar. However, PET correct classification ratios were lower than PET/CT and CT sections(Table 1). In addition, the highest specificity (97.3%) among the models was found in the logistic regression model of CT(Table 2). ***Conclusion:*** In our study, machine learning algorithms seem successfully detect the region on cross-section in fusion PET/CT and CT images. Studies in which large patient groups will be evaluated with fully automatic models are required.

## EP-0743

### Assessing the Feasibility of Deep Learning-Based Attenuation Correction using Photon Emission Information in 18F-FDG PET Images for Dedicated Head and Neck PET Scanners

***M. Shahrbabaki Mofrad***[1]*, A. Ghafari*[1]*, A. Amiri Tehranizadeh*[2]*, M. Ay*[1]*, S. Farzenefar*[1]*, P. Sheikhzadeh*[1]*;*
*[1]Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** In this study, we investigated the feasibility of directly predicting measured attenuated corrected (MAC) images from non-attenuated corrected (NAC) in the head and neck $^{18}$F-FDG PET images using only head and neck based training deep learning method. ***Materials and Methods:*** A neural network with ResNet architecture was used to train the data through 2D head and neck PET images of 114 patients without any pathology and artifacts, 21 patients' images were used for validation during training, 24 patients' images without pathology and artifacts, and 12 patients' images with pathology were used for testing. The neural network's performance in the test images was evaluated using RMSE, SSIM, PSNR, and MSE parameters by considering the MAC images obtained from the scanner as a reference. To quantitatively examine the images and evaluate the effect of the data used in the training, we obtained contrast and PSNR for the tumoral/hot areas and evaluated it with Paired-t-test. ***Results:*** Head and neck MAC images predicted by the neural network were very similar to the reference images. The findings for PSNR, SSIM, RMSE, and MSE in the normal test group were 44.02 ± 1.77, 0.99 ± 0.002, 0.007 ± 0.0019, 0/000053 ± 0/000030, and in the pathological test group were 43.14 ± 2.10, 0.99 ± 0.005, 0.0078 ± 0.0015 and 0.000063± 0/000026. In the Paired-t-test, there was no significant difference between SNR and Contrast of the test images without pathology (p value>0.05), but in the pathologic case, the differences were significant (p value<0.05). ***Conclusion:*** The deep learning network was able to directly generate head and neck MAC images similar to the reference head and neck images. The trained model with training on more data can be used in dedicated head and neck PET scanners without need for CT.

## EP-0744

### A cascade AI-threshold system for volume segmentation and characterization of lung masses on 18F-FDG PET/CT

***G. Savelli***[1]*, E. Schiavon*[2]*, M. Interlenghi*[2]*, C. Bnà*[1]*, C. Ferrari*[1]*, M. Bonacina*[1]*, C. Salvatore*[2,3]*, I. Castiglioni*[4]*;*
*[1]Fondazione Poliambulanza Istituto Ospedaliero, Brescia, ITALY, [2]DeepTrace Technologies, Milan, ITALY, [3]Department of Science, Technology and Society, Scuola Universitaria IUSS, Pavia, ITALY, [4]Department of Physics, Università degli Studi di Milano-Bicocca, Milan, ITALY.*

***Aim/Introduction:*** Manual segmentation methods of lung masses on 18F-FDG PET/CT studies are affected by inter and intra-observer variability, long annotation times, missed and false edge detection, in particular in low signal-to-noise or multifocal masses. Lack of objective efficient tools for 18F-FDG PET/CT lung mass analysis hinder their quantitative evaluation and characterization. Aim of this study was to provide 18F-FDG PET/CT physicians with a tool for lung mass segmentation that can be helpful in the clinical workflow improving objective quantitation and characterization and reducing segmentation time. ***Materials and Methods:*** Whole body 18F-FDG PET/CT studies were retrospectively collected from 152 patients with lung masses including a retrospective fully-anonymized dataset of Fondazione

Poliambulanza Hospital (Brescia, Italy). Lung masses were manually segmented by an experienced operator in both PET and CT to extract the reference standard for Metabolic-Tumor-Volume (MTV) and Gross-Tumor-Volume (mean MTV=36.6cm$^3$±48.2, mean GTV=42.4cm$^3$±70.6). Manual segmentation time was measured. An AI system, based on a combination of 2 cascade convolutional-neural-networks and a threshold algorithm for mass raw segmentation plus refinement, was developed on fused CT and PET images. Specifically, U-Net++ neural networks were trained from scratch in a cascade approach, first in 3D then in 2D, using binary cross-entropy as loss function (image augmentation was performed by rotation <15%). Quantitation performances were evaluated in terms of Dice coefficient for both MTV and GTV. Radiomics metrics were extracted characterizing the segmented masses. System segmentation time was measured. ***Results:*** The system segmented the lung mass in less than 1 minute in both PET and CT studies compared to 5-32 minutes of manual segmentation. The majority of lung masses (80%) showed Dice >0.80. Dice >0.85 and >0.90 were found for MTV and GTV, respectively. Very low signal-to-noise ratio or multifocal lung mass showed Dice >0.60 but <0.80 and needed human correction to achieve Dice>0.80. A total of 8 radiomic features for PET and 4 for CT were extracted for all masses for objective quantitative characterization. ***Conclusion:*** The developed cascade AI-threshold system showed promising results in segmenting lung masses on 18F-FDG PET/CT, and could have a positive impact on clinical practice, reducing the time required for lung mass segmentation and improving their objective assessment.

## EP-0745

### A New Thoracic CT and Lung Perfusion SPECT Dataset for Developing Analysis of the Lobar Lung Function Assessment

***E. Amini***[1,2], *R. Klein*[1,3,4];
[1]*Ottawa Hospital Research Institute, Ottawa, ON, CANADA,* [2]*Carleton University, Ottawa, ON, CANADA,* [3]*The Ottawa Hospital Department of Nuclear Medicine, Ottawa, ON, CANADA,* [4]*University of Ottawa Department of Medicine, Ottawa, ON, CANADA.*

***Aim/Introduction:*** Quantitative lobar lung function has valuable information for tailoring treatment plans, including surgical planning. However, application has been limited due to tedious manual segmentation by expert operators. In recent years, deep learning-based segmentation and registration methods have been introduced in an attempt to address this limitation. However, development and validation of solutions is hampered by a lack of openly available dataset representing the wide range of diseases. We present a new thoracic computed tomography (CT)/lung perfusion single-photon emission computed tomography (SPECT) dataset with accurate segmentation of the lung lobes and trachea. ***Materials and Methods:*** In this REB approved study, we collated diagnostic and low-dose CT scans of the thorax with an associated (on average, within 58 days) lung perfusion SPECT. CT scans were acquired using a variety of imaging protocols with CT slice thickness ranging from 0.8 to 3 mm, while SPECT acquisition was standardized according to our local clinical practice (74-185 MBq $^{99m}$Tc-MAA, 128 step, 8 seconds per step, OSEM reconstruction, 128x128 pixels, 4.8$^3$ mm pixels). For each CT scan, the lobes were semi-automatically segmented on sagittal slices using clinically validated software and postprocessed to fix inaccuracies. In addition, the trachea was segmented using a fully automated region-growing algorithm. SPECT data includes raw projection data (with lower scatter window) and CT rigid co-registered reconstructed volumes. Metadata includes patient demographics, imaging parameters, relevant clinical history, excerpts of physician reports, and qualitative fissures information. CT scans were visually scored (3 levels) for lung lobe segmentation difficulty based on overall fissure perceptibility, missing fissures, incomplete fissures, and disease patterns resembling fissures (e.g., emphysema). ***Results:*** The dataset consisted of 150 patients (53% male, ages 18-85) and represents various diseases such as different subtypes of lung carcinoma, lung infiltration, bronchiectasis, interstitial lung disease, and hypersensitivity pneumonitis. The number of lobes on average was 4.8 ranging 3-5. ***Conclusion:*** The presented dataset provides a valuable resource for developing and/or testing fully automated lung lobar function assessment workflow. Another potential use of this dataset is to investigate the relationship between lung structure and function in patients with pulmonary diseases to identify patterns of structural and functional abnormalities that could guide the development of new diagnostic and therapeutic strategies. We plan to make a portion of this dataset openly available.

## EP-0746

### Deep-learning Model for Differentiation of Pediatric Bone Diseases by Bone Scintigraphy: A Feasibility Study

***P. Yang***[1], *L. Jiang*[1], *Y. Xiang*[1], *J. Wei*[2], *Z. Zhao*[1], *H. Cai*[1], *Z. Yi*[2], *L. Li*[1];
[1]*West China Hospital, Chengdu, CHINA,*
[2]*Sichuan Universtiy, Chengdu, CHINA.*

***Aim/Introduction:*** Technetium-99m methylene diphosphonate ($^{99m}$Tc-MDP) Bone scintigraphy (BS) plays a prominent role in pediatric bone disease. We aimed to explore the feasibility of a convolutional neural network (CNN) based deep-learning model for distinguishing benign and malignant pediatric bone disease from bone scintigraphic images. ***Materials and Methods:*** We retrospectively collected 933 bone scintigraphic images from pediatric patients (age 12.91±4.28 years) with benign or malignant bone diseases. The CNN models were constructed and trained based on 745 cases and then validated with the rest 188 cases. The performance of models in differentiating bone diseases was evaluated by diagnostic accuracy, sensitivity, specificity, and receiver operating characteristic (ROC) curves. ***Results:*** CNN-based AI model achieved considerable performance with accuracy of 86.17% (162/188), specificity of 91.67% (110/120) and the sensitivity of 76.47% (52/68) in this test. Furthermore, in the subset analysis of primary bone tumours, CNN model indicated slightly higher AUC value of 0.891 than that of full group (0.851). ***Conclusion:*** The CNN-based approach holds promising feasibility in differentiating benign and malignant pediatric bone disease based on bone scintigraphy.

## EP-0747

### Reliable and Precise Assessment of Liver Function with a Deep Learning Model-Based Workflow Using Hepatobiliary Scan

***H. Sung***[1], *K. Cho*[1], *K. Kim*[1], *H. Choi*[1,2], *G. Cheon*[1,2];
[1]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,*
[2]*Department of Nuclear Medicine, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Accurate assessment of liver function is crucial for patients who are undergoing major hepatectomy surgery. Dynamic hepatobiliary scanning using [$^{99m}$Tc]Tc-Mebrofenin enables the calculation of liver clearance rate, an indicator of liver

function. This study aims to develop a novel machine learning model that can provide dependable and precise results. ***Materials and Methods:*** We collected forty dynamic hepatobiliary scan using [$^{99m}$Tc]Tc-Mebrofenin for our study. Of these, 30 scans were utilized to train the deep learning model for placing ROIs in planar images to determine liver clearance rate. The ROIs for the training were manually drawn by experienced nuclear medicine physicians in the left ventricle, liver, and the entire field of view. The remaining 10 scans were analyzed automatically to calculate liver clearance rate as a validation study. The trained deep learning model and two nuclear physicians estimated liver clearance rate using independently drawn ROIs for the same 10 hepatobiliary scans. The interclass correlation coefficient was employed to compare the results obtained from the machine learning model and physicians, as well as between the two physicians. ***Results:*** Our findings indicate that there was a strong correlation between the deep learning model and the two nuclear medicine physicians, with ICC (2,1) values of 0.88 and 0.85, respectively. Additionally, the ICC (2,1) value between the two nuclear physicians was 0.89, suggesting similar agreement between nuclear medicine physicians and the model. ***Conclusion:*** The deep learning model-based automatic calculation of liver clearance rate was well correlated with those estimated by nuclear medicine physicians. This automatic workflow can provide a reliable and precise result of liver clearance rate using hepatobiliary scan. ***References:*** Ekman M, Fjälling M, Friman S, Carlson S, Volkmann R. Liver uptake function measured by IODIDA clearance rate in liver transplant patients and healthy volunteers. Nucl Med Commun. 1996 Mar;17(3):235-42. doi: 10.1097/00006231-199603000-00011. PMID: 8692492.

## EP-0748

### ORCA - Optimized Registration through Conditional Adversarial networks for improved PET/CT co-registration using synthetic CT

***Z. Chalampalakis****, D. Iommi, I. Rausch, B. Geist, M. Hacker, T. Beyer, L. K. S. Sundar;*
*Medizinische Universität Wien, Vienna, AUSTRIA.*

***Aim/Introduction:*** PET/CT is a hybrid imaging modality providing functional and anatomical imaging information. However, during acquisition, PET and CT data are acquired sequentially, which may result in a regional spatial mismatch from involuntary subject motion. In these cases, a post-acquisition correction is needed to co-register the PET and CT image data. Specifically in whole-body and total-body imaging scenarios, this correction needs to account for complex elastic motion between the PET and CT images. For this problem, we propose ORCA, a generative tool for PET/CT co-registration which utilizes generated synthetic data and diffeomorphic non-rigid image registration. ***Materials and Methods:*** We facilitate the co-registration of complementary PET and CT image data by generating a synthetic CT (sCT) from an FDG PET image. We do so by making use of our prior efforts based on conditional Generative Adversarial Networks (cGAN) [1]. The generated sCT is used for co-registering CT image data to their respective PET data using a recently introduced, fully-automated, whole-body diffeomorphic registration tool (FALCON) [2]. The cGAN was trained with a ResNet-based generative model using 19 FDG-PET/CT datasets of healthy volunteers imaged on a Siemens Vision PET/CT system. Two datasets from the same cohort were used for qualitative assessment of PET/CT co-registration. Both scans included visible arm mismatch between PET and CT, which in one case included PET intra-frame motion. ***Results:*** The application of ORCA on the two test cases resulted in realistic sCT datasets, which visually matched their respective PET data. Visual inspection of the CT co-registrations to their respective PET images showed improved PET-CT alignment in both cases, without the prior seen mismatch. In the test case with PET intra-frame motion the result sCT and subsequent CT registration resulted in a noticeable artifact in the form of additional tissue beyond the expected arm contour. ***Conclusion:*** The proposed tool provides a simple and reliable framework for post-acquisition co-registration of whole-body PET/CT data. In the future, this tool will be retrained with more data, expanded to include PET data from additional frequently used tracers, and finally be distributed as open-source software for the scientific community. ***References:*** 1. ### May Automated PET Lesion Detection Be Improved Focusing "AI-Brain" On Single Organs?

***A. Macula****[1,2], L. Airo[3], S. Colombo Serra[2], M. Alì[4], S. Papa[4], G. Valbusa[2], A. Bifone[1], P. Gandolfo[4];*
*[1]Università di Torino, Torino, ITALY, [2]Bracco Imaging S.p.a., Milano, ITALY, [3]Università di Milano, Milano, ITALY, [4]Centro Diagnostico Italiano, Milano, ITALY.*

***Aim/Introduction:*** Automated lesion segmentation in [18F] FDG-PET/CT images is a huge challenge currently addressed by different AI-based strategies, the most common being deep neural network. The aim of this work is assessing whether the performance of nnUNET [1] as PET lesion detection and segmentation tool can be improved using as input single organ rather than whole body images. As a proof of concept, we applied the here proposed strategy on liver. ***Materials and Methods:*** AutoPET challenge [2] database (composed by 900 [18F]FDG-PET/CT exams) was used for this study. Eligibility criterion was the presence of at least one lesion within the hepatic tissue, resulting in a final database of 116 patients (further divided in training/test set with ratio 80/20). The pre-trained AI segmentation model TotalSegmentator [3] was applied to CT images to get the liver mask for each patient. Then, nnUNET architecture was trained using three different versions of the input images: 1) whole-body [18F]FDG-PET/CT images with windowing centred on typical abdominal HU values; 2) a subset of 90 slices centred over the abdominal region with windowing centred on typical abdominal HU values; 3) a subset of 90 slices centred over the abdominal region with windowing centred on typical abdominal HU values and masked with the liver segmentation previously obtained. Predicted masks of hepatic lesions were compared with ground truth segmentation by measuring Dice coefficient, number of false positive and false negative, volume of false positive and false negative. ***Results:*** Among the three tested strategies, the first one showed the best results both in terms of Dice coefficient and in terms of number/volume of false positive/negative (see Table below). When the network was allowed to look at the whole anatomical context, rather than on liver only, its performance in detecting hepatic lesion resulted improved both in segmentation and in lesion detection accuracy. ***Conclusion:*** On the base of this preliminary

results obtained on the hepatic tissue, there is no advantage in applying organ segmentation before feeding a neural network aimed at detecting lesions in [18F]FDG-PET/CT images. Further studies are needed to deeper investigate the topic, either applying the tested method to other organs (e.g. bones, lungs) or optimizing the AI-method employed. ***References:*** 1. ### CT-free Total-body PET segmentation

***C. Clement***[1], *S. Xue*[1], *Y. Mao*[2], *R. Guo*[2], *M. Viscione*[1], *A. Rominger*[1], *B. Li*[2], *K. Shi*[1];
[1]*Inselspital Bern, Bern, SWITZERLAND,*
[2]*Ruijin Hospital, Shanghai, CHINA.*

***Aim/Introduction:*** Low-dose positron emission tomography (PET) imaging has become feasible with high-sensitivity, long axial field-of-view PET/computed tomography (CT) scanners. However, the incorporation of CT introduces a significant radiation burden. Deep learning (DL)-based methods have been proposed as alternatives for CT-based PET attenuation and scatter correction [1], yet the anatomical localization ability of CT is still needed. This study aims to achieve total-body PET multi-organ segmentation on non-corrected PET images using a DL approach, moving toward completely CT-free PET imaging. Our method uses automatically generated segmentation labels for training and physician-delineated labels for validation, effectively addressing the label scarcity problem in medical image segmentation. ***Materials and Methods:*** We developed a DL-based multi-organ segmentation pipeline for total-body $^{18}$F-FDG PET imaging using a dataset of 114 patients scanned with a Siemens Biograph Vision Quadra. For 108 patients, multi-organ segmentation labels were generated using CT images as input to the Multi-Organ Objective Segmentation (MOOSE) software [2], which served as the ground truth for training. For six patients, board-certified nuclear medicine physicians manually segmented organs, which served as the test set. A 3D U-Net-like model was trained on non-attenuation and non-scatter corrected PET images for 1,000 epochs using the sum of cross-entropy and Dice score as the loss function. The segmentation pipeline was implemented using nnU-Net [3]. ***Results:*** Our preliminary results demonstrate an accurate overlap between physician-delineated labels and our predicted organ segmentations: 40% of targeted organs had Dice similarity coefficients (DSCs) of greater than 0.80, 80% of greater than 0.6, while two organs exhibited lower scores, namely pancreas with 0.58 and adrenal glands with 0.34. ***Conclusion:*** We investigated total-body PET multi-organ segmentation using a DL-based method that does not require anatomical information from CT. Our method shows good quantitative performance, with a high overlap between physician-generated labels and predicted segmentations. This is a significant step toward CT-free PET imaging, with the potential to enhance the efficiency and safety of PET scans. Future work will focus on developing models fine-tuned on manually delineated segmentation labels and expanding the dataset to include data from various scanner types. ***References:*** [1] Guo, R. et al., Nat Communications 13, 5882 (2022). ***Aim/Introduction:*** Brain [$^{18}$F]Fluorodeoxyglucose PET (FDG-PET) allows differentiating various neurological abnormalities. Follow-up FDG-PET scans can help monitor disease progression, or evaluate treatment efficacy. However, the time frame and the amount of radiation exposure hence involved are unfavorable for the patient. In recent years, convolutional neural networks (CNNs) have proven beneficial in various medical imaging tasks, yet their value in medical imaging time series prediction remains unexplored. Here, as a proof-of-principle study, we use CNNs to predict a person's FDG-PET scan in year two from the FDG-PET at baseline and year one. ***Materials and Methods:*** We identified all participants from the Alzheimer's Disease Neuroimaging Initiative who were amyloid-beta positive and who received FDG-PET scans in three consecutive years (n=83). A supervised CNN was implemented and trained on spatially and intensity-normalized scans from baseline and year one, which were subsequently fused to generate a prediction for the year-two scan. The performance of the CNN was evaluated by means of mean absolute error (MAE) and structural similarity (SSIM) using five-fold cross-validation. To demonstrate the necessity of deep learning methodology in this task, the performance of the model was compared to a naïve voxel-wise linear regression model, referred to as "pseudo predictions", using a paired t-test. Finally, to assess the clinical validity of our predictions, we performed voxel-wise t-tests comparing year-two scans of CN with year-two, predicted, and pseudo-predicted scans of Alzheimer's disease (AD) patients. ***Results:*** Our model showed an excellent MAE of 0.040 and SSIM of 0.945, which was significantly better than the MAE (0.052, lower is better, $t = -3.64$, $p = 0.02$) and SSIM (0.935, higher is better, $t = 6.06$, $p = 0.04$) of pseudo predictions. In year-two scans, as well as in predicted and pseudo-predicted scans, significant hypometabolism in the precuneal and inferior temporal parts of the brain, typical of AD, was observed, thus confirming the clinical validity of the predicted scans. ***Conclusion:*** Changes in brain metabolism observed over the period of one year (baseline to year one) enable precise prediction of brain metabolism in year two, thereby motivating further research of prediction in more extended time frames. If successful on a larger scale, our model may be relevant for data augmentation in scientific longitudinal studies, or to document deviations from expected longitudinal brain metabolic degradation in individual subjects (e.g. under therapy).

***Aim/Introduction:*** Normal 0 false false false EN-US X-NONE AR-SA /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin-top:0cm; mso-para-margin-right:0cm; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0cm; text-align:right; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-bidi-language:AR-SA;} Since attenuation correction is one of the critical phenomena in quantitative imaging, especially with PET/CT, and considering that in the PET/CT imaging, CT applies a higher dose to the patient than the radiopharmaceutical. the feasibility of direct scatter and attenuation correction of whole-body 68Ga-Dotatate PET images from uncorrected images (PET-nonASC) was evaluated using deep residual networks. ***Materials and Methods:*** Normal 0 false false false EN-US X-NONE AR-SA /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin-top:0cm; mso-para-margin-right:0cm; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0cm; text-align:right; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-bidi-language:AR-SA;} Non-attenuation/ scatter corrected (NAC) and CT-based attenuation/ scatter corrected(CT_ASC) Whole-body 68Ga-Dotatate PET images of 150 patients from two different centers were used in this study, 15% of data from each center were considered for validation and 15% for the test, a residual deep learning model which uses NiftyNet framework where a highres3dnet model was implemented was used for the train. Image data were compared with the CT-ASC images using different evaluation parameters such as peak signal-to-noise ratio(PSNR), structural similarity index(SSIM), mean square error (MSE), root mean square error(RMSE), and Imaging was also done with the same radiopharmaceutical by a NEMA phantom, and performance of the model was also evaluated. ***Results:*** Normal 0 false false false EN-US X-NONE AR-SA /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin-top:0cm; mso-para-margin-right:0cm; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0cm; text-align:right; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-bidi-language:AR-SA;} Quantitative analysis demonstrated PSNR of 51.12 ± 6.86, SSIM of 0.994 ± 0.003, MSE of 0.00014 ± 0.0001, RMSE of 0.011 ± 0.004 in the test set of images, and PSNR of 32.41, SSIM of 0.902, MSE of 0.0038, RMSE of 0.062 in phantom images. Bias map analysis showed that in all images of the test set, the largest errors were observed in the lung and while the smallest errors were observed in the liver and bladder, and no errors were found in the phantom images. ***Conclusion:*** The results indicate that direct attenuation and scatter correction of whole-body 68Ga-Dotatate PET images using the proposed deep learning model can achieve high and significant accuracy without necessitating the use of CT images or subjecting the patient to high doses.

## EP-0753

### Assessment of CNN Performance in Cases of Breast Cancer, Staging and Restaging- A Tumour Type Not Included in Algorithm Training

***A. Nawwar***[1,2,3], *D. Darian*[4], *J. Searle*[5,2], *T. Shimizu*[6], *I. D. Lyburn*[7,2,8];
[1]*University Hospitals Bristol and Weston, NHS Foundation Trust, Bristol, UNITED KINGDOM,* [2]*Cobalt Medical Charity, Cheltenham, UNITED KINGDOM,* [3]*Faculty of Medicine, Cairo University, Cairo, EGYPT,* [4]*Siemens Healthcare Ltd., Camberley, UNITED KINGDOM,* [5]*Gloucestershire Hospitals NHS Foundation Trust, Gloucestershire, UNITED KINGDOM, Cheltenham, UNITED KINGDOM,* [6]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Chicago, IL, UNITED STATES OF AMERICA,* [7]*Gloucestershire Hospitals NHS Foundation Trust, Gloucestershire, UNITED KINGDOM, CHELTENHAM, UNITED KINGDOM,* [8]*Cranfield Forensic Institute, Cranfield University, Wiltshire, UNITED KINGDOM.*

***Aim/Introduction:*** To quantitatively assess the lesion classification performance of a convolutional neural network (CNN), using semi-automated segmentation, on metastatic breast cancer which is outside the data training set. The CNN was designed with the aim of supporting a reading physician to calculate total disease burden. ***Materials and Methods:*** 30 staging and restaging metastatic breast cancer F18 FDG PET/CT scans were analysed by 3 expert PET/CT readers and subsequently using a CNN algorithm. PERCIST criteria with a cut off of 41% was used in both readings to segment foci and measure metabolic tumour volume (MTV); the initial human read involved manual segmentation using an isocontour tool whereas the CNN algorithm classified foci based on an automated segmentation algorithm. Foci agreement on both reads was recorded for sensitivity/specificity analysis; MTV agreement was assessed with Spearman's rank correlation and Bland-Altman plots. Foci classification was verified by further correlation with other imaging modalities and clinical follow-up. ***Results:*** PERCIST segmentation criteria identified 1191 foci. CNN classification sensitivity, specificity, accuracy and precision for these foci were 72%, 97%, 93% and 81%. This agrees with previous testing on unseen datasets. Good correlation was observed between the ranked MTV as measured by the CNN and the expert readers (Spearman's $\rho = 0.85$, $p>0.001$), however a positive bias was observed in the CNN measured MTV relative to the manual measurement. This additional MTV was likely due to inclusion of physiological false positives (predominantly brown fat and bowel). The CNN classified 21 false positive (FP) and 14 false negative (FN) foci. The tendency to classify FP foci results in a precision score of 81%, however these FP findings are common and were easily identified by users.In total, 89 corrections (7% of total foci) were required by the expert readers when using the CNN (30 FP, 50 FN, 9 not segmented); 3 edits per patient on average using the current segmentation criteria. This demonstrates the robustness of the CNN to data from outside the training set. ***Conclusion:*** The automated segmentation plus CNN classification algorithm requires minimal human interaction for assessment of foci and calculation of MTV in a metastatic breast cancer cohort; minor

discrepancies were clinically insignificant and would not change patient management. This confirms the value of the software in assisting clinical reads and the potential of improving diagnostic confidence and ongoing management.

## EP-0754

### Performance analysis of deep progressive learning denoising method vs conventional methods on low dose 18F-FDG whole body PET/CT scans with low counts/ reduced time protocol

***S. Singh***, *S. Nigam, R. Vajpayee;*
*Globe healthcare, Lucknow, INDIA.*

***Aim/Introduction:*** PET images greatly suffer from noise and for accurate diagnosis, good PET image quality is important. With the introduction of deep learning (DL) denoising techniques, image quality has been shown to improve even with low injected dose of radiotracer. This study evaluates the performance of deep progressive learning denoising algorithm on image quality and semi quantitative parameters with data having low counts and acquired over shorter time protocols. ***Materials and Methods:*** The study retrospectively included 110 patients undergoing an F-18 FDG PET/CT imaging on digital PET-CT scanner (uMI550 United Imaging) with acquisition of 120 seconds per bed position. The list-mode data was rebinned into five datasets: 120 (reference), 90, 60, 45 and 30 seconds corresponding to 100%, 75%, 50%, 37.5% and 25% of the total counts respectively. All images were reconstructed by OSEM algorithm and post-processed with the DL and Gaussian filter (GS). 110 FDG avid lesions more than 1 cm on CT images were selected to determine lesion detectability. Lesions were deemed detectable if focal uptake with SUVmax more than 2 times the surrounding background**.** Standardized uptake values (SUVs) in liver, mediastinum, liver and mediastinal signal-to-noise ratio (SNR) were compared among different subsets. The background noise and lesion contrast was assessed using a 5-point Likert scale along with contrast to noise ratio (CNR) for representative lesions. ***Results:*** Average injected 18F-FDG dose was 3±0.5 MBq/kg body weight. Mean Uptake time was 60±10 minutes. All lesions >1 cm were detectable by both sets of images. Overall, there was significant difference between SUVmax of liver and mediastinum between all subsets of DL based and GS based denoising methods, however difference in SUVmean was non significant. SNR of liver was significantly higher in DL group compared to GS cohort. Image noise was significantly less in the DL group than the GS group ($p<0.05$) in all the subsets. However, significant difference in lesion contrast was only observed in 45s and 30s image cohorts. In DL group, SUV values, SNR, background noise and lesion contrast were showed no significant difference between reference (120s) and 90s cohort. ***Conclusion:*** Deep learning based denoising method results in better reduction in image noise and signal to noise ratio compared to GS method at low dose FDG PET scans. Image acquisition time per bed position can be reduced to 90 seconds without compromising with lesion detectability, image quality and semi-quantitative data.

## EP-0755

### Effects of CNN-based PET image denoising on image quality and lesion detectability

***S. Gnesin***[1], *S. Medici*[1], *M. Jreige*[2], *M. Conti*[3], *J. Schaefferkoetter*[3], *J. O. Prior*[2];
[1]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Siemens Medical Solutions UNITED STATES OF AMERICA, Knoxville, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Positron emission tomography (PET) is inherently noisy, usually reconstructed images are smoothed to reduce image noise before clinical interpretation. Recently AI-based methods including deep learning and convolutional neural networks (CNNs) showed their potential over standard post-reconstruction smoothing. We investigated the impact of AI image denoising on signal detectability of lung nodules in $^{18}$F-FDG PET patient data at different noise levels simulating lower injected activity in lung cancer screening conditions. ***Materials and Methods:*** A CNN with a nested residual architecture was trained for denoising PET images, training data were generated through patient decimated list-mode data. The network learned generate images which resembled full count reconstructions, from noisy input images reconstructed from a subset of the original data simulating decreasing injected activity. We assessed 20 whole-body $^{18}$F-FDG PET whose acquired on a Biograph Vision (Siemens Medical Solutions, Knoxville TN) and reconstructed with the full acquired statistic, 10% and 5% of events respectively with and without additional CNN denoising - yielding 6 total images per subject. The tracer uptake detectability in the lung nodules was assessed by visual analysis by two physicians. We segmented a total of 24 lung lesions in 10 whole-body PET/CT surrounding background and liver background. Lesion detectability was assessed by CNR. We computed liver SNR to assess image quality. ***Results:*** A total of 43 lung nodules were visually assessed. Visual detectability was preserved in 93% (40/43) vs 91% (39/43) and 84% (36/43) vs 77% (33/43) and of lesions in 10% and 5% CNN-denoised vs. non-denoised PET reconstructions. CNN denoised PET images had higher liver SNR compared to the non-denoised counterparts, average SNR increased by a factor 1.4, 5.2 and 5.9 in the full statistics, 10% and 5% reconstructions respectively. CNN-denoised images yielded on average higher lesion CNR in decimated reconstructions. CNR improved by a factor 1.5 and 1.8 in 10% and 5% reconstructions respectively, whereas 10% and 5% CNN-denoised images preserved on average 96% and 89% of the original lesion CNR respectively. CNN denoising decreased the CNR in only 1/24 lesions. ***Conclusion:*** The reduced-count, CNN-denoised images demonstrated visual improvements over the non-denoised counterparts, with an average higher lesion CNR and increased liver SNR. A more robust analysis including the inclusion of a higher number of PET patients and lesions with a structured observer detection task to better reflect the actual clinical significance of CNN denoising for lesion detectability is currently under investigation.

## EP-0756

### Comparison of two artificial intelligence tools for anomaly detection and segmentation in 18F-FDG-PET/CT in a monocentric lung and breast cancers patient cohorts

***M. Mechti***, *P. Blanc-Durand, E. Itti;*
*CHU Henri Mondor, PARIS, FRANCE.*

***Aim/Introduction:*** In cancer care, 18F-FDG-PET/CT evaluates disease and monitors treatment. To enhance scan analysis, auto-segmentation software are developed. This study compares two of them, PAIRE and AUTOID in lung and breast cancer lesion detection and segmentation, assessing anomaly detection and total lesion volume (TLV) estimation. ***Materials and Methods:*** Between September 1, 2019 and September 1, 2022, 131 patients having performed FDG PET-CT for the initial extension assessment of lung and breast cancers, in CHU Henri Mondor (Créteil, France) were retrospectively collected. They were all analyzed using PAIRE v0.2.1(Paris, FRANCE) and AUTOID (Siemens, Erlangen, Germany).

AUTOID failed for 7 patients. Manual corrections of AUTOID predictions in Syngo.via interface (VB60) established the ground truth, including all hypermetabolic, inflammatory, or tumoral lesions. The concordance between AUTOID and PAIRE contours was examined by calculating the True Positive (TP), False Positive (FP), and False Negative (FN) lesion counts for each individual and were secondly manually reviewed and reclassified. A predicted Region of Interest (ROI) that had a minimum of one overlapping voxel with the Ground Truth (GT) was classified as a TP lesion. In contrast, predicted ROIs without any overlapping voxels with the GT were categorized as FP lesions. Lastly, GT ROIs that did not have any common voxels with the predicted ROIs were identified as FN lesions. TLV was performed at 41% SUVmax thresholding. ***Results:*** 131 patients (64 with lung cancer, 67 with breast cancer, average age : 65 years old, 86 women) were included. The sensitivities of PAIRE and AUTOID to detect FDG-avid lesions were 93.0 ± 1.5% (1027 / 1104) and 60.1 ± 2.9% (664/1104), respectively. The false positive rate was 1.6 for PAIRE and 0.5 for AUTOID. Mean TLV were 55 ± 117 and 54 ± 96 mL for PAIRE and AUTOID, respectively, versus 45 ± 90 mL for GT ($p<0.01$ and $p<0.01$). These volumes were correlated with the ground truth, ro=0.82 and 0.70 for PAIRE and AUTOID respectively ($p<0.01$). AUTOID's FP (n=307) were mostly digestive (19%) ; articular (17%); vascular (16%) or muscular (16%) structures. PAIRE's FP (n=1631) were surprisingly mostly tumoral non annotaded lesions (27%) ; inflammatory lesions (22%) ; muscular (8%) or vascular structures (8%). ***Conclusion:*** PAIRE demonstrates superior sensitivity compared to AUTOID, albeit with an elevated false-positive rate. Utilizing artificial intelligence facilitates expedited scan interpretation and offers crucial metrics, including metabolic burden quantification. Perfect ground truth are complex to obtained, multiple review must be performed.

## EP-0757

### Deep Learning for Automatic Prostate Segmentation On 18F-DCFPyL PET/CT In Prostate Cancer.

***M. Cysouw***, *W. I. Luining, B. M. de Vries, D. E. Oprea-Lager, A. N. Vis, R. Boellaard;*
*Amsterdam UMC, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Quantitative data on PSMA-expression on PSMA PET may be useful for tumor phenotyping and initial staging. To quantify intra-prostatic PSMA-expression, pre-segmentation of the prostate is often necessary to exclude background activity (e.g. bladder or rectum) from tumor-specific activity. We aimed to develop a 3D convolutional neural network (CNN) for automated prostate volume segmentation on $^{18}$F-DCFPyL PET. ***Materials and Methods:*** $^{18}$F-DCFPyL PET/CT images from 100 patients with intermediate- to -high risk prostate cancer were analyzed. A fully 3D CNN with U-net architecture was constructed and trained (with and without data-augmentation) in 5-fold cross-validation using manual prostate segmentations as ground truth. Both PET-only and concatenated PET/CT images were used as model input (64x64x64 voxel bounding boxes placed around the prostate). The Sørensen-Dice coefficient (DSC) was used to evaluate prostate volume segmentation accuracy. Next, intra-prostatic tumor volumes were segmented using i) commonly used isocontour-based delineation ($VOI_{ISO}$) and ii) a previously published[1] 3D CNN requiring a predefined prostate volume ($VOI_{CNN}$). Whole prostate and intra-prostatic tumor PET metrics (volume, SUVs, total PSMA) and radiomics features were extracted from the segmentations. Intraclass-correlation coefficients (ICC) were used to assess agreement between data from CNN-based versus manual prostate segmentations. ***Results:*** We observed mean DSC of 0.86 (0.04 SD) and 0.83 (0.06 SD) for the PET model without and with data augmentation, respectively, and 0.87 (0.04 SD) and 0.85 (0.05 SD) for the PET/CT model without and with data augmentation, respectively. In three patients (with urinal catheters) segmentation failed. Spatially shifting the manually placed bounding boxes reduced DSC by a mean -0.11 (0.08 SD) and 0.00 (0.01 SD) for the models trained without and with data augmentation, respectively. Between PET-metrics derived from manual versus CNN-based prostate segmentations, ICCs for the prostate mask, $VOI_{ISO}$ and $VOI_{CNN}$ were 0.95 (0.06 SD), 0.94 (0.12 SD) and 0.99 (0.01 SD), respectively). Between radiomics features derived from the manual versus CNN-based prostate segmentations, ICCs for the prostate mask, $VOI_{ISO}$ and $VOI_{CNN}$ were 0.91 (0.16 SD), 0.89 (0.14 SD), and 0.91 (0.12 SD), respectively). ***Conclusion:*** We developed a 3D CNN that automatically segments prostate volumes on $^{18}$F-DCFPyL PET images and can be used to quantify intra-prostatic PSMA-expression with high accuracy compared to manual segmentations. ***References:*** 1. Kostyszyn D et al. Intraprostatic Tumor Segmentation on PSMA PET Images in Patients with Primary Prostate Cancer with a Convolutional Neural Network. J Nucl Med. 2021 Jun 1;62(6):823-828

## EP-0758

### Assessment of a Deep Learning-Based Noise Reduction Algorithm on the Ultra-Fast Whole-Body Bone Tomoscintigraphies Recorded by a 360° CZT Camera

***A. Bahloul***[1,2], *Y. Lamash*[3], *N. Roth*[3], *A. Dari*[1], *P. Marie*[1,2], *L. Imbert*[1,2];
[1]*CHRU-Nancy, Department of Nuclear Medicine, Nancy, FRANCE,* [2]*Université de Lorraine, INSERM U1254, IADI, Nancy, FRANCE,* [3]*Spectrum Dynamics Medical, Caesarea, ISRAEL.*

***Aim/Introduction:*** High-sensitivity 360° CZT-cameras provide high-quality images with marked reductions in injected activities or recording times. This study aimed to determine whether these parameters could be further reduced with the addition of a deep learning-based noise reduction filter for whole-body bone tomoscintigraphy. ***Materials and Methods:*** We selected the list-mode files of whole-body tomoscintigraphies recorded: (i) almost 3 hours after the injection of 550±32 MBq 99mTc HDP, (ii) in 15 patients (8 women, 65±10 years-old, 28±5 kg.m-2 body mass index) for an oncologic indication (10 with bone metastasis and 5 without) and (iii) with a 360° CZT-SPECT camera providing whole-body SPECT recordings of only 9 minutes. SPECT datasets were reconstructed with the noise reduction algorithm (NR+) and without (NR-), for different recording times (RT): 100% (≈ 9 min), 80% (≈ 7 min), 70% (≈ 6 min), 60% (≈ 5 min), 50% (≈ 4,5 min) and 30% (≈ 3 min). All reconstructed images were corrected for scatter and partial volume and analyzed: (i) visually by a blinded experienced observer through a 4-grade quality score (3: excellent, 2: good, 1: suboptimal with a decreased diagnostic confidence, and 0: impossible analysis), and (ii) quantitatively, with the determined maximal Standardized Uptake Values (SUVmax) from each bone lesion and contrast-to-noise ratios from normal femoral shafts. ***Results:*** At 100% RT, mean quality scores (MQS) were 2.8±0.4 for NR- and 2.9±0.3 for NR+. For NR+, MQS remained unchanged with shorter RT down to 60% (2.9±0.4), then decreased starting from 50% RT (2.2±0.7). For NR-, MQS was already decreased at 80% RT (2.1±0.5). Contrast-to-noise ratios decreased according to RT shortening but remained higher for NR+ than NR- whatever the RT level - i.e., at 100% RT, 2.3±0.3 vs. 2.1±0.3 ($p<0.001$), and at 50% RT, 2.1±0.2 vs. 1.9±0.3 ($p<0.001$). Finally, SUVmax from bone lesions were slightly lower for NR+ than NR- (respective mean SUVmax at 100% RT: 11.7±8.5 vs. 12.6±8.7 ($p<0.001$)) but

remained unchanged between different RT levels. ***Conclusion:*** When applying a deep learning-based noise reduction algorithm to ultra-fast (9 min) whole-body bone SPECT recordings currently provided by the 360° CZT-camera, a further decrease to only 60% of original recording counts is possible, without any significant loss in image quality. This decrease could support (i) shortening whole-body SPECT recordings further (down to 5 min RT) or (ii) decreasing the injected activity to 330 MBq, thus combining a low dose protocol with the 9 min whole-body SPECT recordings.

## EP-0759

### Automatically acquired tumour staging (T) in FDG-avid lung tumours aided by artificial intelligence.

***P. Borrelli***[1], *M. Milà López*[2], *P. Fierro Alanis*[2], *M. Larsson*[3], *R. Rossi Norrlund*[1], *R. Kaboteh*[1], *L. Edenbrandt*[1,4], *E. Trägårdh*[5,6];
[1]*Department of Clinical Physiology, Region Västra Götaland, Sahlgrenska University Hospital, Gothenburg, SWEDEN,* [2]*Servicio Medicina Nuclear Hospital Universitari Joan XXIII de Tarragona, Tarragona, SPAIN,* [3]*Eigenvision AB, Malmö, SWEDEN,* [4]*Department of Molecular and Clinical Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN,* [5]*Department of Translational Medicine and Wallenberg Center for Molecular Medicine, Lund University, Lund, SWEDEN,* [6]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, SWEDEN.*

***Aim/Introduction:*** Lung-cancer is the most prevalent/deadly cancer worldwide. Correctly staging patients is fundamental. Developing an AI-based-tool to automatically identify TNM status is part of an ongoing effort by our research group. The first natural step and aim in this study is to identify FDG-avid tumours in PET-images and correlate them to the morphological finding in CT-images in patients with suspected/known lung-cancer and get the measurements for Tumour staging (T). ***Materials and Methods:*** 58 patients from two hospitals were evaluated Initially, a convolutional neural network (CNN) is employed to identify/segment the lung-tumour in the PET-image. The input to this CNN includes the CT and PET images, as well as an organ mask produced by a separate method. Subsequently, another CNN is applied to the area around the main lung tumour (highest TLG if more than one was detected). The segmentation output by the second CNN aligns with the tumour tissue visible in the CT image, which usually differs slightly to the high uptake region in the PET images, primarily due to breathing artifacts. The second CNN utilizes the output of the first CNN in addition to the PET/CT images. After the tumour CT-segmentation, the largest diameter is automatically calculated in the three planes. Manual measurements were obtained in the three planes and were compared to those automatically obtained. T-stage was assigned to each patient based on the manual and automatically obtained tumour dimensions. ***Results:*** FDG-avid tumours were present in 46/58 patients. The AI-based tool was able to identify 40 of those (sensitivity-87.0%). In 12 patients neither a specialist nor the AI-tool identified FDG-avid tumours (specificity 100%). Manual median diameter 3.4 cm (IQR 2.3 to 4.3), AI-based median diameter 3.0 cm (IQR 2.0 to 3.9). Difference median diameter -0.4 cm (IQR -0.8 to -0.1). Difference between Manual and AI-based Diameter was on average 0.4cm in 25 patients with a manual diameter <4cm. For larger diameters the average difference was larger. These measurements lead to agreement between manual and AI-based T stage in 30/40 patients (75%), one stage difference in nine patients and two stages difference in one patient. ***Conclusion:*** A completely automated AI-based analysis can detect FDG avid lung tumours with high sensitivity and specificity, measure tumour dimension in CT, and assign a T stage comparable to a manual analysis. These results show feasibility of an automated T-staging. The AI method is available for research purposes on request at www.recomia.org.

## EP-0760

### Unsupervised and explainable phenotying on multiparametric contrast enhanced MRI and dynamic 18F-FDOPA PET images of patients with glioma at initial diagnosis

***T. Zaragori***[1,2], *A. Zinsz*[2], *M. Doyen*[1,2], *L. Imbert*[1,2], *J. Oster*[1,3], *A. Verger*[1,2];
[1]*Université de Lorraine, IADI, INSERM, UMR 1254, Vandoeuvre-lès-Nancy, FRANCE,* [2]*Department of Nuclear Medicine & Nancyclotep Imaging Platform, CHRU-Nancy, Université de Lorraine, Vandoeuvre-lès-Nancy, FRANCE,* [3]*CHRU Nancy, INSERM, CIC, Innovation Technologique, Université de Lorraine, Vandoeuvre-lès-Nancy, FRANCE.*

***Aim/Introduction:*** Investigating associations between multiple type of images at the voxel level implies to identify groups of similarly behaving voxels and to explain the construction of these groups by possibly linking them to an underlying physiological process or a specific pathology subphenotype. The objective is to develop an explainable clustering of a multimodal imaging depiction of a glioma for characterization at initial diagnosis. ***Materials and Methods:*** Fifty-six patients having undergone a contrast enhanced (CE) MRI and a $^{18}$F-FDOPA dynamic PET with positive uptake for glioma assessment at initial diagnosis were retrospectively included. After co-registration and semi-automated segmentation, CE MRI images, static tumor-to-background ratio (TBR), parametric $TTP_{ratio}$ and $slope_{ratio}$ dynamic $^{18}$F-FDOPA PET images were analyzed at the voxel level. Unsupervised clustering of 1,481,146 voxels data was performed using an Hierarchical Density-Based Spatial Clustering algorithm after non-linearly projecting the data in a 2D space using the Uniform Manifold Approximation and Projection algorithm. SHAP values were used for the introspection of the unsupervised analysis to understand the mechanism behind the group construction. The percentage of voxels with each cluster label in each lesion was extracted and fed as features for a survival task predicting time-to-treatment failure (TTF). ***Results:*** Four clusters were identified by our proposed method. The two main clusters consisted of voxels mostly without CE, TBR uptake and either low $TTP_{ratio}$/negative $slope_{ratio}$ (C1) or high $TTP_{ratio}$/positive $slope_{ratio}$ (C2). $TTP_{ratio}$ was the most contributive feature to identify C1 along with CE for C2. The two remaining clusters exhibited voxels with CE, high $TTP_{ratio}$/positive $slope_{ratio}$ and were discriminated by their TBR uptake (high uptake C3 and low/no uptake C4) with the model relying more on TBR for C3, while relying on CE and $TTP_{ratio}$ for C4. Regarding TTF prediction, fraction of C1 was the third most important feature (18%) after the total volume (23.9%) and having undergone a surgery (23.5%). Moreover, higher fraction of C1 in a tumor was associated with lower TTF. ***Conclusion:*** We developed a completely unsupervised method that was able to identify groups of similar behaving voxels on multimodal imaging. SHAP values analysis identified mechanisms behind the group construction and its associations with an important clinical endpoint: gliomas at initial diagnosis in which a high percentage of voxels had low $TTP_{ratio}$/negative $slope_{ratio}$ values were correlated to lower TTF.

## EP-0761

### Artificial intelligence Respiratory Gating in PET/CT Imaging: changes on MTV, TLG and SUVmax

***P. Meneses Soares***, *A. Grajeda Gallardo, J. Mucientes Rasilla, R. Jimeno Pernett, M. Mitjavila Casanovas;
HOSPITAL PUERTA DE HIERRO, MAJADAHONDA, SPAIN.*

***Aim/Introduction:*** The Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) are parameters of increasing interest in lesion evaluation using 18F-FDG PET/CT. Respiratory gating during PET/CT reduces artifacts caused by respiratory movements. In the

past, this technique was dependent on gating devices, which led to longer exploration and preparation times. However, with the advent of artificial intelligence (AI), it is now possible to benefit from respiratory gating without the need for a device, avoiding many of the problems associated with its use.The objective of this study is to assess differences between MTV and TLG with and without respiratory gating, as well SUVmax increase in respiratory gating. ***Materials and Methods:*** This is a retrospective study and involved the selection of patients with lung or mediastinal lesions who underwent PET/CT imaging using our newly acquired equipment that integrates AI respiratory gating. Fifty patients met the inclusion criteria and were included in the final analysis. The maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were measured for each lesion, and the mean difference between the results obtained with and without AI respiratory gating was calculated. ***Results:*** The study revealed a mean difference of 13.89% in MTV and 11.52% in TLG between patients undergoing PET/CT imaging with and without AI respiratory gating. Furthermore, the difference in values for the lower pulmonary lobes was significantly higher than for the upper pulmonary lobes, with a difference of 23.7% in MTV and 20.78% in TLG (upper lobes: MTV 7,8% and TLG 5,5%). The global SUVmax increased by 9.3%, while lesions on the inferior pulmonary lobes had an increase of 15.7%, and lesions on other locations had an increase of only 7.47%. Indirectly the changes on the images facilitated lesion delimitation and characterization, particularly in paradiafragmatic lesions. ***Conclusion:*** The use of AI respiratory gating during PET/CT imaging can lead to changes in MTV, TLG and SUVmax. Is important to take that into account. AI respiratory gating leads to improved image quality, well-defined images, less respiratory artifacts and more contrast between normal and pathologic lung metabolic activity. These findings can lead to improved lesion delimitation and characterization resulting in better patient outcomes. ***References:*** Kesner AL, et al. On transcending the impasse of respiratory motion correction applications in routine clinical imaging - a consideration of a fully automated data driven motion control framework. EJNMMI Physics

### Potential airborne releases of 68Ga and 177Lu: a method of preventive assessment

***M. Marengo***[1], *S. Rubow*[2];
[1]*University of Bologna, Bologna, ITALY,* [2]*University of Stellenbosch, Stellenbosch, SOUTH AFRICA.*

***Aim/Introduction:*** The handling of radioactive solutions can lead to the production of airborne radioactivity which can potentially be released into the environment. To reduce this risk to a minimum, containment and protection systems are adopted. However, during processing, unwanted situations may occur, releasing some radioactivity. Given the high activity concentration levels of the products, even a small volume can contain significant radionuclide activity. In this work we present a method for preventive risk assessment, evaluating the potential release of radioactive gases in the case of two important radionuclides, $^{68}$Ga and $^{177}$Lu. ***Materials and Methods:*** The source term, the amount of radioactivity released to air, can be evaluated according to the method introduced by the US Department of Energy. For a liquid to be made airborne, in realistic situations, the bulk liquid must be subdivided into droplets small enough to be entrained in the local airflow. Not considering explosions or fires, this may have different causes, like heating the solution, fall and rupture of the container or resuspension due to the aerodynamic action of ventilation. The key point is the evaluation of the airborne release factor (ARF), the fraction of activity that is released to air. For all the following calculations we assumed a single, conservative ARF value of $3 \cdot 10^{-5}$, according to DOE Handbook 3010 for heating of aqueous solutions.To assess the effective dose to the population living in the area surrounding the facility, the use of 1850 MBq of $^{68}$Ga solution for 2 procedures for 200 days/year, and of 7400 MBq of $^{177}$Lu solutions for 100 procedures/year were considered. A total release of 22.2 MBq/year for each radionuclide was input in the well-known code HotSpot, modelling a gaussian plume emission and different meterological conditions. ***Results:*** The maximum effective dose values calculated for the close proximity of the facility were 0.1 uSv/y for $^{177}$Lu and 0.06 uSv/y for $^{68}$Ga. These values represent the worst case scenario and can be further reduced considering the role of specific containment and filtration systems. ***Conclusion:*** This preventive evaluation method demonstrates that the potential airborne release of $^{68}$Ga and $^{177}$Lu is not radiologically relevant. It can generally also be applied to other radionuclides in aqueous solution, in order to demonstrate compliance during authorization processes. ***References:*** DOE-HDBK-3010-94 Volume I (Reaffirmed 2013), Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities, Volume I

## EP-0763

### CT dose reduction in hybrid PET/CT imaging

***C. Pettinato***, *M. Schiavini, A. Castello, L. Florimonte, C. Canzi, F. Bardo, F. Buffoni, C. Colombo, V. Longari, E. Orunesu, M. Campoleoni, M. Castellani;*
*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY.*

***Aim/Introduction:*** PET/CT imaging is a high dose diagnostic procedure (ACR criteria: ED > 10 mSv). While PET dose reduction can be achieved by reducing the injected activity, CT dose can be controlled using automatic mA modulation algorithms and reducing the applied KVs. Moreover, the introduction of iterative algorithms for CT images reconstruction allows to obtain good image quality while containing patient dose. Dose reduction is particularly important in young patients and in patients enrolled in tight follow-up protocols which include WB PET/CT imaging. The aim of this work was to minimize CT dose in PET/CT imaging personalized on patient weight. ***Materials and Methods:*** All patients underwent a whole-body PET/CT study after the administration of about 3.5-4MBq/Kg of 18F-FDG, using a Biograph Vision 450 PET/CT scanner in flow motion acquisition mode. The CT protocol involved a modulating mA automatic system with constant 120 KV. CT images were reconstructed using the SAFIRE (Sinogram Affirmed Iterative Reconstruction) algorithm. Before each scan, CTDI values shown on the workstation screen were recorded using both 120 and 100 KV and for smaller patients also 80 KV (patient weight < 55 Kg). Evaluation of CT dose optimization was done by calculating the percentage change in the theoretical CTDI values by varying the applied KVs. ***Results:***

25 consecutive patients were enrolled in this study. Mean patient weight and height were respectively 69.4 Kg (range: 41-123 Kg) and 166 cm (range: 150-186 cm) and the mean injected activity was 273.3 MBq (range: 164-400 MBq). The mean CTDI values at 120 KV and 100 KV were respectively 7.2 mGy (range: 2-16 mGy) and 4.6 mGy (range: 1-11 mGy). The mean dose reduction in terms of CTDI values when using 100 KV versus 120 KV was 38.4% (range: 32.4-42.5%). For smaller patients the mean CTDI reduction changing from 120 KV to 80 KV was 71.9% (range: 68.8-75.5%). ***Conclusion:*** CT dose in PET/CT imaging can be easily reduced of about 40% in standard patients and even more, about 70%, for smaller patients by lowering the KV applied and using iterative reconstruction algorithms. In our clinical routine we started using 80 KV for smaller patients (<55 Kg), 100 KV for standard patients (55-80 Kg) and 120 KV for larger patients (>80 Kg). An evaluation of image quality is still ongoing as well as the opportunity to use patient BMI instead of weight to personalize the applied KVs

## EP-0764

### Ambient Dose Equivalent and Occupational Exposure for 177Lu-PSMA-I&T Radionuclide Therapy

***Z. Hu***[1], *C. Liu*[2], *J. Liu*[2], *Z. Yang*[2], *R. Qiu*[1];
[1]*Tsinghua University, Beijing, CHINA,* [2]*Beijing Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction:*** $^{177}$Lu-PSMA-I&T is a commonly used agent for radioligand therapy in patients with advanced metastatic castration-resistant prostate cancer. However, there have been no reports on radiation exposure measurements for this agent. The objective of this study is to assess occupational exposure and ambient dose equivalent for $^{177}$Lu-PSMA-I&T radionuclide therapy and to measure blood clearance. ***Materials and Methods:*** A total of 17 treatments for 9 patients treated with 7.4 GBq $^{177}$Lu-PSMA-I&T at Beijing Cancer Hospital between July 2022 and March 2023 were included in the study. A handheld radiation dosimeter was used to measure the ambient dose equivalent rate at various distances from the patients and at different time points from 0 to 24 hours after infusion. Occupational exposure doses for medical staff were measured using electronic personal dosimeters, while ring thermoluminescence dosimeters were used to measure finger doses for pharmacists and nurses. Blood activity was measured using a gamma counter from 0 to 24 hours after infusion. ***Results:*** The ambient dose equivalent rates at a distance of 1m from the patients were 12.7±1.9 μSv/h and 10.8±1.6 μSv/h at 4 and 6 hours after infusion, respectively, while those at a distance of 3m were 2.2±0.3 μSv/h and 1.8±0.3 μSv/h. The mean effective doses for pharmacists, nurses, and physicians were 0.19±0.08 μSv, 2.64±0.84 μSv, and 1.54±0.39 μSv per patient, respectively. The finger doses for pharmacists and nurses were 200.4±46.1 μSv and 184.1±42.3 μSv per patient, respectively. ***Conclusion:*** Our findings suggest that $^{177}$Lu-PSMA-I&T is a reasonably safe option for outpatient treatment, but attention should be paid to radiation protection for the hands of medical staff.

## EP-0765

### Evaluation of staff exposure to ionising radiation in a PET/CT department

***P. Archontakis***[1,2,3], *K. Silivridou*[2], *K. Mainta*[2,3], *D. Maintas*[2,3];
[1]*National and Kapodistrian University of Athens, Athens, GREECE,* [2]*Iatriko Athinon, Athens, GREECE,* [3]*Institute for Isotopic Studies, Athens, GREECE.*

***Aim/Introduction:*** The aim of this study is to evaluate the staff exposure to ionising radiation in a PET/CT department and categorise the magnitude of each exposure-related task. According to the literature[1], the manual dispensing of radiopharmaceuticals can result in high equivalent dose in extremities, which could be 5-6 times greater compared to what the ring dosimeter detects. ***Materials and Methods:*** The operation chain consists of $^{18}$F radiopharmaceutical vial measurement, dose dispensing, dose injection, patient positioning and discharge. The personnel involved in exposure-related tasks in our department is the medical physicist responsible for vial measurement and dose dispension and two radiology technologists responsible for injecting, positioning and discharging the patients. Thermoluminescent (TLD) and optically stimulated luminescent (OSLD) dosimeters are used to evaluate the effective dose of the staff and ring dosimeters were used to measure and compare the equivalent dose to the fingers for both dominant and secondary hand. In addition, wrist dosimeters were used to create a correlation factor between finger and wrist equivalent dose. So far, the collected data represent a 6-month period, from October 2022 until March 2023 and the corresponding number of patients is 987 with injected activity of 340 ± 68 MBq (±1sd) per patient. ***Results:*** The procedure associated with the highest exposure is found to be the manual dispensing (288 ± 56 μSv/GBq) followed by the manual injection (104± 24 μSv/GBq). The vial measurement equivalent dose is evaluated at 5.1 ± 1.1 μSv/GBq and the correlation factor between wrist and finger equivalent dose is estimated equal to 16. Additionally, the exposure of the dominant hand was around 10% lower than that of the secondary. Finally, the effective dose in μSv/patient is found to be 1.18 ± 0.12 for the medical physicist and 2.00 ± 0.59 for each radiology technologist. ***Conclusion:*** Using an average workload of 12 patients per day divided equally to three operators, the annual equivalent dose from the whole operation chain sums up to 137mSv/operator and the corresponding effective dose to 3mSv/operator. It is evident that the biggest contribution of staff exposure to ionizing radiation comes from manual dispension and injection of the radiopharmaceutical. The most effective way to minimize these contributions is by introducing an automated dispension and injection system. ***References:*** [1]Robert Kollaard et al 2021, Journal of Radiological Protection 41 R60

## EP-0766

### Beta radiation protection in Phosphorous-32 microparticles therapy. Tungsten or methacrylate shielding?

***C. G. Franco Monterroso***, *B. Santos Montero, L. Rey Sánchez, L. García Lama, V. Pascual Pascual, M. A. Hernández Fructuoso; Hospital Universitari Vall d'Hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** Phosphorous-32 ($^{32}$P) microparticles are used in radionuclide therapy as a novel brachytherapy device for the treatment of unresectable locally advanced pancreatic cancer in combination with chemotherapy. Radiation protection requirements related to the preparation and administration of radionuclides in therapy are very important. $^{32}$P is a pure beta-emitter radioisotope with a physical half-life of 14.27 days. Beta particles interact with matter by collision with atomic electrons, and the radioactive process resulting in photons is known as bremsstrahlung. The maximum range of $^{32}$P beta particles in methacrylate and tungsten is 0.7 cm and 0.04 cm respectively. Thus, shielding thicker than the range has no added effect on beta radiation penetrating the shield but will attenuate the bremsstrahlung radiation produced. The aim of this study is to evaluate which shield is better to attenuate the bremsstrahlung radiation during dose preparation in order to reduce personal dosimetry. ***Materials and Methods:*** Four samples of $^{32}$P microparticles (13.4, 25.5, 45.7 and 68.2 MBq) were drawn into a 5

ml plastic syringe and placed into two different syringe shieldings: a tungsten syringe shielding (8 mm tungsten and 15 mm lead glass window) and a 10 mm methacrylate syringe shielding. Each sample equivalent dose rate was measured three times with a commercially dose rate meter (E0111280 series MiniTrace Gamma) in close contact to the shielding and at a distance of 30 cm. For each measurement, background was recorded and the results were corrected for background. ***Results:*** For the methacrylate syringe shielding, the average dose rates obtained for 13.4, 25.5, 45.7 and 68.2 MBq syringes were 0.0, 0.1, 0.1 and 0.3 µSv/h at 30 cm and 5.9, 10.7, 18.3, 30.6 µSv/h in close contact. For the tungsten syringe shield, the average dose rates obtained for 13.4, 25.5, 45.7 and 68.2 MBq syringes at 30 cm were similar to background and 0.1, 1.1, 2.0 and 3.0µSv/h in close contact. Under these conditions, tungsten shielding is 10 times more effective than methacrylate reducing dose rate in close contact for activities greater than 25.5 MBq. ***Conclusion:*** Choosing an appropriate syringe shielding is relevant during the preparation and administration of radionuclides in therapy. Compared to methacrylate shielding, our results suggest a significant reduction of radiation exposure when using tungsten shielding.

## EP-0767

### Study of yttrium-90 radiation attenuation using different types of shielding

***L. Rey Sánchez****, C. G. Franco Monterroso, B. Santos Montero, V. Pascual Pascual, L. García Lama, M. A. Hernández Fructuoso; Hospital Universitario Vall d'hebron, Barcelona, SPAIN.*

***Aim/Introduction:*** Yttrium-90 is used in hepatic radioembolization treatments at high doses, which carries a risk of irradiation for the operator during dose preparation. As a high-energy beta emitter, the use of shields with a low atomic number, plastic/aluminium, is recommended to attenuate the braking radiation (Bremsstrahlung) produced by the radionuclide. The aim of our work was to evaluate which shield is most suitable for attenuating Yttrium-90 radiation. ***Materials and Methods:*** 10 samples with increasing yttrium-90 activities were prepared in 5 ml syringe: 688.2 MBq (Syringe 1,S1), 743.7 MBq (Syringe 2, S2), 791.8 MBq (Syringe 3,S3), 1287.6 MBq (Syringe, S4), 1491.1 MBq (Syringe 5, S5), 2201.5 MBq (Syringe 6, S6), 3052.5 MBq (Syringe 7, S7), 3984.9 MBq (Syringe 8, S8), 4016.35 MBq (Syringe 9, S9) and 4306.8 MBq (Syringe 10, S10). Each sample was placed into a 13 mm thick methacrylate shielding and an 8 mm tungsten shielding with a 15 mm leaded glass window and the equivalent dose rate (µSv/h) in contact and at 30 cm with a Geiger-Müller detector (MiniTrace Gamma E0111280 series) was determined. 3 measurements were performed by syringe. ***Results:*** The mean dose rate in contact of methacrylate shielding syringes S1, S2, S3, S4, S5, S6, S7, S8, S9 and S10 was 421.1 µSv/h, 488.8 µSv/h, 713.63 µSv/h, 1042.9 µSv/h, 1076.5 µSv/h, 1594.2 µSv/h, 2324.2 µSv/h, 3066.5 µSv/h, 3202.9 µSv/h and 3642.4 µSv/h respectively while with tungsten shielding syringes was 157.8µSv/h, 175.0 µSv/h, 217.6 µSv/h, 290.4 µSv/h, 348.3 µSv/h, 483.5 µSv/h, 597.6 µSv/h, 668.8 µSv/h, 743.4 µSv/h and 778.5 µSv/h.The mean dose rate for methacrylate shielding syringes S1, S2, S3, S4, S5, S6, S7, S8, S9 and S10 to 30 cm was 10.8 µSv/h, 13.0 µSv/h, 13.99 µSv/h, 21.3 µSv/h, 25.1 µSv/h, 35.9 µSv/h, 53.8 µSv/h, 68.5 µSv/h, 71.6 µSv/h and 71.9 µSv/h respectively; versus 2.5 µSv/h, 2.8 µSv/h, 3.8 µSv/h, 4.8 µSv/h, 5.0 µSv/h, 7.6 µSv/h, 9.8 µSv/h, 13.6 µSv/h, 13.7 µSv/h and 15.4 µSv/h in tungsten shielding syringes. ***Conclusion:*** In all cases, the dose rate values were lower for tungsten-shielded syringes. Therefore, tungsten shields seem to be more suitable because they offer better radiological protection to the operator; however, methacrylate shields are more ergonomics (greater visibility and lower weight).

## EP-0768

### Evaluating the effectiveness of lead apron in a Nuclear Medicine (PET-CT) facility

***A. Shaikh****[1], R. Vatsa[1], V. Sawant[1], V. Rangarajan[2]; [1]Advanced Centre for Treatment, Research, and Education in Cancer, Navi Mumbai, INDIA, [2]Tata Memorial Centre, Mumbai, INDIA.*

***Aim/Introduction:*** Positron emission tomography-computed tomography (PET-CT) using $^{18}$F-FDG is an essential imaging modality used for staging, re-staging, disease, and response evaluation in cancer patients. A PET-CT technologist is involved in $^{18}$F-FDG dose dispensing followed by patient positioning and image acquisition which involves substantial radiation exposure. The present study aims to assess the radiation exposure of a PET-CT technologist with and without wearing lead apron while handling both $^{18}$F-FDG radiopharmaceutical and patients. ***Materials and Methods:*** A lead apron of 0.5 mm thickness, tested for leakage was used. The absorbed dose was measured by a semiconductor based calibrated electronic pocket dosimeter (dose range 1µSv-10 Sv). The average number of patient intake in the department for PET-CT imaging was 15. To measure the absorbed dose, pocket dosimeter was clipped at chest level while routinely working without lead apron and was placed inside of lead apron at same chest level while wearing lead apron. The absorbed dose readings were recorded simultaneously while dispensing $^{18}$F-FDG, monitoring injection, patient positioning, contrast administration, patient acquisition with contrast and non-contrast study. ***Results:*** A cumulative radioactivity of 294.16 mCi vs 309.92 mCi of $^{18}$F-FDG was dispensed with and without lead apron respectively. The absorbed dose of 20 µSv vs 25 µSv was observed when the $^{18}$F-FDG was dispensed with and without lead apron. was used and these exposure values were higher while working without lead apron as per the recorded data. During the contrast patient acquisition with and without lead apron, the absorbed dose observed was 28 µSv and 45 µSv respectively. The absorbed dose in case of non-contrast patient acquisition with and without lead apron was 8 µSv and 7 µSv respectively. ***Conclusion:*** The present study suggested that the use of lead apron while dispensing $^{18}$F-FDG and patient acquisition reduces the exposure. The study indicated that the use of lead apron will be beneficial in reducing the exposure to the radiation professional with maximum advantage for centres where either the patient work load in very high or the radiation professional staff is limited.

## EP-0769

### A radiation exposure comparison between manual and automated setups during GALLIUM-68 peptide labelling

***M. Costa****[1,2], R. Parafita[1,2], A. Canudo[1,2,2], A. Capacho[1], F. Silva[1], H. Delgado[1,2], J. Correia[1,2], M. Correia[1,2], M. Silva[1,2], M. Andrade[1,2], M. Machado[1], P. Ferreira[1], P. H. Ferreira[1,2], R. Oliveira[1,2], S. Batanete[1,2], S. Teixeira[1,2], V. Vieira[1,2], F. Oliveira[1], D. Costa[1]; [1]Champalimaud Foundation, Lisbon, PORTUGAL, [2]Mercurius Health, Lisbon, PORTUGAL.*

***Aim/Introduction:*** In-house production of radiopharmaceuticals with Ga-68 is a concern for radiation exposed professionals. Our aim is to compare the radiation exposure of the operator during radiopharmaceutical synthesis/production of peptides

labelled with Ga-68 using manual versus automated procedures. ***Materials and Methods:*** Two setups were evaluated: manual and automated. The manual setup used an ITM synthesis module with 36-50 mm thick lead walls containing a 50 mm lead barrier Ge-68/Ga-68 generator. Between the operator and the module, there was an "L" shaped lead barrier (60 mm thick, 360 mm wide and 470 mm tall). The automated setup had an IRE Ge-68/Ga-68 generator with an equivalent 50 mm lead barrier, installed inside a 50 mm lead hot cell. In both setups, lead containers (17 mm thick) were used to accommodate the product and waste. During the production period, the operator wore an EPD Mk2 electronic dosimeter in the chest (centered above the rib cage) to measure the effective dose received in the whole body. The effective dose was then normalized for the amount of eluted activity for each Ga-68 production, thus obtaining the exposure per MBq eluted (μSv/MBq). ***Results:*** Taking into consideration all manual and automated setups, a total of 425 and 93 measurements were registered, respectively. The median (quartiles Q1; Q3) eluted activities were 932 (733; 1158) (manual) and 611 (572; 666) MBq (automated), and the median normalized effective dose was 1.9×10^(-3) (1.1×10^(-3); 2.9 ×10^(-3)) (manual) and 1.7×10^(-3) (1.5×10^(-3); 2.4× 10^(-3)) μSv/MBq (automated). Assuming 3 daily productions and 22 days during 12 months, if all productions were performed by the same operator (worst-case scenario), then the median annual effective dose due to this task would have been 1.48 (0.83; 2.33) (manual) and 1.34 (1.19; 1.89) μSv/MBq (automated). For instance, considering 1 GBq of eluted activity, and the referred worst-case scenario, a median annual effective dose of 1.48 (manual) and 1.34 mSv (automated) is to be expected. ***Conclusion:*** Our data is quite reassuring in terms of professional exposure during radiopharmaceutical Ga-68 peptide labelling "in-house". Considering the worst-case scenario, the median annual exposure when using the manual setup and 1 GBq of eluted activity is approximately 7% of the annual effective dose limit for nuclear medicine professionals (20 mSv). Annual exposure is further reduced by using automated setup, in line with the ALARA principle. Both evaluated setups are safe, as long as, rigorous protocols are implemented and followed.

## EP-0770

### Typical values of quantities related to the patient dose from PET/CT in Bulgaria: first results

***M. Sibinova***[1], *T. K. Todorova*[2], *A. R. Zagorska*[3];
[1]*Sofia University "St Kliment Ohridski", Sofia, BULGARIA,*
[2]*National center of radiobiology and radiation protection, Sofia, BULGARIA,* [3]*Acibadem City Clinic University Hospital Tokuda, Sofia, BULGARIA.*

***Aim/Introduction:*** Positron emission tomography (PET), used in combination with computed tomography (CT) in all modern PET/CT devices is an important part of the oncologic clinical practice. These hybrid systems lead to a significant patient exposure, due to both PET and CT components. The aim of this study is to present the typical values of the quantities related to the patient dose for both imaging modalities independently and to analyze the potential of optimization. ***Materials and Methods:*** A retrospective study of typical radiation metrics for 2021[1] was carried out for nine out of ten Nuclear medicine departments in Bulgaria. Data was collected about the equipment manufacturer and model of the PET/CT device, type of examination, patient age, weight and height, and administered activity per body weight (for the PET part), $CTDI_{vol}$ and DLP (for the CT part) for at least 20 patients per modality for oncology PET/CT examinations. ***Results:*** The typical values for radiation metrics are as it follows: administered activity per body weight: 2.6 (2-3.95), 0.5 MBq.kg-1, CTDIvol: 2.7 (2.5-14.1), 3.8 mGy and DLP: 278 (235-1578), 436 mGy.cm. Median, minimum and maximum in parenthesis, standard deviation values are presented. The highest presented value for the administered activity is for the oldest PET/CT scanner. The results show that the typical CTDIvol values are five-fold higher than the median values. ***Conclusion:*** This study is the first to present and to analyze typical doses from different PET/CT imaging modalities in Bulgaria. The typical values for the administered activity per weight seem to be very well optimized in all Nuclear medicine departments that participated in the current study. Unlike the nuclear medicine part of the examination, there is a significant variation in the typical CT radiation exposure. There is a potential of optimization and an effort must be done in order to optimize the used CT protocols.

## EP-0771

### Radiation Dose Reduction Strategy for SPECT/CT Bone Scan

***M. Alezzi***[1], *O. Kotbi*[1], *G. Hammid*[1], *A. Fouda*[1], *Y. Zabarmawi*[2];
[1]*KING ABDULLAH MEDICAL CITY, Makkah, SAUDI ARABIA,*
[2]*Umm Al-qura University, Makkah, SAUDI ARABIA.*

***Aim/Introduction:*** The aim of this study is to introduce the optimization method of CT parameters to reduce patient radiation exposure in bone SPECT/CT while maintaining image quality. The results of the new protocol were then compared to the results of the standard protocol saved in the nuclear medicine department`s data at King Abdullah Medical City. ***Materials and Methods:*** First part: Using Deluxe Jaszczak Phantom. The cylindrical phantom consisted of six bottles in a pie arrangement. These bottles were placed in the source tank. SPECT/CT scans were carried out with different x-ray tube current values at three different slices of thicknesses (2.5, 3.75, and 5mm). The contrast ratio (CR) and coefficients of variation (COV) in the SPECT images as well as the signal-to-noise ratio (SNR) and CTDIvol were all measured. Second part: The study was done on patients who required a SPECT/CT bone scan of the spine area (thoracic spine (T1-T12) and lumbar spine (L1-L5)). Some patients were excluded from this study because of the image quality that was affected by several factors. Different parameters obtained from the new reduced protocol were compared to old historical data saved in the system for patients who did the same image using the old standard protocol. The difference between the two systems was only in the current of the X-ray tube (the old 60 mA versus the new 40 mA). ***Results:*** The optimal set of parameters for bone SPECT/CT was determined based on a phantom part that has been implemented in clinical practice. Two groups of patients were examined according to the baseline and optimized protocols, respectively. The new SPECT/CT protocol substantially reduced patients' radiation exposure as compared to the old protocol, while also maintaining the required diagnostic quality of SPECT and CT images. ***Conclusion:*** The newly established bone scan SPECT/CT protocol was implemented into clinical practice. It has significantly reduced patients' exposure dose as compared to the old protocol while maintaining the required diagnostic quality of SPECT and CT images. ***References:*** 1. ## EP-0772

### Radiation safety during 177-Lu labellingand therapy: experience in Bulgaria

***A. Zagorska***;
*Acibadem City Clinic University Hospital Tokuda, Sofia, BULGARIA.*

***Aim/Introduction:*** The application of 177-Lu for radioligand therapy is growing worldwide. Special attention must be paid during treatment center design to radiation protection due to the physical characteristics of 177-Lu. The aim of this study is to present our experience and lessons learned in the field of radiation protection in 177-Lu labelling and treatment of patients with 177-Lu. ***Materials and Methods:*** Relevant published national and international recommendations were reviewed. The efficacy of available lead aprons (0.5 mm Pb), four types of vial shielding, and 2 mm lead equivalent screen was investigated regarding radiation protection when handling 177-Lu. Measurements were performed with an Atomtex AT 1123, calibrated in ambient dose equivalent, H*(10), mSv. ***Results:*** For educational purposes and with the support of the IAEA, online training on radiation protection for patients, staff and the public during Lu-177-based radiopharmaceutical therapy was organized. National legislation and the ALARA concept require the preparation of detailed radiation safety protocols. 1) Public: Kurt at al [1] method was used and a patient release criterion of 30 µSv/h at 1 m. Restrictions were proposed to limit radiation exposure to household members of patients and the public. 2) Staff: Nurses and radiochemists were identified as having a higher potential of contamination and external exposure. To avoid unnecessary staff exposure and to facilitate communication with the patient during treatment, 2 mm transparent lead equivalent screen was installed in the patient room. The patient dose rate was attenuated approximately 90% by the lead screen. The attenuation coefficients for 177-Lu of vial shielings were calculated to be between 100 and 1000 times depending on the composition and thickness of the material. The attenuation of available lead aprons was approximately 50 %. In addition to the regular radiation protection training, a dedicated training was organised to cover physical properties of 177-Lu, the effectiveness of shielding and special cases in radionuclide therapy such as extravasation and actions in case of extravasation. 3) Patient: to ensure patient safety, video monitoring was provided. ***Conclusion:*** Two of the available vial shieldings do not provide the required level of protection. The available aprons can be used during 177-Lu treatment. Team training and teamwork are very important to ensure radiation protection of patient and staff. ***References:*** Kurth J, Krause BJ, Schwarzenbock SM, et al. ### Monte Carlo quantification damage by 64Cu incorporate in DNA

***J. Carrasco***, *E. Padilla;*
*Instituto de Ciencias Nucleares, CDMX, MEXICO.*

***Aim/Introduction:*** Topas-nBio was used to calculate DNA damage (Double Strand Breaks) for Auger emitters (AEs) including Cu-64 of interest in Targeted Radionuclide Therapy, when are incorporated in DNA genome of a mammalian cell nucleus. ***Materials and Methods:*** Calculations of DSBs for five AEs $^{125}$I, $^{123}$I, $^{111}$In, $^{99m}$Tc and $^{64}$Cu have been performed by incorporating the AE in DNA genoma of a nucleus of 9.3 um diameter, density 14 Mbp/mm$^3$ and 6.08 Gbp. The Topas-nBio Monte Carlo tool was employed for simulating collision-by-collision the complete trajectories of electron tracks in liquid water when the AE was placed in two configurations off the central axis of DNA: 0.25 nm and 1.15 nm. For all the considered radionuclides, with exception of $^{99m}$Tc, the physical decay process was explicitly simulated with the G4RadiactiveDecay module from Geant4, whereas for $^{99m}$Tc the energies and yields of the Auger electron spectrum were obtained from published data. The DSB yields per decay incorporated in DNA for $^{64}$Cu are firstly reported in this work. ***Results:*** Monte Carlo simulations of DNA damage with Topas-nBio reveal that, the calculated DBS yields for $^{64}$Cu incorporated in genome are 0.171 and 0.190 per decay for 0.25 and 1.15 nm off the DNA central axis, respectively. DSB Yields per decay for $^{111}$In, $^{125}$I, $^{123}$I, $^{99m}$Tc were compared with reported calculated or measured data for validation purposes. ***Conclusion:*** Our results show that $^{64}$Cu may have therapeutic effects in tumor cells when combined with Targeted Radionuclide Therapy. ***References:*** Schuemann, J., McNamara, A. ## EP-0774

### Evaluation of Repeatability of 177Lu Quantitative Imaging Using Monte Carlo Simulation

***K. Ishikawa***[1], *C. Kubota*[1], *Y. Yasumoto*[1], *T. Sakashita*[2], *H. Daisaki*[1];
[1]*Gunma Prefectural College of Health Sciences, Gunma, JAPAN,* [2]*National Institutes for Quantum Science and Technology, Gunma, JAPAN.*

***Aim/Introduction:*** Good repeatability of quantitative values is necessary for accurate dosimetry using $^{177}$Lu imaging. While there are research papers on quantitative accuracy, there have been no reports to date on the repeatability of quantitative values. The purpose of this study is to identify optimal imaging conditions for achieving good repeatability in $^{177}$Lu imaging. ***Materials and Methods:*** A NEMA body phantom was digitally created to mimic imaging of tumors in the liver at 6 hours after 7.4 GBq of $^{177}$Lu (Hot=1.85, BG=0.201 MBq/mL) [1]. Pseudo-projection data (30 projections per condition) assuming a GE Discovery NM/CT 670 scanner were generated under several imaging conditions using the SIMIND program (Lund University) and the digital phantom. Acquisition conditions were as follows: 1) MEGP or ELEGP collimator, 2) main window with 113 keV±10% or 208 keV±10%, 3) upper and lower sub-energy window with 10 keV width, and 4) scan duration with 2.5 min, 5.0, and 7.5 min/60 projection. SPECT images were reconstructed by ordered subset expectation maximization (OSEM) method (3 iterations, 10 subset) after scatter correction (Triple Energy Window method), attenuation correction (Chang method), and noise reduction by Butterworth filter (cut-off frequency; 0.50 cycles/cm) using Prominence Processor Ver3.1 [2]. The SPECT images were converted to Bq/

mL units by applying the Bq calibration factor calculated from simulated Pool phantom images using RAVAT (Nihon-Medi Physics). The repeatability was evaluated by the coefficient of variation (CV: %) of VOIs placed in the BG region (n=12) and each hot sphere. For comparison of CVs in the BG region, one-way ANOVA test was used to confirm the significance, and then the Tukey's test was used for multiple comparisons. A $p<0.05$ was considered statistically significant. ***Results:*** The repeatability of the quantitative values decreased as the hot spheres became smaller. The CV of the BG region in the ELEGP+208 keV condition was significantly lower than the other three conditions ($p<0.05$). The CV can be improved by increasing the scan duration. The scan duration to achieve CV<5% were 2.5 min for ELEGP+208 keV, 5.0 min for MEGP+208 keV, 7.5 min for ELEGP+113 keV, and not achieved for MEGP+113 keV. ***Conclusion:*** The repeatability of quantitative values depends on the combination of collimator, energy window setting, and scan duration. Superior repeatability of quantitative values can be obtained by using ELEGP+208 keV imaging conditions. ***References:*** [1] Annals of Nuclear Medicine (2021) 35:823-833. [2] http://nm.jsrt.or.jp/blog.html

## EP-0775

### Preclinical in vivo tumour dosimetry of a Lu-177-labelled ligand using a gamma probe

***A. Klotsotyra***[1], *D. Arbuznikova*[1,2,3], *N. Steinacker*[1,2], *L. Domogalla*[1,2], *A. Eder*[1,2], *M. Mix*[1];
[1]*Department of Nuclear Medicine, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [2]*Division of Radiopharmaceutical Development, German Cancer Consortium (DKTK), partner site Freiburg, Freiburg, Germany and German Cancer Research Center, Heidelberg, GERMANY,* [3]*Department of Radiation Oncology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY.*

***Aim/Introduction:*** Lu-177-PSMA-617 is widely used in prostate cancer (PCa) therapy and has recently been approved by FDA and EMA. In this study we established a workflow for tumour absorbed dose (TAD) determination in cancer xenografts of nude mice using a gamma probe. ***Materials and Methods:*** 17 mice with implanted LNCaP xenograft tumours were treated with Lu-177-PSMA-617 (G1: n=8, 21.0 ± 7.0 MBq and G2: n=9, 44.7 ± 4.5 MBq). A gamma probe was used to measure tumour and body background (BG) counts per second (CPS), for two weeks p.i. A monoexponential fit was used to determine the BG corrected time-activity curves. Effective half-life ($T_{1/2,eff}$) was computed for each mouse. Tumour size was measured 3 times with a caliper (beginning, middle and end of experiment). For the tumour volume (TV) calculation, tumours were considered as ellipsoids. To determine the calibration factor (CF) for the gamma probe (kBq/CPS), tumours from 4 sacrificed mice were measured with the gamma probe and then in the gamma counter. The CF was derived from the average of all measurements. The tumour absorbed dose rate was tallied according to MIRD formalism using S values for spherical tumours, as an approximation of the ellipsoidal tumours. Correction for time dependent TV was done with absorbed fraction of the full Lu-177 beta-spectrum. TAD for each mouse was computed by integrating the dose rate curve until the end of experiment. Mann-Whitney U-test was used for the statistical analysis of the results at significance level of 5%. ***Results:*** Average TV 3 h p.i. and $T_{1/2,eff}$ were 0.12 ± 0.03 mL and 93.8 ± 13.5 h for G1 and 0.08 ± 0.03 mL and 86.7 ± 8.8 h for G2 respectively. The error of the dose rate curves fitting parameter (λ) was 7.8%. CF for the gamma probe was 0.6 kBq/CPS with 23% standard deviation. The average TAD during the experiments was for G1 0.12 ± 0.02 Gy/MBq and for G2 0.42 ± 0.18 Gy/MBq. Our study revealed a statistically significant difference for TV and TAD in the two groups, although for the $T_{1/2,eff}$ there is no significant difference. ***Conclusion:*** Simple gamma probe measurements can be reliable for TAD estimation in preclinical experiments with Lu-177-labelled ligands. Main error sources are the CF for the gamma probe and the caliper-based TV measurements. Overall accuracy of the method will be increased with ongoing optimization of gamma probe measurements and CF determination.

## EP-0776

### Evaluation of the quantitative accuracy using Monte Carlo simulations in 177Lu imaging

***C. Kubota***[1], *K. Ishikawa*[1], *Y. Yasumoto*[1], *T. Sakashita*[2], *H. Daisaki*[1];
[1]*Gunma Prefectural College of Health Sciences, Gunma, JAPAN,* [2]*National Institutes for Quantum Science and Technology, Gunma, JAPAN.*

***Aim/Introduction:*** High quantitative accuracy in $^{177}$Lu imaging is necessary for accurate dosimetry. Appropriate correction and quantification methods in $^{177}$Lu imaging have not been established. The purpose of this study was to validate the accuracy of the $^{177}$Lu imaging quantification process using Monte Carlo (MC) simulations. ***Materials and Methods:*** Noiseless pseudo-projection data were generated using the SIMIND and two types of digital phantoms (cylindrical and NEMA body phantom). Cylindrical phantoms were used to confirm the accuracy of scatter and attenuation corrections (AC) and to calculate the Bq calibration factor (BCF), while NEMA body phantoms were used to validate the accuracy of activity quantification. Imaging conditions of cylindrical phantom were as follows: 1) MEGP or ELEGP collimator, 2) 113 keV ± 10% or 208 keV ± 10% main window, 3) upper and lower sub-windows with 10 keV width, 4) scan durations with 5.0 min / 60 projections. Projection data were corrected for scattered radiation using TEW method after Butterworth filtering (0.22 cycles/cm) for projection data of sub-windows. Image reconstructions were performed by OSEM with Chang's AC after Butterworth filtering (0.50 cycle/cm). The μ value for Chang's AC was determined to be the value that minimizes the coefficient of variation of the profile curve between 0.10 and 0.20 $cm^{-1}$. BCFs were calculated using the cylindrical phantom. SPECT images of the NEMA body phantom simulating $^{177}$Lu activity with Hot=1.85 and BG=0.20 MBq/mL were reconstructed using appropriate corrections (this simulates tumors in the liver imaged 6 hours after administration of 7.4 GBq of $^{177}$Lu). VOIs were placed in the BG region and Hot sphere to measure the activity and evaluate the accuracy. ***Results:*** Uniform profile curves were obtained by 0.22 cycles/cm for Butterworth filtering of the sub-window and μ values of 0.16-0.17 $cm^{-1}$ at 113 keV and 0.14 $cm^{-1}$ at 208 keV for Chang's AC. The quantification accuracy of BG was within ±5%, and quantification was possible using appropriate imaging conditions and BCFs. The activity of Hot spheres was underestimated by -34 to -28% at 37 mm, -43 to -36% at 28 mm, -52 to -44% at 22 mm, -70 to -64% at 17 mm, -76 to -70% at 13 mm, and -81 to -79% at 10 mm. ***Conclusion:*** MC simulations are useful for validating appropriate imaging conditions and can estimate the accuracy of quantitative values. The agreement between phantom experiments and MC simulations using $^{177}$Lu should be carefully verified in the future.

### EP-0777

**IDAC-Dose 2.2. An internal dosimetry software for diagnostic nuclear medicine using the ICRP computational framework and calculation of the absorbed dose and effective dose to all 12 ICRP reference individuals**

***M. Andersson***[1,2], *K. Eckerman*[3], *S. Mattsson*[2];
[1]*Department of Medical Radiation Sciences,Institute of Clinical Sciences, Sahlgrenska Cancer Center, Gothenburg, SWEDEN,* [2]*Medical Radiation Physics, Malmö, Malmö, SWEDEN,* [3]*Center for Radiation Protection Knowledge, Oak Ridge National Laboratory, Oak Ridge, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Estimations of the radiation-absorbed dose to organs and tissues for patients investigated with radiopharmaceuticals are derived via calculations based on models of the human body and the biokinetic behaviour of the radionuclide. The ICRP estimates of absorbed dose in organs and tissue and the effective dose to patients from various radiopharmaceuticals were in ICRP Publ.128 derived using the computer program Internal Dose Assessed by Computer (IDAC)1.0. To improve the accuracy of the calculations, ICRP has adopted a new computational framework using more realistic voxel phantoms to incorporate in Monte Carlo simulating the energy transport and absorption of photons,electrons and alphas. Together with the new computational framework, ICRP has also updated the effective dose methodology. Therefore, has the internal dosimetry computer program, IDAC-Dose, now been substantially upgraded (IDAC-Dose2.2) and incorporates now absorbed dose and effective dose calculations for all the ICRP reference individuals (male and female of adults,15-yrs,10-yrs,5-yrs,1-yr and 100 days old). ***Materials and Methods:*** With IDAC-Dose2.2 it is possible to calculate the dose from 1252 different radionuclides. The software uses the latest biokinetic models and assumptions of the ICRP TG-36, and includes also the latest tissue weighting factors from ICRP Publ.103. The IDAC-Dose2.2 has 83 source regions where activity can be placed and calculates the mean absorbed dose to 43 different organs and tissues. It is also possible to interpolate the organ doses by weight and age interpolations between the ICRP adult and newborn reference phantoms. IDAC-Dose2.2 was applied on two frequently used radiopharmaceuticals: 2-[18F]FDG and $^{99m}$Tc-pertechnetate. ***Results:*** The absorbed doses and effective dose of $^{99m}$Tc-pertechnetate determined by IDAC-Dose2.2 were compared with the results of the dosimetry program DCAL,showing identical results. IDAC-Dose2.2 was used to calculate absorbed doses for 2-[$^{18}$F]FDG and $^{99m}$Tc-pertechnetate. The effective dose per administered activity was estimated for the adult phantoms to be 0.016mSv/MBq for 2-[$^{18}$F]FDG and 0.014mSv/MBq for $^{99m}$Tc-pertechnetate. ***Conclusion:*** IDAC-Dose2.2 is the main ICRP software for effective dose in diagnostic nuclear medicine. The results from other software, using the same primary data (e.g. ICRP SAF-values and decay data) may differ from the results of IDAC-Dose2.2 if the former do not follow the ICRP computational framework for the absorbed dose calculations. The IDAC-Dose2.2 software is a free software for research and available at www.idac-dose.org. The online version can be operated directly through a web browser and the standalone version is an executable file, which is downloaded and installed directly on the local computer.

### EP-0778

**IDAC-ALPHA: AN online ALPHA DOSIMETRY SOFTWARE FOR NORMAL ORGANS And TISSUES**

***M. Andersson***[1,2], *S. Mattsson*[2];
[1]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Cancer Center, Göteborg, SWEDEN,* [2]*Medical Radiation Physics, Malmö, Malmö, SWEDEN.*

***Aim/Introduction:*** Radiopharmaceuticals are used for the treatment of various cancers since the 1940s. In recent years, the benefit of alpha-emitting radionuclides has emerged as a favourable treatment option. However, most alpha-emitting radionuclides have long decay chains with long-lived daughter radionuclides. This leads to uncertainties in the dosimetry for both tumour tissue and healthy organs and tissues when established dosimetry models are used. Since it is not always possible to image or measure organ- and patient-specific activities of all daughter products to radionuclides used for alpha radiation therapy, one solution might be to also consider generic reference values for dosimetry to improve the accuracy of the dosimetry. ***Materials and Methods:*** IDAC-Alpha [1] has been updated with a new curve fitter, to more accurately predict uptake in organs and tissues and incorporate the biokinetic transfer of daughter elements with regard to the parent uptake. The software now includes $^{227}$Th, $^{225}$Ac, $^{224}$Ra $^{223}$Ra, $^{212}$Bi, $^{213}$Bi, $^{212}$Pb and $^{149}$Tb, and consider also the individual biokinetics of all daughter radionuclides The dosimetry software was applied to a dataset of patients treated with $^{223}$Ra-dichloride [2]. In this dosimetry model, individual biokinetics for each daughter radionuclide was considered. The results were compared with those of a dosimetry model in which the daughter radonuclides are assumed to follow the biokinetics of the parent radionuclide. ***Results:*** Inclusion of element-specific transfer of daughter radonuclides in the biokinetic model for $^{223}RaCl_2$ results in a decrease in absorbed dose of 14% for bone surfaces and 18% for bone marrow, compared with assuming that all daughter radionuclides decay in the same position as the parent nuclide. The decrease is due to a lower activity uptake of the daughter radionuclides in bone compared to the parent nuclide radium. ***Conclusion:*** The software includes separate transfer of the various progenies. Inclusion of the biokinetics of the progeny elements allows better estimation of the absorbed dose and better prediction of radiotoxicity in normal tissue. The IDAC-Alpha software is a software for research and available at www.idac-dose.org. The online software can be operated directly through a web browser. ***References:*** 1)Andersson, M. et al, IDAC-Alpha: An alpha dosimetry software for normal organs and tissues, Radiat.Prot. **Dosimetric model for patients with renal failure undergoing dialysis during I-131 therapy for thyroid cancer**

***V. Nuttens***, *O. De Winter;*
*OLVZ, Aalst, BELGIUM.*

***Aim/Introduction:*** Adapted dosing for renally cleared medicine is commonly used for hemodialysis patients. This study aims to create an easy-to-use dosimetric model that can estimate the

to-be-administered activity to a patient for I-131 therapy who has almost to no renal clearance. ***Materials and Methods:*** Based on literature values [1] [2] renal clearance estimates were used to determine time activity curves. Dialysis in the simulation takes place 42h and 90h after administration of the I-131 capsule and gives rise to a stepwise decrease in activity on the dialysis moments. The time-integrated activity (TIA-ratio) is defined as $\tilde{A}_{dialysis}/\tilde{A}_{normal}$ and gives a measurement of the dose for the patient with dialysis compared to a patient with healthy kidneys [3] with recombinant human thyroid-stimulating hormone stimulation or thyroid hormone withdrawal. ***Results:*** A 50% reduction of administered activity corresponds to a TIA-ratio of 1.2 [1.124, 1.305]. 100% of the activity for normal patients results in a TIA-ratio of 2.4 [2.248, 2.611. Therefore, a 50% dose reduction is recommended for the chosen dialysis scheme. ***Conclusion:*** The dosimetric model can compare the radiation dose for a hemodialysis patient to a normal patient. Furthermore, it can be seen that careful consideration of the administered activity and dialysis scheme is needed when considering I-131 therapy for patients with almost to no renal clearance; the blood pool activity stays high for a longer time and can therefore result in a high dose to the bone marrow.Further work will include validation of the model with blood sample and whole body dose rate measurements. ***References:*** [1] Holst JP, Burman KD, Atkins F, Umans JG, Jonklaas J. Radioiodine therapy for thyroid cancer and hyperthyroidism in patients with end-stage renal disease on hemodialysis. Thyroid. 2005 Dec;15(12):1321-31. doi: 10.1089/thy.2005.15.1321. PMID: 16405403. ## EP-0780

### Comparative analysis of positron-emitters for theranostic applications based on small bioconjugates

***C. Morgat***[1,2], *U. Köster*[3], *C. Champion*[4], *P. Zanotti-Fregonara*[5], *E. Hindié*[1,2,6];
[1]*Nuclear Medicine Department - University Hospital of Bordeaux, Bordeaux, FRANCE,* [2]*University of Bordeaux, UMR CNRS 5287, INCIA, Bordeaux, FRANCE,* [3]*Institut Laue Langevin, Grenoble, FRANCE,* [4]*University of Bordeaux, CNRS, CEA, CELIA, UMR 5107, Talance, FRANCE,* [5]*Molecular Imaging Branch, National Institute of Mental Health, Bethesda, MD, UNITED STATES OF AMERICA,* [6]*Institut Universitaire de France, Paris, FRANCE.*

***Aim/Introduction:*** Targeted radionuclide therapy (TRT) with $^{177}$Lu-labelled small conjugates is expanding rapidly. Appropriate patient selection conditions the success of TRT. Companion diagnostic conjugates are usually labelled with $^{68}$Ga offering good imaging up to ≈2h post-injection with conventional Positron Emission Tomography (PET) scanners. However, the optimal tumor-to-background ratio is often reached later. This work examines some promising positron-emitting radiometals with half-lives between 3h to 24h and $\beta^+$ intensity ($I_{\beta+}$) ≥ 15%: $^{43}$Sc, $^{44}$Sc, $^{45}$Ti, $^{55}$Co, $^{61}$Cu, $^{64}$Cu, $^{66}$Ga, $^{85m}$Y, $^{86}$Y, $^{90}$Nb, $^{132}$La, $^{150}$Tb and $^{152}$Tb. Also, $^{133}$La (7.2% $I_{\beta+}$) has been added because it has been discussed recently, together with $^{132}$La, as a possible diagnostic match for $^{225}$Ac. Comparisons with $^{68}$Ga were made. ***Materials and Methods:*** We compared total electron and photon doses per decay and per positron, possibly interfering prompt γ-ray emission, typical activities to be injected for imaging for same day or next day measurement, positron range, as well as available production routes ***Results:*** For each annihilation process useful for PET imaging, the total energy released (MeV) is: $^{45}$Ti (1.5), $^{43}$Sc (1.6), $^{61}$Cu and $^{64}$Cu (1.8), $^{68}$Ga (1.9), $^{44}$Sc and $^{133}$La (2.9), $^{55}$Co (3.2), $^{85m}$Y (3.3), $^{132}$La (4.8), $^{152}$Tb (6.5), $^{150}$Tb (7.1), $^{90}$Nb (8.6) and $^{86}$Y (13.6). Significant amounts (≥10%) of ≈0.5 MeV photons that may fall into the acceptance range of PET scanners are emitted by $^{55}$Co, $^{66}$Ga, $^{85m}$Y, $^{86}$Y, $^{132}$La and $^{152}$Tb. Compton background from more energetic photons is expected for $^{44}$Sc, $^{55}$Co, $^{66}$Ga, $^{86}$Y, $^{90}$Nb, $^{132}$La,$^{150}$Tb and $^{152}$Tb. The mean positron range (mm) of $^{64}$Cu (0.6), $^{85m}$Y (1.0), $^{45}$Ti (1.5), $^{133}$La (1.6), $^{43}$Sc and $^{61}$Cu (1.7), $^{55}$Co (2.1), $^{44}$Sc and $^{86}$Y (2.5) and $^{90}$Nb (2.6) are lower than $^{68}$Ga (3.6). DOTA chelation is applicable for most discussed radiometals, though not ideal for $^{61}$Cu/$^{64}$Cu, while $^{45}$Ti and $^{90}$Nb require different complexing agents (e.g. DFO). Overall $^{43}$Sc, $^{45}$Ti and $^{61}$Cu have excellent properties and can be economically produced by proton-induced reactions at medical cyclotrons. ***Conclusion:*** In particular $^{43}$Sc, $^{45}$Ti and $^{61}$Cu have overall excellent $\beta^+$ decay-characteristics for theranostic applications complementing $^{177}$Lu-labelled small conjugates and can be sustainably produced. $^{43}$Sc and can be labelled with DOTA just as Lu, but $^{45}$Ti requires different chelates and for $^{61}$Cu this is preferable too.

## EP-0781

### Dosimetry and External Radiation Exposure in 177Lu-PSMA-617 Radioligand Therapy. The INT Pascale Experience

***L. D'Ambrosio****, V. Pirozzi Palmese, C. Maisto, R. de Marino, M. Aurilio, A. Morisco, V. Porfidia, C. Traino, R. De Migno, M. Raddi, F. De Lauro, F. Di Gennaro, S. Lastoria;*
*National Cancer Institute IRCCS Pascale, Naples, ITALY.*

***Aim/Introduction:*** $^{177}$Lu-PSMA-617 radioligand therapy is a promising treatment for patients with metastatic castration resistant prostate cancer (mCRPC). A standard activity of 7.4 GBq at six weeks intervals for a total of four to six cycles is the standard regimen. We present our dosimetric protocol to measure organs at risk absorbed dose and relevant parameters to define radiation protection and safety necessities. In 23 patients dose evaluation of kidneys, parotid and submandibular glands was performed. ***Materials and Methods:*** The protocol includes the infusion of a 10% mannitol solution as protector agent and an external ice pack cooling strategy was used to reduce blood flow supply to salivary glands before therapy. SPECT-TC images were acquired at different times post injection (2.5 h, 20 h, > 90 h pi). The activity concentration in kidneys, parotid glands (PGs) and submandibular glands (SMs) was determined by a commercial software and the absorbed dose was obtained using residence time and personalized organ masses as input data for the OLINDA/EXM® software. Measurements with external probe at different time points (before any excretion, after first voiding bladder and at 1, 1.5, 4, 20, > 90 h pi) were performed to collect the radiation contribution of the entire body and to estimate the activity within the body of the patient. The retention of $^{177}$Lu-PSMA was modelled on a bi-exponential decay process with As and Al the constants of the short and long components and λs and λl the effective decay constants. Dose rates at 1 m at discharge (20 h pi) were measured to determine appropriate radiation precautions to be followed in order to comply with national law. ***Results:*** The mean absorbed dose was 0,11-0,58 Gy/GBq (mean 0,31 Gy/GBq)

for kidneys, 0,16-1,8 Gy/GBq (mean 0,62 Gy/ GBq) for PGs and 0,09-2,2 Gy/GBq (mean 0,58 Gy/GBq) for SM. Our data showed that absorbed dose (Gy/GBq) in OARs appeared to decrease in the next cycles. The mean retention constants As and Al and mean effective half-lives of the short and long component were 0.46, 0.53 and 5.9 h, 74.9 h respectevely. Mean exposure rate at 1 m at discharge was 9.6 microSv/h (4.0-18.5 microSv/h). ***Conclusion:*** Our experience indicates that dosimetry can be easily realized in routine practice if the patients are compliances and the results are similar to previously published papers. We are evaluating absorbed dose to lesions in order to correlate it with the clinical response.

## EP-0782

### Partial volume correction on Lu-177 PSMA-617 parotid gland dosimetry

***G. Mok***[1], *Z. Lu*[1], *G. Chen*[1], *Y. Liu*[1], *A. Afshar-Oromieh*[2], *A. Rominger*[2], *K. Shi*[2];
[1]*University of Macau, Taipa, MACAO,* [2]*University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Parotid gland (PG) highly affects patient's life quality, and thus is a dose-limiting organ in $^{177}$Lu-PSMA-617 therapy. Its activity quantification and subsequent dosimetry are subjected to large errors particularly due to partial volume effect (PVE), which manifests when the object size is about 2-3 times of the system resolution as in the case of $^{177}$Lu-SPECT imaging (8-10 mm) of PG (mean 3.4 cm). This study aims to apply partial volume correction (PVC) on post-therapeutic sequential $^{177}$Lu-PSMA images for personalized PG dosimetry. ***Materials and Methods:*** Sequential quantitative SPECT/CT images at 2, 20, 40 and 60 (n=5)/200 (n=5) h after 6.0-8.0 GBq $^{177}$Lu-PSMA-617 injection with full corrections were analyzed retrospectively for 10 patients in 10 treatment cycles (first:forth:fifth cycle=8:1:1). CT images at latter time points were rigidly registered to those at the first time point [1] focusing on the head. PVC was performed on SPECT images using the reblurred van-cittert deconvolution method [2] based on the reported system resolution [3]. The resultant deformed vectors were then used to align the corresponding SPECT images. The voxel-S-value for soft tissues with density correction was applied on the registered SPECT images to generate dose rate maps. Segmentations of PG were based on the exact CT and expanded CT maps with 1 cm extra margin separately [4]. Median and $D_{50}$ PG absorbed dose was obtained using bi-exponential voxel-based curving fitting and integration. ***Results:*** PG was clearly visualized and separated from the adjacent high uptake regions after PVC on SPECT images at all time points. The median PG absorbed dose was 0.34 and 0.22 Gy/GBq after and before PVC for the exact segmentation, and 1.05 and 0.89 Gy/GBq for the expanded segmentation respectively. The median $D_{50}$ absorbed dose was 2.61 and 1.65 Gy after and before PVC for the exact segmentation, and 1.16 and 0.97 Gy for the expanded segmentation respectively. ***Conclusion:*** PG absorbed dose is generally underestimated by PVE in $^{177}$Lu-PSMA-617 therapy, and can be effectively restored by PVC. Segmentation on the expanded map is suggested even PVC is applied to fully cover the PG activity. The median PG absorbed dose is increased by ~60% after PVC. PVC is important for PG dosimetry in $^{177}$Lu-PSMA-617 therapy. ***References:*** [1] Klein et al., IEEE TMI 29.1 (2009): 196-205.[2] Thomas et al., PMB 61.22 (2016): 7975.[3] Huizing et al., J. Appl. Clin. Med. Phys. 21.9 (2020): 272-277.[4] Violet et al., JNM 60.4 (2019): 517-523. Research support: FDCT 0099/2021/A

## EP-0783

### A new approach for individual dose monitoring in Molecular Radionuclide Therapy

***R. Mirabelli***[1], *L. Campana*[1], *B. Cassano*[2], *F. Collamati*[3], *R. Faccini*[1], *G. Iaccarino*[2], *C. Mancini Terracciano*[1], *S. Morganti*[3], *F. Nicolanti*[1], *M. Pacilio*[4], *A. Soriani*[2], *E. Solfaroli-Camillocci*[5];
[1]*"Sapienza" - Università di Roma, Rome, ITALY,* [2]*IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [3]*National Institute of Nuclear Physics, Rome, ITALY,* [4]*Azienda Ospedaliera-Universitaria Policlinico Umberto I, Rome, ITALY,* [5]*Bambino Gesu` Children's Hospital, Rome, ITALY.*

***Aim/Introduction:*** A systematic measurement of the activity distribution in the body for patients undergoing Molecular Radionuclide Therapy (MRT) would enable treatment improvements and individualization of the activity to be administered. A treatment personalization could increase the local control, while sparing healthy tissues and lowering toxicity. Furthermore, current European regulation (EU Directive 59/2013) considers mandatory the treatment planning and verification in all patients undergoing radiotherapy procedures, including MRT. However, it is not an easy task, since the dose absorbed to tissues depends on several interconnected key factors and the uptake and excretion largely fluctuate from patient to patient. ***Materials and Methods:*** A new approach for individual radioagent biokinetics determination is proposed with the Wearable Individual Dose Monitoring Apparatus (WIDMApp). The WIDMApp system is conceived as a wearable multi-channel detector system for in-vivo radiation detection, a MC simulation for particle interaction and a data analysis tool to deconvolve the activity distribution and its evolution over time in different organs (i.e., time- activity data) [1]. This system could provide an effective tool to characterize more accurately the radiopharmaceutical biokinetics in MRT patients, reducing the need of resources of nuclear medicine departments, such as technologist and scanner time, to perform individualized biokinetics studies. Different studies have been carried out as proof-of-principles of the system. In the first Monte Carlo feasibility studies simulating a MIRD anthropomorphic phantom and in the first experimental feasibility study with an anthropomorphic phantom, combining the simulated results with the data acquired, the unfolding algorithm deconvolved the detected signals and it has been able to assess the decay half-lives that best reproduce the observed exponential decays. ***Results:*** The WIDMApp system has been resulted effective in deconvolving the cumulative detected signal into contributions from different emitting volumes. The results obtained from the first phantom feasibility study and from a Monte Carlo simulation of the system justify the development of an actual prototype to characterize this technique under realistic clinical conditions. ***Conclusion:*** The proof-of-principle of WIDMApp showed that reconstruction of the individual biokinetics using small portable detectors is in principle possible. The relatively simple hardware for the approach proposed would allow its application to large numbers of patients. Taking advantage of the data sampling more frequent than conventional biokinetics studies, the WIDMApp system can be an effective tool for the time-activity trend determination in lesion and organs at risk of toxicity, fully characterizing the accumulation, the uptake and the retention. ***References:*** [1] 10.1002/mp.15311

## EP-0784

### 131I and 177Lu Voxel Dosimetry: characterization, verification and preliminary patient results

***E. Richetta***, *C. Valero, B. Elia, V. Pirro, M. Manfredi, R. Pellerito, M. Stasi;*
*Ordine Mauriziano Hospital, Turin, ITALY.*

***Aim/Introduction:*** Voxel dosimetry software are effective tools for exposure verification after radionuclide therapies, as required by radiation protection regulations, still rarely used in the clinical practice. Aim of this work is to investigate calibration methods, in order to define the best dosimetric protocol. ***Materials and Methods:*** A commercial voxel dosimetry software ($^{131}$I and $^{177}$Lu) was installed for SPECT-CT imaging calculations (3 time-points, 10IT-8SUB, attenuation and scatter corrected) performed with two equipment (NaI detector I:3/8', B:5/8'). The quantitative calibration was performed with a homogeneous phantom (9355 ml) filled with high activity $^{131}$I (2940 MBq - $^{177}$Lu 3681 MBq). Calibration factors (cps/MBq) were obtained and dead time effects investigated. Doses were calculated with different voxel kernels ($^{177}$LuLanconelli 3mm7x7x7, $^{177}$LuGraves 2.3mm353x353x353, $^{177}$LuMCNP 3mm7x7x7 and $^{131}$ILanconelli 3mm11x11x11, $^{131}$IGraves 3mm279x279x279) for different voxel size (2.4mm, 4.8mm) and number of views (128, 64) and compared to MIRD sphere model. Verification and partial volumes curves were performed on NEMA phantom (cylinder 130 ml, 6 spheres) filled with activity ($^{131}$I 7.1 MBq/ml, $^{177}$Lu 15.4 MBq/ml). The dosimetric protocols waere applied (2 SPECT-CT 24h, > 96 h) on patients ($^{131}$I 9 thyroid metastases and $^{177}$Lu Dotatate NET 13 organ at risk or metastases). ***Results:*** $^{177}$Lu absolute calibration factors (I 19.7 cps/MBq, B 35.7 cps/MBq) showed small variations for acquisitions, matrix size, numbers of views (< 5 %) and phantoms (< 1.5%) while for $^{131}$I (I 54.6 cps/MBq, B 98.9 cps/MBq) variations (~15 %) between homogeneous phantom and cylinder insert were found as well dead time effects (up to 30 % from the first to the last acquisitions) requiring corrections. Recovery coefficient curves were applied for small volumes (< 30-50 ml) (130ml 0.95, 11.7ml 0.69, 5.8ml 0.58, 2.7ml 0.41, 1.2ml 0.2, 0.7ml 0.1) up to a 3 ml volume limit for accurate dosimetry. High voxel kernels dose variations were found ($^{177}$LuLanconelli/$^{177}$LuGraves -18.5%, $^{177}$LuLanconelli/$^{177}$LuMCNP -11%, $^{177}$LuMCNP/$^{177}$LuGraves -6.6%, $^{177}$LuGraves/$^{177}$LuMIRD +1.7% and $^{131}$ILanconelli/$^{131}$IGraves -49%, $^{131}$IGraves/$^{131}$IMIRD +28%). For the clinical protocol Graves voxel kernel was chosen. $^{177}$Lu patient doses showed a good agreement (< 5%) for larger volumes compared to MIRD mean doses, while for small targets variations up to 40 %. Higher discrepancies (up to 55%) were found for $^{131}$I. ***Conclusion:*** Voxel dosimetry for radionuclide treatments in an effective tool for $^{131}$I and $^{177}$Lu post for accurate and standardized dose calculations. Many aspects pointed out in this work (voxel kernels, corrections factors) need further investigations.

## EP-0785

### True Single Time Point Dosimetry for [177Lu]Lu-PSMA targeted therapy - Is Haenscheid's method applicable?

***J. Kurth***, *M. Heuschkel, B. Krause, S. M. Schwarzenböck;*
*Rostock University Medical Center, Rostock, GERMANY.*

***Aim/Introduction:*** PSMA-targeted therapy has become an essential pillar of therapy for mCRPC. Studies are underway to apply PSMA therapy also in earlier stages of the disease and in this context, individualized dosimetry of organs at risk and tumors will be an important tool for optimization [1]. However, the resources of the departments and the clinical condition of the patient often do not allow for elaborate imaging. Therefore, single-time-point protocols have been in focus for some time [3]. Hänscheid et al. have elegantly shown for other nuclear medicine therapies [4, 5] that a reliable organ and tumor dosimetry is possible by using single imaging. Our study aimed to investigate whether this relatively simple approach is also applicable to [$^{177}$Lu]Lu-PSMA therapies. ***Materials and Methods:*** Retrospectively, data from 58 consecutive treatment cycles of [$^{177}$Lu]Lu-PSMA-617 therapy have been evaluated (28 patients, mean age 73y, mean activity 6.2 GBq) were included. Imaging was performed by quant. SPECT/CT of the abdomen (2h, 24h, 48, 72h p.i.). The dosimetric calculations for kidneys and tumors followed the MIRD scheme on the one hand and the method of Haenscheid on the other hand [5], whereby 24h, 48h, and 72h, respectively, were assumed as the time of measurement. The calculated absorbed doses were compared using the Bland-Altman method and statistically evaluated. ***Results:*** The absorbed dose for the kidneys and the tumors according to the MIRD scheme averaged 2.34Gy and 15.63Gy, respectively. When using the Haenscheid-method, the doses were underestimated. For the kidneys, the mean error was -20.5%, -7.6%, and -16.2% for 24h, 48h, and 72h, respectively, with significant differences only for the 24-hour measurement. For the tumors, the mean error was -51.8%, -26.6%, and -14.4%, respectively, again with significant differences only for 24-hour imaging. ***Conclusion:*** In principle, Haenscheid's method also seems suitable for estimating organ and tumor doses in PSMA therapy. However, the imaging times must be adjusted depending on the organ/tissue under consideration. Variations in the time of measurement in each cycle to assess the absorbed doses of different organs and tumor lesions with extrapolation of the accumulated doses would be an alternative. ***References:*** [1] Violet J et al. J Nucl Med. 2019. 60(4):517-523.[2] Jackson PA et al. J Nucl Med. 2020. 61(7):1030-1036 [3] Brosch-Lenz J Nucl Med. 2023 Jan 19;jnumed.122.264594. [4] Hanscheid H et al. ## EP-0786

### Accuracy of Few-Time-Point Dosimetry Using Non-Linear Mixed-Effects Modelling in Peptide-Receptor Radionuclide Therapy

***R. Subangun***[1], *D. Hardiansyah*[1], *R. Ibrahim*[1], *B. Patrianesha*[1], *A. Beer*[2], *G. Glatting*[2];
[1]*Universitas Indonesia, Depok, INDONESIA,*
[2]*Ulm University, Ulm, GERMANY.*

***Aim/Introduction:*** Personalized dosimetry is recommended in radionuclide therapy [1]. However, dosimetry with a high number of biokinetic data, e.g. five data, is time-consuming, corresponds to an increased workload for the patient and the staff, and is expensive for the healthcare system. Therefore, a few-time-point (FTP) dosimetry approach, which uses fewer biokinetic data for dosimetry, is highly desirable. The aim of this study was to investigate the accuracy of FTP dosimetry using non-linear mixed-effects (NLME) modelling in peptide-receptor radionuclide therapy (PRRT). ***Materials and Methods:*** Biokinetic data of [$^{111}$In]In-DOTATATE in kidneys at T1= (2.9±0.6) h, T2= (4.6±0.4) h, T3= (22.8±1.6) h, T4= (46.7±1.7) h, and T5= (70.9±1.0) h post injection were obtained from eight patients using planar imaging. The Sum-of-exponential (SOE) function $A_1/\{((1-\alpha)/(\lambda1+\lambda phys))-(\alpha/(\lambda2+\lambda phys))-((1-2\alpha)/(\lambda bc+\lambda phys))\}\ e^{-\lambda phys(t)}\ \{(1-\alpha)\ e^{-\lambda1(t)}-\alpha e^{-\lambda2(t)}-(1-2\alpha)e^{-\lambda bc(t)}\}$ which was selected as the best model for the kidney's biokinetics data of [$^{111}$In]In-DOTATATE in the literature [2] was used in this study. The parameters of the SOE functions were fitted to the all-time-point data in the NLME framework to

derive reference time-integrated activity (rTIAs). The fittings were repeated with FTP data which contain different combinations of single-, two-, three-, four-time point data to derive the predicted time-integrated activity (pTIAs). The accuracy of the different FTP schedules was assessed by calculation the relative deviations (RDs) and root-mean-square errors (RMSE) between the pTIAs and rTIAs. ***Results:*** The lowest RDs and RMSEs were found for those FTDs, which included the T3 measurement. The lowest (mean±SD) of RDs for the single-, two-, three-, four-time point FTDs were (0±8) % (T3), (1±6) % (T3 & T4), (3±5) % (T2, T3 and T4), and (0±2) % (T2, T3, T4, and T5), respectively. The lowest RMSE for the single-, two-, three-, four-time point FTD were 8% (T3), 6% (T3 & T4), 5% (T2, T3 and T4), and 2% (T2, T3, T4, and T5), respectively. ***Conclusion:*** In this study, we showed the accuracy of FTP dosimetry in PRRT. The knowledge of the accuracy of all FTP dosimetry schedules could provide valuable information for physicians to optimise patient care while reducing costs and improving the overall efficiency of the treatment. ***References:*** [1]. Glatting, G., M. Bardiès, and M. Lassmann. Z Med Phys, 2013. 23(4): p. 262-9.[2]. Hardiansyah, D., et al.,. EJNMMI Phys, 2023. 10(1) : p.12.

## EP-0787

### Validation of Pretherapeutic Dosimetry in Metastatic Thyroid Cancer Patient with Chronic Kidney Disease for I-131 Treatment

***A. Al Jabri***[1,2], *J. Cooke*[3], *S. Cournane*[4], *S. Ludgate*[5], *M. Healy*[5];
[1]*Sultan Qaboos University, Muscat, OMAN,* [2]*Trinity College Dublin, Dublin, IRELAND,* [3]*Children's Health Ireland at Crumlin, Dublin, IRELAND,* [4]*St Vincent's University Hospital, Dublin, IRELAND,* [5]*St James's Hospital, Dublin, IRELAND.*

***Aim/Introduction:*** Radioactive iodine (I-131) therapy for remnant ablation post thyroidectomy is standard practice for thyroid cancer treatment. Personalised I-131 has become a legal requirement under Euratom 2013/59. To avoid changing tumour biokinetics leading to cancer cells becoming radioresistant, maximising the administered activity of the first therapeutic attempt is advantageous. There is limited literature investigating the predictability of pretherapeutic (PT) dosimetric assessment in patients with chronic kidney disease (CKD). This case study implemented an adaptation of the European Association of Nuclear Medicine (EANM) blood and bone dosimetry protocol in a patient with papillary thyroid cancer (PTC) with distal metastasis and CKD, to compare I-131 biokinetics before and during treatment (DT). ***Materials and Methods:*** A 67 year old male with history of advanced CKD was diagnosed with metastatic PTC in May 2020 at St James's Hospital, Ireland. He also had secondary Anti-Neutrophilic Cytoplasmic Autoantibody (ANCA) associated vasculitis and pre-existing Glomerulonephritis. He underwent total thyroidectomy and manubriumectomy, then referred for I-131 ablative therapy in November 2020. A dosimetric evaluation was requested to assess the safe administration of a fixed activity of 3.7 GBq. A two-week EANM dosimetry protocol was conducted PT and a similar dosimetric protocol was conducted DT, with the results between PT and DT compared. ***Results:*** The patients data varied between the PT and DT dosimetry assessment in the range: eGFR=22-26 ml/min/1.73m$^2$, Creatinine=210-257 umol/L and Urea=12.8-15.1 mmol/L. Kidney function changed due to compliance with a special renal diet after the PT assessment, as advised by the renal medicine consultant. This led to a large difference in calculated maximum tolerable activities, where the PT dosimetry underestimated the DT dosimetry by 36% difference in the EANM model. He had slower clearance in the PT assessment with a 22% and 41% difference between blood and whole-body residence times, respectively. The estimated absorbed dose per administered activity was 0.30 Gy/GBq in the PT dosimetry, which would have resulted in a 1.1 Gy absorbed dose to the bone-marrow if a 3.7 GBq therapeutic capsule was administered. However, the patient administered activity was 2.64 GBq, which resulted in a bone marrow absorbed dose of 0.51 Gy. ***Conclusion:*** Fluctuation in kidney function resulted in a significant difference in I-131 retention. Implementing dosimetry in patients with CKD requires continuous monitoring of eGFR and creatinine level, as changes in kidney function will alter the accuracy of the estimated results.

## EP-0788

### A phantom study on I-124 digital PET/CT quantification performance for lesion dosimetry in (re)differentiated thyroid cancer

***M. Dotinga***[1,2], *D. Vriens*[1], *L. F. de Geus-Oei*[1,3,4], *P. Dibbets-Schneider*[1], *M. K. Stam*[1], *M. Pool*[1], *F. Smit*[1,5], *E. Kapiteijn*[1], *F. H. P. van Velden*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [3]*University of Twente, Enschede, NETHERLANDS,* [4]*Technical University of Delft, Delft, NETHERLANDS,* [5]*Alrijne Hospital, Leiderdorp, NETHERLANDS.*

***Aim/Introduction:*** Accurate I-124 PET/CT quantification is needed for lesion dosimetry in studies investigating renewed radioiodine uptake after tyrosine kinase treatment to warrant subsequent I-131 therapy in patients with radioiodine-refractory thyroid cancer. In this phantom study, we compare the quantification performance of I-124 and F-18 FDG and determine the I-124 quantification performance for different background-to-lesion ratios and acquisition times for protocol optimization and recovery correction on a digital PET/CT system (Vereos, Philips). ***Materials and Methods:*** A phantom study was performed using a cylindrical phantom and the NEMA image quality phantom with six fillable spheres. Phantom acquisitions were performed according to EARL protocol. For I-124, acquisition duration was varied (1, 2, 4 and 20 min. per bed position). F-18 FDG and I-124 calibration accuracy, coefficient of variation (CoV) and recovery coefficients (RCs) for background-to-lesion ratio 1:10 were assessed and compared to F-18 FDG EARL specifications. For I-124, clinically relevant background-to-lesion ratios were simulated including 1:infinity, 1:500, 1:250 and 1:125. For each ratio, scans were repeated four times and acquisition time duration was adjusted accordingly to obtain similar count statistics and. Sphere RCs obtained within background-adaptive 50% isocontours (A50) were compared between ratios and fitted to obtain a recovery correction curve. ***Results:*** Calibration accuracy and CoV were comparable between phantoms for both F-18 FDG (mean 0.95 and 4.9%, respectively) and I-124 (0.94 and 8.0%). All values were within F-18 FDG EARL specifications. F-18 FDG RCs complied with EARL in contrast to I-124, reaching a $RC_{A50}$ of 0.79 and 0.69 for the biggest sphere, respectively. Increasing acquisition duration did not improve I-124 RCs for all sphere sizes, while CoV was decreased from 17% to 4.4% for 1 to 20 minutes per bed position. An acquisition time duration of 4 minutes per bed position was selected to keep the CoV <10% and total scan time clinically feasible. In the varying background-to-lesion ratios, fit parameters were comparable for $RC_{A50}$ ($p>0.3$) suggesting a single fit can be used in clinical practice for recovery correction. For all sphere sizes, the final fit deviated 0.9±2.9% (range: -6.1-8.1%) from mean measured $RC_{A50}$.

Deviations were <5% for all sphere sizes except 13 and 17 mm. ***Conclusion:*** In contrast to F-18 FDG measurements, I-124 RCs did not comply with F-18 FDG EARL specifications. A single fit can be obtained for I-124 $RC_{A50}$ with background-to-lesion ratios ranging from 1:125 to 1:infinity for recovery correction in pre-therapeutic I-124 lesion dosimetry.

## EP-0789

### Comparison of bone marrow absorbed dose estimated using blood sampling and gamma camera methods for 177Lu labelled radiopharmaceuticals

***G. Katre***[1,2], *T. Srichandan*[1,2], *A. Konuparamban*[1], *S. Ghag*[1], *A. Puranik*[1], *A. Agarwal*[1], *S. Mithun*[1,2,3], *A. Jha*[1,2], *V. Rangarajan*[1,2]; *[1]Department of Nuclear Medicine and Molecular Imaging, Tata Memorial Hospital, Mumbai, INDIA, [2]Homi Bhabha National Institute (HBNI), Deemed University, Mumbai, INDIA, [3]Department of Radiation Oncology (Maastro), GROW School for Oncology and Reproduction, Maastricht University Medical Centre+, Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Internal Dosimetry is a process to estimate the absorbed dose to the organ and tumor, helping in patient selection and treatment planning for radionuclide therapy.$^{177}$Lu-Trastuzumab, $^{177}$Lu-DOTATATE and $^{177}$Lu-PSMA are the choices of radiopharmaceuticals for treatment of HER2 positive (HER2+) metastatic breast cancer, Neuroendocrine Tumours and Prostate cancer respectively. Being one of the dose limiting organ, estimation of absorbed dose to bone marrow is necessary. Therefore, our study aims to calculate and compare absorbed dose to the bone marrow by blood sampling and imaging method. ***Materials and Methods:*** A total of 13 patients (Age 61 ± 11 years) among which 4 patients with histologically proven HER2+ metastatic breast cancer,2 patients with metastatic prostate cancer,7 patients with NETs were included in this study. The sequential whole-body planar acquisition was performed at 4h,24h,72h/96h ,160h post administration for $^{177}$Lu-Trastuzumab and 4h,24h,72h for $^{177}$Lu-PSMA &$^{177}$Lu-DOTATATE along with one SPECT/CT at 72/96 hrs and at 24 hrs for $^{177}$Lu-Trastuzumab and $^{177}$Lu-PSMA &$^{177}$Lu-DOTATATE respectively. The normalized cumulated activity (NCA) for imaging method was obtained by mono-exponential curve fitting in dosimetry toolkit software, Xeleris workstation,GE Healthcare and mean absorbed dose per unit activity (DpA) was estimated using OLINDA/EXM 2.0 software. For blood sampling method the blood samples were collected at 1h ,4h,,8h, 24h &72h post administration for $^{177}$Lu-PSMA &$^{177}$Lu-DOTATATE and at 4h ,24h,72h/96h,160h for $^{177}$Lu-Trastuzumab.Blood cumulated activity concentration were determined by counting blood samples of different time points in calibrated gamma well counter and $T_{eff1/2}$ of radiopharmaceutical was obtained from time activity curve. NCA is calculated using bone marrow mass, blood mass,$T_{eff1/2}$ of RP in blood. DpA values for bone marrow were estimated by using OLINDA/EXM 2.0 Software. ***Results:*** The administered dosage for $^{177}$Lu-Trastuzumab pretherapy, $^{177}$Lu-Trastuzumab therapy, $^{177}$Lu-DOTATATE and $^{177}$Lu-PSMA therapy were 407±44 MBq, 3885±37MBq and 6839±399MBq 7400±209MBq respectively. The DpA for bone marrow calculated by blood sampling method for Lu177-Trastuzumab, Lu177-DOTATATE, Lu177-PSMA were 0.274±0.05mGy/MBq,0.121±0.12mGy/MBq,0.11±0.03mGy/MBq respectively. The DpA for bone marrow calculated by imaging method for $^{177}$Lu-Trastuzumab, $^{177}$Lu -DOTATATE, Lu177-PSMA were 0.273±0.19mGy/MBq, 0.115±0.074mGy/MBq,0.15±0.06mGy/MBq respectively. Paired t test (two-tailed) was applied on the above data and p value of 0.42 was obtained. ***Conclusion:*** Our study shows no significant difference between the two methods used for estimation of bone marrow absorbed dose for 177Lu based radiopharmaceuticals.

## EP-0790

### Lu-177-PSMA Infusion vs Injection: No Difference in Dose Rates of Patients at the Time of Outpatient Discharge

***V. Reijonen***[1], *K. Kiviluoto*[2,1], *V. Ahtiainen*[1]; *[1]Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, FINLAND, [2]HUS Pharmacy, Helsinki University Hospital, Helsinki, FINLAND.*

***Aim/Introduction:*** We aimed to study whether there is a pharmacokinetic difference between intravenous (IV) infusion vs injection administration of Lu-177-PSMA (lutetium-177 labelled prostate-specific membrane antigen) that reflects to the dose rates measured from patients treated for metastatic castration-resistant prostate cancer (mCRPC). Patients received small molecule PSMA-targeted radioligand that has well-known pharmacokinetic, safety and efficacy profiles; however, the treatment could be further optimised (1). ***Materials and Methods:*** We analysed 20 patients who received their first cycle of peptide Lu-177-PSMA therapy for mCRPC: ten patients as a 30 min IV infusion (mean activity 7.1±0.3 GBq diluted in extra 100 ml isotonic saline) and ten patients as a 1-5 min manual IV injection (activity 7.3±0.2 GBq). The patients were treated on an outpatient basis and were measured with a dose rate meter at a one meter (1 m) distance before their hospital discharge. The patients received IV isotonic saline solution initiated approximately 30 min before administering Lu-177-PSMA at a continuous rate between 250-300 ml/h. The patients were encouraged to drink fluids regularly and empty their bladder just before measuring the dose rate for discharge. ***Results:*** Dose rates at 1 m distance from patients with infusion administration (21.6 ± 5.3 µSv/h, range 15.1-29.9 µSv/h) were not significantly different from dose rates of patients with injection administration (20.5 ± 4.6 µSv/h, range 15.0-28.5 µSv/h), t(18)=0.491, p=0.630. Reasons such as IV fluid administration and cooling of the salivary glands affected the time of the dose rate measurement, and when measured from the end of Lu-177-PSMA administration, there was no difference between the groups: 2.8 ± 0.6 h (1.7-3.8 h) after the end of infusion, and 2.8 ± 0.5 h (2.1-3.5 h) after the end of injection, t(18)=0.183, p=0.857. ***Conclusion:*** We did not observe a statistically significant difference between the dose rates measured from patients treated with Lu-177-PSMA infusion vs injection. After less than four hours from the end of Lu-177-PSMA administration, the dose rate at 1 m was below 30 µSv/h for all the patients. ***References:*** 1. van der Gaag S, Bartelink IH, Vis AN, Burchell GL, Oprea-Lager DE, Hendrikse H. Pharmacological Optimization of PSMA-Based Radioligand Therapy. Biomedicines. 2022 Nov 23;10(12):3020.

## EP-0791

### Simplified Organ and Tumor Dosimetry for Lu-177-PSMA-I&T Radionuclide Therapy

***W. Lehnert***, *L. Schatz, A. Karimzadeh, I. Apostolova, R. Buchert, S. Klutmann; University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.*

***Aim/Introduction:*** Multiple time point imaging for accurate internal dosimetry is time consuming and hence can be demanding for nuclear medicine departments as well as patients. The aim of this study was to investigate a possible simplified dosimetry protocol to reduce this burden. ***Materials and Methods:*** This study included 16 patients each treated with 4 cycles of [$^{177}$Lu]Lu-PSMA-I&T. They underwent whole body SPECT/CT imaging (3 bed positions) at four time points at 2h, 24h, 48h and 72h or 120h post-injection (p.i.). Full 3D dosimetry

(reference method) was performed for all patients and dose cycles for organs at risk (kidneys, parotid and submaxillary glands) and up to ten tumor lesions per patient (resulting in 91 lesions overall). For dosimetry calculation time integrated activities were estimated using analytical integration based on a mono- or biexponential curve fit applied to the time activity curves. Trapezoidal integration was used where a fit to all data points was not possible due to long uptake phases with an extrapolation to infinity using a monoexponential function fitted to the last 2 or 3 time points. The simplified dosimetry method generated time activity curves for cycles 2 to 4 using a single time point of imaging assuming the same kinetics as in dose cycle 1. ***Results:*** Compared to the full dosimetry approach the simplified method using the third imaging time point at 48h p.i. resulted in the lowest mean differences and standard deviations for all organs at risk with mean percent deviations of 2.10% ± 16.25% for the kidneys, -2.54% ± 20.11% for the parotid glands and -2.43 % ± 17.35% for the submaxillary glands, respectively, averaged over all dose cycles. For lesions better results were achieved using the fourth time point at 72h or 120h with a mean difference and standard deviation of -3.46% ± 14.14% compared to the reference method. ***Conclusion:*** Simplification of dosimetry protocols is possible for [$^{177}$Lu]Lu-PSMA-I&T therapy. If tumor dosimetry is of interest in addition to safety dosimetry a later (≥ 72h) or second imaging time point should be used to account for the slower kinetics of tumors compared to organs at risk.

## EP-0792

### Single time point tumour dosimetry after 177Lu-DOTATATE therapy

***S. Ballout****;*
*Cambridge University Hospital NHSFT, Cambridge, UNITED KINGDOM.*

***Aim/Introduction:*** A fixed administered activity of 7.4 GBq for 4 cycles remains the standard dosing regimen for $^{177}$Lu-DOTATATE therapy of neuroendocrine tumours. Simplified methods to determine tumour absorbed dose may allow us to implement patient specific dosing regimens which may result in improved efficacy of treatment. Single time point (STP) dosimetry methods using the Hänscheid approximation, Madsen approximation and a cycle 1 effective half-life were evaluated in comparison to multiple time point (MTP) dosimetry using SPECT and SPECT/CT acquisitions on days 0, 4 and 7 after therapy. ***Materials and Methods:*** 17 patients having 62 cycles of therapy at our centre were included in the study. The largest lesion for each patient was analysed across all cycles of treatment. Lesion segmentation was performed via thresholding using 3D Slicer. Recovery coefficients based on phantom work using a NEMA IEC body phantom were used to recover the true activity concentration. S-values based on tumour mass were used to estimate the dose to a lesion, assuming the composition of a tumour was 100% soft tissue. ***Results:*** The mean tumour dose across all therapy cycles using MTP dosimetry was 36 Gy, with doses ranging from 6-75 Gy. The mean dose decreased over four cycles from 44 Gy (n=16) in cycle 1 to 26 Gy (n=15) in cycle 4. Using a cycle 1 effective half-life and a single SPECT/CT on day 4 and day 7 of subsequent cycles, 63% and 93% of results respectively were within + 10% of MTP dosimetry. Using the Hänscheid approximation with a day 4 and day 7 SPECT/CT resulted in 57% and 95% of lesion doses within + 10% of MTP dosimetry. Using the Madsen approximation with a population effective half-life of 130 hours and a single SPECT/CT on day 4 and day 7 after therapy resulted in 34% and 85% of lesion doses within + 10% of the MTP method respectively. ***Conclusion:*** STP dosimetry for tumour lesions is more accurate when using a day 7 SPECT/CT in comparison to a day 4 SPECT/CT. The use of a cycle 1 effective half-life scaled with a day 7 SPECT/CT is most accurate, however the Hänscheid approximation using only a day 7 SPECT/CT was also suitable. Previous research showed that a day 4 SPECT/CT was most suitable for STP kidney dosimetry, so a compromise is needed if both kidney and tumour dosimetry are required.

## EP-0793

### Role of lung density in voxel-based dosimetry of90Y-TARE evaluated with Voxel S-Value (VSV) method and fast Monte Carlo simulation

***R. Moretti***[1]*, A. Capotosti*[1]*, M. Vaccaro*[2]*, C. d. Ribeiro*[2]*, M. Nardini*[1]*, G. Meffe*[1]*, L. Placidi*[1]*, L. Zagaria*[1]*, M. De Risi*[1]*, G. Perotti*[1]*, L. Leccisotti*[1]*, R. Iezzi*[1]*, L. Indovina*[1]*;*
*[1]Fondazione Policlinico Universitario Agostino Gemelli, Rome, ITALY, [2]Università Cattolica del Sacro Cuore, Rome, ITALY.*

***Aim/Introduction:*** In $^{90}$Y-TARE treatments, lung-absorbed dose should be calculated according to the manufacturer's instructions, using the MIRD-scheme.This scheme is derived from the assumption that $^{90}$Y-microspheres deliver the dose in a water-equivalent medium. Since the density of the lung is quite different from that of the liver, the absorbed dose to the lung could vary considerably, especially at the liver/lung interface. The aim of this work is to compare the dosimetric results obtained by two dedicated software packages, implementing a water-equivalent dose calculation and a Monte Carlo (MC) simulation, respectively. ***Materials and Methods:*** An anthropomorphic IEC phantom and a retrospective selection of 24 patients with a diagnosis of hepatocellular carcinoma were taken into account. In the phantom study, the liver cavity was manually fixed at 1.3 MBq/mL on PET series using a dedicated software, while the lung compartment was manually expanded to simulate a realistic situation in which liver and lung are adjacent on CT series. A first simulation was performed with only the liver compartment manually filled with the aforementioned concentration; a second simulation was performed with the lung compartment also manually filled, simulating a 10% lung shunt fraction. Dose values derived by Voxel S-Value (VSV) and MC approach, for both phantoms and patients, were calculated with two different softwares. ***Results:*** In the phantom simulations, the percentage mean dose differences (ΔD%) between VSV and MC in the first and second simulations were found to be respectively: 1.2 and 0.5% (absolute dose variation, ΔD, of 0.7 and 0.3 Gy) for the liver, -56 and 70% (ΔD of -0.3 and -16. 2 Gy) for the lung, -48 and -60% (ΔD of -4.3 and -16.5 Gy) for the liver/lung interface region. The patient study reported similar results with ΔD% between VSV and MC of 7.0%, 4.1% and 6.7% for the whole liver, healthy liver and tumor, respectively, while -61.2% for the left lung and -61.1% for both right lung and lungs. ***Conclusion:*** Both VSV and MC allowed accurate radiation dose estimation with small differences (<7%) in regions of uniform water equivalent density (i.e. within the liver). Larger differences (>50%) were observed for air-equivalent regions in both the phantom simulation study and the patients.

## EP-0794

### A Dosimetric Comparison of Radioembolization and External Beam Radiation Treatment For Liver Cancer

***K. Wysoczynski****, B. Mehadji, P. Park, S. Benedict, E. Roncali;*
*University of California, Davis, Davis, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Liver cancer is a high-impact area in clinical practice with rising mortality [1]. The most common treatment is resection, but the number of tumors, position, and complex

vasculature often prevent surgery. Stereotactic Body Radiation Therapy (SBRT) can provide a localized radiation dose with photons produced by a linear accelerator. Yttrium-90 (Y-90) radioembolization is delivered through microspheres injected into the hepatic artery. We are comparing the dose distribution and conformity of a treatment performed with Y-90 microspheres and a simulated plan for SBRT for a patient. ***Materials and Methods:*** In this study, one patient with hepatocellular carcinoma (single 155 cc lesion) was treated using Y-90 microspheres with an injected activity of 2.27 GBq. We performed radioembolization dosimetry based on a PET scan acquired 24h post-treatment to measure Y-90 activity, using multiple organ and tumor contours delineated on whole-body CT. We also simulated a treatment plan using an SBRT conventional linac with 5 mm leaf width. We compared dose distributions of the two modalities for several organs based on dose-volume histograms. ***Results:*** The microsphere treatment delivered a mean dose of 390 Gy to the gross tumor volume and an average of 47 Gy to the liver volume. The SBRT plan resulted in a mean tumor dose of 51 Gy and mean liver dose of 11 Gy. It is important to note that 2% of the tumor (D2) received at least 54 Gy in the plan, while Y-90 microspheres delivered 908 Gy at D2 of gross tumor volume. The patient received a 5 Gy lung dose with Y-90, but the SBRT plan predicted 0.36 Gy. This large dose with Y-90 is due to the lung shunt fraction of 14.6% for this patient. ***Conclusion:*** While microspheres can deliver extremely high radiation doses to the tumor in just one administration, SBRT is performed over 6-10 fractions. However, Y-90 microspheres deliver more radiation to surrounding tissue. Well-vascularized small tumors benefit the most from radioembolization, but dosage to surrounding organs requires analysis with more patients. To better gauge side effects from these very different radiation modalities, biological effective dose calculation will be performed. Other modalities, such as HDR Ir-192 and proton therapy, will be included in further studies. ***References:*** [1] A.Taebi, C. Vu, and E. Roncali. "Multiscale Computational Fluid Dynamics Modeling for Personalized Liver Cancer Radioembolization Dosimetry." ASME. J Biomech Eng. January 2021.

## EP-0795

### Impact of SPECT acquisition and reconstruction parameters in dosimetry of [177Lu]Lu-PSMA-617 and analogues

***T. Lima****, M. Gravinatti, A. Zander, H. Grünig, U. Bhure, M. Pérez Lago, K. Strobel;*
*Luzerner Kantonsspital, Luzern, SWITZERLAND.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is a transmembrane protein that is overexpressed in prostate cancer cells. Single-photon emission computed tomography/computed tomography (SPECT/CT) is a widely used imaging modality for $^{177}$Lu-PSMA post-therapy imaging, but the impact of SPECT acquisition and reconstruction parameters on dosimetry accuracy and harmonization is not fully characterised. The aim of this work is to understand and characterise the impact of acquisition and reconstruction parameters in $^{177}$Lu-PSMA dosimetry. ***Materials and Methods:*** A standardised phantom with known sphere sizes was used. Lesions and background were filled with $^{177}$Lu and the activity concentration was set to mimic the ones found in patients. The phantom was then imaged in a clinical device with varying acquisition time (5, 10, 15 and 20 seconds per projection), matrix size (128x128 or 256x256), reconstruction iterations (5, 10, 15, 20, 25, 30, 35, 40, 45 and 50) and the use of post-processing Gaussian filter (0, 5 or 10mm). All other parameters were kept as per the manufacturer's recommendation (reconstruction method, subsets, angular trajectory and angular steps). The quantification was evaluated based on the sphere recovery coefficient for different sizes. The lung insert and the background were evaluated based on the residual lung error and coefficient of variance, respectively. Lastly, dosimetry based on the single time-point dosimetry implemented clinically was calculated for each generated dataset. Comparisons were made based on their spheres' absorbed doses both with respect to the mean values and dose volume histograms. ***Results:*** The results demonstrated that acquisition statistics and reconstruction parameters significantly affected dosimetry measurements. Higher count statistics led to more accurate and precise dosimetry estimates, while shorter acquisition times led to higher variability in dose estimates. Smaller voxel sizes improved the accuracy of dosimetry estimates but increase variability. Standardization of acquisition and reconstruction protocols across different institutions may be necessary to ensure consistent dosimetry estimates and improve patient outcomes. ***Conclusion:*** The findings of this study highlight the importance of SPECT acquisition and reconstruction parameters in dosimetry of [$^{177}$Lu] Lu-PSMA-617 and analogues and their impact on accuracy and harmonization. The results suggest that acquisition statistics and reconstruction parameters should be carefully considered and optimized to improve the accuracy and consistency of dosimetry calculations. Standardization of acquisition and reconstruction protocols may be necessary to ensure consistent dosimetry estimates and improve patient outcomes.

## EP-0796

### Commissioning and planning of treatment planning systems for Selective Internal Radiation Therapy

***M. Santoro****[1], G. Della Gala[1], G. Paolani[1], G. Rasoatsaratanany[2], S. Strolin[1], L. Strigari[1];*
*[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]International Centre for Theoretical Physics, Trieste, ITALY.*

***Aim/Introduction:*** Treatment Planning Systems (TPSs) have been recently introduced to personalize $^{90}$Y-selective internal radiation therapy (SIRT). Unfortunately, there are no harmonization or guidelines on commissioning these tools. The aim of this study is to assess the discrepancies among four clinical TPSs for $^{90}$Y-SIRT in terms of volumes of interest (VOIs), mean absorbed doses, and Dose Volume Histograms (DVHs). ***Materials and Methods:*** Two experimental (NEMA homogeneous and abdominal anthropomorphic) phantoms were acquired with a SPECT/CT scanner and filled with $^{99m}$Tc-pertechnetate to mimic $^{99m}$Tc-MAA distribution. Three virtual phantoms were generated in DICOM format by an in-house MATLAB script, two reproducing the experimental ones and assuming to be homogeneously filled. The kernel phantom was generated focusing the activity inside a voxel at the center of the NEMA phantom. VOIs were created within a TPS for each phantom. Images and VOI were imported into four clinical TPSs for $^{90}$Y-SIRT dosimetry. Two methods were used for voxel-based dosimetry calculations within the TPSs: the local deposition method and the dose kernel convolution assuming a known injected activity. The descriptive statistics and differences in calculated volumes and dose metrics were determined and compared with the Bland-Altman analysis using R software. ***Results:*** Differences up to 5% between NEMA homogeneous virtual and experimental phantom were found while trivial differences between anthropomorphic virtual and experimental one were observed. The mean absorbed dose for

the homogenous phantom ranged from 3 to 5.1 Gy. Concerning the two anthropomorphic phantoms, the dose difference was up to 10 times for the cold sphere, where the absorbed dose range of the virtual phantom was shifted 100 Gy higher than the experimental one. Bland-Altman plots showed discrepancies for each VOI volume up to 25% and 10% for homogeneous and anthropomorphic phantoms, respectively. In addition, the Bland-Altman plots comparing the mean absorbed doses of VOIs showed discrepancies of up to 20% for the virtual phantoms and up to 10% for the experimental phantoms. The difference in the mean absorbed dose of smaller volume of kernel phantom obtained from different TPSs largely varied based on the implemented kernels and calculation methods. The DVHs were different for homogeneous and anthropomorphic (virtual and experimental) phantoms due to the image noise and likely the low resolution of the experimental images. ***Conclusion:*** Significant discrepancies in calculated dose metrics were found due to the adopted kernels and calculation methods adopted in the investigated TPSs demanding an appropriate harmonization.

## EP-0797

### Effect of segmentation uncertainty on pre-therapeutic dosimetry of selective internal radiation therapy using Yttrium-90 Microsphere for hepatocellular carcinoma

***A. Nautiyal****, T. Melhuish, G. Lewis, S. Michopoulou;*
*University Hospital Southampton, Southampton, UNITED KINGDOM.*

***Aim/Introduction:*** Precise segmentation of perfused liver volume (PLV), tumour volume (TV) and whole liver (WLV) is the basis and prerequisite for the treatment planning of selective internal radiation therapy (SIRT) using Yttrium-90 ($^{90}$Y)-microsphere. As per EANM practical guidance on dosimetry, uncertainty in the delineation of volume of interest (VOI) is the major factor of variation in the counts and dosimetry calculations in molecular radiotherapy. Our aim was to investigate the impact of PLV, TV and WLV delineation on the estimation of required administered activity and absorbed dose in the tumour and normal liver tissue. ***Materials and Methods:*** Three patients having single hepatic lesions and referred for $^{90}$Y-SIRT were analysed retrospectively. For each patient, three different experiments were performed to estimate the tumour dose (TD), normal liver tissue dose (LD) and required administered activity of $^{90}$Y-microsphere. In the first experiment, TV and WLV VOIs were kept fixed while PLV threshold on SPECT/CT images was changed for each unit (5-28%). In second experiment, PLV and WLV VOIs were fixed while threshold-based TV VOIs (24-50%) were changed for each unit. In final experiment, the VOIs of PLV and TV were fixed while different CT-based WLV VOIs (1-1.74l) were drawn. A standard fixed dose of 120Gy to the PLV was used for all experiments. A commercial dosimetry planning software was used for all volumetric segmentation and dosimetric calculations. ***Results:*** As expected, the parameters i.e., TD, LD and required administered activity of $^{90}$Y microsphere change linearly (r=1) with the diameter of PLV VOI. A strong negative association was noted between TV VOI vs TD (r=-0.97) and TV VOI vs LTD (r=-0.99). Similarly, a strong negative correlation was noted between WLV VOI and LD (r=-0.99). In experiment one, each unit of threshold VOI change around PLV generates an approximate error of 3.5 % in TD estimation, 10 % in LD and 8% in the required administered activity of the 90Y-microsphere. In experiment two, each unit of threshold VOI change around TV generates an approximate error of 2% in TD and 2% in LD. In experiment three, changes in VOI around the liver generate an error of 2% in LD. ***Conclusion:*** The VOI delineation around the perfused liver site substantially changes the tumour dose and required administered activity in the $^{90}$Y-SIRT treatment. To optimise dosimetry, accurate VOI delineation by an experienced operator is required, using high-resolution SPECT combined with diagnostic contrast-enhanced CT or MRI images.

## EP-0798

### Clinical dosimetry of patients treated with Capecitabine, Temozolomide and [177Lu]Lu-DOTA-TOC combined therapy.

***A. Cichonski****[1], J. B. Ćwikła[2], A. Kolasińska-Ćwikła[3], M. Kempińska-Wróbel[2];*
*[1]National Centre for Nuclear Research, Warsaw, POLAND, [2]Medical School, University of Warmia and Mazury, Olsztyn, POLAND, [3]The Maria Skłodowska-Curie National Institute of Oncology, Warsaw, POLAND.*

***Aim/Introduction:*** Accurate and reliable dosimetry evaluation of [$^{177}$Lu]Lu-DOTA-TOC therapy in clinical routine is crucial to ensuring the safety and effectiveness of treatment. The aim of this study was to perform a dosimetry assessment of both organs and lesions using widely-used tools. ***Materials and Methods:*** The study group consisted of 17 patients who were treated for neuroendocrine tumors. The somatostatin receptor-targeted therapy using [$^{177}$Lu]Lu-DOTA-TOC included 3 cycles for 3 subjects, while the rest of the patients had 4 cycles with 2-months intervals. In each cycle, an average dose of 6243 MBq of [$^{177}$Lu]Lu-DOTA-TOC was administered and post-therapy SPECT was performed to follow the tracer concentration in volume of interest at certain time points: 6 hours, 27 hours, 84 hours, and 127 hours average. The TAC curve fitting was performed using a mono-exponential method based on SPECT/CT acquisitions at no less than three time points. In 8 patients also the pre-treatment diagnostic somatostatin receptor scintigraphy with [$^{99m}$Tc]Tc-EDDA/HYNIC-TOC was performed. The uptake of $^{99m}$Tc in SRS and the subsequent therapy with $^{177}$Lu were compared for those patients. Dosimetry evaluation was carried out based on informations obtained from quantitative analysis of SPECT images performed in the workstation application and direct dose calculations were carried out in external software. ***Results:*** The mean cumulated absorbed dose for the liver was 6.1 Gy (SD = 6.5 Gy, N = 17), for kidneys 9.5 Gy (SD = 5.8 Gy, N=17), for the spleen 5.9 Gy (SD = 4.7 Gy, N=12) and heart 0.07 Gy (SD = 0.07 Gy, N = 17). Bone marrow dosimetry results of cumulated absorbed dose were average of 32 mGy (SD = 30 mGy, N = 17). The target lesions dosimetry results was mean absorbed dose 52.4 Gy (SD = 33.5 Gy, N = 44). The contribution of the beta component of 177Lu radiation in the total dose was 95.2% for the liver, 97.2% for the kidneys, 97.2% for the spleen, and 0.48% for the heart. ***Conclusion:*** Dosimetry can be performed in a convenient manner mainly using tools available on clinical workstation to obtain required data and calculations easy to perform in available external software. The heart is an organ out of risk and can be excluded from dosimetry evaluation if needed. The only image-based dosimetry for bone marrow is insufficient and should be completed with blood-based methods.

## EP-0799

### Voxel-level comparison of99mTc-MAA SIRT planning SPECT-CT with90Y-Microspheres post-therapy PET-CT

***S. Heard***, *D. Gillett, R. Crawford, I. Harper, T. C. See, N. Shaida, L. Aloj;*
*Cambridge University Hospitals NHS FT, Cambridge, UNITED KINGDOM.*

***Aim/Introduction:*** Selective internal radiation therapy (SIRT) with $^{90}$Y-Microspheres for liver cancer is typically preceded by $^{99m}$Tc-MAA imaging to assess whether shunting to the lungs will be within safe limits. Increasingly $^{99m}$Tc-MAA SPECT CT is also used to predict the therapeutic activity distribution and hence plan radiation doses to tumours and healthy tissue. The importance of individualised planning taking into consideration overall liver function, volume of affected liver and volume of normal liver likely to receive a significant radiation dose is increasingly recognised. Comparisons between planning and therapeutic activity distribution have been investigated in the literature. We present a detailed voxel-level comparison of predicted and actual perfused volume as well as planned and delivered absorbed dose in both healthy and tumoural tissues. ***Materials and Methods:*** The planning $^{99m}$Tc-MAA SPECT-CTs for ten patients were registered to their respective post-treatment $^{90}$Y-Microspheres PET-CTs. Using dosimetry software package Simplicit90y actual doses to tumour volumes were compared with the planned doses. In addition, 3D Slicer was used to compute dose images (predicted and delivered) and to perform voxel-wise subtraction, generating a difference image for each pair. Furthermore, the total perfused volumes (planned and delivered) were segmented and compared using their Dice coefficient to assess the similarity of the volumes. ***Results:*** The mean doses delivered to tumour and total perfused volume were 120% (range: 65% - 189%) and 107% (range: 81% - 189%) respectively of the planned doses. The mean perfused volume obtained in the post treatment PET CT images was 86% (range: 39% - 114%) of the planned perfused volume. The similarity of the volumes (size, shape and extent) was high with an average Dice coefficient of 0.77 (range: 0.43 - 0.91). Despite a mean difference of only +0.6 Gy the differences seen between the predicted and actual doses at a voxel level varied considerably, beyond the contribution of image noise, with a standard deviation of 44 Gy and a range of -244 to +339 Gy. ***Conclusion:*** $^{99m}$Tc-MAA SPECT/CT is a reliable method to determine perfused volume and predict average absorbed dose when delivering $^{90}$Y-Microspheres. This method, however, is a poor proxy for relative activity distribution within the target volume. Importantly, delivered tumour doses were generally found to be higher than predicted on the $^{99m}$Tc-MAA SPECT-CT. Underdosing tumour lesions is unlikely to occur when this simple approach is used for treatment planning of SIRT.

## EP-0800

### Clinical experience of whole body and tumour dosimetry of 131-I-mIBG treatment for pediatric patients

***I. Torres Espallardo***[1,2], *N. Orrego*[1], *M. Gandia-Ferrero*[2], *V. Cotanda*[3], *C. Olivas*[1], *L. Martí-Bonmatí*[1,2], *P. Bello-Arques*[1], *J. Balaguer*[1], *S. Prado-Wohlwend*[1];
[1]*Clinical Area of Medical Imaging, Valencia, SPAIN,* [2]*Health Research Institute La Fe, Valencia, SPAIN,* [3]*Fundacion IVO, Valencia, SPAIN.*

***Aim/Introduction:*** $^{131}$I-metaiodobenzylguanidine ($^{131}$I-mIBG) is a targeted radiopharmaceutical mostly used for paediatric patients with refractory or relapsed neuroblastoma. Recent research suggests that numerous infusions of high-dose $^{131}$I-mIBG result in a better response. Our therapy approach consists of two injections spaced 3-4 weeks apart. The treatment goal is to deliver a 4 Gy whole-body dose. WB and tumour dosimetry were used in this investigation to assess the connection with clinical outcomes. ***Materials and Methods:*** Six patients were included, each of whom received two administrations. The WB absorbed dose for all individuals and administrations were computed. WB-dosimetry was estimated using the MIRD schema and was based on external dose rate data. Tumor dosimetry was performed using SPECT/CT scans taken at three separate time intervals (72, 96, and 144 hours after treatment). Tumor S-values have been calculated using the uniform and unit density sphere models and the MIRD formalism. ***Results:*** For the entire treatment, the WB-doses were 2.6±1.1 Gy. When the ratio of absorbed dose (D) to given activity (A) is compared between the first (R1=D1/A1) and second (R2=D2/A2) infusions, R1 > R2 results in exitus (2 patients). Two of the four remaining patients have progressed. Interestingly, the dose of the relevant lesions rose significantly from the first to the second cycle (from 0.01 to 0.26 mGy; and from 0.20 to 0.55 mGy). ***Conclusion:*** WB and tumour dosimetry aid in our comprehension of therapy response. These studies are viable in clinical practice, but require a well-established process and a multidisciplinary team. We detected interindividual and intercycle variability in radiation exposure and consequently individual susceptibility to this sort of treatment in our investigation. Further research with larger population is needed to assess the correlation between radiation dose and clinical outcomes in order to predict individual response to $^{131}$I-mIBG therapy. This should be done at multicenter level given small patients sample.

## EP-0801

### DosePredict: An Open-source Software to Support Treatment Planning for Personalised Radiopharmaceutical Therapy

***C. Gomes Ferreira***[1], *V. R. Warschun*[2], *J. Hu*[1], *S. Xue*[1], *L. Mercolli*[3], *T. W. Vidal*[2], *N. Navab*[2], *A. Afshar-Oromieh*[3], *A. Rominger*[3], *K. Shi*[1];
[1]*University of Bern, Bern, SWITZERLAND,* [2]*Technical University of Munich, Munich, GERMANY,* [3]*Inselspital, Bern University Hospital, Bern, SWITZERLAND.*

***Aim/Introduction:*** Radiopharmaceutical therapy (RPT) has been successful in the systematic treatment of multiple metastatic cancers. However, despite the European Council Directive (2013/59 Euratom) requiring personalized or tailored treatment, the current approach still relies on fixed dosages. One of the reasons for this limitation is the lack of tools for pre-therapy dose prediction. To address this issue, we have developed an academic software tool, called "DosePredict" that integrates an AI-based pre-therapy dose prediction algorithm to assist with treatment planning for personalized RPT. ***Materials and Methods:*** "DosePredict" is an open-source client-side software developed in Python, encompassing simplified dose prediction and verification tasks during the general RLT workflow. The current version is restricted for PSMA-directed RPT for prostate cancer. Four main modules are being developed independently and integrated in a Qt- and VTK-based interface to provide separate functionalities: "Pre-therapy Prediction", "Segmentation", "Post-therapy Dosimetry", and "Evaluation". ***Results:*** A deep learning based voxel-wise pre-therapy dosimetry prediction algorithm based on static PET/CT was implemented in the "Pre-therapy Prediction" module[1]. A semi-automatic segmentation algorithm using first deep learning for pre-segmentation followed by optional manual refinement

was implemented for the "Segmentation" module[2]. A voxel-wise multi-time point dosimetry estimation was implemented for SPECT/CT images in the "Post-therapy Dosimetry" model[1]. The "Evaluation" module allows the users to assess the dose volume histogram and evaluate the dose prediction accuracy based on post-therapy dosimetry measurements. ***Conclusion:*** This simple open-source software provides a tool to support the users to implement dose prediction for the investigation of dosimetry-guided RPT treatment, which may accelerate the development for personalized treatment planning. ***References:*** 1. **Comparison of Administered Lu-177 and Ac-225 Activities of PSMA Treatments Against Metastatic Prostate Cancer: Radiobiological Factors**

***V. Ahtiainen***[1,2], *V. Reijonen*[1], *M. Tenhunen*[1];
[1]*Helsinki University Hospital Comprehensive Cancer Centre, Helsinki, FINLAND,* [2]*Helsinki University, Helsinki, FINLAND.*

***Aim/Introduction:*** Potential benefits of alpha emitters are better microscopic dose distribution and radiobiological factors: independence from dose rate and oxygen effect. Experimental models have been presented to define safe and efficient protocols for therapeutical applications being confirmed in the clinical safety trials first. So far, there are no clinical trials comparing alpha and beta emitting radiopharmaceuticals in the same group of patients. We have compared the published results of Lu-177 and Ac-225 labelled PSMA-617 trials (1, 2). ***Materials and Methods:*** Trial (1) consists of 200 patients, n=99 of them treated with up to six Lu-177-PSMA-617 administrations. Meta-analysis (2) collects data from 6 trials with 201 patients treated with 1-8 (median = 3) Ac-225-PSMA-617 administrations. The analysis was performed using calculated average values for administered activities. Consistent and surprisingly similar end-point indicators could be found from both datasets for tumour response (PSA decline>50%) in (1): 66% and (2): 66%, hematological toxicity (anemia>G3) in (1): 8% and (2): 12%, and xerostomia in (1): 60% and (2): 77% of cases, respectively. ***Results:*** Firstly, providing similar biodistribution and kinetics of all data sets (difference in the physical half-life omitted due to the shorter biological clearance), it is possible to compare the ratio of administered activities directly: (1) Lu-177: 37.5 GBq (2) Ac-225: 21.0 MBq. Secondly, if photon radiation is omitted, the locally absorbed energy per decay is (1) Lu-177: 148 keV, (2) Ac-225: 28.2 MeV (alphas) and 675 keV (electrons) [ICRP 107]. Assuming that electron radiation's relative biological effectiveness (RBE) is close to one, the effective RBE of Ac-225 decay chain alphas thus becomes 9.35. This is higher by a factor of ≈1.6 which could be expected based on the alpha energies. Again, this may be due to microscopic dose distribution, underestimation of current RBE for alphas, or low dose-rate effect of beta radiation. ***Conclusion:*** With two patient sets of equivalent dose responses, comparing simple physical/radiobiological factors of alpha and beta emitters is possible. ***References:*** 1. **Preparation of a 99mTc-labeled Bromobenzyl Ether Derivative Targeting PD-L1**

***W. Hongyong****, C. Lu, Y. Liu, J. Wu, H. Wu, G. Han, P. Zou;*
*Jiangsu Institute of Nuclear Medicine, Wuxi, Jiangsu, CHINA.*

***Aim/Introduction:*** The expression level of PD-L1 on tumor surfaces is an important indicator for guiding the use of PD-1/PD-L1 checkpoint inhibitors. Currently, the tumor surface PD-L1 expression level is mainly determined by immunohistochemistry, which has certain invasiveness and cannot reflect the overall immune status of the tumor. In theory, a radiolabeled molecular probe targeting PD-L1 can quantitatively reflect the tumor's PD-L1 level in real-time and comprehensively, providing a basis for immune therapy. Due to the strong affinity between 2-cyanobenzyl bromide derivative and PD-L1, we designed a small molecule bromobenzyl ether derivative suitable for 99mTc labeling to develop a molecular probe targeting PD-L1. ***Materials and Methods:*** Starting from 2-bromo-3-iodotoluene, we synthesized 2-hydroxy-4-(2-bromo-3-phenylbutoxy)-5-chlorobenzaldehyde through a reaction with phenylboronic acid, followed by a reaction with 2,4-dihydroxy-5-chlorobenzaldehyde, and a reaction with 3-cyanobenzyl bromide to generate 2-(3-cyanobenzyl methoxy)-4-(2-bromo-3-phenylbutoxy)-5-chlorobenzaldehyde. The reaction with N-[2-(2-(S-(4-methoxyphenyl) mercapto) ethylamino) ethyl] -S-(4-methoxyphenyl)-2-aminoethylthiol (N2S2) generated the labeling precursor N-[2-(3-cyanobenzyl methoxy) -4-(2-bromo-3-phenylbutoxy)-5-chlorobenzyl]-N-[2-(2-mercapto) ethylamino) ethyl] -2-aminoethylthiol (abbreviated as N2S2-CBMBC). The labeling precursor N2S2-CBMBC was dissolved in ethanol, and then sodium gluconate, stannous chloride, and pertechnetate solution were added. After shaking and heating at 90-100°C for 30 minutes, the cooled solution was obtained as the desired $^{99m}$Tc-N2S2-CBMBC. The labeling rate, radiochemical purity, and stability were examined by isotope HPLC. Furthermore, the oil-water partition coefficient of $^{99m}$Tc-N2S2-CBMBC was measured, and the cell uptake experiment of 99mTc-N2S2-CBMBC was performed. ***Results:*** The total synthesis yield of the labeling precursor N2S2-CBMBC was 12.96%. The labeling rate of $^{99m}$Tc-N2S2-CBMBC was above 94%. After being placed at room temperature for 6 hours, the radiochemical purity remained above 90%. The oil-water partition coefficient was 0.91. The cell uptake experiment showed that the cell uptake of $^{99m}$Tc-labeled 3-cyanobenzyl N2S2 bromobenzyl

ether derivative (8.55%) was 171 times that of $^{99m}$Tc-blank (without labeling precursor) in MDA-MB-231 breast cancer cells, which was consistent with the high expression of PD-L1 on the surface of MDA-MB-231 breast cancer cells reported in the literature. ***Conclusion:*** $^{99m}$Tc-N2S2-CBMBC is a small molecule bromobenzyl ether derivative that is stable at room temperature in vitro and suitable for clinical application, with the potential for targeting PD-L1. It is worthy of further research and development.

## EP-0804

### [113mIn]In-FAPI-46 radiolabeled complex: a new agent for SPECT imaging of FAP-expressing tumors

***f. Bolourinovin***[1], *F. Badipa*[1], *s. zolghadri*[2], *h. yousefnia*[3]; *[1]PARS-ISOTOPE, karaj, IRAN, ISLAMIC REPUBLIC OF, [2]Radiation Applications Research School, Nuclear Science and Technology Research Institute, P.O.Box: 11365-8486, Tehran-Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Applications Research School, Nuclear Science and Technology Research Institute, P.O.Box: 11365-8486, Tehran-Iran, tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Nowadays, targeting of cancer-associated fibroblasts by fibroblast activation protein (FAP) inhibitor (FAPI) is well-proven. FAPI-46 is a quinoline-based FAP-targeted tracer used for imaging of a multitude of different cancers showing has higher tumor accumulation and prolonged tumor retention. In this study, [$^{113m}$In]In-FAPI-46 radiotracer was prepared at optimal conditions using a domestically produced $^{113}$Sn/$^{113m}$In generator as a new agent for single positron emission computed tomography (SPECT) imaging of FAP-expressing tumors. ***Materials and Methods:*** $^{113m}$In was prepared by milking the recently developed $^{113}$Sn/$^{113m}$In generator in the form of [$^{113m}$In] $InCl_3$. Several experiments were performed by changing the amounts of FAPI-46, time, pH and the temperature of the reaction, to obtain the optimal labelling conditions of the FAPI-64 with $^{113m}$In. The radiochemical purity of the final complex was checked by radio thin layer chromatography (RTLC) and high performance liquid chromatography (HPLC). The stability of the radiolabelled complex was checked in PBS buffer (4 ºC) and human serum (37 ºC). Biodistribution of [$^{113m}$In]In-FAPI-46 was studied in normal mice using scarification and SPECT imaging. ***Results:*** [$^{113m}$In]In-FAPI-46 radiolabeled complex was obtained with a radiochemical purity of >99% (RTLC and HPLC) at optimized conditions. The investigation of the stability of the labeled compound showed a radiochemical purity of more than 96% for at least three hours in PBS buffer and in human blood serum. The results of investigating the biodistribution and the images of the indium-m113-FAPI-46 in healthy mice showed that the major portion of the activity excrete via urinary tract and other organs did not demonstrate significant accumulation. ***Conclusion:*** According to the results, [$^{113m}$In] In-FAPI-46 radiolabeled complex can be considered as a new agent for SPECT imaging of the FAP-expressing tumors, however more biological data are still needed.

## EP-0805

### First Experience with [195mPt]Cisplatin Imaging in Lung Cancer Patients

***D. Hoogenkamp***[1], *E. A. Aalbersberg*[1], *K. van der Schilden*[2], *H. N. Hendrikse*[3], *M. P. J. Mooijer*[3], *U. Funke*[3], *B. D. Windhorst*[3], *L. J. de Wit-van der Veen*[1], *M. M. G. Rossi*[1], *J. S. A. Belderbos*[1], *W. V. Vogel*[1]; *[1]NETHERLANDS Cancer Institute (NKI-AVL), Amsterdam, NETHERLANDS, [2]Nuclear Research and Consultancy Group (NRG), Petten, NETHERLANDS, [3]Amsterdamumc (location VUmc), Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Platinum-based chemotherapy reveals heterogeneous responses and the development of nephrotoxicity is common. Patient selection before therapy could aid in increasing effectiveness and decreasing toxicity. Radiolabeled [$^{195m}$Pt] Cisplatin is hypothesized to provide useful in vivo information on its distribution and aid in this process of patient selection. This imaging study evaluates the absorbed dose of [$^{195m}$Pt]Cisplatin SPECT/CT in lung cancer patients. ***Materials and Methods:*** Five patients with locally advanced non-small-cell lung cancer (NSCLC) who received concurrent chemoradiation (66 Gy/24 fractions) with low-dose cisplatin were included. Patients received a single dose of 100 MBq [$^{195m}$Pt]Cisplatin in their second or third week of treatment. For the synthesis of [$^{195m}$Pt]Cisplatin a known procedure was modified [2]. $^{195m}$Pt was supplied by the Nuclear Research & Consultancy Group (Petten, Netherlands) and produced under GMP at the Amsterdam UMC (location Vumc, Netherlands) with a radiochemical purity of ≥95% at a radioactivity concentration of 11.1 ± 4.9 MBq/ml. Up to six SPECT/CTs (Intevo Bold Siemens, Germany) were acquired between 1 and 168 hours after injection. Time-activity curves were generated by mono-exponential fitting of organ specific activities acquired using automated full organ segmentations in 3DSlicer (TotalSegmentator). S-values for $^{195m}$Pt were obtained from IDAC-Dose 2.1. ***Results:*** Tracer elimination depended on renal clearance and bladder voiding, with a half-life of 32 ± 18 hours. Blood clearance was relatively slow, with $T_{50\%}$ at 29,6 ± 15 hours. The liver received the highest [$^{195m}$Pt]Cisplatin amounts; 7.6% ± 1.1% of the total administered [$^{195m}$Pt]Cisplatin at T = 1.5 hours. Also, highest absorbed radiationdose was found in the liver (62.6 mGy ± 11.1 mGy), followed by bladder wall (48.5 mGy ±22.5) and kidneys (42.3mGy ± 9.6mGy). Patients received a mean effective dose of 15.6 ± 2.5 mSv per 100 MBq [$^{195m}$Pt]Cisplatin. Effective dose estimates were highly influenced by estimates of the bladder dose. ***Conclusion:*** [$^{195m}$Pt]Cisplatin as a diagnostic tool is safe to use in patients with NSCLC, with a mean effective dose of 15.6±2.5 mSv (0.16±0.025 mSv/MBq). In following studies, tumor accumulation and imaging quality will be further assessed. ***References:*** [1] E.A. Aalbersberg, B.J. de Wit - van der Veen, O. Zwaagstra, et al. Preclinical imaging characteristics and quantification of Platinum-195m SPECT. Eur J Nucl Med Mol Imaging (2017) 44:1347-1354 [2] J.D. Hoeschele, T.A. Butler, J.A. Roberts, C.E. Guyer. ## EP-0806

### Preparation and quality control of [113mIn]In-PEG4-BBN(7-14) as a new agent for SPECT imaging of GRPR-expressing tumors

***s. zolghadri***, *F. Badipa, H. Yousefnia, B. Alirezapour, A. Bahrami-Samani, S. Shirvani-Arani, F. Bolouri-Novin; Nuclear Science and Technology Research Institute (NSTRI), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Nowadays, due to the suitable characteristics of peptides, peptide-based radiopharmaceuticals have found an important role in the development of diagnostic and therapeutic radiopharmaceuticals. Gastrin-releasing peptide receptors (GRPRs) are overexpressed in many cancers such as prostate, breast, pancreatic, and small cell lung carcinoma. Bombesin (BBN) analogs radiolabeled with different diagnostic radionuclides have indicated excellent efficacy for imaging of tumors with GRPRs. This study aimed to produce [$^{113m}$In]In-PEG4-BBN(7-14) as a new agent for single positron emission computed tomography (SPECT) imaging of GRPR-expressing tumors. ***Materials and Methods:***

$^{113m}$In was eluted from the in-house developed $^{113}$Sn/$^{113m}$In generator in the form of [$^{113m}$In]$InCl_3$. While several experiments were performed to determine the optimal conditions for radiolabeling of DOTA-PEG4-BBN(7-14) with $^{113m}$In, the radiochemical purity of the final complex was checked by radio thin layer chromatography (RTLC) and high performance liquid chromatography (HPLC). The stability of the radiolabelled complex was checked in PBS buffer (4 ºC) and human serum (37 ºC). Cellular studies (binding affinity and internalization) were carried out in PC3 and CHO cell lines, as the GRPRs positive and negative cell lines, respectively. Biodistribution of [$^{113m}$In]In-PEG4-BBN(7-14) was studied in normal mice using organ %ID/g calculation and SPECT imaging. Biodistribution studies in GRPR-expressing animal tumor model are ongoing. ***Results:*** The radiolabeled complex was obtained with a radiochemical purity of >99% (RTLC and HPLC) at the optimized conditions. The radiochemical purity of the complex was higher than 98% for at least four hours in PBS buffer and human blood serum. Cellular studies of [$^{113m}$In]In-PEG4-BBN(7-14) showed the high affinity of the complex to the GRPR-expressing cell line and no affinity to CHO cell line. Also, the radiolabeled complex was rapidly internalized into the PC3 cell lines whereas the internalization into CHO cells was negligible. The biodistribution studies in normal mice demonstrated the renal excretion of the radioactivity and significant accumulation of the radiolabeled compound in GRPR-expressing organs. ***Conclusion:*** The initial results demonstrated that [$^{113m}$In]In-PEG4-BBN(7-14) radiolabeled complex has a high potential for SPECT imaging of the GRPR-expressing tumors.

## EP-0807

### Preclinical evaluation of a novel PSMA-targeting radioligand [99mTc]Tc-BQ0413

***E. Bezverkhniaia***[1], *P. Kanellopoulos*[1], *A. Abouzayed*[1], *M. Oroujeni*[1], *A. Vorobyeva*[2], *U. Rosenström*[1], *V. Tolmachev*[1], *A. Orlova*[1];
[1]*Uppsala university, Uppsala, SWEDEN.*

***Aim/Introduction:*** Several types of radiolabelled PSMA inhibitors have been investigated for imaging of prostate cancer. The most extensively investigated type of high-affinity inhibitors are urea-based ligands. Clinical practice demonstrated good specificity of such tracers labelled with positron emitters. However, current progress in development of SPECT/CT cameras creates a potential of using this modality for detection and staging of prostate cancer. BQ0413 is a PSMA inhibitor, which was optimized using structure modelling. To enable labelling with $^{99m}$Tc, a EEEC chelator was incorporated in BQ0413. The aim of this study was to perform initial preclinical evaluation of [$^{99m}$Tc]Tc-BQ0413. ***Materials and Methods:*** BQ0413 was radiolabelled with $^{99m}$Tc using transchelation from gluconate. Labelling stability of [$^{99m}$Tc]Tc-BQ0413 was evaluated in vitro. In vitro PSMA-binding specificity, cellular processing and binding kinetics of [$^{99m}$Tc]Tc-BQ0413 was evaluated using PSMA-transfected PC-3.pip cells. Biodistribution of [$^{99m}$Tc]Tc-BQ0413 was measured in NMRI mice, and data were used for dosimetry upscaling to humans. ***Results:*** BQ0413 was radiolabelled with radiochemical yield above 95% according to iTLC and radio-HPLC analysis. The label was stable (no measurable release) during 1 h in 300 molar excess of L-cysteine and PBS at room temperature and in human serum at 37° C. The binding of [$^{99m}$Tc]Tc-BQ0413 to PC-3.pip cells was saturable by a commonly used PSMA-11 ligand. Binding to non-transfected PC-3 cells was much lower than the binding to PC-3,pip. These data suggest that the binding was PSMA-specific. The internalized fraction was approximately 40% after 4 h. Real-time binding kinetics of [$^{99m}$Tc]Tc-BQ0413 demonstrated extremely slow dissociation rate. The quilibrium dissociation constant (KD) value was 33±14 pM. The biodistribution profile demonstrated rapid clearance from all of organs and tissues (excluding kidneys). Major clearance was through glomerular filtration. The highest uptake was in kidneys, 80% of injected activity 1 hour past injection. Retention in kidneys was stable between 1 and 6 h and but decreased 7-fold by 24 hours. According to dosimetry estimation, the organ with the highest absorbed dose should be kidneys (0.1170 mGy/MBq). Doses to other organs and tissues are expected below $10^{-2}$ mGy/MBq. The estimated effective dose for humans is 0.0018 mSv/MBq. ***Conclusion:*** PSMA-inhibitor BQ0413 that can be easily radiolabelled with technetium-99m using techniques permitting development of a single-vial kit. BQ0413 demonstrated specific binding to PSMAS-transfected cells. [$^{99m}$Tc]Tc-BQ0413 cleared rapidly from normal organs via kidneys, but the renal uptake and retention were high. The data suggest that evaluation of [$^{99m}$Tc]Tc-BQ0413 in tumor-bearing mice is justified.

### Expanding the Versatility of F-18 Indirect Labeling: Optimizing the Synthesis of TDBFB Boronic Acid Derivatives for Indirect Labeling via Suzuki Coupling

***Y. Yagi***[1,2,3], *H. Kimura*[2], *M. Ando*[1], *K. Kawaguchi*[1], *A. Sato*[1], *A. Shimizu*[1], *M. Fujimura*[1], *T. Higuchi*[3,4];

[2]*Kyoto Pharmaceutical University, Kyoto, JAPAN,*
[3]*University Hospital Würzburg, Würzburg, GERMANY,*
[4]*Okayama University, Okayama, JAPAN.*

***Aim/Introduction:*** Positron emission tomography (PET) utilizes bioactive compounds labeled with F-18 radioisotopes as probes. While nucleophilic substitution reactions with the [$^{18}$F]fluoride ion are commonly used for introducing F-18, it remains challenging to introduce it into electron-rich aromatic rings. To overcome this challenge, we previously reported a new F-18 labeling method that employs the Suzuki coupling reaction with an indirect labeling reagent, the boronic acid derivative 4-(4,4,5,5-Tetramethyl-1,3,2-dioxaborolan-2-yl)-[$^{18}$F]fluorobenzene (4-[$^{18}$F]TDBFB). In this study, we further enhanced the versatility of TDBFB by improving the synthesis of 4-[$^{18}$F]TDBFB. Additionally, we investigated the synthesis of 3-[$^{18}$F]TDBFB and 2-[$^{18}$F]TDBFB. ***Materials and Methods:*** Initially, we investigated various F-18 sources, solvents, reaction temperatures, and additives to synthesize 4-[$^{18}$F]TDBFB from 1,4-benzenediboronic acid bis(pinacol)ester instead of using the diaryliodonium precursor. To evaluate the labeling rate of F-18 fluorination, we used Radio-Thin Layer Chromatography (Radio-TLC) and Radio-HPLC. Subsequently, we utilized the Suzuki coupling reaction to synthesize [$^{18}$F]fluorobiphenyls and a pitavastatin derivative, [$^{18}$F]pitavastatin-OMe, as applications of [$^{18}$F]TDBFB. We monitored the reaction progress using the same method. ***Results:*** At first, the [$^{18}$F]fluoride ion was eluted from the cation

exchange resin using DMAP/OTf, and subsequently heated at 120ºC for 20 min in dimethylacetamide, in the presence of 4-TDBFB precursor and copper catalyst, leading to the confirmation of the target product on Radio-TLC. This reaction condition resulted in a 2-fold increase in yield compared to previously reported conditions[1]. While microwave heating conditions[2] yielded 4-[$^{18}$F]TDBFB in a similar yield to conventional heating conditions, they enabled a shorter reaction time. The reaction progress was also evaluated using 3-[$^{18}$F]TDBFB and 2-[$^{18}$F]TDBFB precursors, yielding similar results. To synthesize [$^{18}$F]fluorobiphenyls and [$^{18}$F]pitavastatin, we employed [$^{18}$F]TDBFB with iodo or triflate precursors for [$^{18}$F]fluorobiphenyls, and a bromine-labeled precursor for pitavastatin. These coupling reactions proceeded successfully. ***Conclusion:*** The study supports the idea that [$^{18}$F]TDBFB could be utilized as a more versatile indirect labeling reagent. ***References:*** 1. ## EP-0809

### Automated One-Pot Synthesis of [18F]AlF-NOTA-Ubiquicidin[29-41] in Aqueous Solution with Preparative HPLC for Clinical PET/CT imaging

***A. Meyer***, *C. Fischer, D. Hellwig;*
*University Hospital, Regensburg, GERMANY.*

***Aim/Introduction:*** Ubiquicidin[29-41], a cationic-rich peptide fragment, exhibits affinity towards bacterial cell membranes. [$^{99m}$Tc] or [$^{68}$Ga] have been used to label the peptide fragment for imaging infection sites. However, the radiolabeling of the NOTA-conjugated Ubiquicidin[29-41] with $^{18}$F, an ideal radionuclide for PET, remains unexplored. Thus, we aimed to develop and optimize a GMP-compliant radiolabeling method for the synthesis of [$^{18}$F]AlF-NOTA-Ubiquicidin[29-41] in aqueous solution suitable for clinical PET imaging. ***Materials and Methods:*** The synthesis process involves a protic reaction solution that enables the formation of the intermediate transition metal [$^{18}$F]$AlF^{2+}$. We utilize a Raytest SynChrom R&D platform for the radiosynthesis of [$^{18}$F]AlF-NOTA-Ubiquicidin[29-41]. A cyclotron-produced activity of 40 GBq $^{18}$F is fixed on a Sep-Pak Accell Plus QMA light and eluted with 0.9% saline. After addition of 500 µL sodium acetate buffer 0.5 M (pH 4.0) and 35 µL $AlCl_3 \cdot 6\ H_2O$ 10 mM, [$^{18}$F]$AlF^{2+}$ is formed within two minutes at room temperature. After addition of 1 mL precursor solution (1 mg/mL NOTA-Ubiquicidin[29-41] in EtOH 10%), [$^{18}$F]AlF-NOTA-Ubiquicidin[29-41] is built at 105 °C within 15 minutes. Purification is performed on a preparative Nucleodur C18 Pyramid column using two mobile phases, one phosphate buffer/EtOH 98:2 (pH 7.0) for elution of ionic impurities (e.g. [$^{18}$F]$F^-$) and the other phosphate buffer/EtOH 90:10 (pH 7.0) for elution of the product at 16.7 minutes (flow rate of 5 mL/min). The product peak is collected in 10 mL Wfl by switching the valve triggered by in-process monitoring. The formulation is sterilized by sterile filtration while being filled into a vial in the dispenser under validated type A clean room conditions. Quality control is carried out according to predefined specifications. ***Results:*** The synthesis of [$^{18}$F]AlF-NOTA-Ubiquicidin[29-41] is carried out within 45 minutes with a radiochemical yield of 15 % and a radiochemical purity (RCP) of 96.5% using 40 GBq [$^{18}$F], 350 nmol $AlCl_3 \cdot 6\ H_2O$ and 1 mg NOTA-Ubiquicidin[29-41] in aqueous acetate buffer (pH 4.0) (n=3 replicates) with a final ethanol concentration of 3.0%. Product activity can be adjusted to meet individual needs by varying the amounts of [$^{18}$F], $AlCl_3 \cdot 6\ H_2O$ and precursor. The formulation is stable with an RCP ≥90% after 10 hours. Bioburden and media fill confirm GMP-compliance. ***Conclusion:*** Our developed GMP-compliant radiolabelling procedure provides reproducible results with sufficient yield to use PET/CT imaging with [$^{18}$F]AlF-NOTA-Ubiquicidin[29-41] for studies to localize and characterize infection sites. The synthesized radiopharmaceutical can potentially improve clinical diagnosis and treatment of bacterial infections.

## EP-0810

### Development of a 18F-PD-L1 radiotracer for cancer patient response to immunotherapy

***M. Goodman***, *L. Chavan, W. Seo, H. Zecca, R. Voll, L. Birnbaum, J. Kelvin, E. Dreaden, N. Jui;*
*Emory University, Atlanta, GA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Introduction: Immunotherapies represent new weapons in the fight against cancer. Monoclonal antibodies are at the forefront of these therapies that target the PD-1/PD L1 axis. Several anti-PD-L1 antibodies have recently received FDA approval for treating recurrent/metastatic disease in melanoma, kidney, bladder, gastric, lung and head and neck cancers. Accurate PD-L1 diagnostic tools are critical to predict which patients are likely to respond to anti-PD-L1 therapies. Here we report the synthesis, radiolabeling and characterization of a new $^{18}$F-PD L1 small molecule, as a radioligand for imaging PD L1 expression in cancer with PET. ***Materials and Methods:*** (2S,4S)-1-(2-cyano-3-(2,3-dihydrobenzo[b][1,4]dioxin-6-yl)phenyl)-4-fluoropyrrolidine-2-carboxylic acid, PD-L1 A2, was designed based on therapeutics by Incyte[1] . PD-L1 A2 was synthesized in five linear steps starting from commercially available 2-bromo-6-fluoro-benzonitrile. Binding affinity for PD L1 was determined by surface plasmon resonance measurement. Radiolabeling of $^{18}$F-PD-L1 A2 was accomplished with an GE TracerLab FX2 N by treatment of a tosylate precursor (3R,5R)-1-(2-cyano-3-(2,3-dihydrobenzo[b][1,4]dioxin-6-yl)phenyl)-5-methylpyrrolidin-3-yl 4-methylbenzenesulfonate with $K_{222}/K^{18}F/K_2CO_3$ in $CH_3CN$ at 100 °C followed by deprotection with 1:1 1N NaOH:$CH_3OH$ v/v, neutralization with $CH_3CO_2H$ and HPLC purification. ***Results:*** PD-L1 A2 exhibited moderate affinity for PD-L1 (Ki = 50 µmole) and good physiochemical properties log $D_{7.4}$ = 1.0. $^{18}$F-PD-L1 A2 was obtained in 66 min in 12.5% decay-corrected radiochemical yield with specific activity >1 Ci/µmole, radiochemical and chemical purities of >99%. ***Conclusion:*** Tosylate precursor 1 is an effective precursor for $^{18}$F-PD-L1 A2. Additionally, the moderate binding affinity and Log D7.4 suggest that $^{18}$F-PD-L1 A2 could be a potential agent for quantitating PD-L1 by PET. ## EP-0811

### rhTATE: A Radiohybrid Approach for 18F or177LuLabelled Somatostatin Analogues Generating Chemically Identical Compounds

***S. Deiser***, *V. König, S. Fenzl, T. Günther, N. Urtz-Urban, S. Inoue, A. Casini;*
*Technical University Munich (TUM),*
*Garching by Munich, GERMANY.*

***Aim/Introduction:*** We recently successfully established the radiohybrid (rh) concept within our group for PSMA-targeted compounds[1], which enables the use of chemically identical compounds for PET imaging, and radioligand therapy, irrespective wether fluorine-18 or lutetium-177 is applied. Hence, we developed rh-based somatostatin analogues, which contain

a novel silicon-based fluoride acceptor (SiFA) building block ("SiFA-SeFe") for $^{18}$F-labelling and a DOTA moiety for $^{177}$Lu-labelling. For a preclinical proof-of-concept study, we used the binding motif of DOTATATE and introduced a novel linker disign to optimize pharmacokinetics of [$^{18}$F]F-[$^{nat}$Lu]Lu-rhTATE. All compounds were evaluated by state-of-the-art experiments and compared with [$^{18}$F]F-SiFAlin-TATE and [$^{177}$Lu]Lu-DOTATATE. ***Materials and Methods:*** All peptides were synthesized by standard solid-phase peptide synthesis (SPPS). $^{18}$F-labelling was conducted via isotopic exchange reaction at room temperature within 10 min (ammonium formate in anhydrous DMSO) using previously dried [$^{18}$F]fluoride with subsequent purification by catridge. Sst2r affinity (expressed as $IC_{50}$) was determined on $CHO_{sst2}$ cells. Lipophilicity (expressed as n-octanol/phsphate buffered saline solution distribution coefficient, $logD_{7.4}$) was determined. Human serum albumin (HSA) binding was determined by high-performance affinity chromatography (HPAC). Biodistribution studies were carried out at 1 h post-injection (p.i.) in AR42J tumour-bearing CD1-nu/nu mice. ***Results:*** Labelling of [$^{18}$F]F-[$^{nat}$Lu]Lu-rhTATE analogues was completed within <30 min and resulted in radiochemical yields (RCY) and purities (RCP) >35% and >95%, respectively. Labelling of [$^{nat}$F]F-[$^{177}$Lu]Lu-rhTATE derivatives was completed within 5 min and resultad in RCY >95% and RCP >95%. All [$^{18}$F]F-[$^{nat}$Lu]Lu-rhTATE analogues showed low nanomolecular affinity (5.2-9.3 nM), elevated lipophilicity ($logD_{7.4}$: -1.68 to -0.18) and high HSA binding as compared with the reference radiopharmaceuticals [$^{18}$F]F-SiFAlin-TATE and [$^{177}$Lu]Lu-DOTATATE (>95% versus 92% and 51%, respectively). In vivo at 1 h p.i., the most promising [$^{18}$F]F-[$^{177}$Lu]Lu-rhTATE derivative revealed high tumour and low liver uptake (27.3±9.0 and 4.5±0.5 %ID/g, respectively), but high kidney accumulation (99.8±8.0 %ID/g), while acivity levels in the blood and the bone were low (<2 %ID/g). ***Conclusion:*** In summary, we have developed a new generation of radiohybrid-based somatostatin ligands that enable the use of chemically identical ligands, irrespective wether fluorine-18 or lutetium-177 is applied. The most promising [$^{18}$F]F-[$^{nat}$Lu]Lu-rhTATE analogue revealed similar pharmacokinetics to the established [$^{18}$F]F-SiFAlin-TATE and [$^{177}$Lu]Lu-DOTATATE and might terefore, be beneficial for future applications as a theranostic platform. ***References:*** [1] A.Wurzer, D. ## EP-0812

### Phenolate-containing AAZTA-like chelators for 68Ga labelling. An in vitro and in vivo study.

***L. Tei***[1], *J. Martinelli*[1], *M. Boccalon*[2], *A. Vagner*[3], *D. Szikra*[4], *G. Trencsenyi*[4], *Z. Baranyai*[2];
[1]*Department of Science and Technological Innovation, University of Piemonte Orientale, Alessandria, ITALY,* [2]*Bracco Research Centre, Bracco Imaging S.p.A., Colleretto Giacosa, Via Ribes 5, ITALY, ITALY,* [3]*Scanomed Ltd., Debrecen, Nagyerdei krt. 98, HUNGARY,* [4]*Division of Nuclear Medicine and Translational Imaging, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, Nagyerdei krt. 98, HUNGARY.*

***Aim/Introduction:*** In the search for chelators with high affinity and selectivity for Ga(III), the heptadentate chelator AAZTA and its derivatives have been recently selected because of their characteristics in between the linear and macrocyclic structure allowing both fast complexation kinetics and high inertness of the Ga(III) complexes.[1] However, this success is weakened by the formation of a hydroxo ternary species characterized by lower inertness and lower radiolabelling performance at neutral pH. The introduction of phenolate donors was shown to increase contemporaneously both the basicity and the rigidity of the ligand and both the stability and the kinetic inertness of the corresponding metal complexes.[2] ***Materials and Methods:*** The ligands AAZ2A-exoHB and AAZ3A-endoHB with the hydroxybenzyl pendant arm on the exocyclic or endocyclic amine were synthesized and a study on the thermodynamic and kinetic properties of the Ga(III) was undertaken. Then, the labelling efficiency of the chelators with $^{68}$Ga was examined at different temperatures, pH and ligand concentration to determine the optimal labelling conditions. Subsequently, the chelator with the best performance was chosen and a bifunctional derivative bearing an isothiocyanate group was synthesized for the conjugation to a cyclo(RGD) peptide for $\alpha_v\beta_3$ integrin targeting. Finally, the tracer was labelled with $^{68}$Ga isotope, and the resulting radiotracer tested for its stability in human serum and then in vivo for targeting B16-F10 tumours with miniPET imaging. ***Results:*** The ligands AAZ2A-exoHB and AAZ3A-endoHB with the hydroxybenzyl pendant arm on the exo- or endocyclic amino groups were synthesized and a study on the thermodynamic and kinetic properties of the Ga(III) was undertaken. The labelling efficiency with $^{68}$Ga was examined at different temperatures, pH and ligand concentration to determine the optimal conditions. Subsequently, the chelator with the best performance was chosen and a bifunctional derivative was synthesized and conjugated to a cyclo(RGD) peptide for $\alpha_v\beta_3$ integrin targeting. Finally, the tracer was labelled with $^{68}$Ga, and the resulting radiotracer tested for its stability in human serum and in vivo for targeting B16-F10 tumours with miniPET imaging. ***Conclusion:*** More basic phenolate O-donor atoms have better coordination abilities than carboxylates to Ga(III), forming complexes with higher thermodynamic stability and improved kinetic inertness. Thus, the conjugates of AAZ3A-endoHB with different targeting vectors can be suitable examples for the development of $^{68}$Ga-based PET imaging tracers with improved chemical properties in vivo. ***References:*** [1] C. Fersing et al. Pharmaceuticals 2022, 15, 234; [2] J. Martinelli et al. Inorg. Chem. Front. 2022, 9, 2271

## EP-0813

### Automated Synthesis Method To Produce The Pet Tracer [68ga]Ga-Fapi-46 For Clinical Applications: Development, Optimization And Validation

***S. Migliari****, G. Ladisa, M. Scarlattei, G. Baldari, L. Ruffini;*
*Nuclear Medicine Division, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is a serine protease selectively expressed in many disorders associated with fibrotic dysregulation.FAP expression in healthy tissues is low, but significantly elevated in sites of tissue remodelling and repair. This specific pattern of expression makes FAP an ideal target for imaging and therapy and then FAP-specific small-molecule inhibitors (FAPIs) have been developed. The most promising molecule has been found FAPI-46, functionalized with DOTA to obtain a PET probe. Our goal was to develop, optimize and validate a new automated synthesis method to label DOTA-FAPI-46 with Ga-68 and a new quality control system to make the radiopharmaceutical available. ***Materials and Methods:*** Synthesis and quality assessment of 68Ga-FAPI-46 radiotracer was done using the automated synthesis module Scintomics GRP® connected to the GMP certified 68Ge/68Ga generator (GalliaPharma®, Eckert and Ziegler). The radiopharmaceutical production process has been conducted by a scale down method from 50 µg of peptide precursor to 10 µg (50-40-30-20-10 µg). Synthesis efficiency and release criteria have

been assessed for all the final products evaluating radiochemical yield (RY%), radiochemical purity (RCP%) with both Radio-TLC and Radio-UV-HPLC, specific activity (As) or molar activity (Am), chemical purity, pH and LAL test. ***Results:*** Best results were yielded with 20 µg DOTA-FAPI-46 and three different batches of validation were obtained with optimal RY% (67.75%) as well RCP% (99.76%) and Am (26.23 GBq/µmol). ***Conclusion:*** The excellent synthesis and QCs results ensure that our developed production process is very efficient and safe for a multi-dose application of 68Ga-FAPI-46 in clinical settings. ***References:*** [1] Lindner T et al. J Nucl Med. (2018). [2] Loktev A et al. J Nucl Med. (2019

## EP-0814

### Synthesis and Biological Evaluation of 18F-labelled Deuterated Tropane Derivatives as Dopamine Transporter Probes

***Q. Hu***[1], *Z. Chen*[1,2,3], *Q. Li*[2,3], *J. Tang*[2], *Y. Fang*[2], *C. Liu*[2], *J. Liu*[1,2], *M. Qi*[2,4]; [1]*Department of Radiopharmaceuticals, School of Pharmacy, Nanjing Medical University, Nanjing, CHINA,* [2]*NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA,* [3]*Jiangsu Key Laboratory of New Drug Research and Clinical Pharmacy, School of Pharmacy, Xuzhou Medical University, Xuzhou, CHINA,* [4]*School of Pharmaceutical Science, Inner Mongolia Medical University, Hohhot, CHINA.*

***Aim/Introduction:*** Dopamine transporter (DAT) is a promising target for positron emission tomography (PET) imaging of many neuropsychiatric diseases. $^{18}$F-labelled N-alkyl tropane analogues were reported to be useful PET radioligands for DAT. However, the drawback of $^{18}$F-labelled tropane analogues is that N-alkyl on tropane is easily metabolized in vivo, which interferes with brain imaging. To develop a more in vivo stable DAT-targeted PET radioligand with high DAT affinity and specificity, in this study, we synthesized and compared a series of $^{18}$F-labelled novel deuterated N-fluoropropyl tropane derivatives ([$^{18}$F]FP-CPT-$d_6$, [$^{18}$F]FP-CFT-$d_6$, [$^{18}$F]FP-CCT-$d_6$, [$^{18}$F]FP-CMT-$d_6$, [$^{18}$F]FP-CIT-$d_6$) for DAT tracing. ***Materials and Methods:*** Five deuterated N-fluoropropyl-$d_6$ tropane derivatives (FP-CPT-$d_6$, FP-CFT-$d_6$, FP-CCT-$d_6$, FP-CMT-$d_6$, FP-CIT-$d_6$) and corresponding non-deuterated compounds (FP-CPT, FP-CFT, FP-CCT, FP-CMT, FP-CIT) were synthesized, and their semi-inhibitory concentrations ($IC_{50}$) were measured by competitive binding assay. These radioligands were obtained by two-step one-pot radio-labelling reactions. The selectivity and specificity of these radioligands were evaluated by cellular uptake and microPET in normal rats. [$^{18}$F]FP-CIT-$d_6$ was selected for further investigation with autoradiography, biodistribution experiments, and microPET of the PD model and compared with its non-deuterated structure [$^{18}$F]FP-CIT. Finally, in vivo metabolic stability was analyzed by radio-HPLC. ***Results:*** Five deuterated N-fluoropropyl tropane analogs and corresponding nondeuterated structure were synthesized. All these compounds had high DAT affinity ($IC_{50}$ = 2 - 21 nM), in which FP-CIT-$d_6$ had the lowest $IC_{50}$ of 2.7 nM. $^{18}$F-labelled deuterated and non-deuterated probes were obtained with radiochemical yields ranging from 10.6 ± 2.8% to 35.1 ± 5.4% with molar activities > 20 GBq/µmol and the radiochemical purities > 99%. [$^{18}$F]FP-CIT-$d_6$ showed the highest cell uptake (12%) and CFT inhibition efficacy (~ 72%) among deuterated probes. MicroPET results showed [$^{18}$F] FP-CIT-$d_6$ has the highest target to non-target ratio (striatum/cerebellum) from 30 to 120 min. Therefore, [$^{18}$F]FP-CIT-$d_6$ was then selected for further biological evaluation. Ex vivo autoradiography experiment confirmed high specific binding of [$^{18}$F]FP-CIT-$d_6$ towards DAT. Biodistribution results indicated that [$^{18}$F]FP-CIT-$d_6$ has a higher striatum/cerebellum value than [$^{18}$F]FP-CIT at 30 - 120 min. Furthermore, in vivo metabolism studies in rats revealed improved stability of [$^{18}$F]FP-CIT-$d_6$ as compared with that of [$^{18}$F] FP-CIT. ***Conclusion:*** The new probe [$^{18}$F]FP-CIT-$d_6$ is a promising candidate with good DAT affinity, specificity and metabolic stability for PET imaging, and might provide reliable diagnosis and prognostic detection of DAT-related neuropsychiatric diseases. ## EP-0815

### 18F-labeled TTCO-PSMA Conjugate as a novel PET agent for prostate cancer imaging

***T. Zhang****, Z. Zhang, G. Dong, L. Le, X. Ji, C. Peng, K. Li, X. Chen; Nanjing Medical University, Nanjing, CHINA.*

***Aim/Introduction:*** In order to achieve more effective prostate-specific membrane antigen (PSMA)-targeted agents for the diagnosis of prostate cancer, a novel $^{18}$F-labeled PSMA-targeting agent ($^{18}$F-TTCO-PSMA) was developed based on the high-affinity Glu-urea-Lys scaffold and biorthogonal linker. ***Materials and Methods:*** $^{18}$F-TTCO-PSMA was obtained by three steps of acylation, reduced by 10% palladium/carbon and bioorthogonal conjugation. Micro PET/CT and biodistribution studies were performed in the LNCaP tumor-bearing mice. ***Results:*** The radiochemical purity of $^{18}$F-TTCO-PSMA was over 97%, which met the quality control standard. The PET/CT imaging results showed that the tumor uptake of $^{18}$F-TTCO-PSMA was 8.8 ± 3.3, 9.1 ± 2.1 and 8.2 ± 2.2% ID/g at 0.5 h, 1.5 h and 3 h, respectively, indicating that the uptake of the probe in the tumor was obvious and did not decrease significantly with time. Although $^{18}$F-TTCO-PSMA had obvious uptake in the kidney, it had an obvious downward trend with time. Compared with $^{68}$Ga-PSMA-11, which has been approved by FDA (2020), the probe had a lower kidney uptake and a significant downward trend over time, while maintaining a high tumor uptake and a low liver and muscle uptake. ***Conclusion:*** The introduction of the linker TTCO improves the stability, pharmacodynamics, and pharmacokinetics properties of the probe due to its biorthogonal structure and improved biocompatibility in function. $^{18}$F-TTCO-PSMA has significant tumor uptake and low non-target uptake, making it a promising PET probe worth further evaluation for its clinical value in patients with prostate cancer.

## EP-0816

### A novel 68Ga-labeled spermine derivative probe for tumor imaging

***K. Qin***[1], *D. Shi*[1], *H. Wang*[1,2,3], *S. Li*[1,2,3]; [1]*Shanxi Medical University, Taiyuan, Shanxi, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Taiyuan, Shanxi, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan, Shanxi, CHINA.*

***Aim/Introduction:*** Polyamine transporter system (PTS) mediates the transmembrane transport of polyamines. The expression of PTS was upregulated in most tumors, making it a promising target for tumor imaging and therapy. It has been reported that radionuclide-labeled spermine can characterize the expression of PTS in cancer cells and image PTS-positive tumors in vivo, such as $^{99m}$Tc-HYNIC-spermine and $^{99m}$Tc -spermine. Persisted uptake in the liver is the main limitation of the currently reported probes targeting

PTS. Developing stable PTS-targeting probes with lower liver uptake is highly desirable, particularly in the context of precise therapy. Given this, we developed a novel gallium-68-labeled spermine derivative for tumor imaging targeting PTS in this study. ***Materials and Methods:*** Herein, the precursor NOTA-Spermine was obtained by the modification of spermine with the bifunctional chelating agent NOTA. Then, the [$^{68}$Ga]Ga-NOTA-Spermine was prepared by labeling the precursor with gallium-68. The biodistribution and stability of [$^{68}$Ga]Ga-NOTA-Spermine were determined in healthy mice, and the cell uptake assays was conducted with A549 (PTS+) cell lines to determine the PTS specific binding. The tumor imaging potential of [$^{68}$Ga]Ga-NOTA-Spermine were explored using micro-PET/CT imaging in DU145 tumor-bearing mice. ***Results:*** [$^{68}$Ga]Ga-NOTA-Spermine were successfully obtained with high radiochemical yields (50-55%) and purity (>98%), and had good stability in serum. Cell uptake showed that [$^{68}$Ga]Ga-NOTA-Spermine could be taken up by A549 tumor cell with the peak uptake at about 90 min (15.4% ±0.68%). Biodistribution showed that there was a low tracer uptake in liver for [$^{68}$Ga]Ga-NOTA-Spermine, which differs from other reported probes. The improvement might facilitate the visualization of abdominal lesions. Static micro-PET/CT scan showed a clear DU145 tumor uptake, and the radioactivity mainly accumulated in kidney with a rapid blood clearance (>60% within 30 min postinjection) and a low uptake in the majority of organs, which facilitated a good tumor-to-no tumor contrast. ***Conclusion:*** We have successfully synthesized a novel $^{68}$Ga-labeled spermine derivative, and the evaluated results suggested that it might be a promising probe in tumor imaging targeted PTS. Further studies of [$^{68}$Ga]Ga-NOTA-Spermine will assess its application in tumors with different expression levels of PTS, as an effective technique for monitoring PTS expression in solid tumors.

## EP-0817

### Micro-PET Imaging Study of the Novel 68Ga-labeled PET Probe 68Ga-NOTAGA-Nap-Gal

***Y. Xu***[1], *P. Zhou*[2], *Y. Wu*[2], *H. Wu*[1], *Y. Liu*[1], *H. Wang*[1], *P. Zou*[1];
[1]*Jiangsu institute of Nuclear Medicine, WuXi, CHINA,*
[2]*Nanjing Medical University, Nanjing, CHINA.*

***Aim/Introduction:*** Synthesize a novel PET probe $^{68}$Ga-NOTAGA-Nap-Gal,which targets tumors with high expression of beta-galactosidase.Perform Micro-PET imaging of the probe and study its uptake in tumors and liver based on imaging results. ***Materials and Methods:*** The precursor NOTAGA-Nap-Gal was labeled with $^{68}$Ga to obtain the target probe $^{68}$Ga-NOTAGA-Nap-Gal, and the radiochemical purity of the probe was detected by radioactive HPLC. Ovarian cancer cells OVCAR-3 and breast cancer cells MDA-MB-468 were cultured and implanted into the armpits of nude mice to establish tumor-bearing nude mouse models. After the tumors grew to an appropriate size, the probe $^{68}$Ga-NOTAGA-Nap-Gal was injected into the tail vein, and 10 min of Micro-PET static imaging was performed at 1 and 2 h after injection. The tumors and livers in the Micro-PET images were delineated in three consecutive layers, and the percentage of injected dose per gram of tissue (%ID/g) was calculated to study the uptake performance of the probe in tumors and livers. ***Results:*** Radiolabeled HPLC showed that the radiochemical purity of $^{68}$Ga-NOTAGA-Nap-Gal probe was greater than 95%, and no further purification was required for subsequent experiments. The Micro-PET imaging of the probe in the xenograft OVCAR-3 and MDA-MB-468 models showed clear visibility of the tumors. The tumor uptake values at 1 and 2 h in the OVCAR-3 model were 3.57±0.48 and 2.68±0.19 %ID/g, respectively, and the liver uptake rates at 1 and 2 h were 4.56±0.73 and 3.58±0.39 %ID/g, respectively. In the MDA-MB-468 model, the tumor uptake values at 1 and 2 h were 2.71±0.44 and 2.12±0.29 %ID/g, respectively, and the liver uptake rates at 1 and 2 h were 4.25±0.53 and 2.95±0.47 %ID/g, respectively. ***Conclusion:*** This probe is easy to prepare and has good imaging effects in high-expressing beta-galactosidase tumor models. Further tissue distribution experiments are needed for validation of in vivo tissue distribution.

## EP-0818

### Atlas-Based Simulation for Pre-Estimation of Absorbed Dose in Critical Target Organs: A Study Using Monte Carlo Simulations with XCAT Phantoms and Real Patient Data in 68Ga-PSMA PET/CT

***N. Vahidfar****, M. Fallahpoor, S. Farzanefar;*
*Tehran University of Medical Sciences,*
*Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The pre-estimation of absorbed radiation dose in critical target organs can be calculated in advance using atlas-based simulations, utilizing advanced anthropomorphic phantoms and Monte Carlo codes, to minimize side effects of radiopharmaceuticals and achieve accurate estimations. In this study, we aimed to calculate S-values (a measure of absorbed dose) of 68Ga-PSMA in different body mass indices (BMIs) using XCAT male phantoms through Monte Carlo simulations, and then compare the results with real patient data. ***Materials and Methods:*** Seven BMIs of XCAT male phantoms were generated, with the spine, prostate, kidneys, and salivary glands chosen as the source organs, and the kidneys, spleen, liver, salivary glands, prostate, spine, small intestine, and lung as the target organs. Dosimetry calculations were performed using the GATE Monte Carlo code for an activity of 20 MBq of both agents. For the patient-based study, six patients with castrate-resistant prostate cancer (CRPC) underwent 68Ga-PSMA-11 PET/CT scans, and the PET images as activity maps and CT as attenuation maps were used for dosimetry calculations with the GATE Monte Carlo code. S-values were reported for critical organs relevant to diagnostic and therapeutic PSMA-based tracers, and standard uptake value (SUV)max measurements were also performed in the same organs for comparative analysis. ***Conclusion:*** The results of this study demonstrated a reasonable correlation between the S-value results obtained from the XCAT phantoms and the patient study, indicating the potential of atlas-based dosimetry applications.

## EP-0819

### Evaluation of Different Ranges of [18F]Fluoride for Production of [18F]F-FAPI-74

***A. MORISCO****, C. Maisto, R. de Marino, L. D'Ambrosio, E. Squame, M. Buonanno Recchimuzzo, A. Esposito, M. Aurilio, P. Gaballo, S. Lastoria;*
*ISTITUTO NAZIONALE TUMORI - IRCCS - Fondazione G. Pascale, Napoli, ITALY.*

***Aim/Introduction:*** Fibroblasts activation protein (FAP) plays a pivotal role in tumors, being involved in remodeling of extracellular matrix and facilitating growth and cellular invasion. Radiolabeled FAP inhibitors (FAPI) are becaming successful pantumoral PET agents. In order to set up reliable conditions for in-house production of the FAP inhibitor [$^{18}$F]F-FAPI-74, we investigated the optimal conditions of synthesis to gain the best

radiochemical yield (RCY). We report the results of [$^{18}$F]F-FAPI-74 production, starting from different ranges (Low and High) of [$^{18}$F] Fluoride. ***Materials and Methods:*** [$^{18}$F]F-FAPI-74 was produced on the TRASIS AllinOne platform in according to the manufacturer's procedure: [$^{18}$F]Fluoride was trapped on QMA, then eluted to the reactor with 72 µg of precursor; the reaction was conducted via $(Al^{18}F)^{2+}$ complex, time reaction was 20 min and the final product was purified trough solid phase (SPE) cartridge. Radiochemical purity (RCP) was evaluated by radio-HPLC. RCP was tested also by iTLC using 1 M ammonium acetate/acetonitrile (1:1) as mobile phase and iTLC-SG as stationary phase. The final products were also tested for pH, radionuclidic purity, Limulus Amebocyte Lysate test (LAL), residual solvents. Radiochemical stability was conducted by radio-HPLC in the time (1h, 3h and 6h). ***Results:*** The low range (L) was performed with a starting [$^{18}$F]Fluoride activity of 21 GBq, the high (H) was performed with a higher activity, 98.7 GBq. The RCY values at end of synthesis (EOS), not corrected for decay, were ≥41% (L) and ≥45% (H) . RCP evaluated on the final product resulted ≥99% in both cases. The identity of [$^{18}$F] F-FAPI-74 was confirmed using the validated radio HPLC method by determining the relative retention of the principal peak with the reference solution using the UV/VIS detector. Stability test performed at 1h, 3h and 6h after EOS revealed a RCP ≥99%, showing no evidence of radiolysis or detectable, increasing, amounts of free [$^{18}$F]Fluoride. The synthesis resulted successful and reliable. ***Conclusion:*** Methodological aspects for an optimal production of [$^{18}$F]F-FAPI-74 have been evaluated to define the best operating procedures. Preliminary observed data suggest a good reliability of used methods, although further evidences are needed. In particular, the medium range of [$^{18}$F]Fluoride should be investigated to confirm the same percentage of RCY (40%) as obtained for ranges L and H. The choice of the optimal range of [$^{18}$F]Fluoride is mainly correlated to the number of performed exams (25/day), being the costs per production of [$^{18}$F]F-FAPI-74 the same for each condition.

## EP-0820

### Peptidic heterodimer-based radiotracer targetingfibroblast activation protein and integrin αvβ3

***K. Liu***;
*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) and integrin αvβ3 are both considered suitable targets for radionuclide theranostics due to their over-expression in the tumor microenvironment or tumor cells. Continuous efforts are being made to optimize the in vivo kinetics and tumor retention of radiopharmaceuticals, while the theranostic efficacy of monospecific tracers can be hampered by tumor heterogeneity. To meet this challenge, we aimed to design and synthesize a bispecific peptide heterodimer targeting FAP and integrin αvβ3 for superior diagnostic sensitivity and prolonged tumor retention. sensitivity and prolonged tumor retention. ***Materials and Methods:*** Hetero-dimer DOTA-FAP-RGD was synthesized and labeled with gallium-68, denoted as $^{68}$Ga-FAP-RGD. The cell uptake and competitive binding assays were assessed in HT1080-FAP (FAP**+/**$\alpha_v\beta_3$**-**) and U87MG (FAP**+/**$\alpha_v\beta_3$**+**) cells. Small animal PET/CT imaging and ex vivo biodistribution studies were performed to compare the pharmacokinetic characteristics of $^{68}$Ga-FAP-RGD with its monomeric counterpart $^{68}$Ga-FAP-2286 or $^{68}$Ga-RGDfK. ***Results:*** $^{68}$Ga-FAP-RGD possessed high stability in phosphate-buffered saline or fetal bovine serum up to 4 h. Cell uptake and blocking experiments demonstrated the specific binding of $^{68}$Ga-FAP-RGD to FAP and integrin $\alpha_v\beta_3$ in vitro. The heterodimer $^{68}$Ga-FAP-RGD has a nanomolar binding affinity (IC50 = 32.1 nM towards FAP and IC50 = 115.9 nM towards integrin $\alpha_v\beta_3$) that comparable to corresponding monomers $^{68}$Ga-FAP-2286 (28.5 nM) and $^{68}$Ga-RGDfK (98.7 nM). Micro-PET/CT scans in HT1080-FAP tumor models revealed improved diagnostic efficiency of $^{68}$Ga-FAP-RGD compared to $^{68}$Ga-labeled FAP-2286 and FAPI-04 with higher tumor to non-tumor (T/NT) ratios. The U87MG tumor accumulation for $^{68}$Ga-FAP-RGD (5.86 ± 0.37 %ID/g) was more stable than that for $^{68}$Ga-FAP-2286 (3.36 ± 3.36 %ID/g) or $^{68}$Ga-RGDfK (0.49 ± 0.10 %ID/g) up to 4 h ($P < 0.001$). The results were further confirmed by ex vivo biodistribution and immunohistochemistry studies. ***Conclusion:*** The peptidic heterodimer-based radiotracer $^{68}$Ga-FAP-RGD showed improved diagnostic efficiency and tumor retention compared to the corresponding monomer $^{68}$Ga-FAP-2286 or $^{68}$Ga-RGDfK, making it a promising strategy for cancer theranostics.

## EP-0821

### Initial clinical experience with 18F-JK-PSMA-7 PET-CT in evaluation of staging and biochemical recurrence of prostate carcinoma.

***P. Chandra***, *S. Chinnappan, G. Chandran, C. L. Abraham; Zydus Hospital, Vadodara, INDIA.*

***Aim/Introduction:*** $^{18}$F-JK-PSMA-7, developed at Research center Julich and University Hospital Cologne, has been shown to have better acutance and higher resolution compared to $^{68}$Ga PSMA 11 and $^{18}$F-DCFPyL (1). Studies related to this promising novel tracer in prostate carcinoma (PCa) imaging are limited. ***Materials and Methods:*** Consecutive patients of PCa from Aug 2022 to March 2023 referred for staging and evaluation of biochemical recurrence (BCR) were included . Vertex to mid-thigh static scans were acquired after 60-90min of injection of 180-300MBq of 18F-JK-PSMA-7. Additional early dynamic PET acquisition for 10-min post injection and delayed PET imaging (at 120 min) were done in few patients to assess the pharmacokinetics. Imaging findings were correlated with biopsy/histopathology findings. ***Results:*** 34 patients were included in this study, mean age 68 years. 27/34 patients were evaluated for staging and 7/34 were for BCR evaluation . Of staging patients, 59.2% were high risk, 18% were intermediate risk and 22% were low risk. Early dynamic imaging showed fast blood clearance, no significant urinary activity with high tumor to urinary activity ratio, especially in higher grade tumors. Of 16 patients with high-risk biopsy, 81% patients had positive nodal metastasis and 43% had both nodal and metastatic disease on PSMA PET-CT. Organ confined disease was noted in all low risk and intermediate risk staging patients. Mean primary tumor SUVmax of patients with high-risk histology was significantly higher compared to intermediate-low risk group (30.85 vs 11.1, p-0.01). Detection rate was 100 % in all 7 patients with BCR even with PSA as low as 0.3ng/ml. All 7 patients of BCR had salvageable disease on PET/CT with operated bed recurrence with locoregional disease in 3 patients. Delayed imaging at 120 min showed 30% higher mean primary tumor SUVmax compared to 60-90min images irrespective of the tumor grade. Non-specific bone lesions showing low grade PSMA uptake was seen in 8% (3/34 patients). No adverse reactions were reported. ***Conclusion:*** $^{18}$F-JK-PSMA-7 PET-CT offers high sensitivity and high-resolution PCa imaging for staging high risk cancers and evaluation of biochemical recurrence. Scan quality is comparable to, if not better than other commercially available PSMA ligands.

As with other urinary excreted PSMA tracers, early dynamic and 2 hr delayed post-diuretic imaging may further improve lesion detectability. ***References:*** 1. Hohberg M et al. Biodistribution and radiation dosimetry of [$^{18}$F]-JK-PSMA-7 as a novel prostate-specific membrane antigen-specific ligand for PET/CT imaging of prostate cancer. EJNMMI Res. 2019 Jul 25;9(1):66.

## EP-0822

### Synthesis and Characterization of Zr/Mannose-Conjugated Indocyanine Green-Loaded Liposomes as Sentinel Lymph Node Multimodal Diagnostic Agents for PET/NIR Fluorescence Imaging

***G. Kim***[1], *D. Jeong*[1,2], *H. Lee*[1];
[1]*Dongnam Institute of Radiological and Medical Sciences (DIRAMS), Busan, KOREA, REPUBLIC OF,* [2]*Dongguk University, Gyeongju, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** The development of multimodal diagnostic agents using radioisotope and near-infrared (NIR) fluorescence molecules is highlighted for improved preoperative positron emission tomography (PET) imaging and intraoperative mapping of sentinel lymph nodes (SLN). We synthesized a nano-sized liposome containing indocyanine green (ICG) inside and bonded non-radiative zirconium to the surface to confirm the labeling potential of zirconium-89. Mannose analogs were introduced to improve the SLN target effect, and the physicochemical properties of the final compound were evaluated. ***Materials and Methods:*** Phospholipids and cholesterol were synthesized into nano-sized liposomes by self-assembly method, and ICG was loaded in the process of redispersing liposomes. To target SLN, mannose analogs were bound to the liposome surface and a chelator, desferrioxamine (DFO), was also introduced. Non-radioactive zirconium was used to confirm the introduction of zirconium-89 and chemically bound to DFO on the liposome surface. ***Results:*** Observations with a scanning electron microscope (SEM) confirmed that the diameter of the liposomes was about 60 nm, and the average hydrodynamic size of the liposome measured using dynamic light scattering (DLS) analysis was confirmed to 233.4 nm. The loading amount of ICG measured using UV/Visible spectroscopy was 33.16 μmol/mg. The binding of DFO and mannose analogs was confirmed using fourier transform-infrared spectroscopy (FT-IR), and the binding of zirconium was confirmed by inductively coupled plasma-mass spectrometry (ICP-MS) analysis. ***Conclusion:*** We successfully synthesized Zr/mannose-conjugated indocyanine green-loaded liposomes. It is expected that effective diagnostic agents for PET/NIR fluorescence imaging targeting SLN will be developed in the future by performing various biological evaluations through zirconium-89 labeling. ***References:*** Ji Youn Lee et al., Naphthol Blue Black and 99mTc-Labeled Mannosylated Human Serum Albumin (99mTc-MSA) Conjugate as a Multimodal Lymph Node Mapping Nanocarrier, Scientific Reports, (2018) 8:13636, DOI:10.1038/s41598-018-31933-1

## EP-0823

### Biological Evaluation of Escherichia Coli Labeled with Zirconium-89 for the Development of Radiopharmaceuticals for Positron Emission Tomography

***D. Jeong***[1,2], *G. Kim*[1], *E. Choi*[2], *S. Park*[2], *H. Lee*[1], *S. Kim*[2];
[1]*Dongnam Institute of Radiological and Medical Sciences (DIRAMS), Busan, KOREA, REPUBLIC OF,* [2]*Dongguk University, Gyeongju, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** In this study, the surface of E. coli, which is self-motile and shows high accumulation in tumor tissues, is stably introduced with the diagnostic radioisotope zirconium-89 through chemical modification, and the possibility of bacterial-based radiopharmaceuticals for positron emission tomography (PET) is confirmed through biological evaluation. ***Materials and Methods:*** The primary amine group expressed on the surface of E. coli was reacted with the fluorescein isothiocyanate (FITC) to quantitatively analyze the primary amine group. After chemically binding the chelator desferoxamine (DFO), the stable isotope zirconium was chelated to confirm the possibility of zirconium-89 binding. The in vitro stability of E. coli labeled with zirconium-89 was evaluated using human serum. The cell uptake of zirconium-89 labeled E. coli for CT-26 and A549 cancer cell lines was evaluated. ***Results:*** As a result of measurement with a fluorescent spectrophotometer, it was confirmed that there were 0.88 pmol (5.29 x $10^{11}$ molecules). Binding of the stable isotope zirconium was confirmed by inductive coupled plasma mass spectrometry (ICP-MS) analysis. The labeling studies of E. coli labeled with zirconium-89 was confirmed through radio-thin layer chromatography (radio-TLC). The labeling rate of zirconium-89 was 99.9%, and it was confirmed to be more than about 95% when the stability was evaluated at human serum and PBS. The cell uptake of zirconium-89 labeled E. coli showed higher uptake of A549 than CT-26 at 24 hours. ***Conclusion:*** Through this study, we labeled the diagnostic radioisotope zirconium-89 on the surface of E. coli and confirmed the in vitro stability of E. coli through biological evaluation. It is expected to contribute to tumor targeting research using PET through various biological evaluation. ***References:*** Kang SR, Jo EJ, Nguyen VH, Zhang Y, Yoon HS, Pyo A, Kim DY, Hong Y, Bom HS, Min JJ. Imaging of tumor colonization by Escherichia coli using $^{18}$F-FDS PET. Theranostics. 2020 Apr 1;10(11):4958-4966. doi: 10.7150/thno.42121. PMID: 32308761; PMCID: PMC7163454.

## EP-0824

### It's Twins!? 68Ga &18F-labelled TriGalactan for Functional Liver Imaging

***M. A. Zierke***[1], *K. Samadikhah*[2], *C. Rangger*[1], *M. Panzer*[3], *A. Schmid*[2], *R. Haubner*[1];
[1]*Nuclear Medicine, Innsbruck, AUSTRIA,* [2]*Werner Siemens Imaging Center, Tübingen, GERMANY,* [3]*Internal Medicine I, Innsbruck, AUSTRIA.*

***Aim/Introduction:*** Non-invasive liver imaging is of great interest in a variety of clinical settings including liver surgery and transplantation. Therefore, functional hepatocytes are addressed via the asialoglycoprotein receptor (ASGR), which is almost exclusively found in liver tissue. Here we present [$^{68}$Ga]Ga-NODAGA-TriGalactan (1) & [$^{18}$F]AlF-NOTA-TriGalactan (2), a diagnostic pair of galactose trimers for PET imaging. ***Materials and Methods:*** Following structural data from Khorev et al. indicating high affinity of trimeric galactose conjugates, Tris(hydroxymethyl) aminomethane was chosen as a synthetic scaffold. Ligands were synthesized in solution using peptide chemistry techniques and CuAAC. To allow for labelling with either $^{68}$Ga or $^{18}$F, NODAGA or NOTA were introduced as chelators, respectively. Radiolabelling of 1 with $^{68}$Ga was accomplished within 10 min in a 1 M acetate buffer (pH=5) at 56°C. Fluorination of 2 via the aluminium-fluoride method occurred within 15 min at 95°C in a 0.1 M acetate buffer (pH=4). In vitro evaluation included octanol/buffer distribution (logD), protein binding, and metabolic stability studies in human blood serum (incubation for 2, 30, 60, and 120 min at 37°C). For biodistribution experiments with 1, healthy BALB/c mice were used. Animals were dissected 10, 30 and 60 min p.i. and accumulation of the tracer was measured (n=3). Additional pharmacologic studies with both compounds were carried out

in healthy C57Bl/6 male mice using PET/MR (n=3). For analysis, PET and MRI images were fused, corresponding ROIs were drawn based on the MRI scan and TACs were generated for selected organs. ***Results:*** Synthesis of the precursors could be achieved in seven steps and radiolabelling resulted in high (>95%) radiochemical purity. LogD values indicated high hydrophilicity of both tracers. Compound 1 showed high metabolic stability in human blood serum (between 99% and 93% intact tracer up to 2 hours incubation) and low plasma protein binding (approx. 6% protein bound fraction after 30 min incubation). Biodistribution data of 1 revealed high liver uptake (32% iD/g) and excellent target-to-background ratios. Small animal imaging data demonstrated that TACs of liver and heart are well separated. Liver uptake peaked between 5-10 min p.i., followed by a slight washout during the rest of the scan. In contrast, imaging with 2 resulted in both high liver and bone uptake indicating partial complex decomposition in vivo. ***Conclusion:*** [$^{68}$Ga]Ga-NODA-GA-TriGalactan showed promising in vitro and in vivo results demonstrating the successful development of a small molecular weight PET radiopharmaceutical targeting the ASGR. ***References:*** Khorev et al. Bioorg Med Chem, 2008.

## EP-0825

### Model of Pharmacokinetic Based on Copper-64 Labeled DNA Bipyramid Nanostructure

***P. Li***, *J. Li;*
*Inner Mongolia Medical University, Hohhot, CHINA.*

***Aim/Introduction:*** DNA is well-known as genetic information carrier with a double-helix structure. From a nanomaterials point of view, DNA is also a kind of material as material to become a molecular probe. DNA nanomaterials can be constructed by self-assembly protocols that exploit the Watson-Crick principle. This nanomaterial is essentially non-toxic and has excellent biological compatibility. DNA nanomaterials of various sizes and shapes have been designed. DNA nanostructures have attracted attention in many fields, such as biosensing, drug delivery, and in vivo imaging due to their excellent properties. However, the pharmacokinetics of DNA nanomaterials is poorly understood. In this study, PET imaging was used to visualize the DNA Bipyramid Nanostructure (DBN) distribution in vivo and to model the DNA pharmacokinetics. ***Materials and Methods:*** DBN was annealed and assembled in TM buffer by rapidly cooling from 95°C to 4°C within 30 minutes. Size exclusion chromatography was used to purify DBN. The amine-functionalized Single-stranded DNA was first conjugated with NOTA in carbonate buffer, and HPLC was used to purify NOTA-ssDNA. NOTA-ssDNA solution was added to 2 mCi of $^{64}CuCl_2$ in NaAc buffer for 1 h at 37 °C, under constant shaking. $^{64}$Cu-ssDNA was purified with a PD-10 column, the highly radioactive component was used for hybridization to produce $^{64}$Cu-DBN. $^{64}$Cu-DBN was administered to the mice, and a 1h dynamic PET imaging was then carried out to monitor the biodistribution process of DBN in vivo. The pharmacokinetic model was established by analyzing Region-of-interest (ROI). ***Results:*** We use the Polyacrylamide gel electrophoresis to characterize the DBN self-assembly process. Dynamic light scattering analysis showed that the average diameter for DBN was 26.91 ± 2.45 nm. Cell Counting Kit-8 test and hematoxylin and eosin proved that DBN was not biotoxic. PET imaging showed that DBN was mainly excreted through the kidneys. ***Conclusion:*** In this study, a simple and fast method for the preparation of $^{64}$Cu-DBN was developed. PET imaging allows us to make a dose assessment of ROI. This approach was used to model the pharmacokinetics of DBN. The model we have developed using nuclear medicine techniques will guide further optimization of DNA nanomaterials. ***References:*** 1. Jiang D, Ge Z, Im HJ, et al. DNA origami nanostructures can exhibit preferential renal uptake and alleviate acute kidney injury. Nat Biomed Eng. 2018;2(11):865-877.

## EP-0827

### Radionuclide cisternography with PET/CT using Cu-64-DOTA

***J. Greiser***[1], *S. Groeber*[1], *T. Weisheit*[1], *T. Niksch*[1], *C. Kuehnel*[1], *M. Schwab*[2], *R. Drescher*[1], *M. Freesmeyer*[1];
[1]*Clinic of Nuclear Medicine, University Hospital, Jena, GERMANY,*
[2]*University Hospital, Clinic of Neurology, Jena, GERMANY.*

***Aim/Introduction:*** The imaging of the cerebrospinal system (cisternography) may help diagnose abnormalities and pathologies of the intracranial cerebrospinal fluid (CSF)-filled cavities, particularly in cases of suspected CSF leaks. Radionuclide cisternography can help to identify and localize CSF leaks, when established CT or MRI procedures fail or cannot be applied. However, SPECT radionuclide cisternography with In-111-DTPA or Tc-99m-DTPA provides lower image resolution compared to PET. Therefore, we have investigated the potential of the PET tracer Cu-64-DOTA as intrathecal agent for PET radionuclide cisternography. ***Materials and Methods:*** Manual Cu-64-DOTA preparation was validated in accordance to GMP guidelines. Quality control included radio HPLC and radio TLC for RCP determination, gamma spectrometry, osmolality and pH testing as well as sterility testing and testing for endotoxins in accordance with Ph. Eur. and USP requirements on agents intended for intrathecal administration, whenever applicable. Cu-64-DOTA and In-111-DTPA were administered on separate days into the CSF cavity of a patient and PET/CT image acquisition was performed. Urine samples were collected for excretion profiling. ***Results:*** Cu-64-DOTA can be prepared from Cu-64-chloride and DOTA in PBS buffer, resulting in high RCY and RCPs ≥ 95.0 %. The formulation was in accordance to Ph. Eur. and USP requirements on agents intended for intrathecal administration, particularly in regard to endotoxin content, pH and osmolality. Additionally, Cu-64-DOTA exhibits very low concentrations of excipients compared to established CT and MRI contrast agents, thus decisively lowering the probability of adverse events in comparison. A CSF leak was detected successfully with Cu-64-DOTA PET, while radionuclide cisternography with In-111-DTPA gave a false negative. Cu-64-DOTA is mainly excreted renally. ***Conclusion:*** Radionuclide cisternography using PET can be performed with Cu-64-DOTA, providing an alternative to established procedures in cases of inconclusive results. Due to the higher image resolution, CSF leak detection with Cu-64-DOTA may be superior to established agents In-111-DTPA or Tc-99m-DTPA.

## EP-0828

### 11C-Labeled histamine derivatives for PET imaging

***X. Shao***, *K. Mhanna, A. Brooks, J. Witek, D. Raffel, P. Scott;*
*University of Michigan, Ann Arbor, MI,*
*UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Histamine is a heterocycle that exhibits a range of biological activities in various pathological and physiological conditions. Based on our success in the imaging of cardiac sympathetic nerves and neuroendocrine tumors using $^{11}$C/$^{18}$F-guanidines,[1] we have designed and radiosynthesized $^{11}$C-N-[2-(1H-imidazolyl-4-yl)ethyl]guanidine (IEG), a $^{11}$C-guanylated derivative of histamine. The automated radiosynthesis of [$^{11}$C]IEG and PET

imaging studies of rats and non-human primates is reported here. ***Materials and Methods:*** Production of [$^{11}$C]IEG was carried out using a GETracerLab FX$_m$. Briefly, [$^{11}$C]cyanogen bromide was formed from hydrogen [$^{11}$C]cyanide[2] and bubbled into a reactor containing the histamine precursor in sodium borate buffer (pH 8.0). The produced [$^{11}$C]cyanamide intermediate was treated with a 35% ammonium chloride in ammonium hydroxide solution to yield [$^{11}$C]IEG. Ammonium acetate buffer (pH 5.0) was added and the product was purified using semi-preparative HPLC (Luna SCX 250x10mm; 10mM $NH_4OAc$ and 400mM NaCl in $H_2O$; 5 mL/min). The peak around 10 min was collected and diluted with USP water for injection. Whole body imaging was performed by dynamic animal PET scanning for 60 minutes in rats and myocardial imaging was performed in a non-human primate (rhesus). ***Results:*** 18.5 ± 5.8 mCi of [$^{11}$C]IEG was synthesized with a radiochemical yield (RCY) of 13.2 ± 8.4% (n = 5) and radiochemical purity (RCP) greater than 95% based on analytic HPLC (Luna SCX column 250x4.6mm, 10mM $NH_4OAc$ and 400mM NaCl in $H_2O$; 2 mL/min; UV 212nm and Rad). The rodent imaging of rats showed uptake and rapid washout in the heart, high uptake and retention in kidney, and no brain uptake was observed. The preliminary monkey imaging showed no myocardial uptake and high uptake and retention in the kidney. ***Conclusion:*** We have successfully synthesized [$^{11}$C] IEG and have developed an effective purification method without any organic solvent. The final injectable doses are qualified for periclinal use and potentially for clinical application. The animal studies showed low myocardial uptake and retention. Further exploration of this finding, as well as structural modifications and PET imaging focusing on the kidney, are currently under investigation and will be reported in due course. ***References:*** [1] Raffel, D. M.; Jung, Y.; Koeppe, R. A.; Jang, K. S.; Gu, G.; Scott, P. J. H.; Murthy, V. L.; Rothley, J.; Frey, K. A. First-in-Human Studies of [18F] Fluorohydroxyphenethylguanidines. Circ.: Cardiovasc. Imaging 2018. [2] Westerberg, G.; Kärger, W.; Onoe, H.; Långström, B. [11C]Cyanogen Bromide in the Synthesis of 1,3-Di(2-tolyl)-[11C] guanidine. J. Labelled Compds. Radiopharm. 1994, 34, 691-696.

## EP-0829

### Synthesis and Preclinical Evaluation of two novel 68Ga-labeled (R)-pyrrolidin-2-yl-boronic acid-based FAP-targeted tracers for Cancer Imaging with Positron Emission Tomography

***S. Bendre***, *H. Kuo, H. Merkens, Z. Zhang, J. Zeisler, N. Coplo, F. Bénard, K. Lin;*
*BC Cancer Research Center, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is a membrane-anchored serine protease overexpressed in the reactive stromal fibroblasts of >90% human carcinomas. Its restricted normal tissue distribution and involvement in tumorigenesis makes it a promising target for developing radiopharmaceuticals for imaging and therapy of carcinomas. Here we synthesized two novel (R)-pyrrolidin-2-yl-boronic acid-based FAP-targeted ligands; SB02055 (DOTA-conjugated (R)-(1-((6-(3-(piperazin-1-yl)propoxy) quinoline-4-carbonyl)glycyl)pyrrolidin-2-yl)boronic acid) and SB04028 (DOTA-conjugated ((R)-1-((6-(3-(piperazin-1-yl)propoxy) quinoline-4-carbonyl)-D-alanyl)pyrrolidin-2-yl)boronic acid). $^{nat}$Ga- and $^{68}$Ga-complexes of both ligands were evaluated in preclinical studies and compared with previously reported $^{nat}$Ga/$^{68}$Ga-complexed PNT6555 [1]. ***Materials and Methods:*** Complexation of $^{nat}$Ga and $^{68}$Ga was conducted in acetate buffer (0.1M, pH 4.5) and HEPES buffer (2M, pH 5.0), respectively. All $^{nat}$Ga complexes were subjected to in vitro FAP binding assays. PET/CT imaging and ex vivo biodistribution studies were performed in HEK293T:hFAP tumor-bearing mice at 1 h post-injection. [$^{68}$Ga]Ga-SB02055 and [$^{68}$Ga]Ga-SB04028 were also subjected to in vivo stability testing at 15 min post-injection. ***Results:*** $^{nat}$Ga complexes were obtained in 36-98% yields. $IC_{50}$(FAP) values for $^{nat}$Ga-SB02055, $^{nat}$Ga-SB04028 and $^{nat}$Ga-PNT6555 were 0.41±0.06, 13.9±1.29 and 78.1±4.59 nM, respectively. $^{68}$Ga-labeled analogues were obtained in 19-58% decay-corrected radiochemical yields with >92% radiochemical purity. PET/CT images showed clear tumor visualization with good contrast by [$^{68}$Ga]Ga-SB04028 and [$^{68}$Ga]Ga-PNT6555, but not [$^{68}$Ga]Ga-SB02055. Biodistribution data showed that while [$^{68}$Ga]Ga-SB02055 exhibited nominal tumor uptake (1.08±0.37 %ID/g), [$^{68}$Ga]Ga-SB04028 demonstrated ~1.5-fold higher tumor uptake (10.1±0.42 %ID/g) than [$^{68}$Ga]Ga-PNT6555 (6.38±0.45 %ID/g). High accumulation in the bladder indicated renal excretion of all three tracers. [$^{68}$Ga]Ga-SB04028 displayed background level uptake in most normal organs/tissues,and comparable to those of [$^{68}$Ga]Ga-PNT6555. However, since the tumor uptake of [$^{68}$Ga]Ga-SB04028 was considerably greater than [$^{68}$Ga]Ga-PNT6555, the corresponding tumor/organ uptake ratios for [$^{68}$Ga]Ga-SB04028 were significantly higher than those of [$^{68}$Ga]Ga-PNT6555. In vivo stability testing revealed no intact [$^{68}$Ga]Ga-SB02055 in the mouse plasma, with ~94% remaining intact in the urine, indicative of its rapid washout. The intact fractions for [$^{68}$Ga]Ga-SB04028 in plasma and urine were ~ 47% and ~ 55%, respectively. ***Conclusion:*** We successfully synthesized and evaluated two novel (R)-pyrrolidin-2-yl-boronic acid-based FAP-targeted PET tracers. While the P2-glycine bearing [$^{68}$Ga]Ga-SB02055 displayed nominal tumor uptake, its P2-D-alanine congener [$^{68}$Ga]Ga-SB04028 demonstrated higher tumor uptake and superior imaging contrast compared to [$^{68}$Ga]Ga-PNT6555. [$^{68}$Ga]Ga-SB04028 is a promising tracer for clinical translation to detect cancer lesions with PET. Efforts are currently underway to replace DOTA with a suitable chelator that would allow labeling with the most widely used isotope $^{99m}$Tc to enable SPECT imaging. ***References:*** [1] Bachovchin et al., JNM, volume 63 (supplement 2) 4028

## EP-0830

### [89Zr]Zr-desferrioxamine-B: A novel agent for PET imaging of Vibrio cholerae infection

***H. Yousefnia***, *F. Mohammadpour-Ghazi, S. Zolghadri;*
*Nuclear Science and Technology Research Institute (NSRTI), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Precise and timely diagnosis of infectious diseases is a crucial step for effective patient care and epidemic prevention. Cholera is an epidemic and acute diarrheal disease caused by the toxigenic Vibrio cholerae. Some bacteria are able to produce siderophores, which can act as small iron chelators to provide this essential metal nutrient. In this study, [$^{89}$Zr]Zr-desferrioxamine-B ([$^{89}$Zr]Zr-DFO-B) was prepared at optimized condition and evaluated as a new PET tracer for detection of Vibrio cholera infection. ***Materials and Methods:*** $^{89}$Zr was produced by $^{89}$Y(p,n)$^{89}$Zr nuclear reaction via 30 MeV IBA cyclotron and separated from Y target and other possible impurities using ZR resin. [$^{89}$Zr]Zr-DFO-B was prepared at optimized condition and its stability, partition coefficient and protein binding was studied in vitro. Finally, the biodistribution of the complex was investigated in normal and cholera mice models using organs %ID/g calculation and imaging. ***Results:*** [$^{89}$Zr]Zr-DFO-B was prepared with high radiochemical purity > 98% (RTLC). The complex was stable in PBS buffer (4 °C) and human blood serum (37 °C) at least for 72 h (> 95%). The radiolabeled complex showed the fast blood clearance

and renal excretion which is related to the hydrophilic nature of [89Zr]Zr-DFO-B. The tracer also demonstrated high uptake of Vibrio cholera strain in vitro and in vivo that could be blocked with an excess of iron-DFO-B. ***Conclusion:*** According to the results, [89Zr]Zr-DFO-B radiolabeled complex can be considered as a high potential agent for PET imaging of Vibrio cholerae infection, however more biological data are still needed.

## EP-0831

### Preclinical evaluation of [18F]FEAO, a novel radiotracer for myocardial perfusion imaging in PET

***M. Dziuk***[1], *E. Witkowska-Patena*[1], *S. Krajewski*[2], *J. Towpik*[2], *L. Steczek*[2], *K. Gotowicz*[2], *P. B. Kozanecki*[2], *J. Wlostowska*[2], *C. Kozanecki*[2];
[1]*Military Institute of Medicine National Research Institute, Warsaw, POLAND,* [2]*Synektik Research, Warsaw, POLAND.*

***Aim/Introduction:*** Positron emission tomography (PET) is now an established method for myocardial perfusion imaging (MPI). The available tracers show a number of limitations, therefore the 18F-labelled tracer is in high demand now. In this study, we present the preclinical characterisation of [18F]FEAO, a novel MPI radiotracer for PET. ***Materials and Methods:*** The [18F]FEAO biodistribution and pharmacokinetics were analysed by 45-minute dynamic microPET imaging in Wistar rats (n=4). The pharmacodynamics was assessed in vitro in radioligand binding assays for 68 receptors, ion channels and transporters. The tracer metabolism was studied by FEAO incubation in rat, dog and human hepatocytes. The absorption (n=18) and potential toxicity (n=30) of FEAO were assessed in male and female Wistar rats after a bolus intravenous administration of 2 mg/kg of the tracer. The compound concentration in plasma was measured in samples (n=3) collected at 4, 15, 30, 60 minute, 4, and 24 hour time-points after injection. The test item effects on clinical, haematological, biochemical, enzymatic parameters, gross and histopathological lesions in tissues and internal organs were evaluated at 24 hour and 14 day after injection. ***Results:*** The time activity curves yielded from microPET images showed rapid, high and stable myocardial [18F]FEAO uptake with an average standardized uptake value of about 4 throughout the scan time. The scans also confirmed hepatic and renal elimination of the tracer. Radioligand binding assays showed significant responses in 3/68 assays: muscarinic acetylcholine M1 and M2 receptors and potassium channel hERG. The FEAO showed rapid plasma clearance within 1 hour post injection (2.59 L/h/kg) with elimination half-life of 0.26 hour. The compound was mostly metabolised via an oxidative N-dealkylation, while the fluor substituent was not separated from the molecule. The tested level of 2 mg/kg was considered to be the No Observed Adverse Effect Level (NOAEL). ***Conclusion:*** The study revealed a favourable pharmacokinetic and pharmacodynamic profile of [18F]FEAO. The dynamic microPET images clearly visualised the myocardium. In conclusion, the imaging procedure is expected to be safe for the human subjects. Promising study results prompt further tracer evaluation in a clinical trial.

## EP-0832

### LANTana: A phase Ib study nvestigating epigenetic modification of somatostatin receptor-2 with ASTX727 to improve therapeutic outcome with [177Lu]-DOTA-TATE in patients with metastatic neuroendocrine tumours

***R. Sharma***[1], *S. R. Khan*[2], *M. Naik*[2], *T. D. Barwick*[3], *E. O. Aboagye*[4];
[1]*imperial college london, London, UNITED KINGDOM,* [2]*Imperial college NHS Heatlhcare Trust, London, UNITED KINGDOM,* [3]*Imperial College Healthcare NHS Trust London, London, UNITED KINGDOM,* [4]*Imperial College London, London, UNITED KINGDOM.*

***Aim/Introduction:*** Suitability for peptide receptor radionuclide therapy (PRRT) for neuroendocrine neoplasia (NENs) depends on presence of SSTR2 determined by [68Ga]-DOTA-peptide-PET. A significant number of patients will have low or no uptake on [68Ga]-DOTA-peptide-PET, precluding PRRT. The upstream promoter region of SSRT2 is methylated, with percentage of methylation correlating with SSTR2 expression. Demethylating agents increase uptake on PET imaging in vivo such that tumours previously negative on PET imaging become positive, correlating with a dose dependent increase in tumoural SSTR2 expression. LANTana aims to determine whether treatment with the demethylating agent, ASTX727, results in re-expression of SSTR2 using [68Ga]-DOTA-peptide-PET to image epigenetic modification of the SSTR2 locus, allowing subsequent treatment with [177Lu]-DOTA-TATE. ***Materials and Methods:*** 27 participants with a histologic diagnosis of NEN (Ki67<55%) with no or low uptake on baseline [68Ga]-DOTA-TATE-PET/CT will be recruited. Patients will receive 5 days of ASTX727 (fixed dose 35mg decitabine + 100mg cedazuridine). [68Ga]-DOTA-TATE-PET/CT will be repeated day 8+2; where there is significant uptake, [177Lu]-DOTA-TATE will be administered. ***Results:*** Primary objective is to determine re-expression of SSTR2 on PET imaging. Tolerability, progression free survival, overall response and quality of life will be assessed. LINE-1 methylation in peripheral blood mononuclear cells and tumoral methylation will be evaluate.Results from the first 5 patients enrolled will be presented ***Conclusion:*** LANtana is the first human study to investigate epigenetic modification to re-sensitize tumours to SSTR2-targeting radiotheranostic drugs. · This trial will provide prospective evidence on the efficacy of a demethylation strategy to re-express SSTR2 allowing subsequent treatment with [177Lu]-DOTATATE in patients who otherwise would be excluded. · Novel manipulation of receptor expression through the use of demethylation agents may be applicable to other tumour types ***References:*** Torrisani, J., et al., Identification of an upstream promoter of the human somatostatin receptor, hSSTR2, which is controlled by epigenetic modifications. ## EP-0833

### Comparison of [68Ga]Ga-FAPI-46 PET/CT and [18F] FDG PET/CT hepatic tumors

***F. Novruzov***[1], *E. Mehdi*[1], *N. Orucova*[2], *N. Aliyeva*[1], *R. Shukurov*[3], *Z. Dadashov*[2], *F. Valla*[4], *J. Aliyev*[5];
[1]*Azerbaijan National Centre of Oncology, Department of Nuclear Medicine, Baku, AZERBAIJAN,* [2]*Azerbaijan National Centre of Oncology, Department of Nuclear Medicine, Baku, Azerbaijan, Baku, AZERBAIJAN,* [3]*Azerbaijan National Centre of Oncology, Department of Nuclear Medicine, Baku, Azerbaijan, Baku, Azerbaijan, Baku, AZERBAIJAN,* [4]*Sofie, Totowa, NJ, UNITED STATES OF AMERICA,* [5]*Azerbaijan National Centre of Oncology, Department of General Surgery, Baku, Azerbaijan, Baku, AZERBAIJAN.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is commonly expressed in activated stromal fibroblasts found in various types of epithelial tumours. Its ability to detect primary liver tumours is notably higher than other imaging modalities. The objective of this study was to evaluate and compare the

imaging performance of 68Ga-FAPI PET and 18F-FDG PET in hepatic tumours. ***Materials and Methods:*** Two male patients with liver lesions underwent whole-body PET/CT scans using [18F] FDG and 68Ga-FAPI tracers at least one week apart for staging and metastasis evaluation. The tracer accumulation intensity was evaluated using the maximum standardized uptake value (SUVmax) and the tumor-to-background ratio (TBR) methods. ***Results:*** The first case was a 54-year-old male patient with a cirrotic liver who presented to our department with a suspicious lesion. We performed both an 18F-FDG scan and a 68Ga-FAPI scan on the patient. The FDG scan revealed multiple hypermetabolic lesions in the liver with an SUVmax of 9.9. Similarly, the 68Ga-FAPI scan showed lesions with high 68Ga-FAPI concentration and an SUVmax of 11.5. 68Ga-FAPI scan also identified an additional lesion measuring 1.5 cm on the right 8th rib, which displayed high 68Ga-FAPI concentration with an SUVmax of 12.7. The highest tumor-to-background ratio of both scans was 5 and 10 respectively. The second patient, a 60-year-old male, was admitted to our department upon discovering a liver tumor. The FDG scan revealed lesions with moderate FDG uptake (SUVmax=3.2). The patient also presented with portal lymph nodes, which showed no FDG accumulation. Moreover, we observed an infiltrative lesion left lung, which did not show any FDG accumulation. On the 68Ga-FAPI scan, we noticed high 68Ga-FAPI uptake in the liver lesions (SUVmax=13.0). The portal lymph nodes also did not show any accumulation of 68Ga-FAPI. The lesion in the upper lobe of the left lung showed mild 68Ga-FAPI accumulation (SUVmax=2.8). The tumor-to-background ratio of greatest liver lesions was 1,5 and 13 respectively. ***Conclusion:*** In both of our patients, we observed an higher tumor-to-background ratio with higher uptake of tumors on the FAPI scan, indicating its superiority over FDG in liver cancers. As FDG has limited effectiveness in the evaluation of liver cancers, the use of FAPI scans may offer clear advantages.

### Radioimmunotherapy of experimental systemic mucormycosis in a murine model

***J. Carvalho***, *M. E. Malo, K. J. H. Allen, C. Frank, Z. Xiao, R. Jiao, E. Dadachova;*
*University of Saskatchewan, Saskatoon, SK, CANADA.*

***Aim/Introduction:*** Opportunistic fungal infections such as aspergillosis, cryptococcosis, candidiasis, and mucormycosis are causing devastating morbidity and mortality in immunocompromised patients as anti-fungal agents do not work in the setting of immunosuppression. For example, species of Rhizopus lead to high incidence and high mortality from fungal pneumonias in patients with hematologic malignancies and hematologic stem cells transplants. The COVID-19 pandemic has created a novel landscape for opportunistic fungal infections. COVID patients suffer from severe immune dysfunction due to the disease, use of steroids for reducing inflammation, and high incidence of comorbidities (with diabetes being the most prominent). Thus, it is imperative to develop novel diagnostic and treatments tools that would work in the setting of severe immunosuppression and comorbidities, and that would have acceptable risk profiles. Radioimmunotherapy (RIT) uses monoclonal antibodies (mAbs) to target radiation to cancerous or infectious cells, and is not dependent on the immune status of a patient.The aim of this study was to investigate the application of RIT against mucormycosis-causing fungus Rhizopus oryzae in a murine model of systemic infection using mAbs to the pigment melanin or to 1,3-β-glucan - two prominent fungal antigens. ***Materials and Methods:*** Female C57Bl6 mice were infected intravenously with $10^4$ R. oryzae spores. The infection was imaged in mice using microSPECT/CT. Targeting of $^{111}$In-labeled anti-melanin mAb c8C3 and anti-1,3-β-glucan mAb was compared to MOPC21, an irrelevant control mAb. Imaging mAb were administerd 24 hours post-infection with R. oryzae and imaged 48-120 hrs post-infection. For RIT, infected mice were treated with 1.85 or 3.7 MBq of $^{177}$Lu-labeled c8C3 mAb, $^{177}$Lu-labeled 400-2 mAb, or with 3.7 MBq irrelevant control MOPC21 mAb. The mice were sacrificed 48 hrs post-treatment and the fungal burden in their major organs was measured by colony forming units. ***Results:*** microSPECT/CT imaging showed very different patterns of biodistribution in infected mice between mAbs to fungal antigens melanin and 1,3-β-glucan and the control mAb with much slower clearance of the latter from the circulation. RIT of infected mice with $^{177}$Lu-labeled mAbs to melanin and 1,3-β-glucan resulted in dose dependent and statistically significant ($p<0.05$) clearance of the fungal burden from the major fungal dissemination organs, such as brain, lungs, spleen and liver in comparison with $^{177}$Lu-labeled control mAb and untreated mice. ***Conclusion:*** RIT of experimental systemic mucormycosis proved to be effective in immunocompetent mice and its evaluation in immunosuppressed mice is currently underway.

## EP-0835

### [123I]CC1: a Radiotheranostic Agent for PARP-expressing Cancer Imaging and Therapy

***C. Chan***, *Z. Chen, M. Veal, G. Dias, G. Destro, M. Mosley, F. Guibbal, V. Gouverneur, B. Cornelissen;*
*University of Oxford, Oxford, UNITED KINGDOM.*

***Aim/Introduction:*** Fighting cancer has been a worldwide priority for many years. The global increases in cancer diagnoses and deaths have led to a huge demand on the development of cancer research for diagnostic and therapeutic applications. Furthermore, despite the significant improvement in the prognosis for patients over the past decades, the emergence of treatment resistance after the standard of care such as radiotherapy and chemotherapy is frequently observed, and some hard-to-treat cancers such as those of pancreas and brain still remain low survival rates, hence the need for new selective, mechanism-based therapeutics to tackle this life-threatening disease. Targeting DNA damage repair (DDR) signalling is a fast-expanding field for cancer therapy. Among all DDR proteins, poly(ADP-ribose)polymerase (PARP) family is one of the main players in regulating of various DDR pathways to help with DNA damage repair, and its aberrant expressions in many cancers makes it become a potential therapeutic strategy for cancer carrying DDR gene mutations or high PARP expressions. Our on-going efforts has developed and identified a PARP-targeting radiotheranostic agent, [$^{123}$I]CC1, which emits different type of radiations that allows visualisation of the lesion site and precise delivery of ionising radiation to tumour cells for lethal effects, hence enabling clinicians to achieve "see what you treat & treat what you see". Such development may potentially create new directions for personalised therapeutic strategies for cancers. Here, we investigated the therapeutic potential of [$^{123}$I]CC1

in human cancer models: PSN1 (pancreatic adenocarcinoma) and U87MG (glioblastoma). ***Materials and Methods:*** Cu-mediated $^{123}$I-iododeboronation of a boronic pinacol ester precursor afforded [$^{123}$I]CC1. The level and specificity of cell uptake and therapeutic efficacy of [$^{123}$I]CC1 were determined in PSN1 and U87MG cells. Tumour uptake and tumour growth inhibition of [$^{123}$I]CC1 was assessed in mice bearing human cancer xenografts. ***Results:*** In vitro and in vivo studies showed selective uptake of [$^{123}$I]CC1 in both models. Significantly reduced clonogenicity, a proxy for tumour growth inhibition by ionising radiation in vivo, was observed in vitro after treatment with as low as 10 Bq [$^{123}$I]CC1. Biodistribution at 1 h after intravenous administration showed PSN1 tumour xenograft uptake of 0.9±0.06%ID/g. Intravenous administration of a relatively low amount of [$^{123}$I]CC1 (3 MBq) was able to significantly inhibit PSN1 and U87MG xenografts tumour growth, without significant toxicity to normal tissues. ***Conclusion:*** Taken together, these results show the potential of [$^{123}$I]CC1 as a targeted radiotheranostic agent for PARP-expressing cancer imaging and therapy.

## EP-0836

### Theranostics approach to imaging and treating experimental melanoma with 203/212Pb-labeled antibodies to melanin

***R. Jiao***[1], *K. J. H. Allen*[1], *M. Malokja782@mail.usask.ca*[1], *J. Wilson*[2], *B. J. B. Nelson*[2], *F. Wuest*[2], *E. Dadachova*[1];
[1]*University of Saskatchewan, Saskatoon, SK, CANADA,*
[2]*University of Alberta, Edmonton, AB, CANADA.*

***Aim/Introduction:*** Metastatic melanoma continues to be a deadly disease claiming thousands of lives each year in spite of several immunotherapeutic agents introduced into the clinic in the past decade. This leaves a great potential for the development of novel diagnostic approaches as well as the exploration of combination therapies for the treatment of metastatic melanoma. One such approach is targeting melanin pigment with radionuclide therapy. We have been investigating targeting melanin with melanin-specific radiolabeled antibodies as a strategy to treat metastatic melanoma. ***Materials and Methods:*** Female C57Bl6 mice were injected with 0.5M B16F10 murine melanoma cells. Chimeric antibody (c8C3) was used in this study to target the melanin. To image the tumor uptake, c8C3 antibody was labeled with $^{203}$Pb-TCMC, followed by microSPECT/CT for 3h, 24h, 48h, and 120h. The tumor bearing mice were followed by radioimmunotherapy with a c8C3 antibody radiolabeled with an "in vivo generator" $^{212}$Pb/$^{212}$Bi, which emits alpha particles. 5μCi, 10 μCi, or 17 μCi of $^{212}$Pb labeled antibodies were IV injected into the mice. Tumor size and health conditions were monitored 3 times a week; blood was collected at the end of the study for further analysis. ***Results:*** microSPECT/CT produced distinctive tumor imaging of B16F10 tumors. The $^{212}$Pb/$^{212}$Bi-labeled c8C3 antibody demonstrated a significant dose response in slowing down the tumor growth when compared to the untreated and radiolabeled control antibody. No liver or kidney dysfunction were noticed. ***Conclusion:*** We conclude that the $^{203/212}$Pb-labeled antibody to melanin is a promising theranostic modality for metastatic melanoma which warrants further investigation.

## EP-0837

### Co-treatment with Trastuzumab Improved Therapy of HER2 expressing Xenograftswith [177Lu]Lu-ABY-027 Affibody Molecule

***Y. Liu***[1], *T. Xu*[1], *A. Vorobyeva*[1], *A. Loftenius*[2], *V. Bodenko*[3], *A. Orlova*[1], *F. Y. Frejd*[2], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Affibody AB, Solna, SWEDEN,* [3]*Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Human epidermal growth factor receptor 2 (HER2) is overexpressed in several cancers. Affibody molecules are small (7 kDa) scaffold proteins with excellent targeting of HER2, but high renal uptake limits their application for radionuclide therapy. ABY-027 is an Affibody molecule, fused with albumin binding domain to prevent glomerular filtration and therefore reduce renal uptake. Biodistribution of [$^{177}$Lu]Lu-ABY-027 suggests potential for radionuclide therapy of HER2-expressing tumours. Anti-HER2 monoclonal antibody trastuzumab and ABY-027 bind to different epitopes of HER2, which enables possible combination therapy. The aim of this study was to evaluate therapeutic efficacy of [$^{177}$Lu]Lu-ABY-027 alone and in combination with trastuzumab in an animal model. ***Materials and Methods:*** HER2-expressing xenografts were obtained by implantation SKOV3 cells to Balb/c nu/nu mice. Treatment was initiated one week later. Mice were randomized into 5 groups, 10 animals per group. Animals in therapy group were intravenously injected with 20 MBq (20 μg) of [$^{177}$Lu]Lu-ABY-027. Animals in another group were treated with 6 injections of trastuzumab, according to clinical protocol. Mice in combination group were treated with both [$^{177}$Lu]Lu-ABY-027 and trastuzumab, with the same dose as in mono-treatment groups. One control group was treated with 1% BSA in PBS as vehicle and another with 20 μg of unlabelled ABY-027. The animals were euthanized when tumours reached a size of 1000 mm$^3$ or became ulcerated. Survival data were analysed using log-rank Mantel-Cox test. ***Results:*** The treatment with trastuzumab resulted in the median survival of 55.5 days, which is significantly ($p<0.05$) longer than the median survival of mice in the control groups treated with vehicle (33 days) or unlabelled ABY-027 (42 days). Treatment with [$^{177}$Lu]Lu-ABY-027 prolonged median survival till 77 days, which is significantly longer than that of group treated with trastuzumab. In the combination group, eight mice were alive at the study termination (day 90) and tumors in two animals had disappeared completely. Thus, the median survival was not reached and the survival was significantly longer compared to mice treated with trastuzumab or [$^{177}$Lu]Lu-ABY-027 alone. No pathologic change was observed in kidneys and livers for all mice. ***Conclusion:*** The radionuclide therapy using [$^{177}$Lu]Lu-ABY-027 increases survival of mice with HER2-expressing xenografts. It is more efficient than the treatment with trastuzumab alone. Co-treatment with [$^{177}$Lu]Lu-ABY-027 and trastuzumab improved the therapy outcome even further and provided some tumor remissions. This makes the combination of trastuzumab and [$^{177}$Lu]Lu-ABY-027 radionuclide therapy a promising candidate for clinical translation.

## EP-0838

### Organotrifluoroborate Enhances Tumor Targeting of Fibroblast Activation Protein Inhibitors for Targeted Radionuclide Therapy

***Y. Liu***, *M. Xu, J. Chen, X. Cui, Z. Liu;*
*Peking University, Beijing, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is a pan-cancer target and now the state-of-the-art to develop radiopharmaceuticals. FAP inhibitors have been of great success in developing imaging tracers. Yet, the overly rapid clearance cannot match with the long half-lives of regular therapeutic radionuclides. Though strategies that aim to elongate the

circulation of FAPIs are being developed, here we describe an innovation that uses α-emitters of short half-lives to pair the rapid pharmacokinetics of FAPIs. ***Materials and Methods:*** An organotrifluoroborate linker is engineered to FAPIs to give two advantages: 1) selectively increases tumor uptake and retention; 2) facile $^{18}$F-radiolabeling for positron emission tomography to guide radiotherapy of α-emitters, which can hardly be traced in general. The obtained ligands are labeled with F-18 and radiometals. The labeling yield, purity, and stability are tested using HPLC. The binding affinity is measured in HT-1080-FAP cells. PET imaging and biodistribution experiments are performed to evaluate the pharmacokinetics. Finally, [$^{213}$Bi]Bi-FT-FAPI is used for the targeted radionuclide therapy. ***Results:*** A series of FAP inhibitors named FT-FAPIs are synthesized. The F-18 radiolabeling yield is > 30%, the radiochemical purity is > 99%, and the labeling process is < 25 minutes. The $IC_{50}$ of four screened [$^{18}$F]F-FT-FAPIs are 22.35, 10.87, 5.34, and 8.03 nM, respectively. PET imaging shows that [$^{18}$F]F-FT-FAPIs have high tumor uptake and tumor-to-background ratios. Among them, the tumor $SUV_{mean}$ of [$^{18}$F]F-FT-FAPI-02 is 1.30 ± 0.49, 1.35 ± 0.66, and 1.26 ± 0.22 at 0.5, 1, and 4 hours post-injection (n = 4), which are significantly higher than [$^{68}$Ga]Ga-FAPI-04 (0.91 ± 0.16, 1 h p.i.) and [$^{18}$F]F-AMBF$_3$-FAPI without DOTA (0.36 ± 0.07, 1 h p.i.). In the head-to-head comparison, the tumor uptake of [$^{68}$Ga]Ga-FT-FAPI-02 is also significantly higher than that of [$^{68}$Ga]Ga-FAPI-04 (1.56 ± 0.23 vs 0.91 ± 0.16, 1 h p.i.). A cumulative dose of 13.2 MBq of [$^{213}$Bi]Bi-FT-FAPI-02 significantly inhibits tumor growth, while the same dose of [$^{213}$Bi]Bi-FAPI-04 shows no efficacy. Besides, FT-FAPI is successfully labeled by F-18 and Bi/Pb/Tb to mimic the in vivo pharmacokinetics of these difficult-to-trace α-emitters. ***Conclusion:*** Organotrifluoroborate optimizes tumor targeting of FAPI. The high-quality PET imaging of [$^{18}$F]F/[$^{68}$Ga]Ga-FT-FAPI make it promising for cancer diagnosis. A cumulative dose of 13.32 MBq of [$^{213}$Bi]Bi-FT-FAPI suppresses tumor growth. Besides, FT-FAPI owns the ability to address the issue that therapeutic radiometals are not compatible with PET. These results taken together make FT-FAPI a favorable theranostic agent for FAP-targeted cancer diagnosis and therapy.

## EP-0839

### Development of anti-cancer radioimmunotherapy method targeting angiogenesis.

***B. Park****, J. Yoon, Y. An, S. Kim;*
*Ajou University Hospital, Suwon, Gyeonggi-Do, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** In order to develop and verify anti-angiogenic therapeutics targeting ectopic ATP synthase, a β-emitting isotope (Lu-177) was labeled with an anti-ATP synthase mAb to develop a radiopharmaceutical for radioimmunotherapy and its usefulness to cells and animal experiments. ***Materials and Methods:*** Anti-ATP synthase mAb were labeled to Lu-177 through the conjugation with DOTA. Labeling yield was measured for tracer. The expression of Anti-ATP synthase mAb in various tumor cells was evaluate by western blot analysis. The cellular uptake was tested in various cells at 1, 4, and 24 hours. $^{177}$Lu-DOTA-mAb is injected intravenously in tumor animal models, and organs are harvested on days 1, 2, 4, and 7 to obtain biodistribution. Treatment was performed for 4 weeks to evaluate the effect of combination therapy of $^{177}$Lu-DOTA-mAb and sunitinib in tumor animal models. ***Results:*** The average labeling yield is 95±3%. Among 5 cancer cells tested, MKN-45 (human gastric adenocarcinoma) showed the highest cellular binding at 24 hr (0.010688% ±0.00051%), FTC-133 cell (follicular thyroid carcinoma) showed the lowest cellular binding at 24 hr (0.004720%±0.00025%). $^{177}$Lu-DOTA-mAb was injected intravenously in a tumor model, and biodistribution was observed on the 1st, 2nd, 4th, and 7th days. The tumor uptake increased over time, and the MKN-45 model (15.96 ±2.59 %ID/g, @7D) showed higher uptake than in the FTC-133 model (7.65 ± 1.93 %ID/g, @7D). In order to evaluate the effects of single and combined treatment of $^{177}$Lu-DOTA-mAb and sunitinib in tumor models, 4 weeks of treatment showed that the treatment effect of the combined treatment group (MKN-45: 639.54 ± 638 mm$^3$, FTC-133: 2815.76 ± 2341 mm$^3$) was higher than that of single treatment (MKN-45: 1188.92 ± 846 mm$^3$, FTC-133: 4099.96 ± 597 mm$^3$), and in the case of FTC-133 cell, the growth rate was very high. ***Conclusion:*** Lu-177 was labeled to anti-ATP synthase mAb with a sufficient labeling efficiency and its specific binding was confirmed in tumor cells. $^{177}$Lu- anti-ATP synthase mAb showed therapeutic effects in various tumor cells and could be valuable as a target for theragnostic angiogenesis imaging. ***References:*** Park BN (2017) Molecular Imaging. 16:1-10 Lee KH (2003) European Journal of Nuclear Medicine and Molecular Imaging. 30:1032-1037. ### Antimony-119, a promising Auger emitter for targeted radionuclide therapy to eradicate single tumor cells and tumor clusters

***A. Larouze***[1]*, M. Alcocer-Avila*[2]*, C. Morgat*[1]*, C. Champion*[1]*, E. Hindié*[1]*;*
[1]*Université de Bordeaux, Bordeaux, FRANCE,*
[2]*Université de Lyon, Lyon, FRANCE.*

***Aim/Introduction:*** Early use of targeted radionuclide therapy (TRT) to eradicate tumor cell clusters and micrometastases might offer cure. However, it is essential to assign appropriate radionuclides and assess the potential impact of non-uniform targeting. Here, we investigated absorbed radiation doses from antimony-119 ($^{119}$Sb), a promising Auger emitters [1], in comparison with lutetium-177 ($^{177}$Lu). ***Materials and Methods:*** The Monte Carlo code CELLDOSE was used to assess nuclear and membrane absorbed doses from $^{119}$Sb and $^{177}$Lu in single cells (14 µm diameter, 10 µm nucleus) and in a cluster of 19 cells. The radionuclide distributions considered here were: cell surface, intracytoplasmic, or intranuclear, with 1436 MeV released per labeled cell. For non-uniform targeting, four cells were stochastically unlabeled. ***Results:*** In the case of single cell, $^{119}$Sb delivered 17- to 22-fold higher nuclear absorbed dose, and 18- to 48-fold higher membrane absorbed dose, than $^{177}$Lu. In the cell cluster, when all 19 cells were targeted, $^{119}$Sb delivered 7- to 18-fold higher absorbed doses than $^{177}$Lu to cell nuclei and 10- to 44-fold higher absorbed doses than $^{177}$Lu to cell membranes. Nuclear and membrane absorbed doses were mainly dependent upon the location of the radionuclide. With cell surface distribution in particular, membrane absorbed doses were substantially higher than nuclear absorbed doses, both with $^{119}$Sb (1686-1710 Gy vs 40-50 Gy) and $^{177}$Lu (38-41 Gy vs 4.7-7.2 Gy). However, in case of non-uniform targeting, with four unlabeled cells within the cluster, absorbed doses from $^{119}$Sb to unlabeled cells dropped dramatically. For example, with $^{119}$Sb on the cell surface, the membranes of unlabeled cells received on average only 0.9% of the expected absorbed doses, and the nuclei of unlabeled cells received only 14% of the absorbed doses, as compared to a cluster with uniform targeting. With $^{177}$Lu, the

impact of non-uniform targeting was lower. The membranes of unlabeled cells received on average 10% of the absorbed doses, and the nuclei of unlabeled cells received 60% of the absorbed doses, as compared to a cluster with uniform targeting. ***Conclusion:*** To eradicate single cells and small tumor clusters, $^{119}$Sb may be a better candidate than $^{177}$Lu. However, non-uniform cell targeting can result in substantial heterogeneity in absorbed dose distribution. Dual-targeting could be of interest to counter this heterogeneity, which needs to be investigated. ***References:*** [1] Bennett KT et al., Large-Scale Production of $^{119m}$Te and $^{119}$Sb for Radiopharmaceutical Applications, ACS Cent. Sci, 2019, 5, 494-505

## EP-0841

### A Nanodepot Incorporating 177Lu-Labeled Gold Nanoparticles is Ineffective for Treatment of 4T1 Tumours in Balb/c Mice Due to Low β-Particle Energy and Spatially Lower Doses and Shorter Dose Penetration

***R. Liu***[1], *Z. Cai*[1], *E. Wong*[2], *Y. Lu*[2], *M. A. Winnik*[2], *R. M. Reilly*[1,3,4]; *[1]Department of Pharmaceutical Sciences, Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, CANADA, [2]Department of Chemistry, University of Toronto, Toronto, ON, CANADA, [3]Department of Medical Imaging, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, CANADA, [4]Joint Department of Medical Imaging and Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA.*

***Aim/Introduction:*** We previously reported that intratumoural (i.t.) implantation of a calcium alginate seed (nanodepot) incorporating 3.5 MBq of $^{90}$Y-labeled gold nanoparticles ([$^{90}$Y]Y-AuNPs) emitting moderate energy (2.28 MeV) and maximum 12 mm range β-particles strongly inhibited the growth of 4T1 tumours in Balb/c mice [1]. Our aim here was to study the effectiveness and normal tissue toxicity of a nanodepot incorporating [$^{177}$Lu]Lu-AuNPs emitting lower energy (0.5 MeV) and shorter range (maximum 2 mm) β-particles for treatment of 4T1 tumours. ***Materials and Methods:*** Tumour and normal tissue uptake in Balb/c mice with s.c. 4T1 tumours (0.8 × 0.5 cm) was determined up to 14 d post-implantation (p.i.) of a nanodepot incorporating 5.3 ± 3.0 MBq of [$^{177}$Lu]Lu-AuNPs (1 × $10^{14}$ AuNPs). SPECT/CT images were used to construct a radiation absorbed dose map around the nanodepot and calculate dose volume histograms (DVH) for [$^{177}$Lu]Lu-AuNPs and [$^{90}$Y]Y-AuNPs. Treatment was performed in Balb/c mice with s.c. 4T1 tumours implanted i.t. with a nanodepot incorporating 8.5 ± 2.3 MBq of [$^{177}$Lu]Lu-AuNPs (1 × $10^{14}$ AuNPs). Control mice were implanted with a nanodepot incorporating unlabeled AuNPs or received no treatment. Tumour growth was assessed by a tumour growth index (TGI) up to 14 d p.i. Normal tissue toxicity was evaluated by monitoring body weight and hematology and blood biochemistry analyses. ***Results:*** Tumour retention was 89.9% implanted dose/g (%ID/g) at 14 d p.i. but normal tissue uptake was low (<4.5 %ID/g). In contrast to a nanodepot with [$^{90}$Y]Y-AuNPs [1], there was no significant effect on TGI for mice treated with a nanodepot incorporating [$^{177}$Lu]Lu-AuNPs. No normal tissue toxicity was observed for [$^{177}$Lu]Lu-AuNPs. Radiation dose maps estimated 9,000 Gy at the nanodepot surface and 200 Gy at 0.3 cm for [$^{90}$Y]Y-AuNPs, while for [$^{177}$Lu]Lu-AuNPs, doses were 12,000 Gy at the nanodepot surface but 2 Gy at 0.3 cm. DVH indicated that 60% of the tumour volume received 2,000 Gy for a nanodepot incorporating [$^{90}$Y]Y-AuNPs but only 30 Gy for [$^{177}$Lu]Lu-AuNPs. ***Conclusion:*** The low energy and short range of the β-particles emitted by $^{177}$Lu resulted in spatially lower doses and shorter dose penetration than $^{90}$Y which may explain the ineffectiveness of a nanodepot incorporating [$^{177}$Lu]Lu-AuNPs for treatment of 4T1 tumours in mice. ***References:*** 1. ## EP-0842

### Radiation Nanomedicines for Local Treatment of Glioblastoma Multiforme - Epidermal Growth Factor Receptor-Targeted and Non-Targeted Gold Nanoparticles Labeled with the Auger Electron-Emitter, 197Hg

***M. Brown***[1], *Z. Cai*[1], *S. Chen*[2], *V. Radchenko*[2], *W. Chung*[3], *M. Winnik*[3], *J. T. Rutka*[4], *R. M. Reilly*[1,5]; *[1]Department of Pharmaceutical Sciences, Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, CANADA, [2]Life Sciences Division, TRIUMF, University of British Columbia, Vancouver, BC, CANADA, [3]Department of Chemistry, University of Toronto, Toronto, ON, CANADA, [4]Division of Neurosurgery, Hospital for Sick Children and Division of Neurosurgery, Department of Surgery, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, CANADA, [5]Joint Department of Medical Imaging and Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA.*

***Aim/Introduction:*** Glioblastoma Multiforme (GBM) is the most lethal form of brain cancer. Despite treatment, GBM recurs in 90% of patients possibly due to residual disease at the surgical margins. Our aim was to synthesize an EGFR-targeted or non-targeted radiation nanomedicine composed of gold nanoparticles (AuNPs) labeled with the Auger electron (AE)-emitter, $^{197}$Hg that may be infused into the surgical cavity to eradicate residual tumour and improve patient outcome. ***Materials and Methods:*** [$^{197}$Hg]Hg-AuNPs were synthesized by the Turkevitch method by trisodium citrate reduction of tetrachloroauric acid (25 mM) at pH 4.0 refluxed at 100°C for 10 mins, and incorporated $^{197}$Hg into the reaction. [$^{197}$Hg]Hg-AuNPs were stabilized with 0.5% Tween-20 or by surface coating with lipoic acid-polyethylene glycol (LA-PEG2K). Labeling efficiency (LE) was evaluated by ultracentrifugation at 15,000xg for 15 mins and measured $^{197}$Hg bound to AuNPs using a radioisotope dose calibrator. Particle size and morphology were evaluated by transmission electron microscopy, dynamic light scattering, and UV-visible spectroscopy. Stability of [$^{197}$Hg]Hg-AuNPs was determined in DMEM/10% FBS at 37°C for up to 2 d. EGFR-targeted [$^{197}$Hg]Hg-AuNPs were constructed by direct binding of 2 µg of panitumumab (0.2 mg/mL in $ddH_2O$) to 8.0x$10^{11}$ AuNPs. The uptake of EGFR-targeted and non-targeted [$^{197}$Hg]Hg-AuNPs by U251-Luc human GBM cells in vitro was measured. The clonogenic survival of U251-Luc cells treated with targeted and non-targeted [$^{197}$Hg]Hg-AuNPs for 13 h at 37°C then cultured for 10 d was determined. ***Results:*** The LE for [$^{197}$Hg]Hg-AuNPs was 99.0 ± 0.1%. Spherical [$^{197}$Hg]Hg-AuNPs were synthesized in a similar size (25.1 ± 5.3 nm) as unlabeled AuNPs (18.2 ± 2.7 nm) and exhibited similar spectroscopic properties. Approximately 70% of $^{197}$Hg remained bound to AuNPs after incubation for 2 d in DMEM/10% FBS at 37°C. The uptake of Tween-20 stabilized and LA-PEG2K stabilized [$^{197}$Hg]Hg-AuNPs by U251-Luc cells was 12.3 ± 0.1% vs. 2.0 ± 0.0%, respectively. Panitumumab conjugation increased cellular uptake of Tween-20 stabilized [$^{197}$Hg]Hg-AuNPs to 39.7 ± 0.2%. The clonogenic survival of U251-Luc cells decreased 33-fold to 0.03 ± 0.02 by treatment of 500-600 cells with 0.2 MBq (1 MBq/mL) of [$^{197}$Hg]Hg-AuNPs. Further clonogenic survival assays with EGFR-targeted [$^{197}$Hg]Hg-AuNPs are in progress. ***Conclusion:*** EGFR-targeted and non-targeted [$^{197}$Hg]Hg-AuNPs were accumulated by human GBM cells in vitro and potently killed

these cells by emission of AEs. Future studies will evaluate their effectiveness for treatment of human GBM tumours in the brain of mice and their normal tissue toxicity.

## EP-0843

### Modification and Evaluation of EGFRvIII-Targeting Peptides for the Targeted Radiotherapy of Glioblastoma Multiforme

***F. Schuderer***[1,2], *D. Werner*[2], *M. Rassner*[3], *C. Braun*[3], *J. Galamba Correia*[4], *A. Casini*[1,2];
[1]*Chair of Medicinal and Bioinorganic Chemistry, Department of Chemistry, Technical Unversity of Munich, Garching, GERMANY,* [2]*Chair of Pharmaceutical Radiochemistry, Department of Chemistry, Technical University of Munich, Garching, GERMANY,* [3]*Department of Pediatrics, Dr. von Hauner Children's Hospital, University Hospital, Ludwig Maximilians University of Munich (LMU), Munich, GERMANY,* [4]*Centro de Ciências e Tecnologias Nucleares and Departamento de Engenharia e Ciências Nucleares, Instituto Superior Têcnico, Universidade de Lisboa, Lisbon, PORTUGAL.*

***Aim/Introduction:*** Glioblastoma multiforme (GBM) is the most aggressive form of malignant brain tumours. As there is no cure, but only palliative treatment, the median overall survival is as short as 12-14 months from diagnosis. This demonstrates the pressing need for new treatment options.[1,2] This need is addressed here, by the development of peptide-conjugates designed for the targeted radiotherapy of GBM. The cancer specific mutant of the epidermal growth factor receptor (EGFRvIII) was chosen as a target structure since it is expressed in 25-64% of GBM patients and is absent in healthy adult tissue, presenting the potential for high tumour to brain ratios.[3] ***Materials and Methods:*** All peptides are synthesized by automated or manual solid phase peptide synthesis (SPPS) and purified via reversed phase - high performance liquid chromatography (RPHPLC). Radiolabelling with [$^{177}$Lu]Lu is performed with no-carrier-added [$^{177}$Lu]$LuCl_3$ in 0.04 m HCl with sodium acetate buffer (pH=5.5), at elevated temperatures (80-90°C). Iodination with [$^{125}$I]I using the iodogen-method is carried out at room temperature (15 min), with subsequent RPHPLC purification. For the cell assays two glioblastoma cell lines, stably transduced with EGFRvIII are used, namely DKMGvIII and U87vIII. The rabbit monoclonal antibody RM419, with specific affinity to EGFRvIII is utilized in the process of evaluating the receptor expression of both cell lines and designing the cell assays. ***Results:*** All synthesized peptides were obtained in high purity (> 95% by RPHPLC). Stability issues in one published EGFRvIIItargeting peptide (PEPHC1) were identified and successfully overcome by exchanging the cysteine in the sequence with other amino acids.[4] PEPHC1 and two other published EGFRvIII-targeting peptides - namely, FALGEA by Denholt 2008[5] and VLGREEWSTSYW by Mansour 2022[6] - were successfully modified and labelled with either [$^{177}$Lu]Lu or [$^{125}$I]I. The design of the affinity cell assays and subsequent evaluation of the synthesized peptide structures is ongoing. ***Conclusion:*** Several derivatives of EGFRvIII-targeting peptides, modified for radioactive labelling are currently under investigation for their affinity to that receptor. A combination with a peptide blood-brain barrier (BBB) shuttle is planned, once derivatives with satisfying affinity for the receptor are identified. ***References:*** [1] Bolcaen, J., et al., Theranostics, 2021, 11, 7911-7947.[2] Shergalis, A., et al., Pharmacol. ## EP-0844

### Novel cMet Targeted Radiotheragnostics: Preclinical Development and Optimisation for Clinical Use

***C. Portal***[1], *N. Swanwick*[1], *A. Prignon*[2], *A. Gibson*[1];
[1]*Edinburgh Molecular Imaging Ltd., Edinburgh, UNITED KINGDOM,* [2]*Laboratoire d'Imagerie Moleculaire Positonique (LIMP) UMS28 Small Animal Phenotyping, Sorbonne University, Paris, FRANCE.*

***Aim/Introduction:*** Upregulation of the cMet receptor tyrosin kinase present in many solid cancers is heavily correlated with invasiveness and poor prognosis. A significant number of cMet targeted drugs have however failed in the clinic or are hindered in their development by the current patient selection methods. cMet is therefore an attractive target for the development of (radio)theragnostic approaches where the PET imaging agent would yield a full body assessment of cMet overexpression and allow for selection of patients for the therapeutic counterpart, delivering of a cytotoxic payload to the cancer cell by only relying on the increased presence of the receptor and not its function. ***Materials and Methods:*** The radiopharmaceutical candidate precursors based on a common cMet targeted peptide were screened in vitro for target affinity and radiolabelled with either $^{68}$Ga or $^{177}$Lu to afford the imaging and therapy candidates, respectively, which were tested for in vitro efficacy with cell based affinity assays, cellular toxicity and clonogenic survival assays) with the use of suitable controls. Pharmacokinetics, biodistribution of the optimal candidates alongside in vivo tumour uptake and residence time were assessed in rodent animal models. Further in vivo efficacy experiments were performed on some therapeutic candidates such as in vivo tumour growth assessment. ***Results:*** Several cMet targeted radiotheragnostic ligands were designed, synthesised and assessed. [$^{68}$Ga]EMP-100 emerged as a suitable imaging agent for the assessment of cMet expression in patients: the radiotracer displayed ideal fast tumour accumulation (~5% ID/g @ 1h post injection) and clearance from background tissues and other key organs with excretion via the kidneys, with no signs of toxicity. In parallel, lead optimisation of the therapeutic compound has yielded an increase in target affinity and a longer tumour residence time in animal models (~3% ID/g remaining in tumour @ 72h). ***Conclusion:*** [$^{68}$Ga]EMP-100 was successfully developed and is now ready for clinical development for the whole body determination of cMet expression and subsequent eligibility for treatment with cMet targeted therapies. Ongoing optimisation of the therapeutic candidate should allow its clinical translation in the future. ***References:*** Burggraaf, J et al., Nature Medecine, 2015 Unterrainer, L et al., European Journal of Nuclear Medicine and Molecular Imaging, 2023 Mittlmeier, L et al., European Journal of Nuclear Medicine and Molecular Imaging, 2021

## EP-0845

### Analysis of the effectiveness of 177Lu-Oxodotreotide in the treatment of neuroendocrine tumors sensitive to somatostatin receptors

***Á. Alonso García***[1], *M. L. Bravo-Ferrer Moreno*[1], *A. Blesa Jiménez*[1], *M. A. Asensio Ruiz*[1,2], *M. T. Martínez Martínez*[1,2];
[1]*Radiopharmacy Service, Virgen de la Arrixaca Hospital, Murcia, SPAIN,* [2]*Instituto Murciano de Investigación Biosanitaria (IMIB)-Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** $^{177}$Lu-Oxodotreotide is a radiopharmaceutical indicated for the treatment of somatostatin receptor (G1 and G2) positive gastroenteropancreatic neuroendocrine tumors in adults. The dosage of this treatment consists of 4 doses of 7400 MBq with an interval of 8 weeks. Since its authorization in 2017, its

prescription has been increasing significantly. The objective of this work is to determine the effectiveness of this treatment in clinical practice. ***Materials and Methods:*** A retrospective observational study of patients treated with $^{177}$Lu-Oxodotreotide from April 2016 to June 2022 in our hospital. Demographic, diagnostic, therapeutic and clinical variables were collected. The effectiveness was assessed through the progression-free survival (PSF) and overall survival (OS). The PSF was calculated as the difference between the date of disease progression and the start of treatment of patients who complete the 4 cycles. OS was calculated as the difference between the date of death and the start of treatment of deceased patients who completed treatment. PSF and OS were compared with the efficacy results of the NETTER-1 trial that gave authorization to this radiopharmaceutical. ***Results:*** The study included 32 patients (18 men and 14 women) with a mean age of 59.65 years ± 10.31, with ECOG 0-1, 74.07% and ECOG 2-3, 25.93%, treated with at least one dose of 7400 MBq of $^{177}$Lu -Oxodotreotide. The primary tumor was pancreatic in 59.39% of patients, digestive 9.37%, small intestine 15.63%, paraganglioma 6.24%, and other 9.37%. Treatment was administered as first line in 9.37% of patients, second line 53.13%, third line 31.15% and fourth line 6.25%. Of the patients studied, 24 complete the treatment and of these, 15 developed disease progression and 6 died. The PSF were of 22.9 months (95%CI 14.6-31.2) and an OS 33.3 months (95% CI 16.2-50.4). The PSF values are consistent with the NETTER-1 trial but OS are significantly lower. ***Conclusion:*** Results obtained from PSF have been those expected for the treatment of patients with neuroendocrine tumors sensitive to somatostatin receptors with $^{177}$Lu-Oxodotreotide. However, OS values are lower than expected, probably due to the small sample size of deceased patients, so the study would have to be prolonged over time.

### Targeting Regulatory T cells in experimental colon cancer with radioimmunotherapy.

***Z. Xiao***, *R. Jiao, K. J. H. Allen, M. E. Malo, C. Frank, S. Giri, J. L. C. Carvalho, E. Dadachova;*
*University of Saskatchewan, Saskatoon, SK, CANADA.*

***Aim/Introduction:*** Colorectal cancer remains a formidable threat to human health around the world. Immunotherapy with immune checkpoint inhibitors while becoming a game changer for various types of cancer, produces mixed results in colorectal cancer with only a small number of patients experiencing long term progression-free survival. Regulatory T cells (Tregs) are an immunosuppressive subset of T lymphocytes, and a particular subset of Tregs, so called tumor infiltrating Tregs (ti-Tregs) can interfere with immunotherapy. Radioimmunotherapy (RIT) can precisely deliver highly cytotoxic radionuclides to localized or systemic cancer deposits. In this study we tested the hypothesis that RIT targeting ti-Tregs can eliminate these cells in colon tumors thus potentially increasing the success of immunotherapy. ***Materials and Methods:*** Two syngeneic murine models of colorectal cancers - CT26 in balb/c mice and MC38 in C57Bl6 mice were used. Tumor-bearing mice were imaged with SPECT/CT using 111In labeled anti-ti-Tregs antibody to establish the presence of ti-Tregs in the tumors. The numbers of ti-Tregs in the tumors and in the spleen were analyzed by flow cytometry. Simultaneous RIT of CT26 and MC38 tumor-bearing mice and mechanistic study to evaluate the effects of RIT on tumor progression and on the numbers of ti-Tregs were performed with 225Ac-labeled anti-ti-Tregs antibody. At the completion of the study the tumors were harvested and analyzed for ti-Tregs by immunohistochemistry (IHC). ***Results:*** SPECT/CT imaging demonstrated anti-ti-Tregs antibody binding to ti-Tregs within the tumors while flow cytometry analysis revealed 10 times more ti-Tregs in the tumors than in the spleen. RIT with 225Ac-anti-ti-Tregs antibody had a significant retardation effect on the CT26 and MC38 tumors in mice in comparison with the unlabeled antibody and untreated controls with 400 nCi dose being more effective than 200 nCi dose. There was a decrease of ti-Tregs in RIT treated tumors in both models according to IHC. ***Conclusion:*** RIT with 225Ac-anti-ti-Treg antibody proved to be effective in reducing the numbers of ti-Tregs in both CT26 and MC38 colorectal tumor mouse models. RIT also had a profound effect on the tumor size. The experiments combining RIT and immunotherapy with anti-CTLA-4 antibody are currently in progress.

## EP-0847

### 177Lu-PSMA treatment impacts on the full transcriptome of prostate cancer cells.

***F. Amoroso***[1], *E. O'Neill*[1], *B. Cornelissen*[2,1];
[1]*MRC Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM,* [2]*Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Radiotherapy is an effective therapeutic option for locally advanced prostate cancer (PCa). However, when PCa progresses, metastatic disease is incurable. Despite the promising results of the clinical trials with $^{177}$Lu-labelled PSMA (1), and the ever-mounting interest and investment by the pharmaceutical industry, we are far from curing locally advanced and advance prostate cancer (PCa). Improving our understanding of the (radio)biology of the damage induced by $^{177}$Lu-PSMA will aid in designing new targeted and more effective treatments for PCa patients. ***Materials and Methods:*** We performed a comprehensive analysis on the full transcriptome of a prostate cancer cells (22Rv1), treated with $^{177}$Lu-PSMA, over a period of 10 days, with RNA-Seq. ***Results:*** We recorded a progressive enrichment of genes that are differentially expressed over time as a consequence of $^{177}$Lu-PSMA treatment. Performing pathway analysis, we confirmed the activation of pathways that relate to the induction of genomic reorganization (e.g., of DNA and RNA synthesis-related processes), DNA damage repair (such as Nucleotide Excision Repair) and autophagic processes that are known to correlate with cellular responses to ionizing radiation (2). We also identified new biologies that are impacted by the treatment with this radiolabelled peptide. ***Conclusion:*** With this study we aimed to improve our understanding of the radiobiological effects that beta and gamma emitter $^{177}$Lu-PSMA has on prostate cancer cell lines. We shed the light on new pathways that are not strictly related to the induction of the DNA damage and can represent new therapeutic avenues for prostate cancer patients. ***References:*** (1) Novartis. Phase III VISION study. 2021 (2) Chaurasia M, et al., Free Radic Res. 2016;50(3):273-90. doi: 10.3109/10715762.2015.1129534. Epub 2016 Jan 14. PMID: 26764568.

## EP-0848

### Molecular imaging based response monitoring of non-contact induction heating therapy on infected prosthetic joints

***T. Buckle**, M. M. Welling, D. D. D. Rietbergen, F. W. van Leeuwen, B. G. Pijls;*
*Leiden University Medical Center, Leiden, NETHERLANDS.*

***Aim/Introduction:*** Prosthetic joint infection (PJI) is a devastating and frequent complication following total joint arthroplasty. In PJI bacteria form a biofilm on the implants that protects them from antibiotics, the immune system and treatments such as debridement surgery, resulting in failure of initial treatment of 20-40%. Non-contact induction heating (NCIH) of metal implants is an emerging treatment for PJI that uses heat to kill and weaken bacteria [1, 2]. It is, however, unclear how NCIH performs on implants with complex geometry and how its performance compares to classical cleaning approaches. We therefore used a previously developed method that allows quantification and visualization of the bacterial load on femur prosthesis [3] to determine the possible beneficial effect of NCIH. ***Materials and Methods:*** S. aureus infected femur prosthesis of different materials (cobalt-chromium, titanium alloy or stainless steel) were used as a model system. The infection was topically stained with the bacteria specific bimodal tracer $^{99m}$Tc-UBI$_{29-41}$-Cy5 (8 µM, 1hr). Prior to and after NCIH (40 sec, 20V, 2Ah) and/or cleaning (2 min, with CHD, BET or 3% NaCl) the bacterial load and biofilm was determined using fluorescence and gamma imaging (including freehandSPECT; N=3 per condition). The temperature distribution over the infected area and obtained temperature maximum (Temp$_{max}$) was recorded using 6 thermocouples, complemented with thermal infrared imaging. Microbiological culturing (1-6 days) was used to correlate the imaging findings with the residual bacterial load (CFU at day 1) and re-infection (CFU at day 6). ***Results:*** The effect of debridement could be effectively visualized using both fluorescence- and radioactivity-based assessments. A significant correlation was found between the number of residual viable bacteria and the radioactive signal ($R = 0.445$, $p<0.001$). Classical cleaning methods were prone to residual bacteria in 22.2% of samples on e.g., surface irregulates, transition of prosthesis head and neck and screw hole. CHD yielded the lowest incidence of residual bacteria and subsequent reinfection. For NCIH this number was 33%. Combined therapy using NCIH and CHD yielded effective prosthetic debridement. The effect of NCIH was shown to be temperature/alloy dependent and supported treatment of surfaces that were hard to clean mechanically. ***Conclusion:*** During bacterial debridement of femur prosthesis, combined fluorescent and nuclear assessment confirmed the beneficial effect of non-contact induction heating in combined therapy. ***References:*** 1. ### Association Constant Determination of Macropa as Chelator for the Stable Complexation of Barium-131, Lanthanum-133 and Luthetium-177

***M. Blei**[1,2], B. Drobot[3], J. Kretzschmar[3], H. J. Pietzsch[1], K. Kopka[1,2], F. Reissig[1], C. Mamat[1,2];*
*[1]Helmholtz-Zentrum Dresden-Rossendorf, Department of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [2]TU Dresden, Dresden, GERMANY, [3]Helmholtz-Zentrum Dresden-Rossendorf, Department of Resource Ecology, Dresden, GERMANY.*

***Aim/Introduction:*** Due to its excellent complexation properties, the macrocyclic chelator macropa (mcp)[1,2] was reported to be an excellent complexing agent for $^{225}$Ac[3] and a very promising starting point for the development of $^{223/224}$Ra radioconjugates. To follow theranostic concept, $^{131}$Ba[4] (SPECT) and $^{133}$La[5] (PET) are available as diagnostic radionuclides, due to their chemical similarities with these alpha emitters. We aim to establish a new workflow to evaluate and predict the complex stability of new chelating systems based on the macropa skeleton by obtaining both protonation constants for respective ligands and association constants for their metal complexes starting with mcp. ***Materials and Methods:*** The protonation constants (pKa) of mcp were determined by pH dependent $^{1}$H NMR studies as a prerequisite for the calculation of stability constants (log(K)). Based on this data, the Eu-mcp-complex was examined by time-resolved laser-induced luminescence spectroscopy (Eu-TRLFS) to determine the speciation of the ion and pH-dependency of the complexation. Finally, the association constants of Pb-, La-, Eu-, Tb-, Ba- and Lu-mcp-complexes were determined by isothermal titration calorimetry (ITC) and the log(K) values were evaluated using parallel factor analysis. ***Results:*** Depending on the protonation ability of the functional groups found in mcp (two amines and two carboxylates), four pKa values were obtained (2.45, 3.09, 6.77 and 7.64) as well as the log(K) values for the respective mcp complexes (Table). ***Conclusion:*** The combination of $^{1}$H NMR, Eu-TRLFS and ITC allows us to fully characterize the ligand by determining the pKa values, metal ion speciation, and log(K) values of the resulting complexes, which agrees with previously published data. This method can be easily transferred to other functionalized chelators and their complexes with a wide variety of metal ions which contain radionuclides of radiopharmaceutical interest. Additionally, a reliable comparison of the individual affinities of the different chelators to the metal ions and thus a predictability of the complex stabilities for future radiopharmaceuticals is possible. ***References:*** [1] Roca-Sabio et al., J. ### Development and Characterization of Novel Peptide-Based Apelin Theranostic Probes for Glioblastoma

***E. Besserer-Offroy**[1,2], P. Jeanjean[1], F. Al Banaa[1], S. Kwock[1], E. Breault[3], J. Fournier[3], P. Sarret[3,4], D. A. Nathanson[1,5], J. Czernin[1,5], G. Carlucci[1,5], C. E. Mona[1,5];*
*[1]David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Inserm U1086 - François Baclesse Comprehensive Cancer Centre, Caen, FRANCE, [3]Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, CANADA, [4]Sherbrooke University Hospital - Research Centre, Sherbrooke, QC, CANADA, [5]UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Glioblastoma (GBM) is the most aggressive and life-threatening form of brain cancer, with a 5- year survival rate of 4%. Despite numerous advances in research, a cure has remained elusive. Nonetheless, recent research efforts have identified the apelin receptor (APJ) as a promising therapeutic target for GBM. APJ is a class A G-protein coupled receptor that is highly expressed at the surface of GBM tumor cells and endothelial cells irrigating the tumor. Apelin, APJ's natural ligand, has been shown to promote

GBM proliferation and increase tumor vascularization. The apelin/APJ axis plays a critical role in GBM progression, invasion, and tumor angiogenesis. Hence, APJ represents a potential target for targeted radioligand therapy (RLT) and precision oncology. In this study, we designed, synthesized, and characterized new peptide-derived probes based on apelin-13 for imaging and therapy. ***Materials and Methods:*** RNA-Seq was used to quantify expression of APJ in purified GBM patient samples from UCLA Health, as well as matching Patient-Direct Orthotopic Xenograft (PDOX) and derived gliomaspheres. Peptide-derived probes were synthesized using standard Fmoc-based solid-phase peptide synthesis. A DOTA was conjugated to the peptide sequence at its N-terminus using a PEG linker. Different probes were developed, incorporating amino-acid substitutions in the apelin sequence. To increase probe retention into the blood stream, we also integrated an albumin-binder moiety based on Evan's blue into the probe sequence. Probes were then radiolabeled using $^{68}$Ga, $^{64}$Cu, or $^{225}$Ac. NSG mice were implanted with U87MG, a human GBM cell line, engineered to overexpress APJ, for Apelin receptor PET imaging. Apelin probes labelled with 64Cu were used for biodistribution studies. When tumors reached around 100 mm$^3$, mice were randomized into three groups: (1) vehicle, (2) 60 kBq $^{225}$Ac-Apelin13, and (3) 60 kBq $^{225}$Ac-AB-Apelin13. Tumor growth and overall survival were evaluated. Additionally, DNA-damage and APJ expression were assessed by immunohistochemistry (IHC) on resected tumors. ***Results:*** We found that our newly synthesized PET probes showed promise in PET imaging. 30 min after injection, the reported SUVmax is 2.2 with a tumor to background ratio of 56. Apelin probes with an albumin-binding moiety showed an SUVmax of 2.5 after 30 min and 5.2 after 2 hours. Mice treated with $^{225}$Ac-Apelin and $^{225}$Ac-AB-Apelin-13 showed significant tumor growth delay and increased survival. ***Conclusion:*** These results suggest that apelin probes have the potential to image GBM tumors and deliver RLT; however, orthotopic models will be required to evaluate brain penetration.

## EP-0851

### PATO-Cy5, a bi-modal tracer for image-guided hepatobillary surgery

***D. Rietbergen****, T. Buckle, M. P. van Meerbeek, L. J. Slof, M. van Oosterom, F. W. B. van Leeuwen;*
*Leids Universitair Medisch Centrum (LUMC), Leiden, NETHERLANDS.*

***Aim/Introduction:*** Liver cancer (primary and metastases) is a leading cause of cancer deaths worldwide. Surgical resection of these lesions is increasingly guided by the disrupted bile excretion of the near-infrared fluorescent dye indocyanine green (ICG) [1]. Fluorescence imaging unfortunately only supports the identification of superficial lesions. By exploiting the synergy of in-depth radio- and fluorescence-guidance, bi-modal (radioactive and fluorescent) tracers can help advance the precision of hepatobiliary surgery. ***Materials and Methods:*** A library of tracers containing Cyanine 5 (Cy5) infrared fluorescent dyes with varying end-groups (e.g. -SO3-, Ar) and chelates (e.g., DTPA, $Mas_3$, $Mag_3$) was synthesized and evaluated for (photo)physical properties. Bile excretion was initially evaluated in 2D hepatocyte mono-layer cultures, using cholyl-glycylamido-fluorescein and non-functionalized dye as a control. These results were further substantiated via flow cytometry. Lead selection was based on (photo)photophysical and bile excretion properties. Following radiolabeling with $^{99m}$Tc, the selected lead compound had its pharmacokinetics assessed in mice (%ID/g, SPECT/CT imaging and fluorescence imaging. The ability to provide real-time surgical guidance at 4 hrs p.i. was studied in a porcine model using ICG as control. Ex vivo assessment of excised lesions was performed to validate the location of the fluorescence signal. ***Results:*** The dye-chelate combination in hHEPATO-Cy5 (serum binding: 94%, LogP: 0.80 ± 0.03, Absorption/emission: 640/665 nm, brightness: 3445) helped to provide a molecular signature that promotes bile excretion. In vitro hHEPATO-Cy5 showed fast clearance (within 10') in a manner that is similar to that of (fluorescent) bile salts. Biodistribution of hHEPATO-Cy5 in mice confirmed hepatobiliary clearance; uptake levels decreased over time (11 ± 3 %ID, 238 ± 108 %ID/g and 22 ± 9 %ID/g at 2hr vs. 2.0 ± 0.3 %ID, 2 ± 0.6 %ID/g and 0.1 ± 0.1 %ID/g at 24hr for liver, gallbladder, and intestines), respectively, yielding negligible background in the liver at 4hr post injection. During robot-assisted hepatobillary surgery in a porcine model, hHEPATO-Cy5 supported fluorescence-based lesion identification, comparable to the guidance provided by ICG. ***Conclusion:*** The unique molecular composition of hHEPATO-Cy5 promotes hepatobiliary excretion, hereby allowing the use of the agent for the surgical identification of lesion margins. ***References:***

### Modifying Biodistribution of EpCAM-targeting DARPin Ec1 by Fusion with Albumin Binding Domain (ABD): Effect of ABD Position

***M. Oroujeni***[1]*, A. Vorobyeva*[1]*, A. Hani Binti Rosly*[1]*, J. Garousi*[2]*, Y. Liu*[1]*, A. Schulga*[3]*, E. Konovalova*[4]*, A. Orlova*[1]*, S. Deyev*[3]*, V. Tolmachev*[1]*;*
*[1]Uppsala University, Uppsala, SWEDEN, [2]Royal Institute of Technology (KTH), Stockholm, SWEDEN, [3]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [4]Russian Academy of Sciences, Moscow, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The epithelial cell adhesion molecule (EpCAM) is overexpressed in several types of cancer and can be used as a target for the delivery of drugs and toxins. Designed ankyrin repeat protein (DARPin) Ec1 is a scaffold protein, which has a high affinity to EpCAM (68 pM) and small size (18 kDa). A rapid renal excretion of Ec1 provides an excellent imaging of EpCAM-expressing xenografts in mice. However, the use of DARPins for targeted delivery of cytotoxic payload would require increased bioavailability and longer residence in circulation and decreased accumulation in kidneys. We have tested a hypothesis that a fusion of albumin binding domain ABD to DARPin Ec1 and ABD position could influence renal uptake and the biodistribution of DARPin Ec1. ***Materials and Methods:*** ABD was fused to Ec1 either at N- or at C-terminus. The constructs were designated as ABD-Ec1 and Ec1-ABD, respectively. DOTA chelator was conjugated at C-termini of both variants for labelling with $^{111}$In. In vitro characterisation was performed using EpCAM-expressing

cell lines, SKOV-3 and OVKAR3. Biodistribution was measured in mice bearing SKOV-3 xenografts at 48 h after injection. To check in vivo specificity, EpCAM-negative Ramos xenografts were used. To evaluate the effect of ABD fusion, biodistribution of ABD-fused Ec1 variants was compared with a non-ABD-fused Ec1. ***Results:*** Radiolabelling with $^{111}$In was resulted in radiochemical purity >98%. Both constructs bound specifically to EpCAM in vitro. $K_D$ values for both variants were in subnanomolar range (0.523±0.212 and 0.368±0.086 nM for Ec1-ABD and ABD-Ec1, respectively), but affinity was significantly reduced in the presence of human albumin serum for Ec1-ABD (2.6±1.9 nM). Uptake of both radioconjugates in SKOV-3 xenografts was significantly ($p < 0.05$) higher than in Ramos xenografts at 48 h after injection, confirming EpCAM-specific accumulation in vivo. Significantly ($p < 0.0001$) higher blood concentration was observed for both ABD-fused Ec1variants compared with non-ABD-fused Ec1. The blood half-life of ABD-Ec1 ($T_{1/2}$=12 h) was longer than for Ec1-ABD ($T_{1/2}$=10.3 h). The renal uptake was significantly ($p<0.0001$) lower for [$^{111}$In]In ABD-Ec1 and [$^{111}$In]In Ec1-ABD (12.1±1.1 %ID/g and 9.6±1.2 %ID/g, respectively) compared with [$^{111}$In]In-Ec1 (168±28 %ID/g). Tumor uptake was significantly ($p < 0.005$) higher for [$^{111}$In]In-ABD-Ec1 (13.2±1.5 %ID/g) than for [$^{111}$In]In Ec1-ABD (6.6±1.2 %ID/g) and [$^{111}$In]In-Ec1 (2.7±0.5 %ID/g). ***Conclusion:*** ABD fusion prolonged the blood residence resulting in higher accumulation in tumour and reduced renal uptake. Position of ABD influenced the overall biodistribution and tumour targeting using DARPin Ec1-ABD fusion.

## EP-0853

### Development of new bone-seeking radiolabeled compounds

***K. Ogawa****, K. Nishizawa, K. Mishiro, N. Effendi, T. Fuchigami, M. Munekane, H. Wakabayashi, S. Kinuya;*
*Kanazawa University, Kanazawa, JAPAN.*

***Aim/Introduction:*** Previously, we evaluated oligo-aspartic acid derivatives as carriers for developing bone-seeking radiopharmaceuticals (1, 2). In this study, we hypothesized that the density of carboxy groups is important for higher bone affinity, and thus γ-carboxy glutamic acid peptides [$(Gla)_n$] could be a superior carrier to bone. N,N′-Bis-[2-hydroxy-5-(carboxyethyl)benzyl]ethylenediamine-N,N′-diacetic acid (HBED-CC) was selected as a chelator for radiogallium. [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ (n = 2, 5, 8, 11, and 14) were synthesized and evaluated in vitro and in vivo by comparison with [$^{67}$Ga]Ga-HBED-CC-$(Glu)_n$. In this fundamental study, the radiogallium complexes were prepared using the easy-to-handle radioisotope, $^{67}$Ga rather than $^{68}$Ga. ***Materials and Methods:*** After HBED-CC-$(Gla)_n$ was synthesized using Fmoc-based solid-phase methodology, [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ was prepared by complexing $^{67}$Ga with HBED-CC-$(Gla)_n$. Hydroxyapatite binding assays, biodistribution experiments, and SPECT/CT imaging were performed. ***Results:*** [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ were prepared with radiochemical purities of over 95% without any purification. In the hydroxyapatite binding assay, binding of [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ tended to increase with the length of the amino acid chain. As a whole, the binding affinity of [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ was higher than that of [$^{67}$Ga]Ga-HBED-CC-$(Glu)_n$. In biodistribution experiments, [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ showed higher accumulation in the bone than [$^{67}$Ga]Ga-HBED-CC-$(Glu)_n$. In particular, [$^{67}$Ga]Ga-HBED-CC-$(Gla)_5$, [$^{67}$Ga]Ga-HBED-CC-$(Gla)_8$, and [$^{67}$Ga]Ga-HBED-CC-$(Gla)_{11}$ showed higher accumulation in bone and rapid clearance from the blood. SPECT/CT images of [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ showed high accumulation in bone. ***Conclusion:*** [$^{67}$Ga]Ga-HBED-CC-$(Gla)_n$ showed superior characteristics as bone imaging agents. Therefore, oligo Gla peptides could be more suitable as a carrier to the bone. ***References:*** 1. K. Ogawa et al. PLoS One. 8(12):e84335. (2013) 2. K. Ogawa et al. Sci Rep. 7(1):13971. (2017)

## EP-0854

### Development of fluorinated α-methyl-3BPA derivatives for BNCT/PET theranostics

***F. Hirano****[1], N. Kondo[1], Y. Murata[2], A. Sudani[2], T. Temma[1];*
*[1]Osaka Medical and Pharmaceutical University, Osaka, JAPAN, [2]Stella Pharma Corporation, Osaka, JAPAN.*

***Aim/Introduction:*** Since BNCT achieves an anti-cancer effect by nuclear reaction of $^{10}$B with thermal neutrons, it is required to selectively deliver $^{10}$B into the tumor and estimate the $^{10}$B accumulations in advance. 4-Boronophenylalanine (BPA), the only marketed BNCT agent accumulating in the tumor via L-type amino acid transporter 1 (LAT1), has insufficient selectivity over LAT2 and poor water solubility, necessitating solubilizers. We have recently demonstrated that 3BPA, a meta-isomer of BPA, exhibits extremely high water solubility with sustaining similar tumor targetability without solubilizer addition [1]. In this study, we designed fluorinated α-methyl-3BPA derivatives with the expectations of improving LAT1/LAT2 selectivity and future BNCT/PET theranostics application and evaluated the efficacy as BNCT agents. ***Materials and Methods:*** We designed and synthesized α-methyl-3BPA (αMe-3BPA), fluorinated 3BPAs (F-3BPAs), and fluorinated αMe-3BPAs (F-αMe-3BPAs). Water solubility was determined by measuring boron concentration in the saturated aqueous solution of compounds using ICP-MS. The compounds were incubated with HEK293 cells of forced expressing LAT1 or LAT2 (HEK-LAT1, 2), followed by boron measurement. After intravenous injection of α-methylated derivatives into LAT1-positive T3M4-xenograft mice, tissues were excised and weighed, followed by boron measurement. ***Results:*** All compounds had more than ten times higher water solubility than BPA. While F-3BPAs showed similar accumulation ratios (HEK-LAT1/LAT2) to BPA, α-methylated derivatives exhibited more than five times higher ratios than BPA due to reduced accumulation in HEK-LAT2 cells, suggesting that α-methylation improved LAT1/LAT2 selectivity. Similarly, biodistribution studies revealed that α-methylated derivatives enabled comparable tumor accumulations to BPA with reduced accumulations in muscle and plasma, leading to more than four times higher tumor-to-muscle ratios and more than 1.5 times higher tumor-to-plasma ratios, respectively, of α-methylated derivatives than BPA. It is suggested that the improved LAT1/LAT2 selectivity of α-methylated derivatives successfully contributed to lessening accumulations in non-target tissues. αMe-3BPA and F-αMe-3BPAs showed comparable biodistributions, which indicated a minimal effect of fluorination on the chemical properties of compounds. ***Conclusion:*** α-Methylated 3BPA derivatives improved LAT1/LAT2 selectivity in vitro and tumor-to-muscle and tumor-to-plasma ratios in vivo with sustaining high tumor accumulations. The fluorinated α-methyl-3BPA derivatives (F-αMe-[$^{10}$B]3BPA/[$^{18}$F]F-αMe-3BPA) could be promising candidates for future BNCT/PET theranostics. ***References:*** [1] Kondo N, Hirano F, Temma T., Pharmaceutics, 14(5), 1106 (2022).

## EP-0855

### In Vivo Stability Evaluation of Astatobenzene Derivatives Having Neighboring Substituents

***S. Hirata***[1], *K. Mishiro*[1], *K. Washiyama*[2], *T. Fuchigami*[1], *M. Munekane*[1], *K. Takahashi*[2], *Y. Arano*[3], *S. Kinuya*[1], *K. Ogawa*[1]; [1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Fukushima Medical University, Fukushima, JAPAN,* [3]*Chiba University, Chiba, JAPAN.*

***Aim/Introduction:*** Astatine-211 ($^{211}$At) is a promising α-particle emitting radionuclide for targeted alpha therapy (TAT). In basic research on the radioiodinated and astatinated compounds, radiohalogens are generally introduced into an aromatic ring. However, for some astatinated compounds, a release of free astatine from the aromatic ring is observed. The deastatination reaction could attenuate therapeutic effects and induce adverse effects by accumulating free astatine in non-targeted tissues. Until now, a reliable way to improve in vivo stability of the aromatic carbon-astatine bond has not been established. Therefore, we aimed to improve the in vivo stability of the astato group in astatobenzene derivatives by modifying substituents on the aromatic ring. A hippuric acid derivative, (4-astatobenzoyl)glycine, was reported to undergo considerable in vivo deastatination while its radioiodinated variant has high in vivo stability[1]. We designed and evaluated some (4-astatobenzoyl)glycine derivatives having two identical neighboring substituents next to the astato group. To compare the in vivo stability, we also synthesized the corresponding radioiodinated derivatives. ***Materials and Methods:*** For the synthesis of the radiolabeled compounds, corresponding precursors having tributylstannyl group were prepared. Astatinated or radioiodinated compounds were synthesized by oxidative trialkyltin-halogen exchange reaction using oxidant and [$^{211}$At]At$^-$ or [$^{125}$I]NaI and purified by HPLC. The in vitro stability in murine plasma and biodistribution in normal mice of the radiolabeled compounds were evaluated. ***Results:*** After HPLC purification, each radiohalogenated compound was obtained with >95% radiochemical purity. In in vitro stability experiments in murine plasma, all radiolabeled compounds remained >80% intact. In in vivo biodistribution experiments in normal mice, each compound showed a different biodistribution. One astatinated compound showed high in vivo stability comparable to the corresponding iodinated compound, although deastatination occurred in other astatinated compounds, as indicated by an increase of the radioactivity level over time in the stomach and thyroid. ***Conclusion:*** Our study suggested that structural modification of the aromatic ring can improve the in vivo stability of astatobenzene derivatives. These results would contribute to developing more effective $^{211}$At-labeled radiopharmaceuticals for TAT. ***References:*** [1]S. Wilbur et al. Bioconjug Chem. (2004)

### Development of FAP-Targeted Inhibitors with Extended Blood Circulation

***L. Feng***[1], *X. Zeng*[2], *J. Fang*[2], *H. Liu*[2], *X. Zhang*[3], *D. Jiang*[1], *R. Zhuang*[2];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Center for Molecular Imaging and Translational Medicine, State Key Laboratory of Molecular Vaccinology and Molecular Diagnostics, School of Public Health, Xiamen University, Xiamen, CHINA,* [3]*Department of Nuclear Medicine & Department of Medical Research Center, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein inhibitors (FAPI)-based nuclear imaging tracers have garnered significant interest for cancer imaging in clinical settings. However, their limited blood circulation and tumor retention have posed great challenges for targeted radionuclide therapy. Our aim is to modify FAPI-04 to extend its blood circulation and increase its tumor uptake. ***Materials and Methods:*** FM, as modified based on clinically used FAPI-04, was synthesized and labeled with $^{68}$Ga and $^{177}$Lu, followed by radiochemical characterization using high-performance liquid chromatography (HPLC). Subsequent in vivo PET imaging and $^{177}$Lu treatment were carried out in both 4T1 tumor-bearing mice and ovarian cancer patient-derived xenograft models. ***Results:*** HPLC analysis showed that the radiochemical purity (RCP) and radiochemical yield (RCY) of FM labeled with $^{68}$Ga/$^{177}$Lu were both above 99%, and the resulting products exhibited excellent stability within 2 h. FM exhibits a higher retention capability in circulation compared to FAPI-04, with a blood circulation half-life of 7.11 ± 0.34 h. Imaging results demonstrated that the tumor-to-muscle ratio of probe [$^{68}$Ga]Ga-FM reached 9.21, while probe [$^{177}$Lu]Lu-FM primarily accumulated in the liver and kidneys, with tumor uptake reaching a level higher than that of kidneys at 24 h post-injection, and further increasing in subsequent time points. ***Conclusion:*** The $^{68}$Ga- and $^{177}$Lu-labeled probes targeted to FAP were successfully prepared. These probes demonstrated high retention in blood circulation, exhibiting promising properties for potential applications in tumor diagnosis and therapy.

## EP-0858

### Method development for the analysis of 14C-acetaminophen by HPLC-MS

***P. Chang***, *S. Farn;*
*Institute of Nuclear Energy Research, Tao-Yuan, TAIWAN.*

***Aim/Introduction:*** Carbon-14 ($^{14}$C) is commonly employed for the study of drug pharmacokinetics and metabolism. The laboratory of drug metabolism at the Institute of Nuclear Energy Research (INER) in Taiwan has developed a systemic platform that has been certificated by OECD GLP for evaluation of drug safety, efficacy, pharmaceutical kinetics, properties, and potential metabolism by using $^{14}$C-labeled molecules. In the study, $^{14}$C-labeled acetaminophen was used as a radiolabeled drug to validate the developed method for the quality and quantitative analysis of $^{14}$C-labeled compounds. ***Materials and Methods:*** $^{14}$C-labeled acetaminophen was provided by a commercial company. HPLC-MS was conducted on an Agilent 1100 HPLC system interfaced with a Sciex 4000 QTRAP triple-quadrupole mass spectrometer. $^{14}$C-acetaminophen was analyzed by an MS detector monitored in positive ionization mode for compound structure identification. The HPLC also connects to a UV detector and a liquid scintillation analyzer (LSA) for compound quantification. The compound structures of various peaks in LC-LSA chromatography can be deduced with the assistance of the peaks of LC-MS chromatography at their respective retention time in LSA spectra. ***Results:*** The stability and homogeneity of the C-14-APAP solution were assessed by comparing the quantity of C-14-APAP in the solutions under different tested conditions. The variation of the concentration within 4 and 24 hours was below 2%, indicating good stability. The RSD value of the concentrations in the upper, middle, and down layers is below 2%, indicating significant homogeneity. The mass-to-charge ratio (m/z) of $^{14}$C-acetaminophen and acetaminophen precursors were 154 and 152, separately, indicating single-charged [M+1] ions were predominant in the MS spectra. The m/z of $^{14}$C-acetaminophen

and acetaminophen precursor has a mass difference of 2 Dalton. Two most high-abundance fragment ions at m/z of 112 and 95 in MS/MS spectra of $^{14}$C-acetaminophen were observed. In the spectra of acetaminophen, they were 110 and 93. ***Conclusion:*** The developed method is capable of qualitative and quantitative determination of $^{14}$C-acetaminophen. Although the current study aimed to identify $^{14}$C-labeled acetaminophen, these results will allow us to elucidate the relevant metabolic profiles of the drug candidates using $^{14}$C-radiolabeled drugs during the drug discovery and development process.

## EP-0859

### Radiolabeling and biodistribution evaluation of orally administered nanovaccines against enterotoxigenic Escherichia coli formed by vesicles of their outer membrane encapsulated in Gantrez®-mannosamine nanoparticles

***G. Quincoces***[1], *M. Berzosa*[2], *F. Pareja*[1], *M. Collantes*[3], *M. Ecay*[3], *R. Ramos-Membrive*[1], *J. Simón*[1], *V. Betech-Antar*[4], *J. Rosales*[4], *I. Peñuelas*[1];
[1]*Radiopharmacy Unit. Nuclear Medicine Department. University Clinic of Navarra, Pamplona, SPAIN,* [2]*Microbiology Department. University of Navarra, Pamplona, SPAIN,* [3]*UNIMTRA. Nuclear Medicine Department. University Clinic of Navarra, Pamplona, SPAIN,* [4]*Nuclear Medicine Department. University Clinic of Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** Enterotoxigenic Escherichia coli (ETEC) represents a major cause of mortality in children in developing countries. Since there is no effective vaccine against this pathogen, the development of nanovaccines formed by ETEC outer membrane vesicles (OMV) in zein nanoparticles coated with Gantrez®-mannosamine (NPZ-GM) is being investigated. The biodistribution of the vaccine complex and its components was evaluated by means of radiolabeling and molecular imaging in vivo and ex vivo. ***Materials and Methods:*** Radiolabeling of OMV and NPZ-OMV-GM was performed by reduction of technetium-99m with $SnCl_2$ [40µl $SnCl_2$ $2H_2O$ (0.50mg/ml for OMV and 0.25mg/ml for NPZ-OMV-GM). OMV was radiolabelled [40µl $SnCl_2$ $2H_2O$ (1 mg/ml)] and encapsulated in the nanoparticles using the coacervation/desolvation method.The particle size was determined by DLS and the radiochemical purity by radioTLC. $^{99m}$Tc-OMV (26.2±1.1MBq), $^{99m}$Tc-NPZ-OMV-GM (96.2±0.5MBq) and NPZ-OMV-$^{99m}$Tc-GM (4.70±0.5 MBq) were oral administered to BALB/c mice and MicroSPECT/CT images were acquired 1, 4, 7 and 10 h later, then the animals were euthanized and the radioactivity of the digestive and lymphatic systems was quantified in a gamma counter. ***Results:*** The Radiochemical Purity of the radiolabeling was greater than 98 %. The particle size of the nanovaccines was 200 nm (PDI<0.2). In vivo and ex vivo biodistribution studies demonstrated slower transit of encapsulated OMVs through the intestine than free OMVs. The ex vivo study detected a significantly higher signal in the lymph nodes of mice treated with encapsulated OMVs compared to the other groups ($p<0.01$ ANOVA). ***Conclusion:*** The encapsulation of OMV increase their residence time in the intestine when they are administered orally in the murine model increasing their exposure to the immune system and therefore their potential effectiveness as a vaccine.

## EP-0860

### Effects of DOTATATE on plasma protein-binding and tumour cell-uptake of 68Ga- and 177Lu-DOTATATE

***L. Schneider***, *Y. Zhao, M. Zuhayra, U. Lützen;
Department of Nuclear Medicin, Molecular Imaging, Diagnostics and Therapy UKSH, Kiel, GERMANY.*

***Aim/Introduction:*** Peptide-Radio-Receptor-Therapy (PRRT) with $^{177}$Lu-DOTATATE has shown encouraging results in treatment of neuro-endocrine malignant tumours (NET). $^{68}$Ga-DOTATATE-PET/CT with its high-quality imaging is in great demand for diagnosis. Previous study has reported that modified DOTATATE with albumin binding motif increases tumour uptake of $^{177}$Lu-DOTATATE through prolonged blood retention. On the other hand, elevated blood maintenance of $^{68}$Ga-DOTATATE extends the "washout time" thereby reducing the specificity and sensitivity of PET imaging. In the present study, we investigated different concentrations of the precursor, DOTATATE, on plasma binding and tumour cell uptake of $^{68}$Ga- or $^{177}$Lu-DOTATATE to provide the optimal concentration for the synthesis of the radiotracer. ***Materials and Methods:*** $^{68}$Ga-DOTATATE or $^{177}$Lu-DOTATATE in the presence of different amounts of DOTATATE (0.5 to 1000 µg/ml) were added to plasma or cultured SH-SY5Y cells, human neuroblastoma cells highly expressing SSTR2, and incubated for 30 min. The plasma-bound fraction was separated using ammonium sulfate as a protein precipitation agent. After washing out the unbound tracer, cell fractions bound to the tracers were collected with 0.1N NaOH and neutralized with 0.1 N HCl. The radioactivity of the plasma and cell fractions were measured in a γ-counter. Protein levels in the fractions were measured with the protein analysis kit. The data are expressed as cpm/mg protein. ***Results:*** According to standard protocol $^{68}$Ga-DOTATATE was prepared using 2.5 µg/ml and $^{177}$Lu-DOTATATE using 10 µg/ml of DOTATATE. The plasma binding for $^{68}$Ga- and $^{177}$Lu-DOTATATE was significantly enhanced when DOTATATE was increased to 40/400 µg/ml in the final product ($p<0.05$). A reduction of the $^{68}$Ga-DOTATATE- and $^{177}$Lu-DOTATATE plasma binding was detected when DOTATATE was used at concentration of 5 or 10 µg/ml ($p<0.01$). Interestingly, the cell-uptake of $^{68}$Ga-DOTATATE significant decreased when the concentration of cold DOTATATE was up to 20 µg/ml ($p<0.01$). The cell-uptake of $^{177}$Lu-DOTATATE decreased at 400 µg/ml of DOTATATE without statistical significance ($p = 0.8889$). ***Conclusion:*** Our results demonstrate that high concentrations of DOTATATE diminishes the tumor cell-uptake of $^{68}$Ga-DOTATATE, while lower concentration of DOTATATE reduces the plasma binding and leads to an increase of the sensibility and specificity of PET scan. Concomitant addition of DOTATATE, which increases blood retention of $^{177}$Lu-DOTATATE without affecting tumour cell uptake, may be beneficial for PRRT treatment. These findings require further confirmation in order to test the potential of the simultaneous treatment with $^{177}$Lu-DOTATATE and DOTATATE in chemo-or radio-resistance NET models.

## EP-0861

### Evaluation of influence of albumin binding domain position on biodistribution of HER2-targeting DARPin-DM1 drug conjugates using radiolabeling

***A. Vorobyeva***[1], *T. Xu*[1], *Y. Liu*[1], *M. Oroujeni*[1], *A. Schulga*[2,3], *J. Garousi*[4], *E. Konovalova*[2], *Y. Liao*[1], *A. Zikrileh*[1], *P. Kanellopoulos*[1], *O. Bragina*[5,3], *T. Gräslund*[4], *A. Orlova*[1], *S. M. Deyev*[2,3], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*ShemyakinOvchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION,* [3]*Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION,* [4]*Royal Institute of Technology (KTH), Stockholm, SWEDEN,* [5]*Tomsk National Research Medical Center, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Designed ankyrin repeat protein (DARPin) G3 has the potential for tumor-targeted delivery of cytotoxic drugs due to selective and high-affinity binding to human epidermal growth factor receptor 2 (HER2). Fusion with albumin-binding domain (ABD) might extend its half-life in vivo. By introducing a

single cysteine for conjugation, the drug number and position can be well-controlled. We developed two drug conjugates based on G3 carrying maytansinoid DM1 and having ABD at the N or C terminus of G3 (G3-ABD-DM1 and ABD-G3-DM1). The aim of this study was to investigate the impact of ABD position on HER2 targeting and biodistribution. ***Materials and Methods:*** The drug conjugates were radiolabeled site-specifically at N-terminal $(HE)_3$-tag using technetium-99m tricarbonyl, and studied for binding specificity, affinity, and cellular processing using HER2-overexpressing cell lines. Cytotoxicity in cell lines with high and low HER2 expression was investigated. Biodistribution of $^{99m}Tc(CO)_3$-labeled drug conjugates was performed in Balb/c nu/nu mice bearing SKOV3 xenografts at 4, 24 and 48 h post-injection (pi). The biodistribution at 48 h pi was compared with DARPin G3 (without ABD fusion). Tumor targeting specificity was evaluated using mice bearing HER2-negative Ramos xenografts. ***Results:*** The drug conjugates were labeled with 50-80% radiochemical yield and purified with radiochemical purity over 95%. Binding to HER2-overexpressing cancer cells was specific and preserved in the presence of albumin. The internalized fraction was between 20-30% at 24 h. Both constructs had a more substantial cytotoxic effect in the presence of albumin, with lower IC50 values for G3-ABD-DM1 (1.4-6 nM) in cell lines with high HER2 expression. The biodistribution of $^{99m}Tc(CO)_3$-labeled drug conjugates was characterized by an extended half-life in blood and renal clearance. G3-ABD-DM1 had a longer half-life than ABD-G3-DM1, which resulted in a larger area under the curve (AUC) for the tumor. The highest tumor uptake was at 24 h pi for both conjugates, 6±1 %ID/g for G3-ABD-DM1 and 5±1 %ID/g for ABD-G3-DM1. The uptake was significantly lower in HER2-negative Ramos xenografts. The AUC for hepatic uptake of G3-ABD-DM1 was smaller than for ABD-G3-DM1. The combination of more potent cytotoxicity and favorable biodistribution profile suggests G3-ABD-DM1 as a preferable candidate for therapy. ***Conclusion:*** Radiolabeling using residualizing $^{99m}Tc(CO)_3$ label enabled quantitative characterization and comparison of DARPin-drug conjugates in vitro and in vivo. Placing ABD at the C terminus of G3 provided a conjugate with more favorable HER2 targeting properties and biodistribution.

## EP-0862

### Preparation, double radiolabeling of Albumin Nanoparticles (HSA-NPs) with technetium-99m and gallium-67 and in vivo biodistribution studies using microSPECT/CT to accelerate their pharmaceutical development as nanovaccines

***F. Pareja del Rio***[1], *E. van Brandwijk*[1], *J. A. Simon*[1], *A. Bronte*[1], *V. Betech-Antar*[1], *F. Minguez*[1], *M. Romera*[1], *J. J. Rosales*[1], *M. Collantes*[1], *R. Ramos*[2], *G. Quincoces*[1], *I. Peñuelas*[1];
[1]*Nuclear Medicine Department. Clínica Universidad de Navarra., Pamplona, SPAIN,* [2]*Nuclear Medicine Department. Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** Developing new vaccines is essential to fight against emerging infectious diseases such as COVID-19 or Shigelosis. The use of antigen protein-loaded nanosystems for subcutaneous administration as vaccines has very many advantages, and the study of their biodistribution using molecular imaging of radiolabeled nanoparticles (NP) can help accelerate their pharmaceutical development. With this purpose, we have optimized the preparation and simultaneous double radiolabeling procedures of antibody-loaded human serum albumin (HSA) NP with technetium-99m and gallium-67 for in vivo biodistribution studies by microSPECT/CT molecular imaging. ***Materials and Methods:*** As a model antigenic protein, we used a widely available IgG1: bevacizumab (BVZ). After tagging it with a chelator (p-NCS-benzyl-NODA-GA) and purifying it by size exclusion chromatography, 4.5mg of BVZ-NODAGA were added to 37MBq of $[^{67}Ga]GaCl_3$ (obtained from [$^{67}$Ga]Ga-Citrate) at pH=4. After 30' at 37ºC, the radiochemical purity was analyzed by RadioTLC (ITLC-SG with 1M Na-Citrate and AcNH4:methanol (50:50)). PEG coated HSA-NPs loaded with [$^{67}$Ga]Ga-NODAGA-BVZ were prepared by desolvation/coacervation by adding 1mL (4mg) of the labeled antibody to 100mg of HSA in 7.84mL of water, 8mL of ethanol and 500µL of PEG35,000 (100mg/mL). Ethanol was removed by using a rotary evaporator, and the nanoparticles obtained in 6 mL. Particle size was determined by Dynamic Light Scattering (DLS). Finally, 1 mL of PEG-HSA-[$^{67}$Ga]Ga-NODAGA-BVZ NPs were directly radiolabeled with 74 MBq of $[^{99m}Tc]NaTcO_4$ using 40µL of 0.07mg/mL $SnCl_2$ as reducing agent. For biodistribution studies, 150µL of the double-radiolabeled NPs (5.55MBq of gallium-67 and 11.1MBq of technetium-99m) were administered subcutaneously to healthy balb/C mice and MicroSPECT/CT images obtained 1,18 and 42h post-administration. Images were reconstructed by using the photopeaks of technetium-99m and gallium-67 and analysed in PMOD. Control mice received either $[^{99m}Tc]TcO_4^-$ and $[^{67}Ga]GaCl_3$ subcutaneously. ***Results:*** The radiochemical purity of the double radiolabeling procedure was bigger than 95%. The particle size was 250 nm (PDI <0.2) before and after radiolabeling, showing no significant modifications of the NP. At 18h and 42h post-administration, activity was observed in axillary and inguinal lymph nodes, suggesting stimulation of the immune system. In comparison with the controls of $[^{99m}Tc]TcO_4^-$ and $[^{67}Ga]GaCl_3$, no activity was observed in stomach, intestine, salivary glands and bone marrow. ***Conclusion:*** We have stablished a procedure for preparation and double radiolabeling of BVZ-loaded HSA-NPs and made MicroSPECT/CT studies showing accumulation of the radioactivity in lymph nodes. These studies could be used as a role model to accelerate the pharmaceutical development of new nanovaccines for subcutaneous administration.

## EP-0863

### Pharmacological implications of molar activity of 225Ac-labeled PSMA targeting agents in prostate cancer tumor models.

***R. Hernandez****, A. Thickens, H. Comas Rojas, N. Clemons, A. Carston, Y. Medina Guevara, L. Lambert Lepesevich, A. Pinchuk; University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The pharmacological implications of administering high molar activity (MA) $^{225}$Ac-PSMA targeted alpha therapy (TAT) agents remain relatively unexplored. Here, we studied the impact of MA and injected mass dose on the biodistribution of two PSMA-targeting TAT agents in murine models of prostate cancer. ***Materials and Methods:*** Subcutaneous PSMA-expressing PC3-PIP tumors were generated in male immunocompromised nude mice. Two urea-based PSMA ligands, ART1 and PSMA-617, with different pharmacokinetics, were labeled with $^{225}$Ac at a MA of 0.04, 0.4, or 4.0 GBq/µmol. Radiolabeled compounds were purified via solid-phase extraction and formulated in an injectable solution. PC3-PIP-bearing mice (100 $mm^3$) were administered low, medium, or high MA $^{225}$Ac-ART1 or $^{225}$Ac-PSMA-617 (n=3-5) 4-40 KBq (~0.1-1.0 µCi) intravenously, and serial ex-vivo biodistribution was performed at days 0, 1, 2, 5, and 7 post-injection (p.i.). Tumor and normal tissue distribution were quantified as injected activity per gram of tissue (%IA/g). PSMA blocking studies were carried out by co-injecting $^{225}$Ac-ART1 with PMPA (40 nmol). ***Results:*** High

MA $^{225}$Ac-ART1 showed markedly different biodistribution with significantly higher (P < 0.01) liver (21.8± 0.9 %IA/g at 48 h p.i.) and spleen uptake (6.2 ± 1.2 %IA/g at 48 h p.i.) compared to medium and low MA, across all timepoints. Notably, $^{225}$Ac-ART1 tumor uptake increased with lowering MAs with peak values at 48 h p.i. of 3.0 ± 0.7, 5.4 ± 0.2, and 8.0 ± 2.1 %IA/g in the high, medium, and low groups, respectively. At 3 h p.i., high MA $^{225}$Ac-PSMA-617 uptake was higher for liver and spleen (2.6 ± 0.07, 1.3 ± 0.5, respectively) and lower for tumor (13.9 ± 2.4) compared to medium and low MA. At 24 h p.i., this trend continued for liver and spleen uptake, but the tumor uptake was not significantly different across the MA range for $^{225}$Ac-PSMA-617. Low MA had the best tumor-to-normal tissue ratios for both TAT agents. Notably, co-injecting high MA $^{225}$Ac-ART1 with PMPA had a similar biodistribution as low MA administration. ***Conclusion:*** Our results showed the significant impact of administered MA on the biodistribution and clearance of PSMA-based TATs agents. High accumulation in normal tissues was largely PSMA-driven and negatively affected tumor uptake in the high MA administrations, which demonstrates the importance of MA and mass dose optimization in developing effective TAT agents.

## EP-0864

### In vitro stability of 99mTc-FITC-SFN for Oral Drug Delivery System

***M. Asensio Ruiz***[1,2], *Á. Alonso García*[1], *M. Bravo-Ferrer Moreno*[1], *A. Blesa Jiménez*[1], *A. A. Lozano-Pérez*[2,3], *M. T. Martínez Martínez*[1,2]; [1]*Radiopharmacy Service, Virgen de la Arrixaca Hospital, Murcia, SPAIN,* [2]*Instituto Murciano de Investigación Biosanitaria (IMIB)-Arrixaca, Murcia, SPAIN,* [3]*Departamento de Biotecnología Genómica y Mejora Vegetal, Instituto Murciano de Investigación y Desarrollo Agrario y Medioambiental, Murcia, SPAIN.*

***Aim/Introduction:*** Silk Fibroin Nanoparticles (SFN) are a promising tool as a Drug Delivery System (DDS) for anti-inflammatory purposes (1). The objective of this work is to characterize in vitro the stability in gastric and intestinal media of SFNs labeled with FITC and $^{99m}$Tc for oral biodistribution studies. ***Materials and Methods:*** 1 mg of FITC-SFN ($4\times10^{11}$ nanoparticles/mg; Zaverage=161.5±1.95nm; PdI=0.152±0.009; Zpot= -31±1.57mV) were labeled by incubation with 20 µg of $SnCl_2$ and 37 MBq of sodium pertechnetate, as described previously (2). The radiolabeled nanoparticles were recovered by centrifugation, and subsequently SFN were incubated during 4 hours at 37ºC under gentle stirring in artificial gastric and intestinal media prepared according to the Royal Spanish Pharmacopoeia. Radiolabeling efficiency (RLE%) was determined as percentage of added radiactivity linked to nanoparticles. Radiochemical Purity (RCP%) was analyzed by iTLC with SG/methyl ethyl ketone. The in vitro stability of the radiolabeling was evaluated by measuring the RCP% for 4 hours. Dynamic Light Scattering (DLS) was performed after a decay period of 12 τ½. ***Results:*** RLE% was of 98.92±0.15 % (n=3) and the Radiochemical Purity (RCP%) was >98% (n=3). When incubating the $^{99m}$Tc-FITC-SFN in gastric medium (n=3), 5.35 ± 2.34% of $^{99m}$Tc eluted at t=0, maintaining this value after 4 hours of incubation. Regarding the hydrodynamic characteristics, there was an increase in Z average and Zpotential (Zaverage=4828±1467nm;PdI=0.311±0.086;Zpot.=12± 0.404mV). When incubating in intestinal medium (n= 3), <1% of $^{99m}$Tc was eluted at t=0 and after 4 hours of incubation. No significant variations in the hydrodynamic characteristics were seen (Zaverage=156.8±2.12nm; PdI=0.201±0.012; Zpot.= -30.7±2.1mV). ***Conclusion:*** The changes in the hydrodynamic characteristics and the percentage of eluted $^{99m}$Tc are expected due to the acid pH. $^{99m}$Tc-FITC-SFN remains stable in gastric and intestinal medium after 4 hours of incubation, optimal for oral biodistribution studies.

### Development of new molecular drug delivery tools based on PET imaging : in vivo performance research of nucleic acid nanomaterials

***Q. Xia****;*
*Department of Nuclear Medicine ,School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.*

***Aim/Introduction:*** For developing new molecular drug delivery tools, Three typical three dimensional (3D) DNA origami frameworks with distinguished structural properties were subjected to mice intravenous injection to systematically investigate their in-vivo behaviors. ***Materials and Methods:*** Tracing the radioisotope $^{89}$Zr trapped at the inner space of the frameworks, positron emission tomography (PET) imaging was employed to record the real time bio-distribution of the structures and acquire their pharmacokinetic parameters in the major metabolic organs, e.g. kidney and liver. ***Results:*** The 43 nm diameter icosahedral framework(DIF) outstand in liver accumulation and retention. The DIF structure which showed the longest mean residence time(MRT) with pretty high local concentration. The calculated drug clearance rate (CL) of each sample in different organs further demonstrated the lowest CL of DIF in liver (1.21E-3 mbq/min*ID/g). And the surface modifications (e.g. ssDNA and PEG) could further regulate its performance. Decorated by a specific liver-targeting-agent, triantennary N-acetylgalactosamine (GalNAc), the significantly enhanced icosahedral framework uptake in liver cells, especially in hepatocytes, was discovered through flow cytometry analysis. ***Conclusion:*** To summarize, 3D DNA origami frameworks performed differently in pharmacokinetics and bio-distributions compared with the reported sister structures (tFNA, 2D sheets and 1D rod).The icosahedra framework (DIF) with the smallest size and most rigid construction resulted as the most liver preferred structure, and the ssDNA extensions on DIF remarkably enhanced its liver targeting efficiency. With the modification of GalNAc, a specific hepatocyte targeting agent, DIF was further improved in liver cell uptake, especially in hepatocyte.Compared wiht the other origami frameworks and the dsDNA-G, the better performance of DIF-os and especially DIF-G indicated that a qualified and powerful liver-delivery vehicle/strategy could be developed upon the DNA icosahedral framework.Therefore, as the 2D DNA origami sheets have been successfully applied to treat kidney disease, the 3D DOFs possess the potential in dealing with hepatopathies.

## EP-0866

### Preparation and in vitro evaluation of an anti-HER2 Affibody radiolabelled with Zr-89

***D. Niculae***[1,2], *R. Leonte*[1], *R. Cornoiu*[1], *D. Cocioaba*[1], *L. Chilug*[1], *S. Baruta*[1], *B. Burghelea*[1], *L. Craciun*[1], *A. Popa*[1], *A. Necsoiu*[1], *D. Draganescu*[2];
[1]*Horia Hulubei National Institute for Physics and Nuclear Engineering, Bucharest (Magurele), ROMANIA,* [2]*University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.*

***Aim/Introduction:*** $^{89}$Zr, a positron-emitting radionuclide with a half-life of 78.41 hours has opened possibilities of positron emission tomography (PET) imaging and visualization of in-vivo processes with favorable pharmacokinetics of emerging biovectors such as affibodies. A combination of small size, ease of engineering, high affinity, and specificity vectors, they proved to be a suitable alternative to monoclonal antibodies for molecular imaging of receptor-overexpressing tumors. ***Materials and Methods:*** $^{89}$Zr was produced with high yield and high specific activity on a TR-19 cyclotron via $^{89}$Y(p,n)$^{89}$Zr nuclear reaction, by irradiation of 250 µm nat-yttrium foils on the fully automated Solid Target Irradiation System installed on the extension line. The optimal parameters were set based on the SRIM/TRIM simulations of the particular geometry, at 15.2± 0.3 MeV extracted proton energy degraded to 12.9 MeV (± 0.78MeV straggling) by an aluminum foil and irradiated for 4 hours at a 20 µA beam current. An Affibody molecule was synthesized, consisting of three alpha helices, with 63 amino acids. The affibody binds selectively to HER2 receptors with picomolar affinity. Its molar mass of about 7 kDa (7260.14), theoretical pI: 5.37, and Kd: 60 pM resulted from post-synthesis characterization.$^{89}$Zr radiolabelling was performed after the conjugation of affibody with DFO, using zirconium oxalate solution, purified on ZR cartridges, pH 4.5-5.5, 500±25 MBq/ml. ***Results:*** $^{89}$Zr-oxalate as a labelling precursor was successfully optimized on a customized target and beam geometry and standardized post-purification, radiolabelling, and evaluation procedures were implemented. The irradiation process yielded an activity of 2.95 ± 0.25 GBq/batch EOB, [$^{89}$Zr]Zr-oxalate complies with technical specifications. antiHER2 affibody was conjugated with DFO (DFO to affibody molar ratio 3:1) at 37ºC for 30 min, at pH = 8.9 - 9.1, and purified on PD10. Radiolabelling of DFO-affibody resulted in PRC > 95%. Preclinical evaluation of $^{89}$Zr-DFO-antiHER2 affibody, performed in vivo on HER2+ models (BT 474 and MCF7 breast cancers, and SKOV3 ovarian cancer) against HER2- line (A431 epidermoid carcinoma), shows a stable uptake in cancer cells. Specific binding and fast uptake were observed for BT 474 and MCF7 breast cancers, while a higher initial uptake on SKOV3 ovarian cancer resulted in medium retention after 2 h of incubation. The uptake profiles of the 89Zr radiolabelled affibody were compared with those of a full antibody anti-mErb2/HER2. ***Conclusion:*** 89Zr-DFO-antiHER2 affibody in vitro preclinical evaluation shows positive results, therefore it will be further evaluated in vivo as PET imaging agent of HER2 positive cancers.

## EP-0867

### The Impact of Renal Uptake on 18F-DCFPyL Biodistribution

***G. Chaussé***[1], *S. Plaha*[2];
[1]*McGill University, Montreal, QC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA.*

***Aim/Introduction:*** $^{18}$F-DCFPyL (PSMA) has intense renal uptake. Given that a standardized dose is administered to all patients, large kidneys may drain more of the radiopharmaceutical and thereby decrease uptake to the remainder of the organs. Biodistribution of 18F-DCFPYL PET imaging can be calculated as "Total Body Uptake" (sum of the product "Volume X SUVmean" of all organs with uptake). We investigated if: 1-the change in the volume of high-uptake organs (the kidneys) affected uptake to other organs, and 2-if 18F-DCFPyL renal uptake correlated with renal function. ***Materials and Methods:*** 11 patients with history of surgically treated renal cell carcinoma underwent PET/CT scans two hours following intravenous injection of $^{18}$F-DCFPyL as part of a clinical trial (NCT02899312). Informed consent was obtained prior to any procedure in conformity with local ethic committee recommendations and in accordance with the ICH E6 guidelines and Declaration of Helsinki. Some patients were treated with partial nephrectomy, others with complete nephrectomy, resulting in variable renal uptake. Images were manually segmented using tools from a commercially available software (MIM software, v.7.0). Segmented organs were the salivary glands, lacrimal glands, liver, spleen, kidneys, and bowel. The bladder is considered excreted and therefore excluded. $SUV_{mean}$ and volumes were collected for each organ. We compared the renal volume against the renal total uptake (Volume x $SUV_{mean}$) and correlated that with the renal function (creatinine level at the time of the scan). The 11 patients were sorted by renal volume or renal total uptake, divided into above or below the median and tested with a student T test. ***Results:*** There is a statistically significant inverse correlation between renal volume and $^{18}$F-DCFPyL biodistribution to other organs and a statistically significant correlation between renal function and $^{18}$F-DCFPyL renal uptake. ***Conclusion:*** Renal function and volume appear to impact overall radiopharmaceutical biodistribution. $^{18}$F-DCFPyL may be able to measure renal function, however larger cohorts with highly variable renal volumes would be needed to confirm these findings.

### Preparation of Ga/Ni Solid Target for Cyclotron-produced 68Ge by Electrodeposition

***Y. Shen***;
*China Institute of Atomic Energy, Beijing, CHINA.*

***Aim/Introduction:*** The main applications of $^{68}$Ge are its use as a long-lived positron source for attenuation corrections and calibration of PET/CT , and its role as mother radionuclide for the preparation of $^{68}$Ge/$^{68}$Ga radionuclide generators. The $^{68}$Ge/$^{68}$Ga radionuclide generator systems attracted interest in nuclear medicine because of its significant potential for PET/CT imaging using $^{68}$Ga labelled radiopharmaceuticals. The low melting point of the target material in the production reaction $^{69}$Ga (p, 2n) $^{68}$Ge has limited the availability of $^{68}$Ge. In order to use the existing industrial cyclotron hardware to produce $^{68}$Ge, a method of electrodepositing gallium-nickel alloy was set up in this study. ***Materials and Methods:*** The Ga/Ni solid target was prepared by electric deposition method for cyclotron producing $^{68}$Ge. Acidic requirements were met through the preparation of the gallium-nickel alloy targets and by optimizing the plating bath

composition and electrodepositing conditions, the influences of current density, temperature, pH value, Ga/Ni concentration on the target quality were investigated. ***Results:*** The gallium-nickel solid targets with a gallium content of 75% was prepared by electric deposition method. After three irradiation tests, the process was certified to produce targets of Germanium 68. ***Conclusion:*** This process is user-friendly, the preparation of the targets is of stable quality, and it can be applied to the cyclotron production of Germanium 68. ***References:*** 1.G.-J-Meyer, Macke, H., Schuhmacher, J. , & Knapp, W. ## EP-0869

### Developing Actinium-225 large-scale supply

***S. Bertrand***[1], *S. Van den Berghe*[1], *W. Leysen*[2], *J. Mermans*[2], *S. Heinitz*[2], *D. Maertens*[1], *G. Scheveneels*[2], *C. Gameiro*[3], *A. Cea*[2], *P. Vanwolleghem*[1], *M. Sprangers*[2];
[1]*Pantera, Mol, BELGIUM,* [2]*Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM,* [3]*Ion beam applications, Louvain-la-Neuve, BELGIUM.*

***Aim/Introduction:*** Within the field of theranostic, one of the most promising therapeutic radioisotope is the alpha-emitting Actinium-225 (225Ac). Alpha emitters present high LET (linear energy transfer- about 100 KeV/µm) and short path length in (50-100 µm) which results in high cytotoxic potency limited to few cancerous cells while sparing surrounding healthy tissues[1]. In addition, 225Ac has apropriate half-life (10 days) which facilitate smooth logistics process and a centralized industrial distribution scheme. One of the main challenges for worldwide patient access is to ensure the availability of high-quality -225Ac in large quantities. The project aims at establishing a new factory that will be able to produce large-scale quantitiesof 225Ac for patient use. ***Materials and Methods:*** Given the objective to supply large scale amounts of Actinium, the "gamma route" 226Ra(g,n) 225Ra -> 225Ac was selected.To enable the large-scale and high-quality production via the gamma route, several challenges must be tackled:- The source material 226Ra has very limited availability. - The overall process efficiency must be high to allow long-term operation and avoid Radium losses- The cross-section of the gamma route reaction is low, so the gamma flux on the Radium target and Radium quantity in the target must be high to enable commercial production of 225Ac.- Handling of 226Ra target material which is radioactive and releases radioactive Radon- The end-product quality must respond to pharmaceutical drug quality standards. ***Results:*** The commercial production facility aims at producing, with an electron beam accelerator, large quantities of purified $^{225}$Ac enabling commercial distribution. The process described should lead to the cumulated production of more than 100 Ci of $^{225}$Ac per year and per accelerator. Several production lines could be added to supply a growing demand. ***Conclusion:*** As clinical trials are progressing, the demand for $^{225}$Ac is continuously increasing. It has been estimated that the worldwide demand could easily reach several hundreds of Ci per year as soon as the first commercial products reach the market (around 2027). It is essential that the radioisotope supply community provides confidence to the pharmaceutical companies that a high quantity, high quality and reliable $^{225}$Ac supply chain will be achieved. This joint effort and other ongoing initiatives are a clear sign of the commitment to make this supply chain a reality. ***References:*** [1] R.Eychenne, M. Chérel,, F. Haddad, F. Guérard, J-F Gestin, Pharmaceutics 2021, 13, 906

## EP-0870

### CERAD, Center of Design and Synthesis of Radiopharmaceuticals for Molecular Targeting and 30 MeV cyclotron for medical isotope production in Poland

***R. Mikolajczak***, *D. Pawlak, W. Wojdowska, I. Cieszykowska, T. Szyszko, P. Garnuszek;
National Centre for Nuclear research-POLATOM, Otwock, Poland, POLAND.*

***Aim/Introduction:*** In order to meet the high demand for radiometals with potential for medical applications, with a particular focus on their theranostic value, the new research facility is being built at NCBJ/POLATOM: Center of Design and Synthesis of Radiopharmaceuticals for Molecular Targeting, CERAD. It's main component is the 30 MeV cyclotron which accelerates protons and alpha particles to 30 MeV and deuterons to 15 MeV. It will be a powerful tool for production of novel radioisotopes for medical use, which were not available in Poland up today. Among them the radioisotopes such as $^{18}$F, $^{44/43}$Sc, $^{64}$Cu, $^{67}$Cu, Ge$^{68}$, $^{89}$Zr, $^{123}$I and $^{211}$At will be produced. Installation of a new high-current cyclotron at NCBJ, with an equipment and infrastructure, combined with already existing scientific base, creates the unique and pro-development research capabilities. ***Materials and Methods:*** The cyclotron of CERAD, Cyclone 30XP, provided by Ion Beam Applications, Belgium, next to protons and deuterons also accelerates alpha particles, it is equipped with the alpha ion source. The new building not only hosts the cyclotron but also a number of dedicated labs with hot-cells for radioisotope processing, with the QC and research laboratories. The entire facility offers a space of 2500 m$^2$. The upcoming infrastructure will be open to PRISMAP, SECURE and other users projects. ***Results:*** The infrastructure of CERAD can be used for both research and commercial activities, it creates the platform for comprehensive studies oriented at research and design of new medicinal products, in particular radiopharmaceuticals, and at implementing diagnostic and therapeutic procedures for diseases, which are currently treated ineffectively. ***Conclusion:*** The CERAD project has found its place on the Polish Roadmap of Large Research Infrastructure because it will not only offer new radioisotopes but also a possibility to design innovative radiopharmaceuticals. The research potential of NCBJ as consortium leader is supported by partner institutions: University of Warsaw, Warsaw Medical University, Institute of Nuclear Chemistry and Technology, Jagiellonian University Medical College and Medical University of Bialystok. ***References:*** CERAD project is co-financed under Smart Growth Operational Programme 2014-2020, Priority IV: INCREASING THE RESEARCH POTENTIAL, Measure 4.2. Development of modern research infrastructure of the science sector.

## EP-0871

### Cyclotron production of 68Ga with in-target dissolution

***D. Szikra***, *V. Forgács;*
*University of Debrecen, Debrecen, HUNGARY.*

***Aim/Introduction:*** $^{68}$Ga was produced from $^{68}$Zn metal with proton irradiation. The irradiated target material was dissolved in the target system and transferred to the hotcell for purification and labeling. ***Materials and Methods:*** The d.o.t.s. solid target system from Syniq Ltd was installed on a GE PETtrace cyclotron and used for isotope production. ***Results:*** 40 mg $^{68}$Zn target material was irradiated with 50 uA proton beam for 10-180 min, yielding 7-60 GBq $^{68}$Ga at the end of bombardment. The irradiated target material was dissolved with 7 M HNO3 and transferred to the hotcell via capillary line. The target solution was purified on a Trasis mini AiO module. The target solution was neutralized with ammonium formate and trapped on TK230 resin. After rinsing with 0.01 M HCl the gallium was eluted with 0.75M HCl and concentrated on CUBCX resin. The final elution was done with 0.5 ml 1 M HCl and 4.5 M 0.01 M HCl. The purified gallium was mixed with 1M NaOAc pH 4.5 buffer and reacted with 20 ug PSMA-11 for 5 minutes at 100 °C. Overall decay corrected yield was approx. 70-75%. 20-21 GBq $^{68}$GaPSMA-11 was produced from 2h irradiation. ***Conclusion:*** The produced $^{68}$GaPSMA-11 met the requirements of PhEUR and thus suitable for human application.

## EP-0872

### Development of New Automated Methods for [18F]-NaF Productions using FDG synthesizer.

***S. NGOKPOL***, *S. Kijprayoon, T. Saonam;*
*Bangkok hospital, Bangkok, THAILAND.*

***Aim/Introduction:*** The shortage of technetium-99m has caused an urgent need for [$^{18}$F]sodium fluoride for PET imaging of bone metastasis. We modified a fully automated method for [$^{18}$F]NaF synthesis by re-configuring a commercial FDG synthesizer. ***Materials and Methods:*** The Lookout program was used to sequence the steps for automated synthesis using an Excel spreadsheet. The [$^{18}$F]fluoride solution is transferred to the synthesis module. The [$^{18}$F]fluoride ions are trapped in the QMA-light Sep-Pak cartridge. The QMA cartridge is then washed with sterile water for injection and eluted with 0.9% NaCl. The final product was passed through a 0.22 µm sterile filter to a sterile product vial. ***Results:*** [$^{18}$F]NaF was successfully produced consistently with a high yield. The non-decay corrected yield after synthesis is at least 85%. Module cleaning and preparation before synthesis takes 25 minutes. The total synthesis time is 7 minutes. Quality control of [$^{18}$F]NaF is performed according to USP and EP requirements. The QC results are passed. ***Conclusion:*** This design of fully automated synthesis showed reproducible, user-friendly, and very good radiochemical yields. This module could be used for [$^{18}$F]NaF production in our department. ***References:*** 1. F. Dehghan, S. Jaloo, H. Afarideh*, DEVELOPMENT OF NEW COMBINED SYSTEM FOR PRODUCTION OF FDG And NaF RADIOPHARMACEUTICALS, Proceedings of Cyclotrons2013, Vancouver, BC, Canada, 390-392.2. C. Collet et al., [2015], Applied Radiation and Isotopes 102:87-92.

## EP-0873

### How Can Nuclear Physicians Mitigate the Patient's Fear of Medical Radiation Exposure? -Lessons Learned from Fukushima Dai-ichi Nuclear Power Plant Accident -

***K. Ohno***[1], *M. Kajisako*[2];
[1]*Kyoto Collage of Medical Science, Kyoto Nantan, JAPAN,* [2]*Kyoto University Hospital, Kyoto, JAPAN.*

***Aim/Introduction:*** On March 2011 Fukushima Daiichi Nuclear Power Plant (FNP-1) accident has occurred. All over the world, people were anxious about the effects of ionizing radiation, especially about internal exposure. At the same year we had a medical accident of nuclear medicine at a small municipal hospital in Japan. Forty-nine pediatric patients had received larger-than-standard dose of radiopharmaceuticals. This sensational news confused the local community. The municipality established an accident investigation committee. This party was able to gain the trust of the media and patients' families by using risk communication method lessons learned from FNP-1 accident. We will publish the results with the aim of providing nuclear medicine professionals around the world with useful materials for risk communication in the event of an accident. ***Materials and Methods:*** The committee decided to obtain the consent of the parties concerned for the following 1 The hospital's administrative staff will fully cooperate with the disclosure of the hospital's internal documents. 2.The hospital will release the full text of the investigation report on the web. 3.The academic societies concerned will accept the recommendations in the report. The committee also decided that they would brief the media representatives after each meeting and respond to questions and answers. In addition, a member who is a nuclear medicine specialist, will meet all family members to directly hear the actual situation. After that, the committee will conduct individual interviews. ***Results:*** All the committee's decision-making policies were approved. The media was briefed in detail on the progress of the investigation. They gradually became more interested in the internal system that caused the accident than in the effects of radiation. The patient's family blamed themselves because they had chosen this hospital for their child. During the individual interviews, they wished to know the disclosure of accurate exposure doses and the effects and impact on the future growth of their children. The anxiety of the patients' families and its change over time was remarkably similar to that of the parents of pediatric patients who were concerned about radiation exposure. ***Conclusion:*** In a serious medical radiation accident, it is effective for experts to continue to provide carefully explanations that are acceptable to the media and for family members to respond in a manner similar to that used to deal with patients who are concerned about radiation. The law changed to require doctors to chart the actual dosage to the patient.

## EP-0874

### A low energy cyclotron, as an enabler for cancer diagnosis in emerging countries

***J. Geets***, *E. Kral, J. Harray, V. Petry;*
*Ion Beam Applications SA, Louvain-La-Neuve, BELGIUM.*

***Aim/Introduction:*** A new low energy cyclotron was released with the aim of providing access to cancer diagnosis with modern nuclear medicine PET/CT for the largest number of patients across the globe, hence bridging healthcare disparities and democratizing advanced treatment for all. ***Materials and Methods:*** Installation requirements are set to their minimum. Unlike all the other accelerators, this new cyclotron does not request compressed air, dry nitrogen nor expensive helium cooling and democratizes the set-up of a new production center with its independence from resource scarcity. The choice of a low energy proton beam was driven as tradeoff of sufficient for $^{18}$F production but also easier to shield and reducing infrastructure cost as well as long term activation for future decommissioning. Reliability is a key success factor of this cyclotron. For the first time,

the ease of the maintenance has been pushed a step further by removing the needs for adjustments and jigs for each task like ion source maintenance or target maintenance. Thanks to its unique design, energy consumption and its impact on operating cost has been reduced to the minimum. The power consumption of subsystems such as magnetic power supply or ion source power supply, have been further reduced by at least a factor two compared to other accelerators. The use of turbomolecular pumps for vacuum system is more efficient than conventional resistor driven oil diffusion pumps while being tolerant to mains network outage. The guidance for safe and reliable operation has been specifically addressed through the entire redesign of its software. Production workflow has never been that intuitive. The full center can run with no specific requirement on staff education. Dedicated training can turn any hospital technician into a site operator. Besides the cyclotron as source of $^{18}$F, the system is packaged with synthesis unit for FDG & other tracers, dispensing unit, and integrated quality control system in shielded compartment. ***Results:*** This new cyclotron has been successfully qualified in factory. Waiting for the building completion of the first customers for shipment. Work is currently in progress. ***Conclusion:*** From first results and practical implementation, the system clearly addresses the need of emerging countries to access to modern nuclear medicine modalities for cancer diagnosis. This solution paves the way to reliable and safe FDG production bridging healthcare disparities across the globe.

### Radiosynthesis and Formulation of [18F]mFBG : The challenge of a clinical use radiopharmaceutical for a pediatric population

***J. Fouque***, *L. Trump, B. Irumva, M. Steffann, E. Da Costa Branquinho, Q. Bruyer, C. Provost, O. Madar; Institut Curie, Saint-Cloud, FRANCE.*

***Aim/Introduction:*** Neuroblastoma is the most common childhood cancer in France and is still diagnosed/followed by a SPECT radiopharmaceutical, the [$^{123}$I]meta-iodobenzylguanidine ([$^{123}$I]mIBG). This radiopharmaceutical requires thyroid blockade, leads to poor resolution image and needs at least 24h of biodistribution to have a sufficient ratio signal/noise. In this context, the development of PET radiopharmaceutical, the [$^{18}$F] meta-fluorobenzylguanidine ([$^{18}$F]mFBG), is relevant to simplify the scan procedure, to improve resolution and detection of neuroblastoma. We focused on the development of a performant radiosynthesis while offering a well-tolerated formulation for children. ***Materials and Methods:*** The radiosynthesis of [$^{18}$F]mFBG was previously developed on an All-in-one synthesizer (Trasis) using a boronate ester precursor (BEp). A new development was designed using a spirocyclic iodonium(III) ylide precursor (SIYp). In both cases, the multi-steps radiosynthesis starts with a radiofluorination followed by a deprotection. For the BE precursor, the formulation consisted in a cationic exchange on a cartridge after the HPLC purification. For the SIYpj, the formulation was combined with the HPLC purification by using an injectable eluent. Using BEp, sodium ascorbate (NaAsc) was inserted to mix the bulk, while using SIYp, NaAsc was inserted since the deprotection step. ***Results:*** The optimal conditions with BEp allowed to obtain a RCY of 14 ± 4% with 240 ± 27 GBq of starting activity (n=4) and 10 ± 2% with 384 ± 42GBq (n=3). For the SIYp, RCY of 27% with 13 GBq of starting activity (n=1), 14% with 130 GBq (n=2) and 13% with 240 GBq (n=1) were obtained. The RCY drastically decreases with the rise of starting activity indicating a sensitivity towards radiolysis. Even if the NaAsc was inserted earlier in SIYp radiosynthesis no improvement of the RCY was observed. We suppose that the radiolysis already occurs during the radiofluorination. Consequently, the two radiosynthesis are close in term of RCY but the sequence with SIYp is simpler and faster, 45 vs 53 min, and thus activity yield is more interesting for clinical production. ***Conclusion:*** [$^{123}$I]mIBG scintigraphy will eventually be replaced by [$^{18}$F]mFBG in few years. Offering a PET imaging in the management of neuroblastoma for pediatric population is highly valuable. The radiosynthesis based on BEp or SIYp seems to be very sensitive to radiolysis. To conclude, two robust processes were developed on the AIO for the radiosynthesis of MFBG with moderate yields, sufficient for clinical trials. ***References:*** Matthew Tredwell et al.; Angew. Chem. 2014 ; Benjamin H.Rotstein et al.; Chem. Sci. 2016

## EP-0876

### Automated Production of 177Lu-Labelled Radiotracers Using Microfluidic Approach

***S. Lahdenpohja***[1], *C. Piatkowski*[2], *L. Tanguy*[2], *B. Kuhnast*[1]; [1]*Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Orsay, FRANCE,* [2]*PMB Alcen, Peynier, FRANCE.*

***Aim/Introduction:*** Lutetium-177 ($T_{½}$=6.76d, $E_{β\text{-max}}$=0.497MeV, maximum range in tissue 2.5mm) is one of the most important theranostic radionuclides as it has favourable nuclear characteristics for cancer therapy.[1,2] Production of therapeutic doses (typically >5GBq) of $^{177}$Lu-radiopharmaceuticals demands automated manufacturing process from the safety and quality point of view. In this study, our goal was to show the usability of an automated microfluidics based radiosynthesiser in dose-on-demand type of production of $^{177}$Lu-radiotracers. In addition, we aimed to develop a solid phase extraction (SPE) based method for $^{177}LuCl_3$ concentration to adjust the volume in which $^{177}LuCl_3$ can be delivered for subsequent labelling reactions. ***Materials and Methods:*** Two different labelling approaches were studied; in the first approach aqueous $^{177}LuCl_3$ (0.04M HCl) solution was mixed directly with precursor in 0.1M ammonium acetate in a microfluidic cassette. Three different peptides were labelled with 10 min reaction time at 37°C. Manual reaction was conducted in parallel to verify the effectiveness of the microfluidic process. For proof-of-concept, full labelling synthesis with formulation step was conducted in the microfluidic cassette. Radiolabelled compounds were analysed with radioHPLC. In the second approach, acidified $^{177}LuCl_3$ solution (approx. 4M HCl) was trapped on a lanthanide dedicated SPE resin and eluted with only 200µL of diluted HCl before mixing with precursor in 0.5M ammonium acetate. Different methods for washing the resin after trapping step were studied to increase the pH of the eluant without compromising the elution efficiency. ***Results:*** Direct mixing of $^{177}$Lu-solution and precursors in a microfluidic cassette yielded $^{177}$Lu-DOTA-PSMA with 55±6% (manual 59%) radiochemical conversion (RCC), $^{177}$Lu-DOTA-cRGD with 30±8% RCC and $^{177}$Lu-DOTA-octreotide with 23% RCC. As a proof-of-concept, formulated

$^{177}$Lu-DOTA-PSMA was produced with 100% radiochemical purity. In the second approach, trapping efficiency of $^{177}$Lu was >95% and elution efficiency with 200µL 0.04M HCl was 66±2% (manual 87%). ***Conclusion:*** Novel fully automated microfluidic approach can be used for $^{177}$Lu-labelling of peptides. Trapping and elution of $^{177}LuCl_3$ from an SPE resin using a microfluidic cassette is a method to control and standardise the volume of $^{177}LuCl_3$ before its use in subsequent labelling reactions. Further studies are needed to adjust the pH of the eluant for suitable buffering of subsequent labelling reactions. ***References:*** [1]Am.J.Nucl.Med. Mol.Imaging;2021;11(6):443 [2]Oncologist;2022;27(6):e957

## EP-0877

### Comprehensive analysis of environmental monitoring data from the GMP radiopharmaceutical facility of the UMCG obtained between 2010-2022

***H. Boersma***[1], *L. B. S. Bekhof*[2], *T. W. T. Poiesz*[2], *M. M. Woerdenbag*[1], *D. Giesen*[1], *H. T. Tholen*[1], *G. Luurtsema*[1], *M. N. Lub-de Hooge*[1], *H. J. Woerdenbag*[2];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*University of Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** In this study, the quality of manufacturing conditions at the GMP radiopharmaceutical facility of the UMCG was evaluated. Hereto, data obtained from environmental monitoring over the period 2010-2022 were analysed. ***Materials and Methods:*** The data were sorted according to the GMP classification of the respective premises with their corresponding limits, and frequencies were determined per location. The analysed environmental monitoring techniques included active air sampling, passive air sampling, contact prints, and particle counting. The data were compared and statistically evaluated using a 2-sided Fisher's exact test ($p < 0.05$ was considered significant). In addition, the Contamination Recovery Rate (CRR) over time was calculated and analysed. ***Results:*** The frequencies of conducted measurements gradually increased between the start and end of the assessed period. There was a trend of increased action limit excursions observed between 2010-2022 for active air sampling and contact prints. Interestingly, environmental monitoring in grade A areas significantly less complied to GMP specifications than the combined data from all sampled premises at the facility ($p < 0.00001$), which could not be explained by seasonal conditions. Furthermore, the Glovebox A cabinet revealed more microbiological excursions than other grade A areas($p < 0.0001$), which may be explained by the higher number and complexity of manual activities performed in this cabinet during radiopharmaceutical production. The CRR found for cleanroom conditions was sufficient. A trend was also found for reduced action limit excursions for passive air sampling and particle counting, suggesting improved GMP compliance over time for this specific type of environmental monitoring. ***Conclusion:*** From this comprehensive data analysis we learn that, in order to be fully compliant to requirements set in the upcoming GMP Annex 1 revision (in force as of August 2023), strategies to further improve microbiology and thereby the product, are advised. For example, improved cleaning procedures, efficient working methods as well as optimization of the conditions under which aseptic manufacturing is performed. The evaluation of a recent optimisation of our cleaning procedure is now work in progress.

## EP-0878

### Fully Automated Radiosynthesis Quality Control and GMP Validation of [68Ga]Ga-PentixaFor for CXCR4 PET Imaging: First Taiwan Experience

***M. Li***[1], *L. Hung*[1], *S. Yang*[1], *T. Lin*[1], *Y. Huang*[1], *W. Pai*[2];
[1]*Koo foundation Sun Yat-Sen Cancer Center, Taipei, TAIWAN,* [2]*Advancharis Science and Research Co., Ltd, New Taipei City, TAIWAN.*

***Aim/Introduction:*** PentixaFor is a promising radiopharmaceutical for PET in the detection of lymphoproliferative diseases. [$^{68}$Ga]Ga-PentixaFor has shown high-affinity specific binding to the binding pocket of CXCR4 lymphomas. The preparation process of [$^{68}$Ga]Ga-PentixaFor was fully automated for clinical use to meet the radiation safety and GMP PET drug guidance requirements in Taiwan. Base on risk-based QMS, our strategy was to evaluate the automated synthesis of [$^{68}$Ga]Ga-PentixaFor on Part 11 compliant systems and sterilized reagent kit/labelling cassette for clinical application. ***Materials and Methods:*** GMP grade PentixaFor and [$^{69}$Ga]Ga-PentixaFor were obtained from PentixaPharm (Germany). Radiosynthesis parameters were set up by specific labelling conditions (95 °C, 5 min) with the MLPT(EZ, Germany) module. The automated synthesis platform (MLPT), reagent kit (EZ-102, GMP for APIs), disposable cassettes (C4-GA-PEP, plastic reaction vial) for $^{68}$Ga-labelling, and pharmaceutical-grade $^{68}$Ge/$^{68}$Ga generator (GalliaPharm®) used in the process validation tests were purchased from EZ (Germany). The parameters such as temperature, precursor concentration, reaction time, buffer concentration with volume used, bubble point test for 0.22 um filter integrity, and pH, as well as product purification step (C18 Cartridges), were optimized and set up in control program. Process optimization was conducted regarding product quality (Radio-HPLC, GC, MCA, TLC, Bacterial Endotoxin Test) and quantity (>5 mCi/dose, 1 MBq~60MBq/nmol), as well as process reproducibility. ***Results:*** The reproducible and GMP-compliant automated production of [$^{68}$Ga]Ga-PentixaFor with on-line documentation was developed. The decay-corrected radiochemical yield was >83% (n = 3, process validation test) at the end of the synthesis with a labeling synthesis duration of 20 min and a quality control including release procedure of 20 min. The average radiochemical purity of the products was >95% (n = 3) with the total amount of the peptide in the preparation of 50µg (n = 3, GMP grade, ABX). Radionuclide purity (>99.9%), radiochemical purity (>95%), sterility, endotoxin content, residual solvent content (EtOH < 10%), and sterile filter integrity tests met the acceptance criteria. The product was stable at room temperature for 2 hrs. ***Conclusion:*** The fully automated GMP-compliant manufacturing process was developed and thoroughly validated. The resulting [$^{68}$Ga]Ga-PentixaFor will be using in a clinical study for accurate evaluation of several lymphomas for noninvasive detection of CXCR4 receptor relative disease at Koo Foundation Hospital. This process validation and quality control methodology could be compliant with GMP regulations for future clinical application in Taiwan. ***References:*** Cancers 2022, 14, 3814. EJNMMI Radiopharmacy and Chemistry 2023, 8:4.

## EP-0879

### Radiosynthesis of Theranostic FAP-2286: This Is the Way

***M. Aurilio***, *C. Maisto, A. Esposito, V. Porfidia, M. Buonanno, R. de Marino, A. Morisco, E. Squame, S. Lastoria;
National Cancer Institute G. Pascale, Napoli, ITALY.*

***Aim/Introduction:*** FAP targeting using FAP-based radiolabelled tracers is a promising tool for diagnosis and therapy of numerous malignant tumors. One of the most promising compounds

with the highest reported FAP affinity is FAP-2286. FAP-2286 is a FAP-targeted peptidomimetic functionalized with a DOTA chelator that can therefore bind theranostic pairs, such $^{68}$Ga and $^{177}$Lu. The aim of this work was to optimize the synthesis of the radiopharmaceutical, in diagnostic and therapeutic form, using a single synthesis module and standardized quality controls, in order to have an easy and reliable procedure optimizing economic resources. ***Materials and Methods:*** The radiolabelling with $^{68}$Ga/$^{177}$Lu was performed using a cassette-based automatic module. $^{68}GaCl_3$, eluted from generator with starting activity of 1220 ±74 MBq, is used without purification and added to a solution of 50 microgram FAP-2286 dissolved in 1 ml of 0,7 M sodium acetate buffer. The reaction mixture was heated to 90 °C for 10 minutes and after was loaded for purification with the preactivated C18 cartridge and eluted with ethanol. For preparation of [$^{177}$Lu] Lu-DOTAFAP-2286, the same automatic module was used. A solution of 7400 MBq of $^{177}$Lu, in 300 microliter 0.05 M HCl, was added to a peptide dissolved in 2 ml of ascorbic buffer pH 4,5 (40 MBq/microgram peptide). The labelling reaction was carried out at 120°C for 4 minutes and then at 100°C for 26 minutes. No purification step was applied. Both radiopharmaceuticals were formulated in 0,9% saline solution after sterile filtration. Quality controls were performed according to regulatory guidelines to establish a clinical routine production. ***Results:*** Radiochemical, chemical and radionuclide purity, pH, half-life, residual organic solvents were assessed for both the radiolabelled preparations. FAP-2286 showed good radiochemical yield (RCY) when radiolabelled with $^{68}$Ga, in the range of 70-80%, and a RCP > 99 % without significant amount of both free $^{68}$Ga and colloidal $^{68}$Ga. For the radiosynthesis of [$^{177}$Lu]Lu-DOTAFAP-2286, we obtained high molar activities, about 60 GBq/mmol, with high RCP > 99.8% that was stable for 24 hours. ***Conclusion:*** $^{68}$Ga/$^{177}$Lu-FAP-2286 was successfully synthesized fully-automated. All quality control parameters were in accordance with the EuPh and the stability was > 24h for [$^{177}$Lu]Lu-DOTAFAP-2286.The automatic synthesis therefore test making FAP-2286 a very convenient theranostic agent and will facilitate the implementation of this radiopharmaceutical pair in clinical practice.

## EP-0880

### The Optimization of the Current ININ Method of Lu-177 DOTA-HYNIC-iPSMA

***Y. Omar***[1], *Y. Atteya*[1], *N. Taha*[2], *M. AbdelKawi*[1];
[1]*Misr Radiology Center, Cairo, EGYPT,* [2]*Ain Shams University, Cairo, EGYPT.*

***Aim/Introduction:*** PSMA (Prostate-Specific Membrane Antigen) is an overexpressed cell surface protein in prostate cancer cells, making it an attractive target for cancer diagnosis and treatment. One way to target PSMA is through radiolabeled small molecules that bind specifically to the protein.The chelators can be conjugated to PSMA-targeting small molecules for radiolabeling with therapeutic isotopes like Lutetium-177 (Lu-177). The chelators DOTA (1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid) attached to HYNIC (6-hydrazinonicotinic acid) generates a rigid chemical structure that minimizes the number of intramolecular hydrogen bonds, producing a favorable spatial orientation of the active site (Lys {Nal) - NH-CO ~ NH-Glu) in the molecule for biological re-comforting by the PSMA protein. ***Materials and Methods:*** The labelling process was improved by using softer conditions, lower temperatures, and less time. In the optimized method, the DOTA-HYNIC-iPSMA molecules shows reduced degradation and a higher radiolabeling efficiency. It also shows better stability of molecules and robust post-labeling compared to the current method of labeling from ININ (Instituto Nacional De Investigaciones Nucleares). The current labelling process from ININ Kits includes 50 mg of mannitol and 100 mg of ascorbic acid, after being reconstituted with 1.1 ml of 1 M sodium acetate buffer at pH 5.0 and heated up to 95° C for 30 min incubation. This method showed degradation in the compound due to long reaction times and higher temperatures. The optimized method for labelling required a lower temperature of 85° C, a shorter reaction time of 10 min, and a lower quantity of ascorbic acid. ***Results:*** The optimized method shows a better purity on the HPLC system, radiolabeling efficiency above 98%, and reproducibility. ***Conclusion:*** Lu-177 DOTA-HYNIC-iPSMA molecule radioligand is a promising approach for the treatment of prostate cancer. The optimization of the labelling method from the current kits produced by ININ shows better purity, shorter labelling time and lower temperature compared to the current condition. ***References:*** 1-Luna-Gutiérrez, M., Hernández-Jiménez, T., Serrano-Espinoza, L. et al. Freeze-dried multi-dose kits for the fast preparation of 177Lu-Tyr3-octreotide and 177Lu-PSMA(inhibitor) under GMP conditions. J Radioanal Nucl Chem 314, 2181-2188 (2017).

## EP-0881

### Automated cassette-based synthesis of [18F]Fluoro-L-DOPA via Cu-mediated process for routine production in a GMP environment

***N. Emmanuel***, *D. Goblet, G. Decoux, C. Gameiro;*
*IBA, Louvain-la-Neuve, BELGIUM.*

***Aim/Introduction:*** The continuously growing success of [$^{18}$F] fluoride for PET imaging has resulted, in the recent years, in a need of diversity of radiotracers. For this purpose, specific methodologies have been explored for the labelling of a variety of chemical structures. Cu-mediated $^{18}$F-fluorination is an efficient method for the labelling of aromatic and heteroatomic compounds such as arylstannanes[1]. [$^{18}$F]Fluoro-L-DOPA, a tracer used for the detection of neuroendocrine tumors and diagnosis of Parkinson's disease, was successfully obtained using this method. Robust automated synthesis in a GMP environment is crucial to ensure a reliable routine production of this radiopharmaceutical. In this abstract, optimized and fully automated synthesis of [$^{18}$F] Fluoror-L-DOPA in a disposable, cassette-based module and its quality control results (according to the European pharmacopoeia) will be described. ***Materials and Methods:*** Fully automated synthesis has been established on a cassette-based platform. The [$^{18}$F]fluoride was trapped on a QMA cartridge and eluted with 900 µL of TEA into the reactor. After a thorough drying of the [$^{18}$F] fluoride, the precursor solution (BBTE 20 mg, an arylstannane, in 1 mL dimetylacetamide containing the Cu-catalyst) is added to the same reactor. The fluorination was performed at 100 ☒ for 10 minutes. The reaction mixture was then diluted with EtOH 30% (8 mL) and purified from its metallic component (Sn, Cu) with a tC18 cartridge. [$^{18}$F]Fluoro-L-DOPA was eluted from tC18 to the reactor with 2 mL of acetonitrile and 2 mL of HBr 48% were added for hydrolysis. The hydrolysis was performed at 150°C for 10 min. Subsequently, NaOH was added to neutralize the pH before purification on HPLC column (Synergi Hydro-RP). The overall synthesis time was 60 minutes, including the purification step. Quality control tests were performed including appearance, pH, radionuclidic purity, radiochemical purity, chemical purity, chiral purity, ICP-MS and residual solvents, according to the European pharmacopoeia (04/2019:2481), where possible. ***Results:*** In this

present study, automated radiosynthesis of [18F]Fluoro-L-DOPA has been achieved with radiochemical yields of 25-30% non-decay corrected (n.d.c) for incoming activity up to 74 GBq. In all runs (n=3), radiochemical purity was >95% and residual solvents below ICH Q3 limits. [18F]Fluoro-L-DOPA enantiomeric purity was confirmed by chiral HPLC analysis. ***Conclusion:*** Fully automated, optimized and simplified synthesis of [18F]Fluoro-L-DOPA has been obtained on cassette-based module with high radiochemical and chemical purity. Ready-to use consumables are available to help streamline routine clinical production in a GMP setting. ***References:*** [1]F. Zarrad,B.D. Zlatopolskiy,P. Krapf,J. Zischler and B.Neumaier,Molecules 22;2231, 2017.

## EP-0882

### The Use of a Mobile Clean Room for (Re)loading of a More Durable Sr-82/Rb-82 Generator

***R. Claessens***[1], *J. C. Vink*[2], *K. Baggerman*[2];
[1]*Rubigen b.v, 's-Hertogenbosch, NETHERLANDS,*
[2]*Baggerman Farma Consult, Eindhoven, NETHERLANDS.*

***Aim/Introduction:*** We developed a Sr-82/Rb-82 generator to be (re)loaded every 4 weeks under aseptic conditions in a mobile clean room with a usability period of 12-13 weeks. ***Materials and Methods:*** The design of the generator is based on the 'Ottawa generator' [1] with a few changes. The generator is loaded with Sr-82 up to 3 times every 4 weeks (3700 MBq Sr-82 for first loadings, 2600 MBq for reloadings). After 12 weeks the generator is replaced by a fresh one. PEEK (polyether ether ketone) is used as column material to allow disinfection with a hypochlorite solution once a week. (Re)loading at a central facility is a logistic challenge. Instead, after inspectorate approval a mobile clean room at the client's premises is used to load and test the generators. ***Results:*** Between 2012 and 2021 79 generators were produced and 205 generator loadings were performed. All samples taken met the specifications from the US Pharmacopeia (USP). The maximum elution volume over 12 weeks was 50 l. Between 2017 and 2021 the average value per year for the Sr-82 break-through in a generator after 4 weeks of clinical use declined from 14,5 to 2,5 percent of the limit value (USP). In 2019 a marketing authorization for The Netherlands was obtained from the Dutch Medicines Evaluation Board. The mobile clean room was equipped with a GMP class A biohazard bench used for assembly of the generator system. The heavy (900 kg) generator wagon can't be placed in a biohazard bench. Instead, loading of the generator is performed in a GMP class C environment under a screen of air filtered by a high efficiency particulate air (HEPA) filter, thus simulating the conditions in a biohazard bench. The mobile clean room is equipped with all instruments needed for analysis of the generator eluate, including an electrically cooled high purity Germanium gamma detector. ***Conclusion:*** By introducing the concept of reloading every 4 weeks a Sr-82/Rb-82 generator is developed that has less decline of activity than a conventional generator, using the same activity of Sr-82. The concept requires the use of a mobile clean room for loading and quality control. The generator is delivered ready for use meeting all specifications from the USP. ***References:*** T.M. Alvarez-Diez et al. Manufacture of Sr-82/Rb-82 generators and quality control of Rb-82 chloride for myocardial perfusion imaging in patients using positron emission tomography. Applied Radiation and Isotopes 1999; 50: 1015-1023.

## EP-0883

### [68Ga]Ga-Pentixafor automatized synthesis using a new module: development and quality control before use in routine for CXCR4 PET imaging

***T. Daniel***, *C. Balouzet Ravinet, J. Clerc, R. Batista, Y. Mouraeff;*
*Hôpital Cochin, Assistance publique - Hôpitaux de Paris, Paris, FRANCE.*

***Aim/Introduction:*** We have recently acquired a new radiopharmaceutical drug synthesis module and drug control equipment, allowing the development of radiosyntheses for clinical research. As Pentixafor labeled with Gallium 68 is a promising radiopharmaceutical drug in several indications such as hematological malignancies and solid cancers, we aimed at setting up its synthesis process with our equipment. Existing methods do not use this type of module, so the synthesis is not yet described. We present here the method to develop an optimized and automatized radiosynthesis in order to submit an Investigational Medicinal Product Dossier (IMPD) to the French National Agency for the Safety of Medicines and Health Product (ANSM). ***Materials and Methods:*** Quality controls were performed in accordance with the European Pharmacopoeia (EP) and the International Council for Harmonization (ICH) Q2 standards. The radiochemical purity (RP) was assessed by Instant Thin Layer Chromatography (ITLC) and radio-High Pressure Liquid Chromatography (HPLC). We adjusted the elution of the C18 cartridge and optimized the synthesis and heating times to achieve the highest labeling yield with a RP above 95%. The optimized method was validated by performing 3 syntheses under Good Manufacturing Practices (GMP) conditions. ***Results:*** Among 22 syntheses carried out in 3 months, 2 were removed due to the detection of a cassette leak. Temperatures ranging from 90°C to 98°C with heating time ranging from 4 to 7 minutes were evaluated with 50 µg of peptide. The labeling yields ranged from 60% to 95% while the RP assessed by ITLC ranged from 83% to 98%, and from 97% to 100% by HPLC. Performing the synthesis at 97°C for 4 min was determined to be the best compromise between RP and yield. With these settings, the mean radiolabeling efficiency under GMP-conditions was 87.0% (Standard deviation (SD) 6.67%). The average RP was 99.1% (SD 0.25%) assessed by ITLC and 99.8% (SD 0.09%) by HPLC. Endotoxin levels were <5 EU/mL, and pH was 6.5. We assessed the stability of the radiotracer for up to 4 hours at room temperature. ***Conclusion:*** The [68Ga]Ga-Pentixafor synthesis method we described here complements the other existing methods in the literature. However, any comparison should be approached with caution given the differences in settings. This development of an optimized and robust synthesis process, and the validation of the quality controls with respect to the EP, allowed us to support the IMPD's request. It could be suitable for multidose application in clinical settings.

## EP-0884

### Formulation of a Kit for Preparing 89Zr-DFO-Pembrolizumab Injection Under Good Manufacturing Practices for Imaging the Uptake of Pembrolizumab into Brain Metastases in Patients with Lung Cancer by PET

***S. Borlase***[1], *C. Chan*[1], *R. Reilly*[1,2];
[1]*Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, CANADA,* [2]*Joint Department of Medical Imaging and Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA.*

***Aim/Introduction:*** Pembrolizumab is a checkpoint immunotherapy that binds to programmed cell-death protein-1 (PD1) on T-cells and inhibits its interaction with PDL-1 on tumour cells which enables a cytotoxic T-cell response. Pembrolizumab is used to treat metastatic lung cancer. However, delivery across the blood-brain-barrier for the treatment of brain metastases is limited. Imaging pembrolizumab uptake into brain metastases by PET is crucial to predict its effectiveness for treating brain metastases. I will formulate a kit under Good Manufacturing Practice (GMP) conditions to prepare $^{89}$Zr-DFO-pembrolizumab injection for imaging its uptake into brain metastases by PET in patients with metastatic lung cancer in a planned clinical trial. ***Materials and Methods:*** Pembrolizumab was reacted with p-isothiocyanate desferrioxamine (p-SCN-DFO). DFO-pembrolizumab was purified by ultrafiltration on an Amicon Ultra-0.5 device, repeated 6 times. The purity and homogeneity of DFO-pembrolizumab was assessed by SDS-PAGE. MALDI-TOF mass spectrometry was used to determine the number of DFO/pembrolizumab. Preliminary studies were conducted to determine the optimal conditions for conjugating pembrolizumab with DFO and labeling with $^{89}$Zr. The labeling efficiency at increasing specific activities was determined. Radiochemical purity was measured by instant thin layer-silica gel chromatography (ITLC-SG). Kits were formulated by dispensing DFO-pembrolizumab through a 0.22 µm sterilizing filter into unit-dose vials. Quality control testing included labeling efficiency with $^{89}$Zr (ITLC-SG), purity (SDS-PAGE), pH (5.2-5.7), PD1-binding (surface plasmon resonance), sterility and endotoxins (USP). ***Results:*** Pembrolizumab (1 mg) was reacted with a 5, 10, 15 or 20-fold molar excess of p-SCN-DFO which introduced 1.2±0.5, 1.9±1.0, 2.5±0.8 and 3.3±0.7 DFO/pembrolizumab, respectively. SDS-PAGE revealed a pure and homogenous immunoconjugate with a single band at 150 kDa. The labeling efficiency of DFO-pembrolizumab with $^{89}$Zr at specific activities of 10, 18, 26, 46 and 100 MBq/mg was 97.3%, 98.6%, 98.8%, 99.2%, and 99.1%, respectively for pembrolizumab conjugated with 2.5±0.8 DFO. Kits were formulated by reacting pembrolizumab (30 mg) with a 20-fold molar excess of p-SCN-DFO resulting in 6.4 DFO/pembrolizumab. DFO-pembrolizumab (1mg/vial) was dispensed into unit-dose glass vials. The pH was 5.5. Kits were labeled with $^{89}$Zr at a specific activity of 18.5 MBq/mg which achieved a labeling efficiency >95%. Sterility and endotoxin results are pending. A commercial surface plasmon resonance assay for assessing PD1 binding is being adapted and results will be reported. ***Conclusion:*** We report here for the first time, a kit formulated under GMP conditions for preparing $^{89}$Zr-DFO-pembrolizumab injection in high radiochemical purity suitable for patient administration.

## EP-0885

### Investigation of the Radiolabelling Potential of the Aurora A Kinase Inhibitor Alisertib with Iodine-123 [123I]

***E. Uygur***[1], *C. Sezgin*[1], *B. Y. Akdağ*[2], *T. Özbey*[2], *Y. Parlak*[1], *K. B. Karatay*[3], *F. G. Gümüşer*[1], *F. Z. Biber Müftüler*[3];
[1]*Manisa Celal Bayar University, Manisa, TÜRKIYE,* [2]*TENMAK, Ankara, TÜRKIYE,* [3]*Ege University, İzmir, TÜRKIYE.*

***Aim/Introduction:*** Alisertib (ALS) is an Aurora kinase inhibitor of interest for cancer therapy [1]. Overexpression of Aurora kinase can cause chromosomal instability and cell transformation. Since Aurora kinase overexpression is frequently shown in tumor cell lines, it is thought to have a causal relationship with tumor formation. Many studies have reported that Aurora Kinase A expression is increased in many malignancies such as prostate cancer, colorectal cancer, and T-cell lymphomas. Many studies on the imaging of Aurora Kinase A (AURK-A) expression are in the literature [5-6]. In this study, ALS was radiolabelled with Iodine-123 [$^{123}$I]I ($t_{1/2}$: 13.2 hours, γ: 159 keV) using the iodogen method and quality control studies of the [$^{123}$I]I-ALS was performed by Thin Layer Radio Chromatography (TLRC) method. ***Materials and Methods:*** The [$^{123}$I]I radionuclide was produced at the TENMAK Nuclear Energy Research Institute according to [$^{124}$Xe]Xe (p,2n ), [$^{123}$Cs]Cs, [$^{123}$Xe]Xe, [$^{123}$I]I the nuclear reaction. The radioiodination ([$^{123}$I]I-ALS) reaction was carried out by the iodogen method. The radiochemical yields of [$^{123}$I]I-ALS and the stability of the compound were determined by TLRC. The ALS compound was labelled with inactive iodine (K[$^{127}$I]I) and the molecular structure analysis of the K[$^{127}$I]I-ALS was determined by High-Performance Liquid Chromatography (HPLC) and Nuclear Magnetic Resonance ($^{1}$H-NMR) methods. ***Results:*** [$^{123}$I]-NaI was obtained at a concentration of 890 MBq/mL. The radiochemical yield of [$^{123}$I] I-ALS was found to be 95.1 ± 0.98% (n=3. The radiochemical yield of [$^{123}$I]I-ALS was over 90% at the end of 24 h. The retention times of ALS and K[$^{127}$I]I-ALS were found to be 2.54 and 2.21 minutes, respectively at HPLC. To obtain the experimental $^{1}$H-NMR, ALS/Iodine/Iodogen ratios were prepared stoichiometrically as 1/2/1, the pH value was adjusted to 8 with 1N $NH_4OH$ and incubated for 12 hours and the reaction was completed with 0.1-N $Na_2SO_3$. According to the $^{1}$H-NMR results, the ppm values of hydrogens attached to carbons to which [$^{123}$I]I is likely to bind are expected to be 7.85 and 7.79, respectively. ***Conclusion:*** The ALS compound was radiolabeled with [$^{123}$I]I with high purity. The iodine molecule of ALS is thought to be bound at the ortho or para position in the aromatic benzene ring. However, more comprehensive structural analyses may be needed using $^{1}$H-NMR, $^{13}$C-NMR and X-ray crystallography methods. It is thought that this study, which is a preliminary study for the imaging of AURK-A expression, should be supported by in vitro and in vivo preclinical studies.

## EP-0886

### Radiolabeling of [225Ac]Ac-PSMA-617 vs [225Ac]Ac-DOTATATE: What Analogies? What Differences?

***A. Esposito****, M. Aurilio, M. Buonanno, A. Morisco, C. Maisto, L. D'Ambrosio, D. Di Martino, S. Lastoria;*
*IRCCS INT "Fondazione Pascale", Naples, ITALY.*

***Aim/Introduction:*** Alpha-emitters have gained a great interest as novel cytotoxic agents for Targeted Alpha-Therapy (TAT). They enable the release of α-particles with a short path length in tissue and high linear energy transfer, leading to a higher double strain breaks probability in DNA. Thus, they are currently investigated as candidates in cancer treatment, especially in micrometastasis. Actinium-225 ($^{225}$Ac) is an α-emitter that with its decay chain, generates 4 α-particles contributing to increase its cytotoxicity if compared with other α-emitters. One of the most suitable chelating agents for complexation of this isotope is DOTA. Our goal was to standardize a method for the radiolabeling of more DOTA-peptides. For this purpose, the DOTA-peptides most commonly used, PSMA-617 and DOTATATE, were radiolabeled with $^{225}$Ac. ***Materials and Methods:*** [$^{225}$Ac]Ac-PSMA-617 and [$^{225}$Ac]Ac-DOTATATE were synthetized at the same conditions: 100 micrograms of peptide was added to 350 microliters of gentisic buffer (acid 0,25M and sodium acetate 0,35M) pH 5.5. This solution was added to 100 microliters of $AcCl_3$ (8±0,3 MBq) and heated at 97±2°C for 30 minutes. $^{225}$Ac-DOTA-peptides were monitored via iTLC using Silica gel as stationary phase and, Sodium Acetate 0,1M pH 5 and Acetonitrile/Water 1:1 as mobile phases. The iTLC strips were acquired at time 0 and reacquired

at 3 hours, when $^{221}$Fr and $^{213}$Bi were in Secular Equilibrium with $^{225}$Ac[1], to establish with accuracy the radiochemical purity (RCP) of radiopharmaceuticals. The stability was evaluated via iTLC at 24 hours. ***Results:*** The mean RCP of [$^{225}$Ac]Ac-PSMA-617 and [$^{225}$Ac]Ac-DOTATATE post-synthesis were 97,05±1,34 and 94,43±4,91 respectively, while at 3 hours were 96,55±0,07 and 93,18±0,95. The mean stability at 24 hours was 90,7±0,14 for [$^{225}$Ac]Ac-PSMA-617 and 81,03±2,09 for [$^{225}$Ac]Ac-DOTATATE. ***Conclusion:*** The RCP of [$^{225}$Ac]Ac-DOTATATE and [$^{225}$Ac]Ac-PSMA-617 was acceptable, demonstrating that our in-house radiolabeling method was suitable for both peptides.The different stability at 24 hours of [$^{225}$Ac]Ac-PSMA-617 and [$^{225}$Ac]Ac-DOTATATE, probably, was the result of the respective structures of the peptides. DOTATATE is an octapeptide, whereas PSMA-617 is a peptidomimetic inhibitor that demonstrated high radiolytic stability for at least 72 hours[2]. Therefore, it is necessary to identify a stabilizing system for [$^{225}$Ac]Ac-DOTATATE that is not essential for [$^{225}$Ac]Ac-PSMA-617. ***References:*** [1]Kelly JM, et all. A suitable time point for quantifying the radiochemical purity of $^{225}$Ac-labeled radiopharmaceuticals. EJNMMI Radiopharm Chem. 2021 Dec 20;6(1):38.[2]Benešová M, et all. Preclinical Evaluation of a Tailor-Made DOTA-Conjugated PSMA Inhibitor with Optimized Linker Moiety for Imaging and Endoradiotherapy of Prostate Cancer. J Nucl Med. 2015 Jun;56(6):914-20.

## EP-0887

### Comparison of 111In and201Tl Radiopharmaceutical Adsorption on Acrylic Phantoms

***T. Inagaki***[1], *N. Fujita*[2], *R. Isobe*[1], *T. Nagahara*[1], *S. Abe*[2], *K. Kato*[1]; *[1]Nagoya University Graduate School of Medicine, Nagoya, JAPAN, [2]Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN.*

***Aim/Introduction:*** Radiopharmaceuticals are known to adsorb onto phantoms during phantom experiments. When adsorption occurs in phantom experiments, it hinders the analysis, e.g., making it difficult to set the region of interest. In addition, adsorption affects clinical imaging conditions because the imaging conditions used in clinical practice are determined from such experiments. In a previous study, $^{111}$In radiopharmaceuticals were found to adsorb on the inner wall of the phantom during phantom experiments. Therefore, adsorption should be observed over time even for $^{111}$In and $^{201}$Tl radiopharmaceuticals, which are long half-life nuclides in nuclear medicine examinations. In this study, we evaluated the adsorption of $^{111}$In and $^{201}$Tl radiopharmaceuticals on acrylic phantoms and examined the changes in adsorption by different nuclides. ***Materials and Methods:*** The phantom was an acrylic container (75 × 75 × 60 mm). Four radiopharmaceuticals ($^{111}$In-pentetreotide, $^{111}$In-DTPA, $^{111}InCl_3$, and $^{201}$TlCl) were used. The solutions of $^{111}$In-pentetreotide, $^{111}$In-DTPA, $^{111}InCl_3$, and $^{201}$TlCl were sealed in the phantoms, respectively, and the liquid volume was 50 mL. Counts were collected by planar imaging of the prepared phantom using a SPECT/CT system. The radiopharmaceutical solution was drained from the phantom and lightly rinsed with water. Then, the counts were collected by planar imaging again. Finally, the adsorption rate was determined. The adsorption rate was calculated as the counts of the phantom after the removal of the solution relative to the counts of the phantom filled with the solution. ***Results:*** The adsorption rates for $^{111}$In-pentetreotide, $^{111}$In-DTPA, $^{111}InCl_3$, and $^{201}$TlCl were 0.54%, 0.15%, 29.2%, and 0.17%, respectively. $^{111}InCl_3$ planar images showed a large amount of radiopharmaceuticals remaining in the phantom. The images of $^{111}$In-pentetreotide showed radiopharmaceutical adsorption along the inner wall of the phantom, while no adsorption was observed in the images of $^{111}$In-DTPA and $^{201}$TlCl. ***Conclusion:*** Among the four radiopharmaceuticals, $^{111}InCl_3$ showed the highest adsorption rate, and little adsorption occurred with $^{111}$In-DTPA and $^{201}$TlCl.

## EP-0888

### Cassette-Based Sterility Testing of Radiopharmaceuticals: A Novel Approach to Ensuring Quality and Safety

***M. Nousch***[1], *G. Reischl*[2], *R. Schulze*[3], *K. Tautz*[4], *D. Freitag-Stechl*[1]; *[1]CUP Laboratorien Dr. Freitag GmbH, Radeberg, GERMANY, [2]Universitätsklinikum Tübingen, Tübingen, GERMANY, [3]Sächsisches Staatsministerium für Soziales und Gesellschaftlichen Zusammenhalt, Dresden, GERMANY, [4]Eckert & Ziegler GmbH, Berlin, GERMANY.*

***Aim/Introduction:*** Sterility testing is an essential part for the manufacturing process of all pharmaceutical products that are used to treat human diseases. These tests assess the presence or absence of microorganisms and ensure patient safety. Although sterility testing of most pharmaceutical products is part of the production routine, these tests can be challenging for radiopharmaceuticals. The safety precautions accompanying the work with radioactive substances often requires the use of specialized laboratories. Only few laboratories world-wide are equally authorized to handle radioactivity, and are also equipped to carry out sterility tests. Hence, the aim of this project was to develop a concept and for a half-automated system which facilitates sterility testing of radiopharmaceuticals. ***Materials and Methods:*** A system was designed which utilizes a sterile, single-use cassette that contains all the necessary components for conducting the sterility test, including the filtration membrane and culture media. It was tested whether this setup in general is sterile and can be used for the analysis of radiopharmaceuticals such as $^{68}$Ga, $^{177}$Lu and $^{64}$Cu containing substances. Additionally, we tested whether aerobic and anaerobic growth is possible in our system. To this end, a defined number of microorganisms was introduced into the filter units, various amounts of specific growth media were added in the last filter step and general growth was analyzed. For assessing aerobe growth, Bacillus subtilis, Candida albicans or Aspergillus brasiliensis were incubated in tryptone soya broth (TSB) at 25°C. For assessing anaerobic growth Staphylococcus aureus, Pseudomonas aeruginosa or Clostridium sporogenes were incubated in Thioglycolate broth at 32°C. ***Results:*** By establishing a closed system in which the individual parts can be sterilized, we were able to minimize the risk of introducing microbial contamination. The different sterile parts were connected in a clean bench. The process itself can run on a normal lab bench. Growth was only detected in filter units that have been deliberately exposed to solutions containing microorganisms. All tested bacterial, yeast and fungi strains were able to display significant growth within five days of incubation. ***Conclusion:*** Our system is designed to be easily integrated with existing automated radiopharmaceutical production systems, streamlining the process and minimizing human intervention. The overall setup allows microbial growth if microbes are present. This innovative proof of concept study has the potential to revolutionize the quality control of radiopharmaceuticals by providing a base for standardized sterility testing which could be introduced into many routine production processes.

## EP-0889

### Determination of Extractables and Leachables in Radiopharmaceuticals

***M. Nousch***[1], *M. Janich*[1], *S. Becker*[2], *T. Otten*[2], *M. Zurbruegg*[2], *R. Schulze*[3];
[1]*CUP Laboratorien Dr. Freitag GmbH, Radeberg, GERMANY,* [2]*Intertek (Schweiz) AG, Reinach, SWITZERLAND,* [3]*Sächsisches Staatsministerium für Soziales und Gesellschaftlichen Zusammenhalt, Dresden, GERMANY.*

***Aim/Introduction:*** The presence of extractables and leachables in pharmaceutical products can have a significant impact on product quality, safety, and efficacy; and ultimately the success of life-saving treatments. During production and storage of (radio) pharmaceuticals, polymeric materials are directly exposed to the formulation and therefore small molecules can be release from the polymers into the drug formulation. These phenomena could be particularly pronounced for radiopharmaceuticals because radiation is known to have an impact on the polymer structures, leaching behavior and degradation of polymer additives. Hence, this study aims to develop robust and reliable analytical methods for the identification and quantification of extractables and leachables in radioactive pharmaceutical products. ***Materials and Methods:*** To simulate worst case conditions and real-world scenarios, storage vials used in $^{68}$Ga tracer preparations were subjected to accelerated aging and various storage conditions using a range of solvents (e.g. water, ethanol, and dimethyl sulfoxide) with varying polarities and pH values. Analyses of extractables and leachables were performed by headspace (HS)/direct injection gas chromatography-mass spectrometry (GC-MS), liquid chromatography-mass spectrometry (LC-MS), or inductively coupled plasma mass spectrometry (ICP-MS). For all identified critical substances a risk assessment was conducted based on established toxicological thresholds. ***Results:*** The developed analytical methods demonstrated excellent specificity, linearity and recovery, meeting the ICH guidelines' requirements. A total of 38 extractables and 3 leachables were identified and quantified in the investigated $^{68}$Ga-containing radiopharmaceutical. Most of these compounds were plasticizers, antioxidants, lubricants, and their degradation products or elemental impurities, which are commonly found in pharmaceutical packaging materials. The risk assessment indicated that many of the extractables and most of the leachables in these $^{68}$Ga preparations were present at levels below the established toxicological thresholds. ***Conclusion:*** Results of the study demonstrate the successful development of a robust and reliable analytical methodology for the determination of extractables and leachables in radioactive pharmaceutical products. By combining (HS)GC-MS, LC-MS, and ICP-MS a wide range of chemicals were identified and quantified that can be released from polymeric materials by the exposure to radioactive substances. The study indicates that all detectable chemicals released from container closure vials through the exposure to $^{68}$Ga, were below the established toxicological threshold. Hence, our developed methodology can contribute to the ongoing efforts to develop safer, more effective, and regulatory-compliant radioactive pharmaceuticals for the treatment of various diseases.

## EP-0890

### Comparative analytical methods for testing residual solvents in quality control of PET radiopharmaceuticals

***V. Mendi Barcina***[1], *M. De Arcocha Torres*[1], *Á. Gutiérrez González*[2], *I. Martínez Rodríguez*[2], *N. Martínez Amador*[2], *F. Gómez de la Fuente*[2], *A. Sánchez Salmón*[2], *J. Jiménez Bonilla*[2], *M. Pombo López*[2], *A. Bota Bota*[2], *R. Quirce Pisano*[2];
[1]*Radiopharmacy Unit. Nuclear Medicine Service Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN,* [2]*Nuclear Medicine Service Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN.*

***Aim/Introduction:*** The manufacture of PET radiopharmaceuticals produced according to Good Manufacturing Practices (GMP), calls for compliance with a set of quality controls, published in the European Pharmacopoeia and the ICH guidelines. These include residual solvent testing.Depending on the number of standards used, there are several options for performing a calibration: with a single concentration of the chemical standard, the "single point calibration" or using three or more concentrations of chemical standard, the "multi-point calibration". The aim of this study was to assess the correlation between results obtained with "single point calibration" and "multi-point calibration" models to carry out Gas Chromatography (GC) method of analysis for the routine quality control (QC) of L-[methil-11C]- methionine to secure the quality of the finished product. ***Materials and Methods:*** A calibration curve is elaborated following the internal standard (IS) method (isopropanol 0.8 mg/ml), with decreasing concentrations of ethanol (12.5;2.5;0.5;0.1;0.02 mg/ml), ratio (1:1). On the other hand, 10 standard samples with known concentration of ethanol (12.5;11;10;9;8;7;6;5;4;3 mg/ml) are prepared with IS, ratio (1:1). The analytical response from the different standard samples are interpolated in the calibration curve, to know the concentration. The samples were injected three times.Furthermore, using the standard sample with the highest concentration (12.5 mg/ml), the calibration factor (area/concentration) is obtained, necessary to calculate the concentration of each standard. Data analysis was performed through the Paired t-test as statistical analysis. ***Results:*** Excellent linearity was found between 0.02 and 12.5 mg/ml, with a correlation coeficient for calibration curves ($r^2$) equal to 0.9999. The standard deviation (SD) between average different concentrations (n=10) obtained by two methods was 0.02 to 0.03. The Paired t-test did not show statistical significant differences between the different calibration methods: single point calibration with IS vs. multi-point calibration with IS ($p = 0.97$). ***Conclusion:*** According to the results obtained in our study, the single-point method with internal standard is an alternative to carry out in the residual solvent test, when looking for faster, easier and more adaptable methods to specific samples and analytes, with the advantage of the quickness and simplicity of the assay compared to the multiple injection method with internal standard.

## EP-0891

### Highly efficient, biocompatible radiolabeling method for in vivo cell tracking

***R. Hernandez***, *A. Thickens, Z. Rosenkrans, L. Lambert-Lepesevich, J. Kink, E. Aluicio-Sarduy, A. Pinchuk, J. Engle;*
*University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Current cell labeling methods for in vivo cell tracking using PET/CT suffer from low activity incorporation yields and poor radiolabel stability. We addressed these limitations by directly conjugating the chelator Deferoxamine (DFO) to ubiquitous cell surface glycans, which enabled efficient and stable $^{89}$Zr-radiolabeling of live cells under biocompatible conditions. ***Materials and Methods:*** DFO was derivatized with aminooxy acetic acid, and the resulting aminooxy-DFO (AOD) was purified by flash chromatography and identified by NMR and mass spectrometry. Reactive aldehydes were generated in the cell surface of the monocytic cell line U937 through sialic acid oxidation with $NaIO_4$ (5-1000 µM) at four or 37 °C for 15 min to 2 h. Subsequently, cells were incubated with AOD (100-500 µM) at room temperature for up to 1h in the presence of aniline, and cells were washed and resuspended in PBS. Next, AOD-conjugated ($5\text{-}7 \times 10^6$) cells were radiolabeled with $^{89}$Zr (37-74 MBq) at room

temperature for 1h, then washed thrice to eliminate unlabeled $^{89}$Zr, and the radiochemical yield was measured. Cell viability was assessed at each step via trypan blue staining. For in vivo PET/CT imaging, male NSG mice (N=3) were administered $^{89}$Zr-U937 cells (3-5 x $10^5$, 5.6 MBq) via tail vein injection and static PET/CT scans acquired at 3, 24, 72, 164, and 192 h post-injection (p.i.). Region-of-interest analysis and biodistribution studies were performed to quantify the longitudinal in vivo distribution of the labeled cells. ***Results:*** The glycan-reactive AOD was generated with excellent chemical purity (>95%). Glycan oxidation with $NaIO_4$ had minimal effect on cell viability at the tested temperature and reaction times. Similarly, AOD conjugation and $^{89}$Zr-labeling did not affect viability, which remained over 93% post-radiolabeling. The exceptional radiochemical yields observed, ranging from 6.1-10.2 MBq per $10^6$ live cells, a 100-fold improvement over other methods, enabled tracking fewer cells (~300,000) with improved detectability. PET/CT images showed initial accretion of injected cells in the lungs (19.9±0.3 %IA/g) and the liver (23.7±0.7 %IA/g) at 3 h p.i., and their subsequent redistribution to the liver (31.5 ± 0.8 %IA/g) and spleen (13.5±2.0 %IA/g) at later time points. The low bone uptake and minimal whole-body radioactivity excretion were indicative of the excellent stability of the label in vivo. ***Conclusion:*** Our results showed unprecedented $^{89}$Zr radiolabeling efficiencies and negligible impact on cell viability, affording improved imaging performance and hinting at the potential clinical value of this method for in vivo cell tracking.

## EP-0892

### Comparative methods of labeling red blood cells

***M. Crespí Busquets***[1], *J. Romero Herrera*[1], *S. Maymó Garrido*[1], *D. Rodriguez Puig*[1], *C. Munuera Sañudo*[1], *E. Pineda Fernández*[1], *M. Bueno Raspall*[1], *M. Cortés Romera*[2];
[1]*Radiopharmacy Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN,*
[2]*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** To compare two methods of red blood cells labeling; the first one by following the Guidelines of the Spanish Agency for Medicines and Health Products (AEMPS) (Reference method: MR) and the second method by labeling red blood cells with ethylenediaminetetraacetic acid (EDTA) as a chelator for the extracellular stannous pyrophosphate (Alternative method: MA). ***Materials and Methods:*** These comparatives methods were applied in samples of 17 patients. Two samples of 4,4 mL of blood were obtained from every patient by adding 0.6 ml of ACD-A anticoagulant in each syringe. The RM sample was transferred to a Falcon™ tube with 2,5 µg $Sn^{2+}$. It was incubated at 37 ºC for 10'. Subsequently, washing was performed by adding 40 ml of physiological saline (SF), centrifuging for 10' at 1000 G and finally the cell button was separated from the plasma manually by using a sterile Pasteur pippete. Later around 28 - 35 mCi of [99mTc]$NaTcO_4$ were added into the cell button and incubated for 10' at 37ºC. Afterwards, a second wash was carried out the same as the previous one to obtain the final blood button and the supernatant. In that moment it is measured the activity obtained in both parts to calculate the yield of the radiolabeling. For the MA, the sample was incorporated into a Falcon™ tube with 22.34 µg of $Sn^{2+}$. After it was centrifuged at 1000 G for 5' and the plasma was removed, obtaining the blood button. Later than, the sample was homogenized by adding 0,5 ml of 2,2 % EDTA, 5 ml of SF and around 28 - 32 mCi of [99mTc]$NaTcO_4$. It was incubated at 37 ºC for 5' and centrifuged for 3' at 1000 G. Finally, the supernatant was removed. After that the activity of the final button and the supernatant was measured to be able to calculate the yield of the radiolabeling. The labelings were made in parallel by measuring the time invested. ***Results:*** The mean labeling yield was 81,1 ± 5,8 % for the MR and 97,1 ± 1,5 % for the MA. The time invested for the MR and MA was 68 ± 5 min and 25 ± 4 min respectively. ***Conclusion:*** The MA simplifies the technique by decreasing the labeling time and improving the reproducibility and the yield of the radiolabeling. We would recommend MA in daily clinical practice.

## EP-0893

### Automated Production Of [18F]UCB-J Using A Dibenzothiophenium Salt Precursor For Labelling

***D. Pritchard***, *F. Sirindil, M. Glaser, R. Awais, F. Twyman, E. Eedan, K. Sander, E. Arstad;*
*University College London, London, UNITED KINGDOM.*

***Aim/Introduction:*** [$^{11}$C]UCB-J is a leading PET tracer for imaging of the synaptic vesical glycoprotein 2A (SV2A), but practical applications are limited by the challenging radiosynthesis and the short half-life of carbon-11 (20 min).[1] Although the tracer contains a 1,2,3-trifluorophenyl moiety, labelling of UCB-J with fluorine-18 (half-life 110 min) has proven exceedingly difficult. Potential precursors for labelling have either been found to be synthetically inaccessible, or have shown low reactivity, giving low radiochemical yields (<5%) and requiring harsh reaction conditions which cause racemization.[1] We recently reported that racemic UCB-J can be labelled with fluorine-18 under mild conditions using a dibenzothiophenium salt precursor.[2] With the aim to enable large scale production and distribution of [$^{18}$F]UCB-J, we have automated the labelling of this tracer using a Good Manufacturing Practice (GMP) compatible synthesis module. ***Materials and Methods:*** Automated labelling of [$^{18}$F]UCB-J was established on a GMP compatible synthesis module using a disposable cassette. We investigated the impact of the reaction temperature, reaction time and precursor load on the activity yields and the amount of non-radioactive UCB-J formed in the reaction to assess the molar activity that potentially can be achieved when the method is scaled up to high activity levels. ***Results:*** Direct labelling of [$^{18}$F]UCB-J proceeded under mild conditions (100 °C) and with a short reaction time (<10 min). Activity yields in excess of 20% (n=3) were obtained with <45 min total production time (excluding formulation). When using an enantiomerically pure precursor, no racemization of the tracer was observed with chiral HPLC. There was a clear trend of increased formation of non-radioactive UCB-J with increased reaction time. Although the molar activity is likely to be moderate even when scaled up to high activity levels, our preliminary results suggest that the method readily can allow production of multiple patient doses of [$^{18}$F]UCB-J and meet the release specifications that have been established for [$^{11}$C]UCB-J. ***Conclusion:*** Translating the labelling of [$^{18}$F]UCB-J from manual labelling to automated production was straightforward and gave comparable activity yields. The results are encouraging and suggest that the method can allow GMP compatible production of this tracer. We are currently developing a formulation step and investigating scale-up of the method for multidose production. ***References:*** (1) G Becker, S Dammicco, M.A. Bahri and E Salmon, Molecules, 25(10), 2303.(2) F Sirindil, S Maher, M Scholl, K Sander and E Årstad. Int. J. Mol. Sci., 2022, 23, 15481.

## EP-0894

### Ga68-PSMA-11 : push it to the limit with prepurification

***M. Debarge***[1], *A. Lombard*[1], *S. Journo*[1], *N. Veran*[1], *Q. Citerne*[1], *B. Demore*[2,1];
[1]*Nancy University Hospital, Vandoeuvre-lès-Nancy, FRANCE,*
[2]*Lorraine University, EA 4360 APEMAC, Nancy, FRANCE.*

***Aim/Introduction:*** Awaiting Pharmaceutical companies are able to provide enough radiolabelled 18F-PSMA to serve the growing needs of nuclear medicine, in particular for monitoring of radionuclide therapy , Gallium 68 (68Ga) is still essential for peptide labelling in PET imaging, especially 68Ga-PSMA-11. The highest market authorized generator calibration available is 1.85 GBq of Ge-68, so 1.3 GBq of Ga-68 at start of synthesis (SOS). These characteristics led us to develop a dual generator fractionate elution to meet our needs, method used since 2022 January, which provide around 2 GBq SOS. A new Ga-68 pre-purification method provided by a synthesizer manufacturer allow theorically the simultaneous use of not only two generators, but maybe three, or more, with a significant increase of PSMA PET imaging by synthesis. ***Materials and Methods:*** Using manufacturer synthesis kits and synthesizer and some programming changes, from one to four 68Ga generator's elutions are injected through an ion exchange (SCX) cartridge, followed by elution to the reactor with a mixture of sodium and hydrogen chloride, where PSMA-11 precursor in sodium acetate buffer is waiting for labelling. After 95°C heating for 7 minutes, bulk is purified on HLB cartridge, eluted with ethanol and reformulated in 10 ml of sodium chloride. Final product, residual cartridges and waste activities are measured and decay corrected to end of synthesis time (EOS). European pharmacopeia compliant quality control is performed. ***Results:*** First tests were failures with multiple peaks in hplc and a low radiochemical purity. Ascorbic acid addition (1mg) lead to a good final quality product. One, two, three and four generator synthesis provided a radiochemical purity higher than 97% in HPLC and higher than 99% in TLC. Corrected yield of all synthesis are closed to 85% (82% to 88%). 7% of activity is found in waste (free 68Ga identified by HPLC), 4% in ion exchange cardridge and 4% in purification cartridge. All synthesis complies with clinical quality control specifications. The highest final product activity obtained is 1.94 GBq EOS (more than 3.2GBq SOS) which mean around 30% increase over staged routine elution way. ***Conclusion:*** Generators number not affect the final product quality with this prepurification method and can be used to increase the final 68Ga-PSMA-11 activity and serve the growing demand. However, the high concentration sodium chloride eluent for SCX can lead to radiolysis and has to be neutralised by ascorbic acid addition, which is not present in all market available precursor.

## EP-0895

### Initial experience on the cassette-based synthesis of 11C-Pittsburgh Compound-B

***H. Gama Romero***, *F. Trejo-Ballado, E. Zamora-Romo, M. Mendoza-Figueroa, G. Tecuapetla-Chantes, U. Rabadán-Domínguez, G. Contreras-Castañón, A. Zárate-Morales, A. Flores-Moreno, M. Ávila-Rodríguez;*
*Unidad Radiofarmacia-Ciclotrón, Facultad de Medicina, Universidad Nacional Autónoma de México, MEXICO.*

***Aim/Introduction:*** The compound 2-(4'-N-[$^{11}$C]methylamino-phenyl)-6-hydroxybenzothiazole, also know as [$^{11}$C]Pittsburgh Compound B ([$^{11}$C]PIB), is a radiotracer extensively used to target beta-amyloid plaques in the brain, one of the hallmarks of Alzheimer's disease. The aim of this work is to report our initial experience on the production of this radiotracer using a single-use cassette and kit of reagents in a commercially available synthesizer. ***Materials and Methods:*** The disposable cassette consist in four manifolds with 6 three-way valves, and together with the reagent kit (excluding the chemical precursor) can be obtained from the manufacturer of the synthesizer [1]. The synthesis of [$^{11}$C]PIB was accomplished by using the so-called "wet" method. Briefly, carbon-11 was produced in an 11 MeV cyclotron in the chemical form of $CO_2$, trapped on a molecular sieve, desorbed at 200°C, and flushed through a solution of $LiAlH_4$ in tetrahydrofuran to form [$^{11}$C]methanolate by reduction of [$^{11}$C]$CO_2$. Then hydriodic acid is added to the reactor obtaining [$^{11}$C]methy iodine, wich is carried as a gas in a steam of nitrogen through a silver triflate reactor at 190°C to make the conversion to [$^{11}$C]methyl triflate. The compound [$^{11}$C]$CH_3OTf$ is flush through a tC-18 cartridge pre-load with the chemical precursor (1 Mg, 6-OH-BTA-0), were the chemical synthesis takes place at 65°C to obtain [$^{11}$C]PIB. The product is purified by reverse phase semipreparative HPLC using MeCN:$H_2O$ (60:40, v/v) as mobile phase. The colected fraction is reformulated by SPE using a tC18 cartridge, eluted with EtOH, and diluted with saline. ***Results:*** [$^{11}$C]PIB was obtained in a radiochemical of 12.7±0.9 % n.d.c. (n=5) with a radiochemical purity >98%. The total duration of the process from start of synthesis to the transfer of final product is approximately 20 min, however the preparation of the synthesis module, which includes the placement and test of the cassette, conditioning of the triflate reactor and the molecular sieve trap, takes about 2 h. In addition to the cassette, only a molecular sieve module needs to be connected to the synthesizer. ***Conclusion:*** The synthesis of [$^{11}$C]PIB in a multipurpose synthesizer using a disposable single-use cassette and a reagent kit is very convenient, reliable, and facilitates reproducible production conditions. The final product complaints to all the quality control requirements obtaining [$^{11}$C]PIB in enough quantity and quality to be used in clinical applications. Project supported by UNAM-DGAPA PAPIIT-IT200221, SECTEI/226/2021 and CONACYT-PRONACES 322512. ***References:*** [1] Trasis manual, AllinOne 11C PiB Specific Application V.1.0, Doc. Ref 003895

## EP-0896

### GMP Production of 89Zr-DFO-Pembrolizumab for Immuno-PET: predicting response in non-small lung cancer

***I. Hrynchak***[1], *M. Silva*[1], *S. Silva*[2], *A. Fonseca*[1], *A. Falcão*[3], *A. J. Abrunhosa*[1,3];
[1]*ICNAS Pharma Unipessoal, Lda, Coimbra, PORTUGAL,*
[2]*Pulmonology, Leiria Hospital Center, Leiria, PORTUGAL,*
[3]*CIBIT/ICNAS, Institute for Nuclear Science Applied to Health – University of Coimbra, Coimbra, PORTUGAL.*

***Aim/Introduction:*** Programmed cell death protein 1 (PD-1) antibody - Pembrolizumab - is the standard first line treatment for non-small cell lung cancer (NSCLC) in patients with programmed cell death ligand 1 (PDL-1) expression ≥ 50%. However, non-responders to this treatment exist in a higher-than-expected percentage which raises concerns and requires special attention. The accurate evaluation by immuno-PET, using [$^{89}$Zr]Zr-DFO-Pembrolizumab, seems to represent a valid and clinically useful strategy to predict response to immune checkpoint inhibitors and improve global NSCLC treatment strategy [1,2]. Such radiopharmaceutical availability, nevertheless, requires substantial process development and validation.Therefore, the current work addresses practical considerations on the GMP-compliant, production of [$^{89}$Zr]Zr-DFO-Pembrolizumab from a medical cyclotron using a liquid target, with clinically proven

results and ready to be distributed outside the production center. ***Materials and Methods:*** Zirconium-89 ($^{89}$Zr) has been produced by our group through the bombardment of $Y(NO_3)_3.6H_2O$ in nitric acid solution ($HNO_3$) via the $^{89}Y(p,n)^{89}Zr$ nuclear reaction at 14 MeV, in a liquid target setup. After purification on hydroxamate resin, the [$^{89}$Zr]Zr-oxalate has been directly used for radiolabeling the DFO-Pembrolizumab [conjugation via random lysine using p-Bn-SCN-DFO (1:10)]. The product was isolated by size exclusion chromatography using a PD10 column and formulated to arrive at an injection dose of 37 MBq (2.5 mg of [$^{89}$Zr]Zr-DFO-Pembrolizumab + 2.5 mg Pembrolizumab). ***Results:*** Until now, several clinical doses (i.e., 37 MBq) of [$^{89}$Zr]Zr-DFO-Pembrolizumab were successfully produced with high radiochemical purity (98.68 ± 2.12 % by HPLC), in compliance with the current GMP, and injected in patients with NSCLC. The [$^{89}$Zr]Zr-DFO-Pembrolizumab injection was shown to be safe and feasible. Whole-body [$^{89}$Zr]Zr-DFO-Pembrolizumab images which were obtained on day 7 show selective accumulation at tumor sites. ***Conclusion:*** The automated labeling is GMP-compliant and results in acceptable product quantities (~37 MBq/patient) with excellent quality. This work also highlights the feasibility of [$^{89}$Zr]Zr-DFO-Pembrolizumab production using the widely installed base of medical cyclotrons that are already optimized to produce and distribute $^{18}$F-labeled radiopharmaceuticals produced routinely from liquid targets. ***References:*** [1] Kok IC, et al. Ann Oncol. 2022 Jan;33(1):80-88. doi:10.1016/j.annonc.2021.10.213.[2] Neimeijer ALN, et al. J Nuc Med. 2021 Jul. doi: 10.2967/jnumed.121.261926.

## EP-0897

### Optimizing of automated production of Gallium-68 radiolabeled clinical agents by cyclotron liquid target system

***Y. Shimizu***[1], *K. Miyake*[2], *Y. Nakamoto*[2];
[1]*Kyoto University Hospital, Kyoto, JAPAN,* [2]*Kyoto University Graduate School of Medicine, Kyoto, JAPAN.*

***Aim/Introduction:*** In recent years, Gallium-68 radiolabeled agents such as $^{68}$Ga-DOTATOC (a somatostatin receptor-targeting PET imaging agent) and $^{68}$Ga-gozetotide (a PSMA-targeting PET imaging agent) have been developed and used clinically. Those $^{68}$Ga-radiolabeled agents are produced with $^{68}GaCl_3$, which is usually obtained from a $^{68}$Ge/$^{68}$Ga generator. There have been problems with the stable supply of $^{68}GaCl_3$ due to the rising cost of $^{68}$Ge/$^{68}$Ga generators and supply delays. Recently, a novel production method of $^{68}GaCl_3$ based on a cyclotron liquid target system has been developed. In this study, we optimized the production method of $^{68}$Ga-radiolabeled agents and evaluated the routine production of $^{68}$Ga-DOTATOC and $^{68}$Ga-gozetotide using a cyclotron liquid target system and following a multipurpose automated synthesizer. ***Materials and Methods:*** $^{68}$ZnO was dissolved in 0.6 M $HNO_3$ and then irradiated with protons at 40 μA for 60 min on a PETrace860 $^{68}$Ga liquid target system (GE Healthcare). After the irradiation, the target solution was transferred to FASTlab multipurpose synthesizer (GE Healthcare) and then purified on hydroxamate-based resin and trioctylphosphine oxide (TOPO)-based resin columns. The obtained $^{68}GaCl_3$ was then reacted with DOTATOC or PSMA-11 ($^{68}$Ga-gozetotide precursor) dissolved in 1.2 M sodium acetate solvent at 95°C for 10 min. Those reactants were purified on a C18 Sep-Pak column to obtain $^{68}$Ga-DOTATOC or $^{68}$Ga-gozetotide, and quality tests (radiochemical purity, pH, endotoxin, sterility test, etc.) were performed. ***Results:*** $^{68}GaCl_3$ was obtained with a radioactivity of 2.0 ± 0.6 GBq (0.5 ~ 2.8 GBq) (n=29). $^{68}$Ga-DOTATOC and $^{68}$Ga-gozetotide were acquired with a radioactivity of 1.4 ± 0.3 GBq (0.6 ~ 1.9 GBq) (n=24) and 0.8 ± 0.2 GBq (0.5 ~ 1.0 GBq) (n=3) respectively, and passed all quality tests. As for the routine production, sudden decreased yield (lower than 1.5 GBq) of $^{68}GaCl_3$ production was observed 8 out of 29 times, and in 2 of them, $^{68}$Ga-radiolabeled agents could not be acquired. It is predicted to be owing to some trouble with metal contamination and was able to be improved by replacing the transfer line from the cyclotron. ***Conclusion:*** Our results suggest that the optimized production method with the cyclotron liquid target system can provide enough radioactivity and quality of $^{68}$Ga-radiolabeled agents for clinical use.

## EP-0898

### Single center experience in the [18F]DPA-714 production using commercial disposable cassettes on AllinOne synthesizer

***M. Riondato***[1], *A. Democrito*[1], *C. Ghersi*[1], *S. Grugni*[2], *M. Bauckneht*[1], *S. D. Morbelli*[1], *C. Marini*[3], *G. Sambuceti*[1];
[1]*University Policlinic Hospital of Genoa, Genoa, ITALY,* [2]*Gamma Servizi srl, Borgherello Pavia, ITALY,* [3]*CNR Institute of Molecular Bioimaging and Physiology (IBFM), Milan, ITALY.*

***Aim/Introduction:*** The translocator protein 18 kDa (TSPO) is a validated diagnostic/imaging biomarker for the evaluation of inflammatory related-disease state and progression, as well as a recognized target for the development of new therapeutic agents for neurological, psychiatric disorders and oncological applications.Labelled ligands based on pyrazolo[1,5-a]pyrimidine acetamide core constitute a unique class with high affinity and selectivity for TSPO. Among several radiotracers [$^{18}$F]DPA-714 is nowadays widely used as a PET imaging probe in Clinical Trials. In this work we present our experience in the production and quality controls for the preparation of the IMPD for a Clinical Trial application. ***Materials and Methods:*** The synthetic process is fully automated on a Trasis AllInOne 36 synthesizer implemented with a HPLC semipreparative purification module, using an in-house designed cassette based on FDOPA and a dedicated sequence adapted from the Cybulska et al. method [1]. [$^{18}$F]DPA-714 was synthesized by a one-step labelling process using 25-40 GBq of [$^{18}$F]Fluorine and 4.5-5.5 mg of Tos-DPA-714 as precursor in 1 mL of ACN at 95°C (nucleophilic aliphatic substitution) for 10 min, followed by semi-preparative high-performance liquid chromatography (HPLC). The purified product was trapped on C18 cartridge and then removed with 1,8 mL ethanol 70%, reformulated with NaCl 0.9% to 15 mL and finally sterilized by filtration. All tests have been designed and performed according to the European Pharmacopeia specification if available and literature. ***Results:*** [$^{18}$F]DPA-714 production process was easily implemented for its simplicity and robustness, enabling rapid training of radiopharmacy personnel. Radiochemical yields were in the range 17,4-22,6 % (ndc) with molar activities of 364-613 GBq/μmol. The final volume was 15 ±0,5 mL and the radiochemical purity was 98,6-99,0 % at EoS. A full set of quality control tests were on three consecutive production batches for [$^{18}$F]FDPA-714 in order to prepare the dossier relative to the manufacturing qualification of clinical production, including stability studies (6h EoS). The results of quality controls such as chemical/radiochemical purity, radionuclide purity, sterility and content of bacterial endotoxin complied with the requirements of the European Pharmacopoeia and other designed specification. ***Conclusion:*** The developed [$^{18}$F]DPA-714 synthetic process is reliable and robust using an automated module with modified

disposable cassettes, thus being implementable for routinary productions. The process and quality control complied with the standards required for human use Clinical Trials. ***References:*** Cybulska, K.A. et al., Optimised GMP-compliant production of [$^{18}$F] DPA-714 on the Trasis AllinOne module. ## E: Other Studies -> E1 Case Reports

### EP-0899

**18F-FDG- PET/CT guided biopsy has an essential role in the diagnosis of primary extranodal diffuse large B-cell lymphoma of bone- a clinical case.**

***Z. Dancheva***, *S. Spasova, T. Stoeva, I. Kobakova, M. Dyankova, S. Chausheva, T. Yordanova, B. Chaushev, A. Klisarova, B. Balev;*
*St Marina University Hospital, Varna, BULGARIA.*

***Aim/Introduction:*** Primary bone lymphoma exclusively affects skeletal tissue. It is a rare disease, estimated to be 3-7% amongst primary bone tumors and less than 2% amongst all lymphomas in adults. [1] We present a case demonstrating the clinical impact of 18F-FDG PET/CT in the multimodality approach to the diagnosis of primary extranodal diffuse large B-cell lymphoma of the left hemipelvis. ***Materials and Methods:*** We present a 50 years old male patient with an anamnesis of trauma 7 months before final diagnosis. He complained of a growing pain in his left pelvis and hip, weight loss and subfebrile temperature. After an examination by an orthopedic surgeon and a normal bone radiography, a treatment with antibiotics and analgesics was started. A non-contrast enhanced MRT of the hip was performed after 5 months of unsuccessful treatment, concluding it was a tumor mass- chondrosarcoma or fibrosarcoma of the left pelvis. A new radiography was performed, showing diffuse osteosclerotic and osteopenic changes of the left hemipelvis with small areas of bone destruction, suspicious of osteomyelitis or lymphoproliferative disease. Controversies persisted also after the bone biopsy, revealing only osteomyelitis of the bone. ***Results:*** 18-F FDG PET/CT was performed in order to characterize the metabolic aspect of the lesion, to exclude another primary tumor, and choose a proper biopsy place. Our findings were diffuse cortical changes- osteosclerosis and cortical thickening, affecting the left hemipelvis, corresponding to diffuse high glucose metabolism- characteristics close to osteomyelitis. There were also four soft tissue masses found, causing cortical destruction, where the biopsy was proposed. After the PET- directed biopsy a thorough pathological and immunochistochemical analysis were performed revealing an intense membrane expression of CD20 in 100% of tumor cells and positive CD79a, proving the lymphogenic origin of the tumor. On the second round high proliferation activity- Ki67 - nuclear expression in >50% of tumor cells and positive Bcl6 were found, confirming the final diagnosis- large B-cell lymphoma of the bone. ***Conclusion:*** As it was stated in the literature, the diagnosis of primary bone lymphoma was delayed due to unspecific clinical signs and equivocal imaging findings. 18F-FDG PET/CT acted as a key imaging method in the multidisciplinary management, guiding the biopsy, which finally led to the correct diagnosis. ***References:*** Dubey P, Ha CS, Besa PC, Fuller L, Cabanillas F, Murray J, et al, Localized primary malignant lymphoma of bone. Int J Radiat Oncol Biol Phys. 1997 Mar 15;37(5):1087-93. doi: 10.1016/s0360-3016(97)00106-5. PMID: 9169817.

### EP-0900

**A rare finding in 18F-FDG PET/CT restaging - unilateral diaphragmatic crura increased uptake in patient with pneumonectomy - a Case report**

***T. Stoeva***, *T. Yordanova, M. Dyankova, S. Chausheva, Z. Dancheva, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** The knowledge of normal and pathological uptake of F-18 fluoro-2-deoxy-glucose ($^{18}$F-FDG) whole-body positron emission tomography (PET) with computed tomography (CT) is essential for identification of the presence and extent of malignant disease. The advantages of combining functional and anatomical information can help us to precisely localize and stage primary non-small-cell lung cancer, find a proper biopsy place, evaluate the tumor response after treatment and help in radiotherapy planning. However, there are some artefacts and pitfalls which can easily misguide the $^{18}$F-FDG-PET/CT interpretation. ***Materials and Methods:*** We present a case of a 74-years-old male with lung carcinoma. Baseline $^{18}$F-FDG-PET/CT was positive in the upper part of the left lung without nodal or distant metastases. Histopathology confirmed non-small-cell lung cancer. The patient's symptoms were alleviated after left pneumonectomy and chemotherapy. Stable disease was reported after postoperative computed tomography. Due to generalized pain syndrome, another $^{18}$F-FDG-PET/CT was performed after two and a half years. ***Results:*** The follow-up $^{18}$F-FDG-PET/CT revealed increased uptake in the contralateral, right diaphragmatic crura. This was an unusual finding, because diaphragmatic crus uptake is usually bilateral. Hyperventilation and increased compensatory work of the right lung was thought to be the potential underlying mechanism of this condition. ***Conclusion:*** This rare and unusual case report of unilateral diaphragmatic crus increased uptake after pneumonectomy enriches the knowledge of possible artifacts and pitfalls. It gives us the opportunity to be more precise in $^{18}$F-FDG- PET/CT post treatment restaging, which is always a challenge.

### EP-0901

**Osteomyelitis in patient with multiple myeloma- the invisible threat seen in 18F-FDG PET/CT**

***T. Stoeva***, *M. Dyankova, Z. Dancheva, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** Herein, we aim to present a rare PET/CT finding in a patient with multiple myeloma (MM)- osteomyelitis of the sternum. ***Materials and Methods:*** We present a male patient with complaints of pain in the left hip joint area, initially only during exercise and at a later stage in a relaxed state due to multiple myeloma. The patient underwent staging 18F-FDG PET/CT, which revealed a single osteolytic lesion in the left acetabulum and high metabolic activity in the seventh left rib. Due to acute aortic dissection (Stanford type A, DeBakey type I), aortic valve reconstruction was performed with intervascular prosthetics of the ascending aorta and aortic wall, with a complicated postoperative period due to osteomyelitis of the sternum. Sequestrectomy, surgical revision of the graft and long-term antibiotic treatment were implemented. After 9 courses of chemotherapy, a remission of the disease was registered. ***Results:*** A post-treatment 18F-FDG

PET/CT scan revealed a prevascular soft tissue mass in the anterior mediastinum with high metabolic activity, propagating through the sternum, with a well-defined fistula course to the skin surface. The sternum itself had a highly altered structure, in places, especially around the metal osteosynthetic elements with destruction and pronounced sclerotic transformation. In addition, when osteomyelitis develops against the background of an osteolytic lesion, the clinical outcome is often poor. In severe cases, the infection leads to life-threatening complications. Although bone infections are manageable in most reported cases with broad-spectrum antibiotics, prolonged hospitalization, antibiotic treatment, and additional surgeries can significantly increase disease burden and seriously affect prognosis with increased mortality. Drug-resistant bacterial infection could potentially be a major threat to MM patients in the future. ***Conclusion:*** Patients with MM who are immunocompromised by chemotherapy, transplantation, or steroid drugs may be susceptible to infections. Vertebral osteomyelitis of bacterial or fungal origin is particularly specific in immunocompromised patients [1]. Medical literature rarely highlights the risks of bone infection associated with myeloma bone disease. Although the literature to date consists mainly of individual case reports rather than rigorous prospective studies, it is suggested that this may be an area that merits further investigation. ***References:*** Yu S.F., Lui C.C., Pei S.N., Liu J.W., Cheng T.T. Unsuspected multiple myeloma presenting as Escherichia coli infectious spondylitis: a case report. Int J Rheum Dis. 2010;13(4):e55-e58

## EP-0902

### 18F-FDG PET/CT in a patient with two metachronous tumors and the possible diagnostic pitfalls

***T. Stoeva****, Z. Dancheva, M. Dyankova, S. Chausheva, T. Yordanova, B. Chaushev, A. Klisarova;*
*UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

***Aim/Introduction:*** We aim to present a case of a patient with two metachronous malignancies and the possible diagnostic pitfalls in the interpretation of 18F-FDG PET/CT images. ***Materials and Methods:*** We present a patient with two metachronous malignancies- carcinoma of the right kidney and multiple myeloma (MM). In June 2018 a laparoscopic partial kidney resection was performed. In 2019 was established progression of the disease- single metastatic lesions in the left lung. A one-month treatment with Pazopanib was conducted and a complete response was reported. MM was diagnosed in October 2020. After conducted chemotherapy, partial response was reported. The patient was referred to 18F-FDG PET/CT due to CT findings of enlarged abdominal lymph nodes. ***Results:*** The performed restaging 18F-FDG PET/CT revealed generalized malignant lymphadenopathy, represented by multiple lymph nodes- bilaterally paraaortic, retrocrural, in the mediastinum and in the right supraclavicular space. Multiple scattered metabolically active osteolytic bone lesions were found as well, possibly associated with the known multiple myeloma. The absence of pre-therapeutic 18F-FDG PET/CT made it difficult to assess the response to the treatment of multiple myeloma. Persistence of high metabolic activity in the osteolytic lesions, exceeding that of the liver, can be considered in two ways - as a poor response to treatment for myeloma disease or as secondary lesions related to progression of renal carcinoma. Given the less common generalized lymphadenopathy in multiple myeloma, it was likely a progression of the renal carcinoma. After conducting laboratory tests and histological verification of the findings, MM progression was established and treatment was started. ***Conclusion:*** The combination of these two types of carcinoma in one patient is rare. Usually, the second neoplasia is caused by immunosuppression as a result of treatment (chemotherapy, radiotherapy) of the first. Multiple myeloma and renal cell carcinoma have similar risk factors (obesity, smoking, hypertension). Pathophysiological mechanisms are common to both renal carcinoma and multiple myeloma—in particular, the role of interleukin-6, which is produced by renal cells and stimulates the proliferation of myeloma cells. This should direct the clinicians attention to the possibility of recurrence of one malignant disease, even though progression of the other metachronous tumor is subsequently proven.

## EP-0903

### A case report of abnormal bone imaging caused by bevacizumab

***T. Yi****, C. Yu;*
*The Second Affiliated Hospital of Guilin Medical University, Guilin, CHINA.*

***Aim/Introduction:*** Bevacizumab has osteoarthritis records in its adverse drug reaction instructions, but the corresponding literature is very few, and its related adverse reaction meta-analysis has not been clearly reported. ***Materials and Methods:*** A 43-year-old female with stage IVA of cervical poorly differentiated squamous cell carcinoma treated with docetaxel plus nidaplatin plus bevacizumab for 6 sessions and radiotherapy. She did not have clinical symptoms related to osteoarthritis, such as morning stiffness, and no corresponding positive serological indicators. Then SPECT/CT whole-body-scan(WBS) examination was performed to evaluate the bone metastasis of the tumor. ***Results:*** WBS showed radioactivity concentration was symmetrically distributed in bilateral shoulder, elbow, wrist, knee, ankle, interphalangeal joint, and interphalangeal joints, but no signs of metastasis in the whole body bone . SPECT/CT fusion images showed abnormal radioactivity increase in those joints listed above, but no obvious bone destruction was seen on fusion CT . The arthritis caused by bevacizumab should be considered because of the recent history of Bevacizumab. ***Conclusion:*** SPECT/CT WB scan is a highly sensitive examination method for bone related lesions. From this case, it may be concluded that SPECT/CT WB scan is a sensitive method for clinical diagnosis of suspected osteoarthritis adverse reactions caused by drugs. ***References:*** 1.Alqahtani MM, Fulton R, Constable C, et al. ### Primary colorectal cancer with increased 68Ga-PSMA expression on PET/CT: incidental second malignancy in primary staging for prostate cancer (PC)

***M. Dyankova***[1,2], *S. Chausheva*[1], *Z. Dancheva*[1], *T. Stoeva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Imaging Diagnostics, Interventional Radiology and Radiotherapy, Varna, BULGARIA,* [2]*St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA.*

***Aim/Introduction:*** $^{68}$Ga-prostate-specific membrane antigen (PSMA) PET/CT has shown superb results in imaging of Prostate Cancer (PC). PSMA has been found in tumor-associated neovasculature endothelial cells in various nonprostatic malignant diseases, including colorectal cancer and multiple other types of solid tumor. Nevertheless, synchronous malignancies with increased PSMA expression are not common (0.7%) in PC patients. ***Materials and Methods:*** We present a case of a 71-year-old male, in whom a second primary metastatic rectal cancer was detected with a PSMA PET/CT imaging performed for PC staging. The male was recently diagnosed with prostate adenocarcinoma, Gleason score 6 (3 + 3) with high initial serum prostate-specific antigen levels (PSA) 75.0 ng/ml. He was referred for staging with 68Ga-PSMA PET/CT prior to treatment. ***Results:*** PSMA-PET was performed and fusion PET/CT images revealed a larger focus of intense pathologic PSMA activity, which correlated to widely thickened rectal wall-presacral tumor and one pelvic lymph node with increased tracer uptake (with SUVmax-values up to 8.9), which were subsequently histologically proven as moderately differentiated primary rectal adenocarcinoma with associated pelvic lymph node metastasis and inflammatory ascites. PSMA expression has also been reported in known primary PC. ***Conclusion:*** In present case report we demonstrate the significance of histological confirmation of lesions with increased 68Ga-PSMA expression, but atypical for PC involvement. This case with considerable nonprostatic PSMA activity highlights the need for careful interpretation of PSMA PET/CT results and also provides premise to study the possible role of PSMA-targeted radiopharmaceutical therapy in progressive/ advanced colorectal cancer. Keywords: 68Ga-PSMA PET/CT, synchronous primary colorectal cancer, adenocarcinoma

## EP-0905

### Unusual recurrence of secondary renal hyperparathyroidism caused by a ectopic undescended parathyroid adenoma:a case report

***w. Weng****;*
*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

***Aim/Introduction:*** Recurrence of secondary renal hyperparathyroidism is not uncommon after parathyroidectomy. However, recurrence caused by ectopic undescended parathyroid adenoma is rare. ***Materials and Methods:*** Here, we report a case of 59-year-old female with progressively elevated serum intact parathyroid hormone after underwent parathyroidectomy for secondary hyperparathyroidism. A suspected abnormal nodule near the bifurcation of carotid artery was found by $^{99m}$Tc-sestamibi scintigraphy with single positron emission tomography / computed tomography (SPECT/CT). ***Results:*** After excision of the suspected nodule near the bifurcation of carotid artery, the intact parathyroid hormone value of the patient decreased. The nodule was pathologically confirmed as a parathyroid adenoma. ***Conclusion:*** Ectopic undescended parathyroid adenoma is an exceptional cause of Secondary hyperparathyroidism, intense pre-operative localization diagnostic is necessary.

### Incidental Paget bone disease as a potential pitfall in 18-F FDG PET/CT in melanoma patient

***S. Moustafa****;*
*Assiut university hospital, Assiut university, EGYPT.*

***Aim/Introduction:*** Paget bone disease is a chronic progressive bone disease of uncertain etiology charchetrized by excessive bone remodeling along three stages (resorption, mixed and finally burnout or sclerotic phase). Scintigraphic features of this disease depend on its stages. It can be misdiagnosed as a metastatic bone lesions, so accurate diagnosis is mandatory to guide for the right management. I have reported the case of incidental only pagetiod bone disease in patient with newly diagnosed left foot melanoma yet no osseous metastases. It was diagnosed by the typical CT feature as well as the specific scintigraphic feature of the complementary of the bone scan. ***Results:*** Figure 1: A 64 years old presented to our oncology department after tumoral excision

from sole of left foot, pathologically proven as superficial spreading melanoma. The patient is requested to do F-18 FDG PET/CT for as post-operative staging imaging modality. PET/CT showed diffuse FDG activity within the left hemiplevis appreciated at the left acetabulum and ischium mimicking metastases corresponding to heterogeneous sclerosis and ground glass appearance at CT image. Complementary bone scan and added SPECT/CT images for the pelvis, showed the characteristic scintigraphic intense uptake at a right hemiplevis. ***Conclusion:*** Benign etiologies should be on our mind while assessing and interpretatating bone lesions showing 18-F FDG and/or 99mTc-MDP uptake during staging and follow-up, both due to changing the treatment plan and its effect on survival by proper management. ***References:*** 1. ## EP-0907

### Pitfall In Tumor Assessment FDG-PET/CT Imaging In Hodgkin Lymphoma Due To Cocaine-Induced Nasal Inflammation

***A. Jougla***[1], *J. Alberini*[1,2,3], *B. Durand-Bailloud*[1], *R. Ahond-Vionnet*[1]; *[1]Department of Nuclear Medicine, Hôpital Pierre Beregovoy, Nevers, FRANCE, [2]Department of Nuclear Medicine, Centre Georges-François Leclerc, Dijon, FRANCE, [3]ICMUB Laboratory, UMR CNRS 6302, University of Burgundy, Dijon, FRANCE.*

***Aim/Introduction:*** Chronic inflammation can accumulate 18F-FDG and mimic tumor involvement. We present a case of cocaine-induced chronic inflammation of the nasal cavity, found by serendipity in a patient referred for FDG-PET/CT scan in staging and tumor response assessment for a Hodgkin lymphoma. ***Materials and Methods:*** A 25-year-old male patient presented a gradually growing cervical lymph node on the right side. Diagnosis of Hodgkin Lymphoma was established on the lymph node biopsy. In this context, the patient was referred to our department to perform sequential three FDG-PET/CT scans at baseline, then three months later after two cures of chemotherapy and finally four months later at the end of chemotherapy and radiotherapy. ***Results:*** At baseline, PET/CT scan revealed increased FDG uptake in cervical lymph nodes (SUVmax = 22.6) and in retropharyngeal region, both on the right side. Moreover an intense FDG uptake was found in the right nasal cavity. This FDG uptake involved the nasal septum and the middle and inferior nasal concha (SUVmax = 11.6). No FDG uptake was observed in the left nasal cavity, nor in the sinuses. The thickness of nasal mucosa was increased on CT scan. The patient reported regular cocaine intake, twice a month, snorting exclusively through the right nostril. The second PET/CT scan performed after two cures of chemotherapy showed a complete disappearance of the FDG uptake in cervical lymph nodes and in retropharyngeal region, in favour of a metabolic complete response. However, intense FDG uptake described in the right nasal cavity (SUVmax = 10.8) was still observed with a morpho-metabolic stability. Then the patient underwent a clinical examination by an otorhinolaryngologist who confirmed chronic inflammation of the nasal mucosa with synechiae unrelated to the Hodgkin lymphoma. At the end of treatment (chemotherapy and irradiation of the cervical lymph nodes), FDG-PET/CT confirmed the metabolic complete response. A slight decrease of the FDG uptake in the right nasal cavity (SUVmax = 7.5) was observed and could be explained by the reduction of cocaine intake reported by the patient. ***Conclusion:*** To our knowledge, this is the first report of nasal FDG findings due to cocaine-intake. This case illustrated a setting of cocaine-snorting which induced chronic inflammation in the nasal cavity, which can mimic malignancy and could be misinterpreted as active residual lymphoma lesions.

## EP-0908

### Suspected Central Pontine Myelinolysis detected by 18F-FDG PET/CT in a patient with septic shock

***L. Locantore****, M. Cucca, E. Biggi, R. J. Egoue Mongoue, I. Ravelli, D. Riolo, M. Zuffante;*
*Nuclear Medicine Unit, AOUI, Verona, ITALY.*

***Aim/Introduction:*** We describe the case of a 59-year-old Caucasian male with a known history of alcohol abuse who was admitted in Intensive Care Unit (ICU) due to coma in sepsis. ***Materials and Methods:*** Emogas data analysis showed metabolic acidosis with severe hypoglycaemia, treated by initial 500 ml of 20% glucosate solution. Patients had also renal impairment with serum Creatinine of 2.53 mg/dl and increased CRP (263 mg/L) Not significant abnormal sodium or potassium levels were found; anyway patient was treated with 1500 cc of elettrolitic solution. Antibacterial therapy with Pip/Tazo was also administered, prior to blood colture results (finally showed S.hominis positivity). Patient underwent brain MRI to value septic cerebral embolism and/or vascular injuries. Patients was also scheduled for 18F-FDG-PET/CT (PET/CT) to value the origin of sepsi and/or the presence of septic embolism localizations. ***Results:*** MRI found some small vascular chronic lesions and diffusion restriction in the pons, thus suggesting central pons myelinolysis (CPM). PET/CT found bilateral lung consolidations and peripheral ground glass opacities characterized by increased metabolism likely due to septic pneumonia. An intense and diffuse FDG uptake was also found in pancreas due to probably chronic pancreatitis. Brain evaluation showed intense increased uptake of the pons, together with right periventricular white matter inhomogeneous increased uptake. These finding, according to MRI results and to other case reports, was suspected for central pontine myelinolysis with possible extrapontine foci of demielinization. After 7 days from PET/CT patient had negative perypheral blood colture, inflammatory index decreasing and negative lactates, with renal function improvement. Patient remained apiretic but ventilated by ETT ; infectivologists decided to withrawal antibacterial therapy. Patiens is still today hospitalized in ICU. ***Conclusion:*** CPM is a demyelinating lesion of the pons, resulting in several neurological symptoms. The exact cause of CPM is not clear, but a relation between loss of myelin and osmotic stress was suggested, together with rapid correction of hyponatremia. In our case, this last evidence was not so clear, while we could hypotize CPM due to chronic alcohol abuse. PET/TC could be useful to detect CPM when clinically or radiologically suspected. ***References:*** 1.Rønne F, Tfelt-Hansen PC, Rørdam L. Central Pontine Myelinolysis and Localized Fluorodeoxyglucose Uptake Seen on 18F-FDG PET/CT. World J Nucl Med. 2017 Jan-Mar;16(1):56-582.Uchino A, Yuzuriha T, Murakami M, Endoh K, Hiejima S, Koga H, Kudo S. ## EP-0909

### FDG PET/CT in the Evaluation of Multi-systemic Involvement in Erdheim Chester Disease

***M. Guven***[1], *M. Eroglu*[2], *A. Oral*[1], *C. Eraslan*[2], *Z. Ozcan*[1];
[1]*Department of Nuclear Medicine, Ege University, Izmir, TÜRKIYE,*
[2]*Department of Radiology, Ege University, Izmir, TÜRKIYE.*

***Aim/Introduction:*** Erdheim-Chester disease (ECD) is a rare non-Langerhans cell histiocytosis that presents with different clinical findings due to involvement of mainly bone and extra-bone organs. It may produce a multi systemic clinical picture involving the skeletal system, central nervous system (NS), respiratory system, skin, cardiovascular system, kidneys, retroperitoneal area, and eyes, or it may be asymptomatic as well. This presentation will highlight the multimodality imaging findings in a case of ECD, a relatively rare condition in nuclear medicine practice that is notable for involvement of the brain and paranasal sinuses in addition to typical multiple bone/bone marrow lesions on FDG PET imaging. ***Materials and Methods:*** A 49-year-old female patient who presented with diabetes insipidus, progressive weakness, and balance disorders was diagnosed with ECD after bone marrow biopsy. Whole body FDG PET/CT imaging was performed to assess the extent of the disease using non-contrast enhanced low dose CT protocol. ***Results:*** FDG PET/CT showed multifocal hypermetabolic findings in bone marrow regions in addition to lytic sclerotic findings in the bone structures. Additionally, hypermetabolic activity were noted at the level of the pons in the brainstem and focal FDG uptake in the pituitary infundibular portion. There were hypermetabolic inflammatory changes in the bilateral maxillary sinuses and sclerotic changes in the para-sinusoidal bone surfaces. MRI performed to examine the central nervous system (CNS) in detail revealed diffuse infiltrative foci consistent with the disease in the pituitary-infundibulum and bilateral cerebral hemispheres. At the level of the pons in the brainstem, MRI showed no significant specific contrast enhancement consistent with the metabolic activity on PET/CT, but pathologic signal enhancements were noted in these areas. ***Conclusion:*** ECD is easily recognized on metabolic imaging with its typical features of bone and bone marrow involvement. CNS findings are less common and are considered a sign of poor prognosis. In this case, hypermetabolic findings in the pons and pituitary gland were notable even over the physiological cerebral FDG uptake. Moreover, FDG uptake indicated additional areas with abnormal signal enhancement on cerebral MRI. Additionally, the increase in hypermetabolic thickness in the maxillary sinus, which is less common, showed that the disease involved the respiratory system. This case report aims to raise awareness among nuclear medicine physicians of ECD, which elicits a wide range of imaging findings and underlines the contribution of FDG PET/CT imaging in the assessment of disease extent.

## EP-0910

### Accidently Detected Lung Masses as Carcinoma in 99mTc (V)-DMSA SPECT Imaging

***E. Gharehpapagh***[1], *S. Rezaei*[1], *L. Namvar*[2];
[1]*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [2]*Tuberculosis and Lung Disease Research Center, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** A 74-year-old woman with a previous history of asthma, diabetes mellitus, hypertension, and cervical vessel stenting after falling recently underwent CT scan. Several pulmonary masses were randomly identified in the chest CT report, including one with a diameter of 30 mm in the upper lobe of the right lung. There was a possibility of carcinomatosis lymphangitis due to the RUL lesion and interstitial edema, and further evaluation was recommended. ***Materials and Methods:*** On the control CT performed 10 days later, the same masses were found without changes, also several enlarged lymph nodes in the mediastinum and lungs' hilum, and no evidence of thrombosis or pulmonary artery stenosis on both sides. $^{99m}$Tc (V)-DMSA imaging was requested by the attending physician for further evaluation of pulmonary masses. The whole body scan, as well as thoracic SPECT images, were taken two hours after the intravenous injection of 590 MBq of $^{99m}$Tc (V)-DMSA. ***Results:*** The scan showed two lesions with increased radiotracer uptakes, one in the lower region of upper lobe and the other in the superior segment of Rt. and Lt. lungs respectively. The lesions had posterior locations in both lungs best detected by SPECT projections. In semi-quantitative analysis, the lesion to background ratio was 1.52 on the right side and 1.61 on the left side. As well, there were some patchy lesions with slightly increased uptake in the upper and middle parts of both lungs. The possibility of malignancy in two obvious lesions in the right and left lungs based on the $^{99m}$Tc (V)-DMSA scan report. ***Conclusion:*** Consequently, the patient underwent lung transbronchial biopsy and bronchial washing cytology which showed the result of lung cancer, adenocarcinoma poorly differentiated. The chemotherapy was started for this patient.

## EP-0911

### Unusual uptake of bone metastases in 99mTc-MAG3 dynamic renal scintigraphy

***K. Aslaner***, *B. Arca, D. Has Simsek, F. Buyukkaya, Y. Sanli, S. Kuyumcu;*
*Istanbul University, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Neuroendocrine tumors (NET) are a heterogeneous group of tumors originating from neuroendocrine cells that can arise from different organs. In metastatic NETs, peptide radionuclide therapy (PRRT) makes significant contributions to disease survival. Kidney is one of the critical organs in PRRT, and renal function is evaluated with dynamic renal scintigraphy before the treatment to determine obstructive pathologies or renal disfunction. In this case report, unusual uptake of bone metastases were demonstrated in $^{99m}$Tc-MAG3 dynamic renal scintigraphy of a patient who was planned $^{177}$Lu-DOTATATE therapy for metastatic NET. ***Materials and Methods:*** An 18 years old female patient with a diagnosis of paraganglioma was referred to our clinic for PRRT due to progression under systemic chemotherapy and sandostatin treatment. $^{68}$Ga-DOTATATE PET/CT images of the patient showed intense somatostatin receptor expression in metastatic lymph nodes in bilateral retrocrural areas and multiple metastatic lesions in the vertebral column, calvarium,pelvis and extremities, most prominently in the L1-L3 vertebrae. The patient was eligible for $^{177}$Lu-DOTATATE therapy, and $^{99m}$Tc-MAG3 dynamic renal scintigraphy was planned before the treatment. ***Results:*** $^{99m}$Tc-MAG3 dynamic renal scintigraphy showed unusual increased activity in metastatic bone lesions in lumbosacral vertebrae. In presentcase, increased activity in bone metastases was prominent in early images and decreased in late images, suggesting that may be related to increased blood flow secondary to malignancy. The stomach was not visualized in all images which ruled out the possibility of free $^{99m}$Tc-pertechnetate. In literature, similar few case reports were published and emphasized that detection of skeletal involvement on dynamic renal scintigraphy is frequently associated with malignancy[1-3]. ***Conclusion:*** Increased activity of metastatic bone lesions on $^{99m}$Tc-MAG3 dynamic renal scintigraphy is a rare finding. Extrarenal

involvement on dynamic renal scintigraphy has been reported to be associated with malignancy due to increased vascularity, and incidental bone uptake in dynamic renal scintigraphy needs further investigation due to the malignancy risk. ***References:*** 1) Wang T, Zhao J, Xing Y. ### Contribution of SPECT-CT in the Differentiation of Ectopic Thyroid Tissue and Thyroglossal Duct Cyst

***G. Deniz***[1], *E. G. Isik*[2], *D. Has Simsek*[2], *Y. Sanli*[2], *B. Arca*[2], *S. Kuyumcu*[2];
[1]*Istanbul University Istanbul Faculty of Medicine Nuclear Medicine Department, Istanbul, TÜRKIYE., Istanbul, TÜRKIYE,* [2]*Istanbul University Istanbul Faculty of Medicine Nuclear Medicine Department, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The thyroid gland forms between the first and second pharyngeal sacs, near the base of the tongue. During migration, the thyroid tissue may remain attached anywhere along the thyroglossal duct. However, thyroglossal duct cysts and ectopic thyroid tissue can be difficult to detect using methods such as USG and planar scintigraphy. To detect the presence of ectopic/pyramidal thyroid tissue in the thyroglossal duct and to determine the anatomical localization of the thyroid tissue, Tc99m-pertechnetate SPECT/CT can be used. In this case, we aimed to detect ectopic/pyramidal thyroid tissue with SPECT/CT. ***Materials and Methods:*** A 41-year-old female patient, who had a subtotal thyroidectomy 20 years ago, was referred to us with a complaint of swelling in the neck. In previous thyroid ultrasound (USG) imaging, it was not possible to distinguish between ectopic thyroid tissue and thyroglossal duct cyst in the anterior region of the neck, located superior to the thyroid gland. Thyroid scintigraphy and SPECT/CT imaging were performed. Uptake was observed in the thyroid bed, consistent with residual thyroid tissue on the right. Additionally, in SPECT/CT, the patient exhibited activity involvement due to lobulated ectopic/pyramidal thyroid tissue starting from the infrahyoid region and extending to the lower level of the thyroid cartilage with no thyroglossal cyst. ***Conclusion:*** Thyroid tissue can also be found in other parts of the descending tract, where thyroglossal duct cysts can be observed. However, the probability of ectopic thyroid in the cyst wall is less than 5%. While it does produce thyroid hormones, its concentrations are often below normal.[1 2] In our case report, tracer involvement was observed in the anterior midline of the neck in the planar thyroid scintigraphy. However, it did not provide information about the anatomical localization of the ectopic thyroid tissue. On the other hand, ultrasonography did not provide many benefits in the differentiation of thyroglossal duct cysts and ectopic thyroid tissue. In SPECT/CT, on the other hand, the localization of the lesion, whether it is located within the cyst and its relationship with the surrounding tissue can be clearly understood. ***References:*** 1. ## EP-0913

### Case report: Pulmonary Langerhans cell histiocytosis (PLCH) - is it a challenge for 18F-FDG PET/CT?

***M. Dyankova***[1,2], *T. Stoeva*[1], *Z. Dancheva*[1], *S. Chausheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Imaging Diagnostics, Interventional Radiology and Radiotherapy, Varna, BULGARIA,* [2]*St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA.*

***Aim/Introduction:*** Pulmonary Langerhans cell histiocytosis (PLCH) is a rare disease presenting with nonspecific symptoms. Initial 18F-FDG PE/CT assessment of PLCH and therapeutic response evaluation in this form of malignant involvement is a complex challenge and requires a diverse approach. ***Materials and Methods:*** A 18-year-old man with an acute onset of progressive shortness of breath, hospitalized urgently in a clinic with evidence of spontaneous left-sided pneumothorax. A left thoracocentesis and pleural drainage were performed. A month later pneumothorax recurred contralaterally on the right side. From the performed conventional imaging studies were found diffuse advanced changes, involving both lungs. A lung and pleural biopsy was performed with histological and immune histochemical analysis result - LCH. ***Results:*** FDG- PET/CT revealed multiple bilateral pulmonary thin-walled cavitating lesions with a diffuse distribution- "honey-comb" type, thickened interlobular septa, reticulonodular changes with inhomogeneous mild to moderately increased uptake, corresponding with lung involvement from the LCH. Pneumothorax and small pleural effusion on the left side were found as well. Moreover malignant involvement by LCH of left costal pleura was suspected. Restaging PET/CT two month later after chemotherapy and corticosteroid therapy showed significantly enlarged emphysematous bullae compared to the previous scan. Significantly increased pneumothorax on the right with a small -onset pleural effusion. Metabolically active changes, newly emerged on the right costal pleura with appearance of malignant involvement from LCH. There was no sign of previously found left pleural effusion and metabolically active changes on the costal pleura. The newly appeared metabolically active changes on the right costal pleura and pleural effusion couldn't define progression of LCH, given the peculiarities of the course of the disease- migrating nature of the lesions. Restaging PET/CT was defined as stable disease (SD). ***Conclusion:*** In the early stage of the PLCH, the small-sized nodules develop from cavitating lesions into initially thick-walled, then thin-walled cysts, which finally confluence and form the lung parenchyma mainly apically with relative preservation of the lung parenchyma basally. The described findings are difficult to distinguish from emphysema and lead to a delay in the diagnosis of the disease and initiation of appropriate treatment. Deep knowledge of the nature of PLCH is the basis for timely diagnosis, correct treatment and appropriate assessment of the therapeutic response. Keywords: : Pulmonary Langerhans cell histiocytosis, 18F-FDG PET/CT

### Diagnostic pitfall in a PET/CT case of thyroid cancer with 18F-FDG multi-uptake

***T. Yi***, *C. Yu;*
*The Second Affiliated Hospital of Guilin Medical University, Guilin, CHINA.*

***Aim/Introduction:*** Thyroid tuberculosis is a rare disease, even in areas of high prevalence such as India, and thyroid tuberculosis combined with thyroid cancer is even more rare. ***Materials and Methods:*** A 59-year-old female with low back pain was hospitalized, and before the hospitalization her MR of thoracolumbar spine showed that the bone destruction of T3 vertebral body and accessories, considering metastasis,

abnormal signal of T11 vertebral body, considering the possibility of hemangioma and multiple intervertebral disc herniation considered multiple metastases of malignant tumors. The patient had chronic renal insufficiency with regular hemodialysis for more than 4 years. The right pleura was considered to be tuberculous pleurisy before this hospitalization and had never been treated with anti-tuberculosis drugs. There were no clinical symptoms related to tuberculosis in this case. Meanwhile, PET / CT found that there were abnormal metabolic increases in many organs including thyroid. MRI and CT found that bone destruction also considered the source of malignant tumor, which was considered to be caused by the metastasis of thyroid cancer. ***Results:*** However, the final surgical pathology found that the thyroid tuberculosis and neck lymph nodes were also tuberculosis, while the focus of thyroid cancer was only 0.2cm, which is micro papillary carcinoma. No signs of metastasis were found. ***Conclusion:*** This case emphasizes the importance of comprehensive analysis of medical history. The history of dialysis for more than 4 years was ignored, of which induced tuberculosis was not uncommon. Therefore, dialysis leads to systemic blood circulation transmission, which increases the probability of thyroid and axillary lymph node infection with tuberculosis. At the same time, although PET / CT is sensitive, its specificity is relatively low. As to multiple abnormal 18F-FDG metabolisms, it cannot be simply diagnosed as tumor and secondary metastasis through by the "monism". ***References:*** 1.Abrantes AM, Pires AS, Monteiro L, et al. ### Persistent bone focal uptake of 18F-PSMA-1007 in patient with prostate cancer and undetectable levels of PSA under hormone therapy

***G. Bellettati***[1], *S. Pacella*[2], *A. Castello*[2], *E. Lopci*[3], *L. Florimonte*[2], *M. Castellani*[2];
[1]*University of Milan, Milano, ITALY,* [2]*Fondazione IRCCS Ca'Granda, Ospedale Maggiore Policlinico, Milano, ITALY,* [3]*Humanitas Clinical and Research Hospital, Rozzano, ITALY.*

***Aim/Introduction:*** Prostate cancer (PCa) is the second most common malignancy in men. Serum prostate-specific antigen (PSA) is a well-established biomarker for PCa screening and a reliable marker for disease monitoring. PET/CT whole body with radioligands for PSMA proved to be important for evaluation of treatment response. Our case report presents the role of $^{18}$F-prostate-specific membrane antigen (PSMA)-1007 PET/CT in detecting persistent bone focal uptake in a patient with biochemical response (BR) to androgen deprivation therapy. ***Materials and Methods:*** PSMA is a transmembrane protein overexpressed in the PCa cells and its metastases. PET/CT imaging with different radioligand of PSMA is increasingly used in staging, in assessment of biochemical recurrence and treatment response of PCa. $^{68}$Ga-PSMA-11 is the most widely used radiopharmaceutical, even though $^{18}$F-PSMA-1007 has been recently registered for the detection of PCa and its metastases. ***Results:*** A 75-years-old man with PCa (Gleason score 4+3) and PSA of 11 ng/mL at the time of diagnosis underwent staging $^{18}$F-PSMA PET/CT in July 2022. Along with increased uptake on the prostate gland, PET/CT also showed two areas of intense uptake on the 6$^{th}$ right rib and on the left iliac bone highly suspicious for BM. Patient started hormonal therapy with initial BR (PSA 2.5 ng/ml) confirmed by the reduction of uptake on prostatic gland and disappearance of bone uptake areas at PET/CT with $^{68}$Ga-PSMA performed in September 2022. Another $^{18}$F-PSMA PET/CT performed two months later showed again intense uptake on the same skeletal sites. PSA decreased (PSA <0.03 ng/ml). A subsequent MRI confirmed the metastatic nature of the left iliac bone; latest $^{18}$F-PSMA PET/CT performed in April 2023 confirmed the same skeletal foci. ***Conclusion:*** The findings of our case report suggest some interesting topics to focus on: -the different sensitivity of $^{68}$Ga-PSMA and $^{18}$F-PSMA in the detection of bone metastases and the risk of false positive imaging of fluorinated radioligand; -the role of MRI in the interpretation of nuclear medicine imaging. Taking into account all these aspects, our clinical report could underline the importance of $^{18}$F-PSMA PET/CT for early detection of suspected bone metastasis, as well as suggesting an interesting topic of discussion for oncologists regarding the timing for changing the treatment. ***References:*** 1. ### Isolated limb perfusion (ILP) in a patient with myxoid liposarcoma (MLPS) of the lower extremity - case report

***J. Peric****, I. Žagar;*
*Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** Myxoid liposarcoma accounts for 30% of all cases of liposarcoma and 10% of all soft tissue sarcomas. Management of the locally advanced extremity soft tissue sarcoma is demanding, especially in cases of tumor recurrence or tumor adjacent to the neurovascular structures and joints. Hypertermic ILP with TNF-α and Melphalan is indicated in patients with limb sarcomas where amputation would be the only radical treatment. ***Materials and Methods:*** We present the case of a 44 years old male, in whom MRI and CT imaging revealed a 12 x 15 x 25,5 cm large tumor in the left soleus muscle, with no signs of distant metastatic spread, histologically proven to be a grade 2 myxoid liposarcoma. During the ILP procedure, the major vessels of the tumor bearing left lower limb were exposed and cannulated, limb was separated from the systemic circuit by a tourniquet, its circuit maintained by extracorporeal perfusor (heart/lung machine) and gradually heated up to a tissue temperature of 40$^0$C. For continual leakage measurements a conventional scintilation detector with a 3x3 inch NaI (Tl) crystal, connected to a dedicated analyzer with acquisiton, processing and display software was positioned above the heart ROI at a minimal distance. After stabilisation of the limb circuit, 15 MBq activity of Tc-99m-labeled human serum albumin (99mTc-HSA) was injected into sistemic circuit and a homogenous radiopharmaceutical distribution was reached in 5 - 10 minutes. A ten-fold higher activity of the radiopharmaceutical was then injected into isolated limb circuit. As no leakage was shown, a TNF-α injection folowed into isolated limb circuit 20 minutes after and a cytostatic Melphalan (phenilalanin mustard, 1,2 - 1,5 mg/Kg body weight) injection at 45 minutes. One-minute activity measurements were continually repeated during one-hour

isolated limb perfusion, at the end of which the limb was washed-out and the vessels were repaired. Mild erythema of the limb was present after procedure, with no other complications. Left lower limb MRI imaging 2 months after ILP revealed stable disease. ILP was followed by external beam radiotherapy of the left lower limb (50 Gy in 25 fractions). ***Results:*** A follow-MRI revealed tumor shirinkage, necrosis and pseudocapsule formation; a follow-up CT revealed no distant metastatic disease. Extensive trumor resection and reconstruction with free latissimus dorsi flap coverage followed. ***Conclusion:*** ILP proves to be an effective limb sparing treatment in patients with advanced sarcomas, in whom otherwise amputation would be the only radical treatment.

### Phase analysis using CZT-SPECT for evaluating mechanical synchronization: a case report on Left bundle branch-optimized cardiac resynchronization therapy(LOT-CRT)

***Q. Sun***[1,2], *S. Li*[2,3];
[1]*Department of Nuclear medicine, Shanxi Cardiovascular Hospital, Tai yuan, CHINA,* [2]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Tai yuan, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Tai yuan, CHINA.*

***Aim/Introduction:*** LOT-CRT is an innovative technique which combining left bundle branch area pacing (LBBP) and conventional CRT implanting coronary venous (CV) electrode . Currently, limited large sample follow-up studies suggest that LOT-CRT could improve the long-term prognosis for patients with HF. Accordingly, it is necessary to confirm which implantation technique can accurately improve LV synchrony and the outcome for individual patients. ***Materials and Methods:*** A patient with dilated cardiomyopathy underwent LOT-CRT enrolled in this study. Mechanical systolic synchronization parameters included PSD and PHB were evaluated by CZT-SPECT GMPI phase analysis technique before LOT-CRT. Moreover, resting GMPI was performed three times on day three after implantation. First time: unclosed electrode (LOT-CRT); Second time: LBBP means closed CV electrode; Third time: CV pacing means closed left bundle branch electrode. We analyzed which locations during pacing lead implantation played an important role in improving mechanical synchronization for patient response.The patient were followed for 6 months after LOT-CRT. ***Results:*** Mechanical synchronization parameters were analyzed. The results suggested that there were a few differences in mechanical synchronization between LBBP and LOT-CRT and the parameters between CV pacing and the preoperative parameters were not significantly different. At 6-month follow-up, This is a responder to LOT-CRT implantation. There were significant improvement between baseline parameters and 6 months parameters . In addition, his heart failure symptoms have significantly improved from NYHA class IV toll. ***Conclusion:*** The pacing effect of LBBP is similar to LOT-CRT . Moreover, CV pacing was ineffective in improving the mechanical synchronization for the patient. ***References:*** [1] Keping Chen, Yuqiu Li, Yan Dai, Qi Sun, Bin Luo, Chao Li, Shu Zhang. ## EP-0918

### Study of joint infection in a Jehovah's Witness patient with 99mTc-Besilesomab

***P. Guardia Jimena****, A. Santos Bueno, E. Sánchez de Mora, C. Salgado Garcia, A. Jiménez Heffernan;*
*Hospital Universitario Juan Ramón Jiménez, Huelva, SPAIN.*

***Aim/Introduction:*** Jehovah's Witnesses refuse transfusions of blood components, including their own, what is not known is that their religion allows fractions of primary components such as albumin or immunoglobulins and it is individual to accept them. Besilesomab is a murine immunoglobulin of the IgG1 isotype indicated for the diagnosis of inflammation/infection in peripheral bones in patients with suspected osteomyelitis. ***Materials and Methods:*** We present a 53-year-old Jehovah's Witness patient who underwent total left knee arthroplasty. One month after the operation he suffered a traumatism in the left knee, associated with cellulitis and great inflammation, so he was followed in consultation due to intense pain, functional limitation and joint effusion that required arthrocentesis of serohematic fluid with negative cultures. Low-grade fever was confirmed, so three-phase bone scintigraphy and labeled leukocyte scintigraphy were indicated before a new intervention. ***Results:*** The patient comes to our service reluctant to undergo tests due to his religious background, the indicated tests were explained, and initially, a three-phase bone scintigraphy with 99mTc-hydroxyphosphonate (740 MBq) was performed, showing increased uptake in early phases, compatible with an active inflammatory process, uptake at tibial level in the late phase, unable to confirm mobilization due to the short time since the intervention (6 months). Scintigraphy with labeled leukocytes was indicated, it is exposed to the patient who completely rejects its performance. Immunoscintigraphy with antigranulocytes antobodies is proposed and explained. The patient understands, asks his family for advice and accepts the test signing the informed consent. After the administration of 555 MBq of 99mTc-Besilesomab, images were acquired at 4 and 24 hours postinjection, showing increased periprosthetic uptake which decreases in the delayed images, confirming the inflammatory process and ruling out underlying infection. Finally, the patient underwent a new surgery finding correctly cemented components, negative tissue cultures and generalized fibrosis that was removed significantly improving the pain. ***Conclusion:*** The scintigraphy with 99mTc -Besilesomab allowed us to rule out infection in a patient who refused other tests due to his religious beliefs, which allowed surgery that improved his quality of life. ***References:*** Sniecinski R, Levy JH. What is blood and what is not? Caring for the Jehovah's Witness patient undergoing cardiac surgery. Anesth Analg. 2007 Apr;104(4):753-4. doi: 10.1213/01.ane.0000255644.73211.f2. PMID: 17377074.

## EP-0919

### Perineural Spread Into Cerebello Pontine Angle, High Grade Salivary Duct Carcinoma Mimicking as Vestibular Schwannoma diagnosed on F18 FDG PET/CT - A Case report

***A. Dixit***;
*Rajiv Gandhi Cancer Institute And Research Centre, North West Delhi, INDIA.*

***Aim/Introduction:*** Salivary duct carcinoma (SDC) is a rare malignant epithelial tumor mostly involving the parotid gland representing 1-3 % of salivary gland neoplasm. Histologically similar to ductal carcinoma of female breast with aggressive clinical course. Perineural invasion by SDC mimicking vestibular swannoma has rarely been reported on F18 FDG PET /CT scan. MRI head and neck has low to intermediate sensitivity for diagnosis of parotid gland tumor. ***Materials and Methods:*** 60 year old lady, presented with complaints of facial paralysis since 4 years, she was on alternative medicines. On MRI brain- a well defined extra axial lobulated enhancing lesion is seen at the right cerebello pontine angle diagnosed as Acoustic Schwannoma. She received stereotactic radiotherapy 1800 cGy (3 cycle) to the lesion. Follow up MRI brain with clinical symptoms suggested progressive disease. She underwent F18 FDG PET/ CT scan showing the right cerebello pontine angle lesion, and right parotid gland lesion, cervical lymphadenopathy with bony lesions. ***Results:*** Biopsy from the right parotid gland lesion suggested high grade SDC. She received 5 cycles of paclitaxel based chemotherapy and on follow up F18 FDG PET/ CT scan suggested partial response to treatment. ***Conclusion:*** SDC is a rare, aggressive salivary malignancy often diagnosed at an advanced stage. MRI has low- to intermediate-signaling intensity on T2-weighted images with ill-defined borders, and invasion into surrounding structures. However, F18 FDG PET /CT with few limitations appears to be a better non-invasive tool for tumor staging and guiding biopsy sites for diagnosis in cases of salivary duct carcinoma mimicking vestibular Swannoma and early treatment response assessment. ***References:*** 1. ## EP-0920

### SAPHO syndrome - a rare and challenging diagnosis on FDG PET/MRI

***J. Foukal***, *T. Koprivova, H. Kašpárková;*
*Fakultni nemocnice Brno, Brno, CZECH REPUBLIC.*

***Aim/Introduction:*** The SAPHO syndrome encompasses a variety of osteoarticular disorders that are frequently accompanied by dermatoses but can also occur in isolation. It is rare, although probably underrecognized because its diagnosis may be challenging due to the wide variability in its musculoskeletal and cutaneous manifestations. The pathogenesis is unknown, but a genetic predisposition to an atypical immune response to bacterial infection is suspected. ***Materials and Methods:*** A 41-year-old man was referred for a FDG PET/MRI with a year long history of persisting osteomyelitis of mandible, recurrent spondylodiscitis of thoracic and lumbar spine and persistent joint pain. Although no causative pathogen was identified, the patient has undergone long-term treatment with antibiotics with little to no clinical effect. Paraneoplastic or haemato-oncological etiology was considered therefore, a PET/MRI was performed. ***Results:*** On PET/MRI multiple foci of markedly increased activity surrounding many bones and joints were present, but no pathological activity was present inside the bones themselves. Affected regions included mandible, scapulae, acromio-clavicular and sterno-clavicular joints, ribs, thoracic and lumbar vertebrae, iliac bones. As the presentation was not suggestive of malignancy, atypically extensive image of inflammatory process was considered. Biopsy of the infiltrates around the pelvis and clavicle was performed with findings of inflammatory changes. The clinical presentation, results of PET/MRI and biopsies together led to a diagnosis from the group of autoinflammatory bone lesions of the SAPHO syndrome type or recurrent nonbacterial chronic osteomyelitis. Specific therapy was started, it included corticosteroids, chemotherapy and biological therapy followed by immunosuppressive therapy. ***Conclusion:*** SAPHO is a rare and probably underdiagnosed disease and the path to a correct diagnosis can be long and complex. Even histology alone cannot accurately diagnose the disease; clinical symptoms, imaging and histological findings must be correlated. In the presented case it took more than a year from the first symptoms to the correct diagnosis and therapy. ***References:*** Nguyen MT, Borchers A, Selmi C, Naguwa SM, Cheema G, Gershwin ME. The SAPHO syndrome. Semin Arthritis Rheum. 2012 Dec;42(3):254-65. Duan N., Chen X., Liu Y, Wang J.,Wang Z. Multimodal imaging findings of SAPHO syndrome with no skin lesions: a report of three cases and review of the literature. Experimental and Therapeutic Medicine, (2016); 12(4), 2665-2670.

## EP-0921

### Isolated splenic metastasis from colon cancer

***S. Pacella***[1], *E. Farè*[2], *E. Collovà*[2], *L. Roncoroni*[2], *C. Migliorisi*[2], *A. Calcagno*[2], *M. Carletto*[2], *L. Maffioli*[3];
[1]*IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico, Milano, ITALY,* [2]*ASST Ovest Milanese-Ospedale Civile di Legnano, Legnano, ITALY,* [3]*ASST Sette Laghi, Varese, ITALY.*

***Aim/Introduction:*** Isolated splenic metastases from solid tumors occurs rarely, accounting for less than 1% of all metastases . Isolated solitary splenic metastasis from colorectal carcinoma is exceptional. ***Materials and Methods:*** In this case report we evidenced the importance of $^{18F}$FDG PET/CT in a woman with an isolated splenic lesion detected 7 months after right emicolectomy that it finally revealed to be a metastasis from colon cancer. ***Results:*** A 92-year-woman referred to our Nuclear Medicine Unit because she had an ultrasound suspected lesion of the spleen of unknown origin. 7 months before she underwent a right emicolectomy for a colon adenocarcinoma locally advanced with lymphangioinvasion and neuroinvasion (TNM stage pT4N0), without the expression of MLH1 and of PMS2, but with a BRAF mutation (V600E). So we decided to perform a $^{18F}$FDG PET/CT study in order to characterize this splenic lesion. $^{18F}$FDG PET/CT study showed focal intense area of FDG uptake in the spleen, with no other abnormal findings. After 2 months a splenectomy was performed and histopathologic examination confirmed the lesion as a metastasis from colon adenocarcinoma. ***Conclusion:*** $^{18F}$FDG PET/CT proved to be an important diagnostic tool for characterization of lesions and for early evaluation of treatment response to therapy in colorectal cancer. In this case report $^{18F}$FDG PET/CT guided to the best therapeutic option for this patient that was the surgical approach (splenectomy) in order to find out the nature of this splenic lesion. ***References:*** -Gilardi, Laura MD; Vadrucci, Manuela MD "Isolated

## EP-0922

### The role of 2-[18F]FDG-PET/CT in a rare case of Nasal Cavity Melanoma

***I. C. Ferreira***[1], *R. T. Ferreira*[1], *A. T. Xavier*[2], *S. Carmona*[1], *A. I. Santos*[1];
[1]*Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL,* [2]*Centro Hospitalar Barreiro Montijo, E.P.E., Barreiro, PORTUGAL.*

***Aim/Introduction:*** Malignant Melanoma of the nasal cavity mucosa (MMNCM) is extremely rare, has no established risk factors and is more aggressive than its cutaneous counterpart, with worse prognosis and overall survival. Due to its rarity and nonspecific symptoms, diagnosis and management can be difficult. PET/CT with 2-[$^{18}$F]FDG (FDG-PET/CT) has become important for the diagnosis, staging, and monitoring of various malignancies, including aggressive types of melanoma. We present a case of MMNCM in which FDG-PET/CT was used to detect tumour recurrence, and aided in assessing the extent of disease and guiding treatment decisions. ***Materials and Methods:*** A 69 year-old woman with a history of MMNCM, excised and submitted to local radiotherapy in other institutions with complete response, presented to our hospital two years later with complaints of unilateral epistaxis. Clinical examination was normal. An FDG-PET/CT scan was performed and showed intense focal radiotracer uptake in the posterior right nasal fossa, sphenoid sinus and several deep cervical lymph nodes, without distant metastasis. Ipilimumab was started. Due to clinical worsening with progressive bilateral amaurosis and headache, the patient was admitted to the hospital and underwent cranial CT and MRI scans. These demonstrated an expansive mass in the right nasal fossa causing bone destruction of the sphenoid, erosion of the posterior ethmoid plate and involvement of both optic channels. ***Results:*** Despite the inexistence of distant metastasis and given the complexity of the lesion's location with its ensuing difficulty of surgical approach, a multidisciplinary team was assembled and transnasaltranssphenoidal total macroscopic excision of the mass was performed, although with positive margins on histologic evaluation, confirming melanoma recurrence. Decompression of neurological structures was achieved, with immediate benefit on quality of life, namely vision improvement and headache control. Seven months later, disease progression was detected and the patient died. ***Conclusion:*** MMNCM is a rare entity with aggressive behaviour and overall poor prognosis, despite adequate local control. Local recurrence and distant metastasis are common. For early and localized tumours, first line treatment is surgery and eventually radiotherapy. Early detection and quality of resection with negative surgical margins are the most important prognostic factors, however, they remain challenging due to nonspecific symptoms and complexity of surrounding anatomical structures. As shown in this case FDG-PET/CT can be a valuable resource for the management of these patients, helping in early diagnosis of local recurrence and at the same time providing accurate whole-body staging, essential for successful therapeutic decisions.

## EP-0923

### A Rare Coexistence of Rectal Adenocarcinoma and Primary Squamous Cell Carcinoma of the Thyroid: Emphasizing the Importance of FDG PET/CT Whole-Body Imaging

***J. Yu***, *X. Cao, Y. Wang;*
*The Fifth Affiliated Hospital of Sun Yat-sen University Department of Nuclear Medicine, Zhuhai, CHINA.*

***Aim/Introduction:*** This case report aims to emphasize the importance of FDG PET/CT whole-body imaging in the early diagnosis and differentiation of a rare coexistence of rectal adenocarcinoma and primary squamous cell carcinoma of the thyroid (PSCCT). PSCCT accounts for less than 1% of all thyroid tumors and has an aggressive nature and poor prognosis. This case highlights the significance of comprehensive diagnostic tools in detecting and managing patients with such unusual tumor combinations. ***Materials and Methods:*** A 40-year-old male with a 6-month history of bloody stools underwent tumor marker tests, revealing a CEA level of 32.80 ng/mL. The patient then underwent 18F-FDG PET/CT imaging, which showed a thickened right intestinal wall at the rectosigmoid junction and an enlarged right thyroid lobe with a hypodense nodule, indicating the need for differentiation between thyroid adenoma and thyroid cancer. ***Results:*** Colonoscopy biopsy revealed tubular adenoma in the descending colon and adenocarcinoma 9cm from the anal verge. Fine-needle aspiration biopsy of the thyroid nodule indicated non-keratinizing squamous cell carcinoma. Immunohistochemical staining demonstrated cancer cells positive for CK-P, p40, CK5/6, p63, weakly positive for CK7, and negative for Tg, TTF-1, CK20, and Villin, confirming the rare co-occurrence of rectal adenocarcinoma and thyroid squamous cell carcinoma. ***Conclusion:*** This case report underscores the advantage of 18F-FDG PET/CT whole-body imaging in early tumor diagnosis and the importance of considering multiple primary malignancies in patients presenting with unusual tumor combinations. Comprehensive diagnostic approaches, including PET/CT imaging and immunohistochemical staining, are crucial for accurately identifying rare cases and guiding appropriate patient care.

## EP-0924

### Gallbladder visualization, a false positive finding on 99mTc-labeled red blood cell

***A. Leiva Montejo***, *A. De Agrela Serrao, D. Cáceres Silva, C. Ruiz Corbalán, T. Rodriguez Lorcano, J. Contreras Gutierrez, J. Navarro Fernández, L. Frutos Esteban, A. Hernandez Martinez, L. Mohamed Salem, M. Castellon Sánchez;*
*Hospital Virgen de la Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** 99mTc-labeled red blood cell (RBC) scan is a used nuclear medicine procedure that can detect gastrointestinal bleeding, which could be a common finding after an abdominal surgery. Gastrointestinal bleeding scintigraphy (GIBS) is performed in this patients to determine the exact anatomical location of bleeding. GIBS allow us a continuous monitoring of the gastrointestinal tract up to 24 hrs whether the suspicion persists. The importance of this study is based on performing sequential images that increases the possibility of detection of intermittent bleeding. ***Materials and Methods:*** A 38-year-old man, known case of type 1 diabetic with nephropathy underwent pancreatic transplantation in October 2022, followed by blood loss within 2 months. In December 2022, during a hemodialysis session, he presented an hypotension episode with a hemoglobin level of 5.6 mg/dl and received multiple blood transfusions. He urderwent

a surgical reintervention due to the suspicion of bleeding in the graft anastomosis. An abdominal CT with contrast was normal. As a result, the Transplant Committee decided to complete the study with a 99mTc-labeled RBC scan. ***Results:*** 99mTc-labeled RBC scintigraphy was performed, it consisted in a dynamic fase that didn't show alterations, but static images at 1 hr and 2 hr revealed an abnormal focal tracer uptake in the right hypochondrium. Single-photon emission computed tomography/ computed tomography (SPECT/CT) images of the abdomen at 2 hr determined the location of the radiotracer concentration which was the gallbladder. Imaging was continued until 24 hr, where this tracer uptake persisted, without any evidence about its displacement along the intestine. ***Conclusion:*** Gall bladder visualization during 99mTc-labeled RBC scan for occult gastrointestinal blood leak is a rare finding. Anemia, multiple blood transfusions and hemodyalisis could explained the uptake tracer in the gallbladder because of the bile labeling, originated by the breakdown of hemoglobin into bilirrubin. Labeled heme part is introduced to the biliary system because heme is the biochemical precursor of bilirrubin. In addition, another possible explanation is the prior multiple blood transfusions which accelerates the breakdown of theses RBCs with unusual concentration of labeled bilirrubin in the bile. Finally, SPECT-CT is an important image tool that provide better anatomical localization of tracer distribution, like in this case, where the 99mTc-labeled RBC showed an uptake in the right hypochondrial region that could have been taken wrong as a positive result for active bleeding, without the SPECT-CT.

## EP-0925

### 18F-FDG PET/CT identifying breast and pancreas metastases of Nasal Mucosal Melanoma

***A. Leiva Montejo***, *C. Ruiz Corbalán, A. De Agrela Serrao, D. Cáceres Silva, J. Contreras Gutierrez, T. Rodriguez Lorcano, J. Navarro Fernández, L. Frutos Esteban, A. Hernandez Martinez, L. Mohamed Salem, M. Castellon Sánchez;*
*Hospital Virgen de la Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** Mucosal melanoma is a rare variant of melanoma representing around 1% of total cases of melanoma diagnosed. Sinus melanomas represent only 20% of nasal mucosa melanomas but are aggressive with less 5-year survival compared to nonsinus type.18F-FDG PET/CT is a useful modality for regional and distant staging of high-risk melanoma at initial diagnosis. ***Materials and Methods:*** A 60-year-old woman presented with nasal respiratory failure and left periocular pain, of 2-month evolution and weight loss (15 kg) in June 2018. No epistaxis, no hyposmia, nor neurological focus. The neck was masses free. Nasal endoscopy revealed a friable and bleeding tumor in the left nostril that respected nasal cavity's floor. Magnetic resonance imaging (MRI) of face and sinuses revealed a lesion in the left nostril which occupied the frontal sinus until the middle turbinate, with fine peripheral contrast uptake. There was no apparent bone destruction. Biopsy from the mass was taken which revealed nasal mucosa melanoma with tumor cells positive for HMB-45 and Melan A, Ki 67 index 80%. ***Results:*** 18F-FDG PET/CT showed increased uptake in the left nostril (SUVmax 14.6) with probable ethmoid cells left anterior involvement (SUVmax 4.2). No other disease location was found. In June 2021, she felt a node in her right breast. Mammography and an ultrasound with biopsy of the lesion was taken which revealed compatible cells with malignant melanoma. After 2 months, other 18F-FDG PET/CT showed a new subcutaneous nodular formation adjacent to the right anterolateral 5th costal arch (SUVmax 17.8). Increased FDG uptake was located in pancreas (SUVmax 7.4), nonspecific, and further diagnostic imaging procedures were recommended in order to study it. The last 18F-FDG PET/CT was performed in December 2021 that showed pathological uptake of the radiotracer in pancreas (SUVmax 11.8) with more extension than previous study and with adjacent lymphadenopathies. The patient died after one year. ***Conclusion:*** Nuclear medicine imaging with 18F-FDG PET/CT could represent an important tool for the evaluation of malignant melanoma, especially in staging, restaging and assessing response to treatment. Besides, a precise delimitation of the tumor provided by 18F-FDG PET/CT is necessary since sinonasal melanoma definitive's treatment is surgical, but if it detects additional disease, surgery could be obviated. On the other hand, 18F-FDG PET/CT is less accurate in melanomas involving skull base and brain, where MRI is superior.

## EP-0926

### 99mTc-labelled heat-Damaged Red Blood Cell scintigraphy in the study of unspecific nodular foci on CT - a case report

***R. Silva***, *M. Silva, H. Martins, D. Leiro, A. Barbosa, L. Costa;*
*Centro Hospitalar Universitário de Santo António, Porto, PORTUGAL.*

***Aim/Introduction:*** Splenosis refers to implants of splenic tissue at any site of the body resulting from spillage of cells, usually after traumatic injury or surgery. The splenic tissue can implant on various organs, and form nodules. Splenosis can present as unspecific symptoms and mimic other conditions. Diagnosis can be challenging, but functional and anatomical imaging techniques, such as $^{99m}$Tc-labelled heat-Damaged Red Blood Cell(***$^{99m}$***Tc-DRBC) with Single Photon Emission Computed Tomography (SPECT) and Computed Tomography (CT) images can be valuable tools. ***Materials and Methods:*** Clinical diaries and diagnostic exams were reviewed in the hospital's informatic system. ***Results:*** A 51-year-old male patient was experiencing unspecific abdominal discomfort, early satiety, and 19.8% weight loss over 11 months. Past medical history was significant for multiple cardiovascular risk factors, and right-sided heart failure with signs of mild pulmonary hypertension in a previous echocardiography. He had a history of abdominal trauma that resulted in splenectomy, and a moderate restrictive lung disorder due to post-traumatic hemidiaphragm paralysis. An abdominal ultrasound showed moderate abdominal ascites, that was later characterized by an abdominal CT, showing hepatic congestion, massive ascites, and a heterogeneous aspect of the mesenteric fat in the anterior portion of the abdomen, with multiple nodular, unspecific foci, with no evidence of primary source of a tumor. A diagnostic hypothesis of peritoneal carcinomatosis was made. He was later electively admitted to a surgery ward to determine the site of possible primary cancer. Blood tests, a diagnostic paracentesis, upper endoscopy with biopsy, colonoscopy, head&neck CT, and a 2-[$^{18}$F]FDG PET/CT were negative for malignancy. A CT was again performed showing nodular foci on the abdomen, which maintained stable dimensions. Considering the history of abdominal trauma and surgery, the hypothesis of splenosis was considered. $^{99m}$Tc-DRBC were administered, and SPECT-CT images were acquired. The exam showed multiple foci with increased radiotracer uptake that corresponded to the morphological changes on CT, confirming the diagnosis. Further evaluation concluded that the ascites was due to decompensated right-sided heart failure due to venous pulmonary hypertension in the context of his restrictive lung disease. Pharmacological treatment was optimized. ***Conclusion:*** The case highlights the importance of considering splenosis in

the differential diagnosis of unspecific, nodular abdominal masses. Despite inconclusive results from various diagnostic tests, the use of 99mTc-DRBC SPECT-CT images was crucial for its non-invasive diagnosis. This underscores the value of combining functional and anatomical imaging techniques, playing a crucial role in the diagnosis of certain conditions.

## EP-0927

### Why Should We Look at the Thyroid Gland in Myocardial Perfusion Scintigraphy?

***B. Pereira***, *P. Soeiro, A. Fernandes, A. Oliveira;*
*Centro Hospitalar Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** Hyperthyroidism's effect on cardiac function is well known. [$^{99m}$Tc]Tc-Tetrofosmin (tetrofosmin) is a radiopharmaceutical frequently used for myocardial perfusion imaging (MPI), for assessing the location of parathyroid adenomas, and less commonly for evaluating amiodarone-induced thyrotoxicosis. ***Materials and Methods:*** A 59-year-old Caucasian male with several high-risk factors for cardiovascular disease (including diabetes mellitus, hypertension and dyslipidemia), underwent an MPI with tetrofosmin after having a myocardial infarction and being treated with a percutaneous coronary intervention of the right coronary artery. The patient's chronic medication included a β-blocker, an ACE inhibitor, a statin, and anti-platelet therapy. ***Results:*** MPI revealed a reversible perfusion defect on the anterior wall and apex and a partially reversible perfusion defect on the inferior wall (SSS - 5; SRS - 1; SDS - 4). Ejection fraction, cardiac volumes, transient ischemic dilation index and motility were normal. Additionally, the thyroid gland revealed intense and homogeneous uptake, which can be associated to an hyperfunctioning thyroid gland or with amiodarone-induced thyrotoxicosis. Previous amiodarone therapy was excluded and the patient was referred to the endocrinology department. Thyroid blood tests and a thyroid ultrasound revealed TRABs-positive hyperthyroidism, compatible with a Graves disease diagnosis. To control the disease, chronic anti-thyroid medication was started. ***Conclusion:*** Hyperthyroidism's impact on the heart is well known and, above all, patients with cardiovascular disease should have it controlled. A watchful eye on the thyroid on myocardial perfusion imaging can add vital information and improve the management of these patients. ***References:*** Elshimy G, Alsayed M, Targovnik J, Sidarous G, Milas KM. The Use of 99mTc-Methoxy-isobutyl-isonitrile (sestaMIBI) Uptake on Scintigraphy (99m-STS) in Amiodarone-Induced Thyrotoxicosis: Case Series and Review of the Literature. Case Rep Endocrinol. 2020 Aug 1;2020:2493460. doi: 10.1155/2020/2493460. PMID: 32832167; PMCID: PMC7421811.

## EP-0928

### Hyperparathyroidism Jaw Tumor Syndrome: A Case Report

***E. Gharehpapagh***, *S. Rezaei;*
*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** A 37-year-old female with complication of a large mass in her right mandible, which may have originated from the parathyroid gland. According to her CT scan, there was an expansible lesion in her mandible body, measuring 80x55 mm, extended to the lower ramus, resulting in the displacement of her inferior alveolar nerve canal to the superior and medial sides. Two possible diagnoses were considered: intraosseous atypical form of neurofibroma, and ossifying fibroma. ***Materials and Methods:*** Biopsy results of this mass showed a vascular myxoid spindle cell lesion, and it was recommended to repeat it due to the incompleteness of the biopsy sample. During the blood test on the patient, Ca=9.2, P=2.5, and PTH=629 were detected. A repeat test after an interval of eight days showed Ca=9.8, iPTH= 738, and VitD3=8. Testing results led to a request for parotid scanning by SPECT method using $^{99m}$Tc-MIBI. Following intravenous injection of 15 mci of the radiotracer, the patient's neck and mandible were scanned in planar and SPECT modes at 15 and 120 min intervals (early and delayed phases). ***Results:*** According to the parathyroid scan, the lower part of the Left thyroid's lobe showed focally increased uptake, which also retention of the radiotracer in delayed images. The right mandible mass also displayed irregular increased uptake with deformity. According to the scan findings, highly probability of parathyroid adenoma in the left lower lobe, as well as, expansible tumoral involvement in the right mandible with MIBI avid pattern was highly supposed. The probable final diagnosis was hyperparathyroidism jaw tumor syndrome. ***Conclusion:*** Afterward, the patient underwent parathyroidectomy and jaw mass resection. As a result of the pathology report, parathyroid carcinoma was diagnosed.

## EP-0929

### PET/CT [18F]FDG Findings in Post-COVID-19 Syndrome with Cognitive Sequelae: A Case Report

***L. Wichert-Ana***, *L. E. Lopes-Santos, D. L. Ferreira, A. C. Trevisan, L. Alexandre-Santos, M. P. Foss, M. Kato, F. B. Rodrigues, F. A. Pitella, O. Y. Fukumori, V. Tumas;*
*Ribeirão Preto Medical School - University of São Paulo, Ribeirao Preto, BRAZIL.*

***Aim/Introduction:*** The long COVID syndrome presents physical symptoms and neurocognitive damage when SARS-CoV-2 infection exceeds 12 weeks. Positron Emission Tomography/Computed Tomography (PET/CT) highlights metabolic changes associated with cognitive dysfunction in critically ill patients, mainly the older, in the post-COVID period. However, there are few studies on cerebral glucose metabolism in patients with cognitive complaints after mild COVID-19 without hospitalisation. This case report aims to describe the findings of [18F]FDG PET/CT and neuropsychological evaluation in a patient with persistent cognitive complaints after mild COVID-19. ***Materials and Methods:*** A female, white, 33-year-old patient without psychotropic drugs presented a positive Polymerase Chain Reaction (PCR) test for SARS-CoV-2. She had symptoms of ageusia, fatigue, intense sore throat, anosmia and myalgia. Two months after the acute phase, the patient reported frequent forgetfulness, difficulty concentrating, slow thinking and difficulty absorbing new information, both in the work and academic environment. Nine months after the onset of symptoms, she underwent a neurological PET/CT scan with 5mCi of [18F]FDG. ***Results:*** PET/CT demonstrated glycolytic hypermetabolism in the posterior cingulate gyrus (PCG) and hypometabolism in the bilateral anterior mesial temporal lobes. The neuropsychological evaluation showed average intellectual efficiency but indicated difficulty in cognitive control—the short-term recall of verbal content and significant impairment in auditory-verbal operational memory. Our findings agree with literature studies on brain regions involved in the performance of neuropsychological tests. GCP hypermetabolism is associated with greater deconcentration and impaired information processing during attentional tasks. In addition, the perisylvian areas of the dominant hemisphere are implicated in components of operational memory, especially the phonological loop, which plays an essential role in the maintenance and

operation of auditory-verbal content. ***Conclusion:*** The metabolic abnormality areas were compatible with the areas involved in the neuropsychological performance of the patient; therefore, the neurological PET/CT findings contributed significantly to the clinical management of the case.

## EP-0930

### A Rare Case of Bone Epithelioid Angiosarcoma In a Patient with History of Acute Myeloid Leukemia andSteroid-induced Osteonecrosis

***D. Bucur***, *F. Paycha;*
*Hopital Lariboisiere, Paris, FRANCE.*

***Aim/Introduction:*** Angiosarcoma of bone is a very rare malignant neoplasm in which the tumor cells exhibit endothelial differentiation, accounting for less than 1% of all primary bone sarcomas. Typically, it is observed in adults, with the highest incidence between 50 and 70 years of age, and it can affect any part of the skeleton, although the axial skeleton and long tubular bones of the extremities are most commonly involved. Epithelioid angiosarcoma is a rare variant that mimics poorly differentiated carcinoma through its epithelial appearance. ***Materials and Methods:*** A 70-years-old male presents with pain in the anterior part of the left thigh for about 3-4 months, progressively worsening, with functional impotence of the left lower limb and without notion of trauma, accompanied by weight loss (~4 kg). The patient has a medical history of Acute Myeloid Leukemia treated 20 years prior with an allogeneic bone marrow transplant, chemotherapy, corticosteroids, and immunosuppressants. It is notable that he did not receive radiotherapy. However, the patient experienced complications from the corticosteroid therapy, including multifocal osteo-medullary infarctions in several bones, involving the humeral heads, femoral heads (requiring bilateral total hip replacement treatment), diaphysis and distal metaphysis of the femurs. ***Results:*** Plain radiographs and a CT scan reveal centromedullary osteolysis of the lower diaphysis of the left femur, corresponding to a Lodwick II lytic bone lesion, destroying the cortical bone, with a moth-eaten aspect and a small spiculated periosteal reaction in its supero-dorsal portion. Two small soft tissue masses accompany the lesion in its antero-superior portion. A bone scan is performed with the SPECT CT configuration showing unique osteoblastic hyperactivity of the distal third of the left femoral diaphysis. FDG PET/CT is subsequently performed to characterize the lesion and assess the extra-osseous condition, revealing increased FDG uptake, particularly of the dissemination to the soft tissue (SUVmax of 43), without abnormal uptake otherwise. The patient undergoes ultrasound-guided biopsy and the diagnosis of epithelioid angiosarcoma is established. ***Conclusion:*** Although most primary malignant bone tumors develop de novo in normal bone, they can arise from pre-existing benign bone conditions or from iatrogenic causes such as chemotherapy. The association of bone infarct with an epithelioid angiosarcoma is very rare, the most common sarcomas being malignant fibrous histiocytoma, osteosarcoma, fibrosarcoma and mixed sarcomas. However, being very aggressive in nature, it should be included in the differential diagnosis, especially taking into account the context and the imaging aspect.

## EP-0931

### 18F-FDG PET-CT in Merkel cell carcinoma: case report

***A. Ciocan***[1], *L. Mititelu*[2,3], *C. Mazilu*[4], *T. Mititelu*[2,3], *A. Mazilu*[5], *D. Cuzino*[6], *M. Oancea*[6], *D. Zob*[7], *D. Costache*[8], *R. Mititelu*[2,4];
[1]*Oncologic Institute "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Dr Carol Davila", Bucharest, ROMANIA,* [3]*Institute of Military Medicine, Bucharest, ROMANIA,* [4]*Clinic of Nuclear Medicine, Central University Emergency Militari Hospital Bucharest, Bucharest, ROMANIA,* [5]*Clinic of Endocrinology, Central University Emergency Militari Hospital Bucharest, Bucharest, ROMANIA,* [6]*Clinic of Radiology, Central University Emergency Militari Hospital Bucharest, Bucharest, ROMANIA,* [7]*Oncologic Institute "Prof. Dr. Alexandru Trestioreanu", Oncology department, Bucharest, ROMANIA,* [8]*Clinic of Dermatology, Central University Emergency Militari Hospital Bucharest, Bucharest, ROMANIA.*

***Aim/Introduction:*** Merkel cell carcinoma (MCC) is a rare but highly aggressive skin cancer with neuroendocrine features that usually presents as a solitary cutaneous or subcutaneous nodule in the areas most exposed to the sun. Staging and degree of extension can be assessed by FDG PET CT, which provides valuable images and quantification tools. ***Materials and Methods:*** We present the case of an 89-year-old man who presented with a laterocervical tumor. The patient's personal pathologic history, biochemical values, and physical examination did not reveal any unusual features. The laterocervical tumor was excised and was found to be a lymph node with the histopathologic features of MCC. Positive immunohistochemical markers AE1/AE3, CK20, chromogranin, and neurofilament confirmed the diagnosis. The patient was then referred to FDG-PET-CT for staging, in part because the primary MCC lesion was not found on physical examination. ***Results:*** The PET-CT scan shown intense uptake of 18F-FDG in the lymph nodes in the left laterocervical region, mediastinum, and lung hilum with a SULmax of up to 15.81 (subcarinal); no other foci of pathologic uptake were detected in other organs. As far as we know, this is the first reported case of MCC that initially presented as carcinoma of unknown primary, with no evidence of the primary lesion and with later reccurence with distant disease. Usually, spontaneous regression of MCC has a good prognosis compared to other skin cancers, such as malignant melanoma. In 1986, the first case of spontaneous regression of MCC was described in the literature by O'Rourke and Bell. To date, less than 60 cases of spontaneous regression have been reported. Two cases have been published so far in which spontaneous regression was followed by recurrence, one distant at the level of the vertex, and one regional, with the primary tumor atypically located on the foot. Our case, as shown by histopathology and PET-CT, can be established as a spontaneous regression of an MCC that presented atypically as carcinoma unknown primary with distant metastatic recurrence. ***Conclusion:*** Even if the spontaneous regression in MCC is usually associated with a good prognosis, there can be situations, such as the case of our patient, that can be followed by distant recurrence. FDG PET CT can be a valuable tool for managing MCC patients and help identify the real extent of highly aggressive variants.

## EP-0932

### Pitfall in 68Ga PSMA PET/CT interpretation - Pathological Uptake in a Patient with Prostate Carcinoma and Pulmonary Tuberculosis

***S. Fares***[1], *I. Rogić*[2], *D. Huić*[2];
[1]*General Hospital Varazdin, Varazdin, CROATIA,*
[2]*University Hospital Centre Zagreb, Zagreb, CROATIA.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein found on the surface of prostate cells. It is typically overexpressed in prostate cancer cells but is also found in small amounts in other tissues such as kidneys,

liver and salivary glands. PSMA expression in non-prostatic lesions can be explained with increased PSMA expression in capillary endothelial cells in non-prostatic tissue (non-prostatic neoplasms, regenerative and inflammatory tissue). Another cause of PSMA uptake in non-prostatic lesions could be increased blood flow in hyperemia, usually present in inflammation. With increasing number of PSMA positron-emission tomography/computed tomography (PET/CT) scans performed in initial staging, biochemical recurrence of disease and in PSMA-targeted prostate cancer therapy it is important to point out a possible pitfall and a false positive finding on Ga-68 PSMA PET/CT scans. ***Results:*** A 74-year-old male patient with known prostate carcinoma (Gleason score 4+4=8, initial prostate-specific antigen - PSA 87.67 ng/mL) and biochemical recurrence of disease (PSA 5,65 ng/mL) was referred to our department in December of 2021 for Ga-68 PSMA PET/CT scan. Since diagnosis of prostate carcinoma in 2014 the patient underwent radical prostate radiotherapy, hormonal therapy and stereotactic ablative body radiotherapy (SABRT). PET/CT scan revealed pathological uptake of Ga-68 PSMA in a soft tissue node in the pelvis indicating prostate cancer metastasis but also revealed pathological uptake in several lesions in both lungs. The patient was referred to an oncologist and hormonal therapy was initiated, but he also underwent extensive pulmonary evaluation including fibreoptic bronchoscopy (FOB), endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA) and transthoracic puncture (TTP). In February of 2022 the patient was diagnosed with pulmonary tuberculosis after isolation of Mycobacterium tuberculosis in bronchoalveolar lavage culture. Combined anti-tuberculosis antibiotic therapy was applied for 6 months and a follow-up CT scan performed 3 months after the completion of antibiotic therapy showed significant regression of pulmonary infiltrates. ***Conclusion:*** Differentiating metastatic pathological PSMA uptake from a false positive finding is key to proper patient management and recognizing the variety of conditions with increased PSMA expression in non-prostatic tissue is necessary to improve specificity of PET/CT reports. With this case report we would like to point out a possible false positive finding in Ga-68 PSMA PET/CT scan and sensitize practitioners for active tuberculosis cases. ***References:*** 1. DA Silver, I Pellicer, WR Fair, WD Heston, C Cordon-Cardo. Prostate-specific membrane antigen expression in normal and malignant human tissues. Clin Cancer Res. 1997 Jan; 3(1):81-5.

## EP-0933

### Papillar Thyroid Carcinoma discovered on peritoneal carcinosis nodes : A case report of a 37-year-old woman

***A. Bauduer***, *M. Krim, A. Latge, S. Zerdoud;*
*Oncopole, Toulouse, FRANCE.*

***Aim/Introduction:*** Papillary thyroid carcinoma (PTC) is the most frequent histological type of thyroid cancer (90%), originating from follicular cells. Distant metastases from PTC are rare and usually occur in lungs or bones. Peritoneal carcinomatosis is defined as an advanced stage of abdominal neoplastic disease ; an extraabdominal primary cancer causing it is rare. A 2018 study interrogating the National Cancer Registry of Ireland identified 5791 patients diagnosed with peritoneal metastasis during the period 1994-2012. Of these, only 9% had an extra-abdominal primary malignancy. We report the case of a Papillar Thyroid Carcinoma discovered on peritoneal carcinomatosis, in which iodine therapy secondly reavealed bone metastasis. ***Materials and Methods:*** A 37-year-old woman in a context of endometriosis underwent a pelvic MRI showing latero-rectal and retro-uterine nodes. Surgical excision was performed and pathological analysis revealed nodes were not endometriosis but secondary lesions from a PTC. PET-CT with 18FDG imaging did not find any significant uptake neither in the thyroid nor in the ovaries and peritoneum. Total thyroidectomy was then performed; however, histological analysis did not find any primary thyroid cancer. 3700 Mbq of $^{131}$iodine were given to the patient. Thyroglobulin level was 71.48 ug/L after stimulation by rhTSH, with no anti-thyroglobulin antibody. The post-therapeutic SPECT/CT revealed mutiple bone uptakes suggestive of metastases. There was no other iodine fixation (nothing in the thyroid area or in the peritoneum). ***Results:*** Patient was seen 2 and 3 months after iodine therapy, thyroglobulin levels were respectively 2.4 ug/L with TSH 0.16 mUI/L and 0.58 ug/L with TSH 0.29 mUI/L, without anti-thyroglobulin antibody each time. Spine MRI confirmed bone metastasis in the vertebrae. Gynaecologic follow-up did not show any abnormality. Multidisciplinary consultation meeting decided to go for 2 new treatments by 5550 Mbq of radioiodine under hormone withdrawal, respectively 6 months and 1 year after the first iratherapy. ***Conclusion:*** This case report kills two birds with one stone : it presents an unusual discovery mode of thyroid carcinoma, and highlights the importance of the iodine in the treatment and staging of these cancers. The originality of our presentation is also the absence of primitive tumour in the thyroid. One hypothesis could be a stroma ovarii but the lack of iodine uptake in the ovaries, the normality of the pelvic MRI and the rarety of these tumours do not strenghten this assumption. ***References:*** M. Flanagan and al. Peritoneal metastases from extra-abdominal cancer - A population-based study. EJSO 2018;44;1811-1817.

## EP-0934

### Recurrent Pituitary Adenoma ACTH-Secretant Detected Using 99mTc-EDDA/HYNIC-TOC - A Case Report

***A. Bajenaru***[1], *C. Mazilu*[2], *M. Mititelu*[2,3];
[1]*Nuclear Medicine Departament, Oncology Institute „Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*Clinic of Nuclear Medicine, Central Emergency Military University Hospital "Dr. Carol Davila", Bucharest, ROMANIA,* [3]*University of Medicine and Pharmacy "Dr. Carol Davila", Bucharest, ROMANIA.*

***Aim/Introduction:*** Recently, 99mTc-labeled peptides have emerged as an option for scintigraphic imaging of neuroendocrine tumors in clinical practice. They have advantages over 111In-pentetreotide, including better image quality on gamma cameras and lower radiation exposure to patients, thus allowing higher doses of radiotracer. ***Materials and Methods:*** We present the case of a 54-year-old woman with a history of HBV infection, obesity, and hypertension. After an endocrinological examination, she was diagnosed with Cushing's syndrome following clinical symptoms and features of hypercortisolism. An IRM examination confirmed the presence of a pituitary adenoma (PA), which was likely responsible for the patient's symptoms. Therefore, she underwent transsphenoidal neurosurgery, and it was confirmed histopathologically to be an ACTH-secreting PA. An increase in ACTH levels 6 months later prompted another IRM examination, which revealed a residual tissue that extended to the cavernous sinus and retrosellar on the right side. The subsequent indication was to perform somatostatin receptor scintigraphy. We performed whole-body and SPECT-CT acquisition after intravenous administration of 740 MBq of 99mTc-EDDA/HYNIC-TOC. SPECT-CT showed residual activity in the sella corresponding to the residual PA detected by IRM; the scan also showed diffuse uptake in the adrenal glands, possibly due to prolonged exposure to high levels of ACTH secretion. ***Results:*** Most neuroendocrine tumors express somatostatin receptors, so they can be visualized by scintigraphy

after intravenous injection of a radiolabeled somatostatin analog. The sensitivity of 99mTc-EDDA/HYNIC-TOC in detecting PA has been reported to be as high as 90.91%. We were able to confirm radiotracer uptake in our patient's residual PA tissue, demonstrating the existence of SSTR at this level. Furthermore, we did not find any other abnormal uptake in the rest of the body, so we ruled out the possibility of ectopic ACTH secretion. Although some previous studies state that ACTH-secreting PA's do not express somatostatin receptors, other studies show their presence in these tumors, and our case confirms their findings. ***Conclusion:*** 99mTc-EDDA/HYNIC-TOC can be used in investigations of well-differentiated PA for assessing the uptake in the sellar region as well as to exclude an ectopic lesion.

## EP-0935

### Two examples of how 18F-FES-PET may assist oncologists in clinical dilemmas in breast cancer patients

***S. Nogueira***, *F. A. B. Da luz, V. Iacone, A. M. S. Petinatti, S. C. Lima, A. Osawa, L. Y. I. Yamaga;*
*Hospital Israelita Albert Einstein, São Paulo, BRAZIL.*

***Aim/Introduction:*** The radiotracer 16-18F-fluoro-17-estradiol ($^{18}$F-FES), which is selective for detecting tumors positive for estrogen receptors (ER), is crucial for monitoring and choosing patients with breast cancer who are eligible for hormone therapy. This report highlights two cases in which $^{18}$F-FES-PET was essential for selecting the best therapy. ***Materials and Methods:*** Case 1: An 81-year-old patient with a left breast mastectomy. In 2022, she underwent a CT scan that identified multiple pulmonary nodules, probably secondary to the underlying disease. After this result, the patient underwent a mammography, ultrasound, and magnetic resonance (MRI) imaging, identifying a nodule in the right breast, Birads 5. Breast and bone scintigraphy exams confirmed the nodule in the right breast and indicated a low probability of bone involvement. The core biopsy anatomopathological evaluation identified the lesion as invasive ductal carcinoma of the right breast, CA 125, 49.78 U/ml. The patient was referred for $^{18}$F-FES-PET/CT to verify if the pulmonary nodules were metastases from ductal carcinoma. The PET/CT images showed a slight increase in radiotracer uptake in the right breast, indicating the presence of ER, but the pulmonary nodules were ER-negative. These finds may suggest a neoplastic lesion of another nature, indicating the need for a change in treatment. ***Results:*** Case 2: Patient 66 years old, with right mastectomy and lymph node dissection in 2003 due to an "in-situ" carcinoma, Human epidermal growth factor receptor-2 (HER2) positive, Ki67 18%, treated with Tamoxifen. In 2021, a control mammogram identified a new nodule in the left breast, Birads 3; in 2022, the ultrasound showed the presence of enlarged axillary lymph nodes (Birads 6); a core-biopsy classified the nodule as multifocal lobular invasive carcinoma, HER2 negative, KI67 30%. After it, she performed a left mastectomy with lymph node dissection. Post-surgical MRI and $^{18}$F-FDG-PET/CT revealed suspected metastasis areas and a slight increase in glucose metabolism strictly in the left breast with unspecific bone tracer uptake. Considering the high risk for systemic disease, the oncologist prescribed an $^{18}$F-FES-PET/MRI, which confirmed the multiple lesions throughout the body. For this result, letrozole and ribociclib were chosen to treat the patient. In PET/MRI performed seven months after the treatment introduction, the $^{18}$F-FES uptake was significantly reduced. ***Conclusion:*** In these reports, it was feasible to demonstrate cases in which the positive or negative result of $^{18}$F-FES in PET/CT or PET/MR might assist the physician in solving clinical dilemmas, allowing for improved therapy targeting.

## EP-0936

### A rare case of bilateral seminal vesicle metastasis in carcinoid tumor of caecum

***A. Kumar***[1], *G. Gunasekaran*[1], *N. Pandit*[2];
[1]*JIPMER, Puducherry, INDIA,* [2]*JIPMER, Pondicherry, INDIA.*

***Aim/Introduction:*** Neuroendocrine tumors (NET) are a rare variegated group of neoplasm that derives their origin from neural crest cells with an incidence of about 4 in 100,000 people. Rare sites of metastasis include the heart, breast, retro-orbital, uterus, skin, brain, spleen, testes, and seminal vesicles. Well-differentiated NETs express Somatostatin receptors (SSTR) and they can be imaged using radiotracers labeled with somatostatin agonists like 68Ga-DOTATOC. Patients showing good SSTR expression can be treated with a novel treatment modality called peptide receptor radionuclide therapy (PRRT) using 177Lu-DOTATATE, the localization of which can be imaged using a gamma camera. ***Materials and Methods:*** We are reporting an interesting case of a 35 years old gentleman with two children, who has been diagnosed with a well-differentiated neuroendocrine tumor of the caecum with multiple metastases to the liver 8 years ago. He underwent a right hemicolectomy with wedge resection of the liver lesion in September 2013. Postoperative Histopathological examination of the specimen revealed a carcinoid tumor of the caecum with a metastatic lesion to the liver. He then underwent transarterial chemoembolization of the left hepatic artery in November 2013 followed by a left lobectomy of the liver in May 2014. The patient lost follow-up following surgery. He then presented with exertional dyspnea in November 2017. On evaluation, he was diagnosed with carcinoid heart syndrome. He was managed symptomatically for the past 3 years. He was then referred to our department for PRRT. He underwent both 18F-FDG PET/CT and 68Ga-DOTATOC PET/CT as a part of the pre-therapeutic evaluation. 68Ga-DOTATOC PET showed increased SSTR expression in the multiple liver lesions and bilateral seminal vesicles. He underwent PRRT with 177Lu-DOTATATE. Post therapy scan following 177Lutetium DOTATATE therapy revealed the same findings as that of 68Ga-DOTATATE PET confirming the seminal vesicle metastasis. ***Results:*** Not applicable ***Conclusion:*** So far in literature, only a single case of unilateral seminal vesicle metastasis is reported in neuroendocrine tumours. The case reported by us is the first case of bilateral seminal vesicle metastasis in literature. We should actively screen the pelvic region for seminal vesicle lesions in neuroendocrine tumours as it may be misinterpreted as nodal metastasis. ***References:*** Carreras C, Kulkarni HR, Baum RP. Rare metastases detected by (68)Ga-somatostatin receptor PET/CT in patients with neuroendocrine tumors. Recent Results Cancer Res. 2013;194:379-84. PMID: 22918770.

## EP-0937

### Different Pattern of Brain Metabolic Changes on 18F-FDG Brain PET in a Patient with Fronto-Temporal Lobar Degeneration: Case Report

***A. Bajenaru***[1], *L. Mititelu*[2,3], *C. Mazilu*[4], *D. Cuzino*[5,3], *C. Sirbu*[6,3], *M. Mititelu*[4,3];
[1]*Nuclear Medicine Departament, Oncology Institute „Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*Institute of Military Medicine, Bucharest, ROMANIA,* [3]*University of Medicine and Pharmacy "Dr. Carol Davila", Bucharest, ROMANIA,* [4]*Clinic of Nuclear Medicine, Central Emergency Military University Hospital "Dr. Carol Davila", Bucharest, ROMANIA,* [5]*Clinic of Radiology, Central Emergency Military University Hospital "Dr. Carol Davila", Bucharest, ROMANIA,* [6]*Clinic of Neurology, Central Emergency Military University Hospital "Dr. Carol Davila", Bucharest, ROMANIA.*

***Aim/Introduction:*** Fronto-temporal lobar degeneration (FTLD) is a heterogenous syndrome associated with the degeneration of the frontal and anterior temporal lobes, being responsible for 5% of all cases of dementia based on autopsy studies. The condition is usually underdiagnosed. ***Materials and Methods:*** We present the case of a 55-year-old patient suffering from severe cognitive impairment with delirium that occurred in 2020 in a context of negative emotional stress. The cognitive decline was progressive, consistent with a possible frontal lobe disorder manifested by abulia, dromomania, apraxia, disinhibition, pregnancy ideation, impoverished speech, decreased appetite, decreased self-care, sleep disturbances and sphincter incontinence, without sensorimotor or coordination deficits. An electroencephalogram showed brief, sharp and non-sustained discharges of slow waves, particularly in the left temporal region. A subsequent MRI scan showed brain atrophy without signal abnormalities in the brain parenchyma. We performed cerebral PET/CT with 18F-FDG. We used CortexID Suite software to assess regional cerebral metabolism compared to a normal database. Z-scores below -2 were considered pathologic. ***Results:*** Brain PET revealed hypometabolic changes in the lateral and medial prefrontal cortical areas and in the anterior cingulate cortex, bilaterally. We also found increased metabolic activity in the temporal and parietal cortex (especially on the right side) and in the occipital area. In most cases, patients with FTLD are characterized by hypometabolism occurring mainly in the frontal, anterior temporal, and anterior cingulate cortex, which is helpful in the differential diagnosis with Alzheimer's disease (AD). Interestingly, we also found brain areas with hypermetabolic activity in our patient. Although the presence of hypometabolism in FTLD is well documented, hypermetabolic areas are mentioned in only a small number of studies. The presence of hypermetabolic areas is atypical of dementia but has been previously documented in FTLD in association with mutations of the C9orf72 gene. Some studies also suggest that neurodegenerative diseases may in some cases show hypermetabolism in the temporal lobes and hyperactivation on fMRI scans and predict a worse prognosis. ***Conclusion:*** PET/CT with 18F-FDG is a useful investigation to evaluate brain metabolism and determine both hypo- and hypermetabolic areas in the brain responsible for a variety of behavioral changes, as well as to differentiate between AD and FTLD. Although no treatment is available for FTLD, differential diagnosis with AD is important because of differences in treatment management; cholinesterase inhibitors should be avoided because of exacerbation of symptoms.

## EP-0938

### Diagnosis of Erdheim-Chester disease by bone scintigraphy

***A. Doumas***[1], *D. Boundas*[2], *P. Exadaktylou*[1], *E. Giannoula*[1], *A. Tsangaridi*[1], *G. Gerasimou*[1], *E. Papanastasiou*[1], *I. Iakovou*[1];
[1]*Aristotle University, Thessaloniki, GREECE,* [2]*Private Nuclear Medicine Centre, Ippokratis, Thessaloniki, GREECE.*

***Aim/Introduction:*** Erdheim-Chester disease (ECD) is a rare histiocytosis, with less than 1500 cases reported worldwide. Recently, it has been identified as a neoplastic disorder due to the discovery of MAPK mutations (RAS-RAF-MEK-ERK). The typical findings of ECD include central diabetes insipidus, renal fibrosis, and sclerotic bone lesions. However, histopathological diagnosis can be challenging due to non-specific inflammatory and fibrotic findings in tissue samples. Most patients with ECD require treatment, except for a small minority with minimally symptomatic single-organ disease. The first guidelines for ECD were published in 2014. Given recent molecular discoveries and the approval of the first targeted monoclonal antibody (vemurafenib) therapy for BRAF-V600-mutated ECD, it is essential to inform nuclear physicians about this disease which presents a characteristic scintigraphic and radiological picture. ***Materials and Methods:*** We present the case of a 54-year-old woman, referred to her orthopedic, complaining of persistent, deep pain in the knee joints. Initially treated with non-steroidal anti-inflammatory drugs for suspected degenerative arthropathy, she was later found to have symmetrical sclerotic lesions in the epiphyses of the tibia and femur on x-ray. Bone scintigraphy demonstrated the typical picture of ECD. The patient was diagnosed with BRAF-V600 mutation in an Academic hospital, which is the hallmark of ECD disease ***Conclusion:*** Although a case of possible ECD has already been described in the Greek literature, we announce this patient's case for the vigilance of nuclear physicians regarding a rare disease, with a characteristic scintigraphic image that can safely establish the diagnosis.

## EP-0939

### Radiation-Associated Angiosarcoma After Breast Cancer detected on [18F]FDG PET/CT

***M. Pudis***[1], *J. Suils-Ramón*[1], *I. Blazquez-Muñoz*[2], *F. X. Sanjuan-Garriga*[2], *A. Palomar-Muñoz*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [2]*Anatomical Pathology Department, Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** Radiation-induced angiosarcomas (RIAS) of the breast are rare but serious complications of radiation therapy. Angiosarcomas are aggressive malignant tumors that develop from the endothelial cells lining blood vessels. They can occur spontaneously or as a result of exposure to ionizing radiation. RIAS of the breast typically occur years after radiation therapy for breast cancer. They can present as a breast mass, skin changes, or both. The diagnosis is often challenging, and biopsy is required for confirmation. ***Materials and Methods:*** A 73-years-old woman diagnosed with breast cancer in her 50's, treated with neoadjuvant chemotherapy, lumpectomy with axillary lymph node dissection (ALND). Pathology revealed infiltrating ductal carcinoma ypT1a ypN1/15 (AJCC 8th ed). According to the protocol, local radiotherapy was performed and the patient has been treated with letrozole ever since. In successive controls, the patient detected a small lump in the irradiated breast. On physical examination, she presented significant induration in the left breast with purpuric areas (Figure A). An [18F]FDG PET/CT showed an FDG avid heterogenous fibrosis (arrows) and nodules (circles) in the subcutaneous adipose tissue of the previously irradiated breast (Figure B), suggestive of RIAS. ***Results:*** Biopsy findings revealed characteristic histological features of angiosarcoma (irregularly shaped blood vessels with atypical endothelial cells and areas of hemorrhage and necrosis), as well as immunohistochemical markers (CD31, CD34, ERG, and c-myc) that confirmed the diagnosis (Figure C). The treatment involved mastectomy, removing the cancerous tissue, followed by radiation therapy and chemotherapy. ***Conclusion:*** It is important for breast cancer survivors who have undergone radiation therapy to be aware of the risk of radiation-associated angiosarcoma and to monitor their breast health regularly. This may involve self-examinations, regular check-ups with a doctor, and breast imaging studies, such as mammography or ultrasound. ***References:***

PMID: 30369653; PMCID: PMC6198847.

## EP-0940

### A rare manifestation of multiple solitary extramedullary plasmacytomas

***M. Dobrenic***[1,2], *J. Batinic*[1];
[1]*Clinical Hospital Centre Zagreb, Zagreb, CROATIA,* [2]*School of Medicine University of Zagreb, Zagreb, CROATIA.*

***Aim/Introduction:*** Extramedullary plasmacytomas are an uncommon type of monoclonal plasma cell tumours that arise outside the bone marrow, usually involving soft tissues in the head and neck region. Multiple solitary extramedullary plasmacytomas are characterised by multiple soft tissue lesions. They differ from multiple myeloma by the lack of systematic abnormalities typical of multiple myeloma (hypercalcaemia, anaemia, renal insuficiency). Very rarely, extramedullary plasmacytoma can involve trachea, causing significant respiratory distress. ***Materials and Methods:*** Case presentation:We herain report a rare presentation of multiple solitary extramedullary plasmacytomas in a 49 year old male patient who sufffered from acute chest pain and dyspnea. A chest X ray showed a whole left lung atelectasis, while a high resolution CT scan of thorax region revealed endoluminal soft tissue mass obstructing left main bronchus, with associated mediastinal precarinal and subcarinal soft tissue lesions. During bronhoscopy, additional soft tissue lesions in oropharynx and larynx were found. Diagnosis of extramedullary plasmacytomas was established following the biopsies of the oropharyngeal and left main bronchus lesions. To evaluate the extent of disease, whole body 18F FDG PET CT was performed, and intense 18F FDG uptake in soft tissue lesions in oropharynx, larynx, mediastinum, and left main bronchus was found. ***Conclusion:*** Ability of 18F FDG PET CT to distinguish between metabolically active and inactive lesions makes it a preferred functional imaging modality for staging of monoclonal plasma cell disorders. Furthermore, the importance of accurate staging of the disease lies with the potential of the plasmacytomas to progress to multiple myeloma.

## EP-0941

### PRRT for symptomatic paragangliomas and bilateral pheochromocytomas in an adult patient with a cyanotic heart condition

***C. Burger***[1], *T. Moalosi*[1], *M. Mix*[2], *M. Conradie*[1];
[1]*Stellenbosch University and Tygerberg Hospital, Cape Town, SOUTH AFRICA,* [2]*Medical Center – University of Freiburg, Freiburg, GERMANY.*

***Aim/Introduction:*** A 46-year-old female with an unrepaired tetralogy of Fallot (TOF), was incidentally diagnosed with bilateral pheochromocytomas and multicentric extra-adrenal paragangliomas during cardiac assessment. She was centrally cyanosed (but comfortable at rest), clubbed and polycythaemic and reported episodes of flushing, palpitations, sweating and headaches. Blood pressures were fluctuating with episodes of hypertension. Raised urinary normetanephrines [24 743 nmol/24hrs (normal range 650-2462)] and metanephrines [928 nmol/24hrs (normal range 152-913)] confirmed functionality of the tumours. Genetic tests did not identify a significant associated variant. She was not considered a surgical candidate for the repair of the TOF or for adrenalectomy. ***Materials and Methods:*** Iodine-123 Metaiodobenzylguanidine ([$^{123}$I]I-MIBG) scintigraphy, Fluorine-18 Fluorodihydroxyphenylalanine ([$^{18}$F]F-DOPA) Positron emission tomography with computed tomography (PET/CT) and Gallium-68 [DOTA0,Tyr3]-octreotide ([$^{68}$Ga]Ga-DOTANOC) PET/CT were performed. Bilateral pheochromocytomas, four cervical paragangliomas and an aortocaval paraganglioma were identified. Discordant uptake was seen between the different radiopharmaceuticals. The measured glomerular filtration rate (GFR) corrected for body surface area was 56 ml/min/1.73m$^2$. Normal left ventricular systolic function was documented with cardiac echocardiography. A multidisciplinary team discussion identified Peptide Receptor Radionuclide Therapy (PRRT) with Lutetium-177 [DOTA0,Tyr3]-octreotate ([$^{177}$Lu]Lu-DOTA-TATE) as the most suitable treatment modality. [$^{131}$I]I-MIBG therapy was deemed impractical due to the need for continuous monitoring in a high care facility. Three cycles of [$^{177}$Lu]Lu-DOTA-TATE were administered, over a period of 7 months. ***Results:*** Chronic hypoxia activates hypoxia inducible factors responsible for development of the multiple paragangliomas and bilateral pheochromocytomas in this patient.[1] As the underlying cause cannot be eliminated, the therapeutic intent was palliation and symptom/blood pressure control by reducing tumor burden and functionality. Blood pressure fluctuated during and immediately after therapy and invasive (arterial) blood pressure monitoring proved essential to improve control. Slow pretreatment hydration, careful titration of alpha blockade while avoiding beta blockade (due to cardiac capacity concerns) and adjusted rate of the amino acid and [$^{177}$Lu] Lu-DOTA-TATE infusions were required. No haematological or renal toxicity two months after the last therapy were noted. Symptoms, general well-being and exercise tolerance improved. Lowering of metanephrine and normetanephrine values were documented. Further treatment with PRRT may be considered. Voxel-based dosimetry results will be presented. ***Conclusion:*** PRRT is possible and may be beneficial in patients with cyanotic heart disease and multiple paragangliomas and pheochromocytomas, but special attention needs to be paid to blood pressure control during and after therapy. ***References: 1*** Wcislak SM et al. Multifocal pheochromocytoma-paraganglioma in a 29-year-old woman with cyanotic congenital heart disease. Surgery. 2019 Jan;165(1):228-231.

## EP-0942

### Nodal Migration of ruptured implant contents detected on [18F]FDG-PET/CT

***M. Pudis***, *J. Suils-Ramón, A. Palomar-Muñoz, V. Carrero-Vasquez, C. Martínez-Ramos, S. Bondia-Bescós, B. Hervás-Sanz, J. Diaz-Moreno, M. Cortés-Romera;*
*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** Extracapsular breast implant rupture refers to a situation where the contents of a breast implant leak out of the fibrous capsule that forms around the implant and migrate outside the breast tissue. This can occur due to a number of reasons, including trauma, normal wear and tear of the implant, or a defect in the implant itself. When the contents of an extracapsular ruptured implant migrate outside the breast tissue, they can potentially enter the lymphatic system and migrate to the lymph nodes. This is referred to as nodal migration of implant contents. ***Materials and Methods:*** A 44-year-old woman with a history of bilateral breast cancer at ages 27 and 35 treated with mastectomy, selective sentinel node biopsy, and reconstruction with breast implants. The genetic study detected the c.291delA mutation of the BRCA2 gene and prophylactic bilateral adnexectomy was

performed at 40 years of age. During clinical follow-up, the patient reported pain in the left sternal region, adjacent to the treated breast. [18F]FDG PET/CT was requested to rule out locoregional recurrence or distant metastasis. ***Results:*** A maximum intensity projection of [18F]FDG PET (Figure 1a) shows heterogeneous FDG uptake around the left breast implant. An axial plane of CT and PET/CT (Figure 1b) shows signs of extracapsular breast implant rupture with an enlarged FDG avid internal mammary lymph node, related to nodal migration of implant contents. ***Conclusion:*** Nodal migration of implant contents can cause a number of health concerns, including inflammation, pain, and infection in the lymph nodes. In some cases, the migrated contents may also interfere with the accuracy of breast cancer screening tests such as mammograms and ultrasounds. PET/CT imaging can be a valuable tool in detecting and evaluating the extent of extracapsular breast implant rupture. ***References:*** Khakbaz E, Lang C, Lelkaitis G, Grønhøj C. Late migration of silicon as a complication to breast transplant rupture: Case report and literature review. Int J Surg Case Rep. 2021 Aug;85:106241. doi: 10.1016/j.ijscr.2021.106241. Epub 2021 Jul 27. PMID: 34333256; PMCID: PMC8346674.

## EP-0943

### Tumoral thrombosis of the inferior vena cava in a patient with multiple-relapsed adrenal cortical carcinoma

***A. Mitoi***[1], *C. Mazilu*[1], *M. Oancea*[1], *M. Alexa*[1], *S. Serbanescu*[1], *A. Militaru*[1], *D. Craciun*[1], *A. Zaharia*[1], *M. Matei*[1], *R. Mititelu*[2,1]; [1]*Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

***Aim/Introduction:*** Adrenal cortical carcinoma (ACC) is a rare and highly aggressive malignancy, with a very poor prognosis, that affects mostly females. ACC can extend in the inferior vena cava (IVC) to form a tumor thrombus. Due to its aggressiveness, ACC usually express high proliferation rate, being therefore suitable for follow up with 18F-FDG PET/CT in the follow-up of ACC patients. ***Materials and Methods:*** We present a unique case of a 67-year-old female who underwent right adrenalectomy for ACC, received adjuvant mitotane therapy, and experienced multiple recurrences over a 10-year period, with the latest recurrence involving invasion of the IVC. In March 2022, MRI demonstrated a gadolinium enhanced lesion located behind the retro-hepatic segment of the IVC and expansion to the IVC. In January 2023, a CT showed the same lesion described on MRI, with dimensional growth and with invasion of IVC. The PET/CT scan performed in March 2023 showed low distribution of 18F-FDG in the hepatic right lobe and a lesion near the right crus of the diaphragm with high metabolic activity, without clear demarcation from the hepatic parenchyma, and with invasion of IVC, the lesion extended from the renal veins level to the diaphragm. ***Results:*** Most of the ACC are nonfunctional and they tend to manifest late during the course of disease. ACC are frequently found incidentally and are often unresectable due to of the extent of the tumor. There are several studies showing that patients with recurrent disease have a poor prognosis, with estimated 5-year survival of 15% and overall survival to about 14 months. PET/CT can make the difference between a benign and malignant tumor thrombus because the tumor thrombus has an intense uptake of 18F-FDG as a result of its hypervascularity and high metabolic neoplastic activity with a cut-off value of 3.63.[1] Previous studies have shown that PET/CT has superior diagnostic accuracy compared to CT for initial staging and restaging of ACC patients. ***Conclusion:*** To our knowledge, this is the first case report of a multiple relapsed ACC, with the last recurrence showing tumor invasion of IVC and PET/CT scans for 10 years. We suggest that FDG PET/CT becomes part of the post-operative follow-up protocol of ACC patients due to the high diagnostic ability of recurrence and metastasis prior to conventional imaging techniques. ***References:*** 1 Sharma P, Kumar R, Jeph S, et al. 18F-FDG PET-CT in the diagnosis of tumor thrombus. Nucl Med Commun. 2011;32(9):782-788. doi:10.1097/MNM.0b013e32834774c8

## EP-0944

### Aneurysmal Bone Cyst in a patient with McCune-Albright Syndrome

***N. Aydin****, G. Mütevelizade, G. Gümüşer, E. Sayıt Bilgin; Celal Bayar University, Manisa, TÜRKIYE.*

***Aim/Introduction:*** Fibrous dysplasia of bone (FD) is a rare bone disease that causes pain, fracture and deformity in the bone. This disease shows a wide spectrum from benign monostotic FD to FD-associated McCune-Albright Syndrome (MAS). McCune-Albright Syndrome (MAS) is characterized by the triad of fibrous dysplasia, cafe´-au-lait spots and precocious puberty, but other endocrinopathies may also be present. ***Materials and Methods:*** A 12-year-old girl who was followed up with the diagnosis of McCune-Albright Syndrome was admitted to our hospital with a painless swelling of 4x3 cm in the frontal region 10 days after her history of sinusitis. In the MRI imaging, lesions with an expanded appearance in the cranial bones, hypointensity in T1 and T2 sequences and heterogeneous contrast brightening were observed. In addition, in the left part of the frontal bone, the T2 signal was high and the T1 signal was isointense cystic lesion, measuring 50x50 mm in size, showing peripheral contrast brightening was evaluated in favor of aneurysmal bone cyst. Increased blood flow and hyperemia in the left femur in 3-phase bone scintigraphy performed by selecting the femur area of interest in order to determine the extent of bone lesions; In the late static images, intense increased Tc-99m methylene diphosphonate (MDP) uptake was observed in the left femur, left tibia, posterior parts of the left 9th and 11th ribs and cranial bones. In the left part of the frontal bone, a well-circumscribed photopenic area was detected in the localization, which was evaluated as an aneurysmal bone cyst on MRI. After pre-operative endovascular embolization, the lesion in the frontal bone was surgically excised. ***Results:*** Secondary aneurysmal bone cysts may develop in the ribs and craniofacial bones due to bone enlargement. Aneurysmal bone cyst formation is common in areas of fibrous dysplasia due to the increased vascularity of the lesion, and these enlarged cysts can rapidly lead to intracranial symptoms. Bone scintigraphy is used to determine the extent of the disease. ***Conclusion:*** Bone scintigraphy is used to determine the extent of the disease. Paget's disease, which may be characterized by similar scintigraphic findings, should be considered in the differential diagnosis; findings should be evaluated together with radiological imaging methods, clinical and laboratory results. ***References:*** Sundaram, Murali. Imaging of Paget's disease and fibrous dysplasia of bone. Journal of Bone and Mineral Research, (2007), 22 (SUPPL. 2).

## EP-0945

### Disseminated infection complicating acupuncture revealed by Gallium-67 scintigraphy

***T. Chow***;
*Tuen Mun Hospital, Hong Kong, HONG KONG.*

***Aim/Introduction:*** Acupuncture is a traditional Chinese medicine treatment by inserting needles in the body for therapeutic purposes. It is generally considered to be safe and major complications are uncommon. Previous systemic review based on published case reports revealed that the main complication of acupuncture was injury of internal organ, tissue or nerve (63%)[1]. Acupuncture infection was uncommon (9%), and most cases were due to tetanus[1]. This is a rare case showing disseminated methicillin-sensitive staphylococcus aureus (MSSA) septic foci after acupuncture revealed by Gallium-67 (Ga-67) scintigraphy. ***Materials and Methods:*** A 20-year-old woman with chronic back pain and otherwise good past health had acupuncture at the back and thighs. One week later, she presented with fever and worsening low back pain and soon developed septic shock requiring admission to intensive care unit. Blood culture showed growth of MSSA. ***Results:*** Contrast CT demonstrated multiple small consolidation scattered in both lungs with basal predominance and patchy hypoenhancement in bilateral kidneys, suggestive of septic pulmonary emboli and pyelonephritis respectively. Ga-67 scintigraphy was also arranged to delineate the extent of infection. Whole body planar images demonstrated numerous septic foci in the pelvis and four limbs. Fused transaxial SPECT/CT images further revealed septic arthritis of right sacroiliac joint and multiple intramuscular septic foci. Echocardiogram showed no evidence of vegetation. The patient received a prolonged 6-week course of antibiotics and recovered uneventfully. ***Conclusion:*** Disseminated MSSA infection complicating acupuncture revealed by Ga-67 scintigraphy was extremely rare. ***References:*** 1. Wu J, Hu Y, Zhu Y, et al. Systematic Review of Adverse Effects: A Further Step towards Modernization of Acupuncture in China. Evid Based Complement Alternat Med. 2015;2015:432467.

## EP-0946

### Mitral annular calcification as a potential false positive for cardiac amyloidosis in [99mTc]Tc-DPD] scintigraphy accurately identified by SPECT/CT - a case report

***R. Nunes***, *V. Alves;*
*Centro Hospitalar Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** Cardiac amyloidosis is defined by the deposition of amyloid fibrils in the myocardium, which is mostly caused by the deposition of misfolded transthyretin (ATTR) or monoclonal immunoglobulin light chains (AL). [$^{99m}$Tc]Tc-PYP/DPD/HDMP cardiac scintigraphy has a pivotal role in the diagnosis of ATTR cardiac amyloidosis. The combined findings of a Perugini visual score of 2 or 3 in the scan and the absence of monoclonal proteins in blood and urine are highly specific for ATTR cardiac amyloidosis and, thus, sufficient for diagnosis of this condition without a tissue biopsy. However, scintigraphy (or SPECT) alone has a lower specificity and, besides AL amyloidosis, other causes for a false positive result may occur. We report a case of mitral annular and valve calcification accurately identified in the SPECT/CT, but which could be misinterpreted as ATTR cardiac amyloidosis if only acquiring planar and SPECT images. ***Materials and Methods:*** We present a case of a 71-year-old female with a history of pulmonary interstitial disease, atrial fibrillation, a mechanical aortic valve, anemia, and hyperthyroidism who was hospitalized in the context of acute hypoxemic respiratory failure after vaccination against Sars-CoV-2. The thoracic CT showed extensive areas of consolidation in both lungs. The transthoracic aspiration biopsy demonstrated areas of fibrosis and a lymphoid infiltrate as well as amyloid deposition in the wall of a vessel of uncertain clinical significance. The transthoracic echocardiography showed concentric left ventricular hypertrophy and mitral insufficiency owing to an extensive calcification of the mitral valve and annulus, but the biventricular systolic function was normal. No infectious agent was detected. The patient progressed favorably with antibiotic and support treatment and was discharged. Subsequently, the hypothesis of systemic and/or cardiac amyloidosis was investigated, which included monoclonal protein testing and [$^{99m}$Tc]Tc-DPD scintigraphy and SPECT/CT. ***Results:*** Monoclonal protein testing was negative. The planar images showed mild diffuse increased tracer uptake in the projection of the heart and raised the hypothesis of cardiac amyloidosis (preferably ATTR amyloidosis). However, the SPECT/CT images accurately located the tracer uptake in the calcifications of the mitral valve and annulus, which is consistent with the previous echocardiogram, and excluded the diagnosis of cardiac amyloidosis. ***Conclusion:*** In our case report, the acquisition of SPECT/CT images changed the most likely diagnosis of cardiac amyloidosis given by the planar imaging, and accurately located the tracer uptake in the mitral annulus and valve calcifications, thus preventing a false positive result.

## EP-0947

### Increased 68Ga-PSMA uptake in avascular necrosis of the hip

***B. Okudan Tekin***[1], *B. Seven*[2];
[1]*Department of Nuclear Medicine, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE,*
[2]*Department of Nuclear Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital, Amasya, TÜRKIYE.*

***Aim/Introduction:*** Avascular necrosis (AVN) or ischemic bone necrosis or osteonecrosis results from disruption of the bone vasculature and can lead to significant morbidity and impairment of patient function. The authors describe the findings of AVN on $^{68}$Ga-PSMA PET/CT imaging of a patient with prostate cancer. ***Materials and Methods:*** $^{68}$Ga-PSMA uptake in the prostate bed suggestive of local recurrence was detected in the images of a 71-year-old male patient who had undergone radical prostatectomy for adenocarcinoma, who underwent $^{68}$Ga-PSMA PET/CT imaging for biochemical recurrence. In addition, increased $^{68}$Ga-PSMA uptake with suspected metastasis was observed in the right femoral head and neck. Then, MRI scan of the patient revealed stage 2/stage 3 AVN findings accompanied by diffuse bone marrow edema in the right femoral head and neck. Stage 2 AVN findings were also reported in the left femoral head and neck. ***Results:*** This case shows the incidentally detected AVN findings on $^{68}$Ga-PSMA PET/CT imaging. ***Conclusion:*** The importance of $^{68}$Ga-PSMA in prostate cancer management is well understood. PSMA expression is not restricted to prostate cells, and benign processes such as inflammation or infection found in atelectasis/pneumonia have been reported to exhibit a diverse, usually mild uptake of $^{68}$Ga-PSMA. The increased availability of PSMA ligands at the site of inflammation/infection as a result of increased regional blood flow and vascular permeability is considered a process of PSMA expression by immune cells. The presented case shows that AVN-related inflammation may cause increased $^{68}$Ga-PSMA uptake.

## EP-0948

### Pseudosarcomatous Periosteal Metastases of Lower Limbs Initially Misdiagnosed for Secondary Hypertrophic Osteoarthropathy then Properly Identified by [68Ga]Ga-PSMA PET/CT in a Patient Treated for Prostate Carcinoma

***D. Filipan***[1], *P. Moreau*[2], *C. Thibault*[3], *F. Montravers*[2], *F. Paycha*[4]; [1]*University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA,* [2]*Service de Médecine Nucléaire, Hôpital Tenon, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE,* [3]*Service d'Oncologie Médicale, Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE,* [4]*Service de Médecine Nucléaire, Hôpital Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE.*

***Aim/Introduction:*** Sunburst periosteal reaction of bone metastases is rare (less than 5% of cases) and only associated with osteoblastic metastases. It is most reported in malignant primary bone tumours such as osteosarcoma, but it can also be found in solid neoplasms (prostatic carcinoma (30%)). ***Materials and Methods:*** A 73-year-old male presented with oligometastatic prostate cancer, Gleason score 9 (4+5), resistant to castration, with osteoblastic phenotype bone and lymph-node metastases. The patient has been treated by radical prostatectomy and taxanes. Painful bone metastases of the right hemi-pelvis and left tibia received external beam radiotherapy. Baseline [99mTc] bisphosphonates bone scan, performed in initial post-surgical assessment, disclosed solitary increased uptake of the right acetabulum. Four years later, the patient's ECOG2 performance status and prostate specific antigen (PSA) rising from PSA nadir 0.09 ng/mL to 2.9 ng/mL, prompted a new bone scan. Acquisition workflow combined planar whole-body scan and additional SPECT/CT field-of-view of tibias. There was high-intensity increased uptake of the right ilium, left femoral diaphysis in partial and along the cortico-periosteal layer of the left tibial diaphysis. These bone turnover disturbances were congruent with divergent spiculated periosteal reaction on CT portion of hybrid imaging. Upper half-skeleton, spine included, exhibited normal uptake. A [68Ga]Ga-PSMA PET/CT study was subsequently performed as a theranostic tool for internal radioligand therapy by [177Lu]Lu-PSMA with palliative intent in this patient bearing a high-volume bone metastatic burden. Diffuse and intense ligand uptake was distributed throughout both hematopoietic axial skeleton and (non-hematopoietic) tubular bones of lower limbs. Most intensive uptake was concentrated at the site of florid aggressive periosteal reaction encompassing the pelvis and lower limbs. No lung metastases were evidenced. ***Results:*** Linear increased uptake of [99mTc]bisphosphonates along cortico-periosteal layer (railroad-track pattern) was initially interpreted as a classical picture of hypertrophic osteoarthropathy, where periosteal new bone formation (typically symmetric and widely distributed) is present primarily in tubular long bones of the extremities. Hence, the divergent spiculated pattern of the periosteal reaction and the production of osteoid was elicited by [99mTc]bisphosphonates, while [68Ga]Ga-PSMA evidenced subperiosteal prostate cancer metastases, properly diagnosing the lesions as pseudosarcomatous periosteal metastases of prostatic cancer. Given the patient's poor clinical condition, no bone biopsy was attempted. ***Conclusion:*** This case exemplifies the importance of hybrid bone-seeking and prostate cancer-targeted molecular imaging both as a key to finding the right diagnosis of an infrequent painful and aggressive bone metastatic disease, and as a theranostic selector for radionuclide PSMA-based therapy.

## EP-0949

### Retroperitoneal Fat-Containing Tumor. Tiptoeing between malignant and benign: A Case Report

***M. Matei***[1], *A. Mitoi*[1], *S. Serbanescu*[1], *C. Mazilu*[1], *R. Mititelu*[1,2]; [1]*Nuclear Medicine Department, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy Dr Carol Davila, Bucharest, ROMANIA.*

***Aim/Introduction:*** Retroperitoneal lipomas are extremely rare, benign tumors of mature adipocytes, usually asymptomatic until they start displacing the adjacent abdominal structures. The aim of this report is to emphasize the importance of metabolic imaging in the differential diagnosis of fat containing retroperitoneal tumors, including benign pathologies - lipoma, renal angiomyolipoma with exophytic expansion or malignant - liposarcoma. ***Materials and Methods:*** We present a case of a 43-year-old female with no prior medical history (menopause onset in January 2021) presented with diffuse and dull abdominal pain with a normal physical examination and normal laboratory tests. Radiological abdominal studies showed a well-defined, retroperitoneal mass of ~14/9/9 cm in the left renal space, which presented with scattered areas of internal soft-tissue density (fine septa and blood vessels) and shifting the upper left abdominal structures (spleen, stomach and the body and tail of the pancreas) anterior and medial. The MRI showed areas with persistent high T2 signal on the FAT-SAT T2 sequence with signs of local invasion - densification of the apical perirenal fat, thus raising the suspicion of a low-grade well differentiated liposarcoma. 18F-FDG PET/CT was recommended. ***Results:*** The patient underwent a PET/CT scan with 18F-FDG that revealed minimal uptake of FDG of the left retroperitoneal mass, probably due to the presence of the fibrous septa and the vascular network. Due to the presence of multiple smaller angiomyolipomas on both kidneys, the mass appeared as if it was bursting from the left renal cortex ("claw sign") with the feeding artery of the tumor originated from the renal cortex ("prominent feeding artery"); these findings were highly evocative for renal angiomyolipoma with exophytic growth. A biopsy was taken from the primary mass; interestingly, histopathological examination and immunohistochemical staining were performed, confirming the diagnosis of lipoma. ***Conclusion:*** This case highlights the importance of PET/CT in assessing retroperitoneal slow growing fat-predominant tumors. The accuracy of the initial radiological diagnosis is important for the design of the operative plan, because of the radical approach in case of liposarcoma and the more conservative path in benign cases. Even though the PET/CT findings were suggestive for renal angiomyolipoma and the histopathological result was indicative of lipoma, the PET/CT was successful in differentiating a benign tumor (lipoma/angiomyolipoma) from a potentially more aggressive malignant tumor, thus changing the further planning of the case.

## EP-0950

### Can PSMA based PET/CT scan be used in management of salivary gland neoplasms?

***N. Ghesani***, *M. Posner, r. Kulkarni, M. Ghesani; Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein of the prostate secretory acinar epithelium that is upregulated in prostate cancer (PC). PSMA-based diagnostics and targeted therapy(theranostics) are utilized in metastatic PC. PSMA PET/CT depicts physiological uptake in the salivary and lacrimal glands, liver, and kidneys,

and in benign and malignant neoplasms, mostly adenomas and adenocarcinomas, of glandular or epithelial origin. Value of PSMA-based theranostics in the neoplasms of non-prostatic origin has been explored. In this report, we demonstrate absence of PSMA uptake in salivary duct carcinoma(SDC) and discrepancy between Fluorodeoxyglucose (FDG) and PSMA uptake in metastases on PET/CT scans. ***Materials and Methods:*** An 85-year-old man with newly diagnosed prostate cancer, Gleason score 7, PSA level - 2 ng/mL, underwent $^{18}$F piflufolastat (PSMA) PET/CT scan. Primary prostate neoplasm was non-PSMA-avid. Minimal radiotracer uptake in the sclerotic lesions in the right iliac bone (SUVmax 1.5) and 10th thoracic vertebra. No PSMA uptake in right submandibular gland and enlarged right neck lymph nodes. Simultaneously, patient was also undergoing work-up for enlarging right neck mass. CT scan demonstrated 1.6 x 1.2 cm mass in enlarged right submandibular gland and right neck lymphadenopathy. Biopsy suspicious for epithelial carcinoma. ***Results:*** Patient underwent right submandibular mass resection and right neck lymph nodes(LN) dissection. Pathology demonstrated high-grade SDC and metastases in all 15 resected LNs, the largest tumor deposit, 4.5 cm. Subsequent $^{18}$F FDG PET/CT scan after surgery demonstrated metastatic lesions in left lobe of the liver, 10th thoracic vertebra, the sternum, left and right iliac wings (SUVmax 24.7). Rt iliac bone biopsy confirmed metastatic SDC. ***Conclusion:*** To our knowledge, this is the first study demonstrating absence of PSMA uptake in the SDC, both at the primary site and in metastases. The metastatic lesions had minimal PSMA uptake but robust FDG uptake. While reporting PET/CT scan, lack of PSMA uptake in the salivary glands should be mentioned since it can represent several entities such has atrophy from prior radiation therapy, sialolith, including primary neoplasm. Variable degrees of immunohistochemical reactivity of PSMA are observed in the salivary gland tumors but most studies demonstrated lower reactivity with SDC[1]. Further prospective studies are needed to explore PSMA positivity in different varieties of salivary gland neoplasms to explore PSMA theranostics in these neoplasms. ***References:*** 1. Nishida H, Kondo Y, Kusaba T, Kadowaki H, Daa T. Immunohistochemical Reactivity of Prostate-Specific Membrane Antigen in Salivary Gland Tumors. Head Neck Pathol. 2022 Jun;16(2):427-433.

## EP-0951

### A rare case of atypical lung carcinoid metastasis detected in the breast on 68Ga-DOTATATE PET/CT

***B. Okudan Tekin***[1], *B. Seven*[2], *A. Albayrak*[3], *A. Yıldırım*[1]; *[1]Department of Nuclear Medicine, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE, [2]Department of Nuclear Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital, Amasya, TÜRKIYE, [3]Department of Pathology, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Lung carcinoid tumors are rare tumors that rarely metastasize. The authors report an unusual case of metastasis to the breast from an atypical lung carcinoid. ***Materials and Methods:*** 68Ga-DOTATATE PET/CT imaging was performed on a 73-year-old female patient, whose mammography scan revealed a nodule in her right breast, which was reported as a metastatic neuroendocrine tumor on histopathological examination. In the obtained sections, mild 68Ga-DOTATATE uptake in the right breast nodule and a nodular lesion with moderate 68Ga-DOTATATE uptake in the right lung middle lobe was detected. Final histopathological findings of the subsequently resected lung lesion confirmed the presence of atypical carcinoids in the setting of diffuse idiopathic pulmonary neuroendocrine cell hyperplasia. ***Results:*** This case shows an unusual metastasis to the breast from an atypical lung carcinoid detected on 68Ga-DOTATATE PET/CT. ***Conclusion:*** Concomitant diffuse idiopathic pulmonary neuroendocrine cell hyperplasia and atypical carcinoid are uncommon. Also, breast metastases are extremely rare and there are only a few cases reported in the literature. PET/CT with 68Ga-labeled somatostatin analogs stands out as a tool in the diagnostic evaluation of lung carcinoids, tumors characterized by high expression of somatostatin receptors.

## EP-0952

### F18-FDG PET-CT in Diagnosis and Staging of Lacrimal Gland Carcinoma: a Case Report

***A. Militaru***[1], *A. C. Rosu*[2], *C. V. Mazilu*[1], *M. M. Matei*[1], *S. I. Serbanescu*[1], *M. G. Alexa*[1], *A. Mitoi*[1], *A. M. Zaharia*[1], *R. M. Mititelu*[1,3]; *[1]Central Universitary Emergency Military Hospital, Bucharest, Bucuresti, ROMANIA, [2]Elias Emergency University Hospital, Bucuresti, ROMANIA, [3]University of Medicine and Pharmacy "Carol Davila" Bucharest, Bucuresti, ROMANIA.*

***Aim/Introduction:*** Lacrimal gland tumors account for 10% of intraorbital masses, making them among the rarest tumors with an incidence of < 1/1,000,000 cases. Epithelial tumors of the lacrimal gland include a number of rare pathologies, among which adenoid cystic carcinoma (ACC), which accounts for approximately 60% of cases of lacrimal gland malignancy. Adenoid-cystic carcinoma is an aggressive tumor that usually develops in the salivary glands, although involvement of the lacrimal gland is very rare. To date, fewer than 100 cases of ACC with lacrimal gland involvement have been described in the literature. ***Materials and Methods:*** We describe the case of a 70-year-old man suffering from left exophthalmos, headache, diplopia, decreased visual acuity, limitation of the left visual field, and progressive limitation of eye movements. A biopsy of the lesion was performed, with histopathologic examination and immunohistochemical staining confirmed the presence of cystic adenoid carcinoma with a Ki67 cell proliferation index of 25%. MRI examination revealed an orbital lesion with optic neuritis likely due to compression. A PET-CT examination with 18F-FDG is performed after preparation of the patient preparation and using dedicated equipment. ***Results:*** PET-CT revealed a solid lesion in the left orbit showing increased and inhomogeneous FDG uptake. Thinning of the bony cortex in the adjacent bony structures is observed. PET-CT also showed high uptake in some laterocervical lymph nodes, bilaterally. High uptake was also noted in a lymph node corresponding to the right pulmonary hillium. No other distant hypermetabolic lesions were noted. Previous studies have shown that FDG PET-CT can detect lesions not observed with other imaging modalities in these rare cases of patients with lacrimal carcinoma, making a very important contribution to the visualisation of distant metastases and locoregional recurrences.[4] Other studies have shown greater sensitivity than an MRI exam at initial stage and bring additional information to the who-body examination. ***Conclusion:*** 18F-FDG PET-CT is important in the management of lacrimal gland tumors because it provides useful information in the initial staging and evaluation of relapse. In our case, FDG PET-CT revealed regional lymph node involvement, not previously diagnosed with conventional imaging and MRI. ***References:*** K. H. Hui et al "Value of positron emission tomography/computed tomography in diagnosis and staging of primary ocular and orbital tumors," Saudi Journal of Ophthalmology, vol. 26, no. 4, pp. 365-371, Oct. 2012, doi: 10.1016/j.sjopt.2012.08.008.

## EP-0953

### 18F-FDG uptake in portal vein thrombosis: the upshot of IIIB-stage pulmonary adenocarcinoma and liver cirrhosis

***M. Alexa***[1], *S. Serbanescu*[1], *A. Mitoi*[1], *C. Mazilu*[1], *M. Matei*[1], *M. Oancea*[1], *D. Craciun*[1], *R. Mititelu*[1,2];
[1]*Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.*

***Aim/Introduction:*** 18F-FDG PET-CT is an essential tool in oncologic diagnosis for the assessment of liver involvement - liver metastases and, to a lesser extent, hepatocellular carcinoma. Portal vein thrombosis is a relatively frequent complication of hepatocellular carcinoma and liver cirrhosis. We present the case of a patient with pulmonary adenocarcinoma who underwent surgical treatment and adjuvant radiotherapy; the patient also had liver cirrhosis and portal vein thrombosis. 18F-FDG PET-CT examination revealed portal vein uptake suggestive of neoplastic thrombosis. No other pathologic changes suggestive of liver metastasis or hepatocellular carcinoma were noted. ***Materials and Methods:*** Our patient is a 55-year-old man, heavy smoker (35 packs per year), who was occupationally exposed to toxic substances in the respiratory tract (for 24 years), with stage IIIB lung adenocarcinoma that underwent surgery (left pneumectomy) and adjuvant radiotherapy; the patient also suffered from chronic hepatitis B infection (currently treated with entecavir), liver cirrhosis, and pulmonary tuberculosis. Initially, the CT and PET-CT showed no local tumor relapse or distant metastases. Six months later, an MRI scan was performed for the follow-up of an incidental hepatic nodule originally discovered during a routine US scan; this revealed extensive thrombosis in the portal vein and both hepatic branches, for which the patient was treated accordingly. Further ultrasonography revealed ascites in small quantity. We performed 18F-FDG PET-CT. ***Results:*** In February 2023, the PET-CT scan showed no ascites; the liver nodule showed no FDG uptake. However, the PET-CT showed dilated portal and splenic veins with hyperdense content and increased 18F-FDG uptake (SULmax up to 6,99). Portal vein thrombosis is a considerably common complication of hepatocellular carcinoma and liver cirrhosis; some previous studies have shown that portal vein thrombosis with tumoral thrombi can occur in patients with hepatocellular carcinoma. A metabolically active portal vein thrombosis detected on PET-CT examination is suggestive of a tumoral thrombus, as the enlarged caliber of the portal vein with linear uptake of F18-FDG underscores its neoplastic origin. Some previous studies have shown that the SULmax value is capable of distinguishing a benign thrombus from a malignant one with high sensitivity, specificity, and accuracy. In this case, no other active liver lesions were detected, probably due to either their small size or the low degree of differentiation in hepatocellular carcinoma. ***Conclusion:*** In short, the PET-CT exam is useful in differentiating tumoral from benign thrombi, facilitating the thorough management of an oncologic patient with multiple comorbidities.

## EP-0954

### Additional value of PET/MRI in diagnostic workflow of cognitive impairment

***M. Pudis***[1], *M. Suarez-Piñera*[1], *S. Flores-Casaperalta*[2], *N. Vidal-Sarro*[3], *L. Rodríguez-Bel*[1], *C. Martínez-Ramos*[1], *S. Bondia-Bescós*[1], *B. Hervás-Sanz*[4], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [2]*Radiodiagnostics (IDI), Hospital Duran i Reynals, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [3]*Anatomical Pathology Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,* [4]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** Hybrid imaging techniques such as PET/CT and PET/MRI combine anatomical and functional imaging modalities to provide more comprehensive information about the disease process. The anatomical component of hybrid imaging (CT or MRI) provides detailed structural information, while the functional component (PET) provides information about metabolic and physiological processes. By combining these two imaging modalities, hybrid imaging can provide more accurate and precise information than either modality alone. ***Materials and Methods:*** A 74-year-old male, presented to his neurologist with complaints of cognitive impairment, including memory loss and difficulty with orientation. His symptoms had been gradually worsening over the past several months, and he had become increasingly concerned about his ability to function independently. Due to the rapid worsening, the neurologist has requested a brain [$^{18}$F]FDG PET/CT scan followed by Amyloid Brain PET/MRI. ***Results:*** An [18F]FDG PET/CT scan (Figure 1) was performed to investigate the cause of his symptoms, but it did not show any typical neurodegenerative pattern. However, it did reveal a mild hypometabolic area in the right parietal lobe, not considered clinically significant. Due to continued cognitive impairment, an amyloid PET/MRI was ordered to rule out incipient Alzheimer's disease. [$^{18}$F]Flutemetamol PET/MRI scan (Figure 2) revealed a focal area of decreased amyloid uptake in the right parietal lobe which corresponded to a lesion visualized on the MRI. Further MRI sequences were performed and a diagnosis of glioblastoma was suggested. Further investigation, including a biopsy of the lesion (Figure 3), confirmed the diagnosis of grade 4, IDH-mutated glioblastoma. An excision was performed to remove as much of the tumor as possible, followed by radiation therapy and chemotherapy. ***Conclusion:*** We presented a rare case of grade 4 glioblastoma (GM) with low FDG uptake. Usually, these kinds of GM are known to exhibit high FDG uptake on PET imaging due to their highly metabolically active nature. This study points out the importance of performing functional and morphological images in a single study in patients with cognitive impairment, being PET/MR the most adequate technique.

## EP-0955

### Pericardial mesothelioma: a case report.

***B. Hervás-Sanz***[1], *P. C. Notta*[1], *L. M. Gràcia-Sánchez*[1], *L. Rodríguez-Bel*[1], *S. A. Bolívar-Cuevas*[2], *D. Castellón-Plaza*[2], *I. E. Sánchez-Rodríguez*[1], *M. Pudis*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Diagnostic Radiology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

***Aim/Introduction:*** Pericardium primary mesothelioma (PPM) is an extremely rare neoplasm that originates in the mesothelial cells.It is frequently limited to the pericardium, causing pericardial effusion and restrictive symptoms such as dyspnea, although it also has the capability to infiltrate adjacent structures.It is more common in males, with a mean age of 46 years.Its etiology is still unknown although it seems to be related to asbestos as is the case with pleural mesothelioma.The diagnosis of this neoplastic process is a challenge and often requires different imaging techniques. The final diagnosis is obtained by biopsy and frequently this occurs directly in post-mortem analysis.The aim of this study is to recognize the features visualized in [18F]FDG-PET/CT, in a patient diagnosed with MPP. ***Materials and Methods:*** A 48-year-old man attended the emergency department presenting chest tightness and dry cough of one month's evolution, for

which a chest X-ray was performed, showing cardiomegaly with suspected pericardial effusion, hence he was admitted for study.Several imaging tests were performed, including [18F] FDG-PET/CT, which showed a hypermetabolic mass in the anterior mediastinum surrounding the great vessels, with cardiac extension and associated with severe pericardial effusion.The patient also had hypermetabolic pulmonary nodules and lymph nodes, all suggestive of tumor dissemination. In the biopsies and subsequent anatomopathological analysis, mesenchymal cells were visualized, finally leading to the diagnosis of metastatic MPP. ***Results:*** Figure 1: A) MIP showing a large uptake in the mediastinum as well as small thoracic deposits and visualization of the bone marrow, suggesting underlying infiltration.B) Axial fusion images show the primary tumor, with cardiac extension, as well as severe pericardial effusion.C) Multiple metastatic hypermetabolic pulmonary nodules associated with small hypermetabolic nodules corresponding to suspicious adenopathy. These findings raise the differential diagnosis between lymphoproliferative process and pericardial tumor. Figure 2: Pleural fluid histological study showing abundant mesothelial cellularity as well as lymphocytes and macrophages. The immunohistochemical study ruled out an underlying lymphoproliferative process, leading to a final diagnosis of PM. ***Conclusion:*** MPP is a very infrequent process, with unfavorable prognosis. The [18F]FDG-PET/CT allows us to obtain a global vision, being able to study its metabolism and extension as well as a differential diagnosis between the different aetiological possibilities.

## EP-0956

### Molecular Imaging Findings in Erdheim-Chester Disease-An Extremly Rare Multisystemic Disorder

***A. Marcuseanu***[1], *A. Budau*[2], *D. Vasile*[1], *A. Lazar*[3], *C. Sterea*[3], *M. Gherghe*[3,4];
[1]*National Institute of Infectious Diseases "Prof. Dr. Matei Bals", Bucharest, ROMANIA,* [2]*Central Military Emergency Hospital "Dr. Carol Davila", Bucharest, ROMANIA,* [3]*Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [4]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, ROMANIA.*

***Aim/Introduction:*** Erdheim-Chester disease (ECD) is a very rare non-Langerhans cell histiocytosis, defined by overproduction and multisystemic accumulation of histocytes, leading to diverse manifestations. The most common involvement sites are represented by the skeleton, central nervous system, lungs, cardiovascular system, kidneys and skin. Due to its complicated and various symptomatology, this disease can be easily misdiagnosed. ***Materials and Methods:*** We report the case of a 53-year-old HIV-positive male patient with a history of progressive pericardial effusion, diagnosed with Erdheim-Chester disease in 2023. Prior to coming into our clinic, the patient had a history of severe weight loss and bilateral exophthalmia since 2021, which led to performing a computed tomography (CT) displaying large pericardial effusion and abdominal fat stranding, as well as blood tests. A CT scan was repeated one year later, describing additional bilateral orbital masses. A bone biopsy was performed and histopathological examination confirmed the diagnosis of non-Langerhans histiocytosis. The patient was recommended a "whole-body" $^{18}$F-Fluorodeoxyglucose ($^{18}$F-FDG) PET/CT to assess the extension of the disease. ***Results:*** The $^{18}$F-FDG PET/CT scan revealed bilateral hypermetabolic intraorbital masses ($SUV_{max}$ 6.63 g/ml in the right eye and 6.78 g/ml in the left eye), circumferential pericardial thickening with increased metabolic activity ($SUV_{max}$ 6.97 g/ml), large areas of hypermetabolic retroperitoneal and perirenal fat ($SUV_{max}$ 4.58g/ml) infiltrating vascular, renal and muscular structures, and appendicular bones involvement ($SUV_{max}$ of 3.15 g/ml in the left humeral diaphysis and, respectively, of 2.87 g/ml in the left proximal femoral epiphysis). The described hypermetabolic findings were consistent with the morphological components found on the previous CT scans. Complementary to the $^{18}$F-FDG PET/CT scan, a $^{99m}$Tc-hydroxydiphosphonate (HDP) "whole-body" bone scintigraphy was achieved, which showed increased radiotracer uptake in all long bones, including the distal femur and tibia, symmetrically and bilaterally. Treatment with Cladribine was established. A future $^{18}$F-FDG PET/CT follow-up scan is scheduled in order to evaluate the therapeutic response. ***Conclusion:*** The diagnosis is usually delayed, because ECD is a rare disease with various onset presentations and multi-organ involvement. The $^{18}$F-FDG PET/CT findings have an essential role in the diagnosis, especially for disease extension assessment, detecting visceral and vascular infiltrations. Furthermore, because the treatment depends on the metabolic activity of the disease, $^{18}$F-FDG/PET CT is of great value for patient follow-up and treatment response.

## EP-0957

### Assessment of False Positive PET/CT Pulmonary Lesions in Gastric Adenocarcinoma Staging

***D. Craciun***[1], *C. Mazilu*[1], *A. Zaharia*[1], *A. Mitoi*[1], *R. Mititelu*[1,2];
[1]*Nuclear Medicine Department, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy Dr Carol Davila, Bucharest, ROMANIA.*

***Aim/Introduction:*** 18F-Fluorodeoxyglucose (18F-FDG) PET/CT scan is a well-established method for staging in oncologic patients so that appropriate treatment can be assigned. Multiple pathologies can mimic a similar pulmonary uptake of 18F-FDG such as tuberculosis, anthracosis or parenchymal metastasis. Anthracosis occurs due to the deposition of small particles during chronic smoke exposure and is diagnosed with a biopsy in order to differentiate from tuberculosis since on a CT scan both have similar characteristics and they can occur simultaneously. ***Materials and Methods:*** A 57-year-old man with a history of tuberculosis, smoking, and occupational exposure to multiple toxic alloys presented with vomiting and severe weight loss. The diagnosis of gastric adenocarcinoma ( Lauren diffuse type) was confirmed by gastric biopsy; multiple pulmonary lesions were seen on the CT scan. The patient fasted for 6 hours before the examination, and the images were acquired with a special PET /CT scanner. ***Results:*** The pulmonary fibrous scar lesions and calcifications showed no metabolic activity, but the nodules exhibited intense 18F-FDG uptake with a SULmax of up to 4.71. These lesions raised suspicion of metastasis or reactivated pulmonary tuberculosis, so accurate differentiation between these conditions is crucial because it significantly impact the treatment strategy. A CT -guided biopsy of the pulmonary nodules was performed, which revealed pulmonary anthracosis. After completion of all essential investigations, the oncologists were able to start neoadjuvant therapy for gastric adenocarcinoma with fluorouracil (5- FU), leucovorin, oxaliplatin, and docetaxel, followed by imaging follow-up, planned surgery, and hyperthermic intraperitoneal chemotherapy (HIPEC). Accurate staging of gastric adenocarcinoma was made possible by interdisciplinary collaboration between the departments of oncology, pathology, and nuclear medicine, which allowed comprehensive correlation of case information. ***Conclusion:*** This case illustrates how a false positive 18F- FDG PET /CT finding

can alter the course of treatment for an oncologic patient when similar pulmonary lesions could have multiple etiologies. It also illustrates how complementary investigations are needed to gain a more complete understanding of the case so that the patient can receive the best treatment.

## EP-0958

### Incidental detection of hydatid cyst on 18F-FDG PET/CT imaging

***B. Okudan Tekin***[1], *B. Seven*[2];
[1]*Department of Nuclear Medicine, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE,*
[2]*Department of Nuclear Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital, Amasya, TÜRKIYE.*

***Aim/Introduction:*** Hydatid cyst is a parasitic infestation caused by Echinococcus granulosus. Most of its symptoms result from a mass effect associated with cyst volume. The main complications caused by cysts are cyst rupture causing cough, chest pain and hemoptysis. The authors present a case with hydatid cyst in the liver on 18F-FDG PET/CT imaging. ***Materials and Methods:*** In an 82-year-old female patient who underwent 18F-FDG PET/CT imaging to evaluate the metabolic activities of nodular lesions located in the upper lobe of the right lung, multiple hypometabolic cystic lesions were detected in the liver, the largest of which was approximately 63x61 mm in size, some of which had intense calcification. Subsequently, in the abdominal US performed on the patient, many cysts were detected that were considered to be compatible with hydatid cyst corresponding to the lesions described in PET/CT. ***Results:*** This case shows the incidentally detected hydatid cyst in the liver on 18F-FDG PET/CT imaging. ***Conclusion:*** Hepatic hydatid disease causes highly variable symptoms and signs and can be found incidentally in an asymptomatic patient. Early diagnosis and appropriate treatment will help reduce the complication rate and prevent recurrence. With the presented case, it is aimed to remind that 18F-FDG PET/CT can contribute to the diagnosis of non-malignant processes such as hydatid cyst.

## EP-0959

### 18F-FDG PET/CT findings in a patient with systemic lupus erythematosus

***B. Okudan Tekin***[1], *B. Seven*[2];
[1]*Department of Nuclear Medicine, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE,*
[2]*Department of Nuclear Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital, Amasya, TÜRKIYE.*

***Aim/Introduction:*** Systemic lupus erythematosus (SLE) is an immune complex disease of unknown etiology that causes excessive production of autoantibodies against components of the cell nucleus. The authors present a case of SLE with diffuse bone marrow involvement on 18F-FDG PET/CT imaging. ***Materials and Methods:*** It was determined that the nodular lesion described in the obtained sections of a 61-year-old male patient who underwent 18F-FDG PET/CT imaging to evaluate the metabolic activity of the nodular lesion located in the lower lobe of the left lung did not show significant 18F-FDG uptake. However, diffuse bone marrow involvement was observed in the axial and appendicular skeleton. ***Results:*** This case shows 18F-FDG PET/CT findings in a patient with SLE. ***Conclusion:*** In conclusion, with the presented case of known SLE, it is desired to reemphasize that 18F-FDG PET/CT is a valuable tool in the evaluation of patients with SLE, as it can visualize not only the degree of disease activity or inflammatory burden, but also the distribution of the disease throughout the body.

## EP-0960

### The importance of metabolic activity imaging in the evaluation of Central Nervous System Rosai-Dorfman Disease: A Case Report

***M. Matei***[1], *C. Mateescu*[1], *A. Rosu*[2], *C. Mazilu*[1], *R. Mititelu*[1,3];
[1]*Nuclear Medicine Department, Central University Emergency Military Hospital, Bucharest, ROMANIA,* [2]*University Hospital ELIAS, Bucharest, ROMANIA,* [3]*University of Medicine and Pharmacy Dr Carol Davila, Bucharest, ROMANIA.*

***Aim/Introduction:*** Rosai-Dorfman disease (RDD), otherwise recognized as sinus histiocytosis with massive lymphadenopathy, is a rare, benign lymphoproliferative disorder of the histiocytes that most commonly involves the lymph nodes. Extranodal disease is relatively frequent and may include skin/subcutaneous soft tissue, nasal cavity/sinus, bone, central nervous system, kidney; other infrequent sites were described in the literature. The involvement of the central nervous system is rare, manifesting more often as dural-based masses, intraparenchymal involvement being less common. ***Materials and Methods:*** We present a case of a 25-year-old woman, with a recent history of RDD affecting the spinal cord, manifested as a dural based mass, located in the right S2 nerve root. Surgery was performed and after the removal of the mass, histopathological studies and immunohistochemical staining were performed, showing S-100, CD68 positive large histiocytes with focal emperipolesis, thus confirming the diagnosis of RDD. One month later following the surgery, the MRI of the cervical and thoracic spine revealed two bone lesions, one of them located at the posterior arch of the tenth right rib, with low T1 signal intensity, isointense T2 signal and hyperintense STIR signal, without cortical bone interruption or expansive changes. The second lesion was located at the left scapula, close to the scapulohumeral joint, being small and focal, showing high STIR signal intensity. A $^{18}$F-FDG-PET/CT scan was recommended for assessing the disease extension. ***Results:*** The PET/CT scan with $^{18}$F-FDG revealed no metabolic activity in the bone lesions, previously described at the MRI, but showed an increased uptake compared to the physiological metabolic activity in the cervical and lower thoracic spinal cord. Incidentally, the cerebellum cortex showed a diffuse hypometabolism of $^{18}$F-FDG without any other changes in the brain metabolism. The CT revealed multiple hyperdense lesions, some of which calcified, located bilaterally in the parieto-temporo-occipital cerebral cortex. These findings may indicate parenchymal involvement of the central nervous system, thus a close follow-up being recommended. ***Conclusion:*** Given the multiple systems that can be affected, this case emphasizes the value of FDG PET/CT in the evaluation of the Rosai-Dorfman disease.

## EP-0961

### Functional change in a patient with neurological symptoms post-exercise disclosed by rest and stress cerebral blood flow perfusion imaging (99m)Tc-ECD SPECT

***R. Moreira***[1], *R. Castro*[2], *D. S. Lobo*[1], *L. R. Sabioni*[1], *H. A. Guenka*[1], *I. Gottlieb*[1];
[1]*Casa De Saude Sao Jose, Rio De Janeiro, BRAZIL,*
[2]*Ipanema Health Club, Rio De Janeiro, BRAZIL.*

***Aim/Introduction:*** 46-year-old man, healthy, with sporadic neurological symptoms post-exercise, characterized by altered state of consciousness, visual clouding, muscle hypertonia in upper limbs and muscle hypotonia in lower limbs, with spontaneous improvement of symptoms, normal cerebral angiotomography and normal magnetic resonance imaging. ***Materials and Methods:*** Single photon emission tomography (SPECT) was performed 60

minutes after the intravenous injection of 30 mCi of 99mTc-ECD in two phases (rest and stress), on differents days. Administration of the radiopharmaceutical in the stress phase occurred after the onset of symptoms, stimulated by cardiopulmonary exercise testing. ***Results:*** Rest phase showed usual distribution pattern of the radiopharmaceutical in the analyzed structures. Stress phase showed focal decrease in radiopharmaceutical concentration in the left occipital lobe and the other cortical regions of the cerebral and cerebellar hemispheres, basal ganglia and thalamus present preserved concentration of the radiopharmaceutical. ***Conclusion:*** Rest and stress cerebral blood flow perfusion imaging (99m) Tc-ECD SPECT identified symptom onset zone.

## EP-0962

### Radioguided occult lesion localization (ROLL) method in metastatic colorectal cancer - a case report

***D. Silva****, H. Duarte, I. Sousa, J. C. Ferro, I. Próspero, D. Barbosa, S. F. Castro, G. Ferreira, J. P. Teixeira, M. J. Sousa, P. Martins, I. L. Sampaio;*
*Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.*

***Aim/Introduction:*** Radioguided surgery (RGS) is one of the fields of Nuclear Medicine (NM) with more significant development in the last few years. It comprises a large number of procedures that are carried out through a multidisciplinary collaboration between surgeons, pathologists, and radiologists, thus, enabling short and long-term benefits to the patient, such as the reduction of iatrogenic lesions, shortening of the surgical time, and the potential improvement of local-regional control of the malignant disease. ***Materials and Methods:*** We present a case of a 58-year-old man diagnosed in 2018 with a transverse colon adenocarcinoma with hepatic metastasis and submitted to surgery. Four years later, a follow-up 18F-FDG PET/CT scan showed a suspicious nodular lesion with intense 18F-FDG uptake in the vicinity of the right internal iliac vessels. One month later, the patient was submitted to a right iliac lymphadenectomy for which histopathology revealed no metastatic involvement in the collected samples. Five months afterward, the patient was reassessed with a new 18F-FDG PET/CT scan, showing a persistent hypermetabolic lesion in the same location. It was then decided to repeat the surgery performing Radioguided Occult Lesion Localization (ROLL) and excision. Two hours before surgery the lesion was CT-guided labelled with 179.5 MBq (4.9 mCi) of $^{99m}$Tc Albumine Macroagregates (MAA). A SPECT-CT was executed immediately before surgery to confirm the proper location of MAA (images were also confronted with those of the PET scan) and to rule out any extralesional spillage that would compromise the correct localization. ***Results:*** During the procedure, surgeons were quickly able to identify the metastatic deposit using the gamma probe and after resection the sample was sent to histological analysis, which later confirmed the malignant involvement. ***Conclusion:*** This case report demonstrates the importance of multidisciplinary teamwork between Surgery, Interventional Radiology and Nuclear Medicine in order to provide the most effective treatment to patients, confirming NM as an important ally to surgeons when patients present non-palpable lesions. RGS has been an ever-evolving part of NM and ROLL has been recognized as a technique that allows an efficient and reliable way to surgically remove occult lesions by making it easier to localize them and to better estimate disease extension.

## EP-0963

### Brown tumours: an unmet need

***B. Pereira****, P. Soeiro, A. Fernandes, A. Oliveira;*
*Centro Hospitalar Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** End-stage renal disease with tertiary hyperparathyroidism, and thus the number of brown tumours, is increasing worldwide. Abnormal parathyroid glands may be identified with [$^{99m}$Tc]Tc-MIBI scan (MIBI). Brown tumours however can prove difficult to diagnose with much debate about the best imaging technique. Some studies advocate X-rays, and others advocate MRI or CT, but there is always some uncertainty with these tests. Histopathological findings are also not specific, sometimes requiring, genetic profiling. The outcome and evolution of these tumours are also unclear, with some regressing after parathyroidectomy. ***Materials and Methods:*** We present the case of a 28-year-old man with end-stage renal disease admitted to our hospital because of bilateral swelling in the oral cavity, mainly on the left side. He also reported feeling tired and having generalized bone pain for the last few months. In the biochemical tests, the main finding was a very high parathyroid hormone (> 5000 pg/mL). Ultrasonography of the neck and head, neck and chest CT revealed three nodules behind the thyroid gland, several small lytic bone lesions (extending from the skull to the sternum, vertebrae, and scapulae) as well as two larger bone lesions on the mandible, interpreted as either ossifying fibromas or brown tumours. A dual-phase and dual tracer MIBI scan with SPECT/CT was requested to localise the hyperplastic parathyroid glands. ***Results:*** The scan showed MIBI uptake in the three nodules located posteriorly to the thyroid gland and in only one of the two known mandibular tumours. A biopsy revealed that both bone lesions were compatible with brown tumours. ***Conclusion:*** This case highlights the utility of MIBI scans detecting brown tumours and their different patterns of uptake, depending on their different metabolic phase. Understanding the significance of these patterns could help determine the best non-invasive method to diagnose them. ***References:*** Vilanilam G K, Nikpanah M, Vo C D, Kearns C. Osteitis Fibrosa Cystica: Brown Tumors of Hyperparathyroidism and End-Stage Renal Disease. Radiographics, 43(5). https://doi.org/10.1148/rg.220211

## EP-0964

### The role of radio-guided surgery in choosing vascularized lymph nodes transfer microsurgery flap after breast cancer surgical treatment.

***D. Rodriguez Oviedo****, A. Maldonado Morillo, B. Manzarbeitia Arroba, M. Alvarez Moreno, M. Tagliatori Nogueira, M. De La Rubia Marcos, C. Sandoval Moreno, C. Galindo, M. Garcia Alonso, M. Castillejos Rodriguez;*
*Hospital Universitario de Getafe, Madrid, SPAIN.*

***Aim/Introduction:*** Lymphedema is a chronic disease with a high incidence that affects more than 200 million people around the world after surgical treatment for breast cancer. It has a medical treatment that is complex, long, and requires a lot of effort from the patient and that's why vascularized lymph nodes transfer (VLNT) microsurgery has become one of the best alternatives for these patients, being a key subject finding the best donor lymph nodes. A common place is the groin, that's why using radio-guided surgery we try to reduce the incidence of iatrogenic lymphedema. ***Materials and Methods:*** Case 1 A 46-year-old woman treated with mastectomy and lymphadenectomy developed lymphedema in the left arm without response to medical treatment. Using 99mTc lymphoscintigraphy technique, administrated one hour prior to

the surgery we can locate lower extremities lymph nodes using a radioactive detection probe during the procedure (Fig1). Fig 1. Using a radioactive probe (white arrow) to identify the groin lymph nodes carrying 99mTc (green arrow) surgeons can safely exclude them from the VLNT flap (blue arrow) leaving intact the leg lymphatic drain avoiding iatrogenic lymphedema. Case 2 A 52-year-old woman developed lymphedema in the right arm after breast cancer surgery treatment with lymphadenectomy. Using a radioactive probe to clear the VLNT flap of any 99mTc lymphoscintigraphy marked lymph nodes (Fig 2.) surgeons can proceed harvesting the other lymph nodes without including the legs nodes. Fig 2. Radioactive probe (white arrow) checking the VLNT flap (blue arrow) for any 99mTc lymph nodes (green arrow) belonging to the leg lymphatic drain system. ***Results:*** After eight weeks of the procedures, none of the patients had developed iatrogenic lymphedema in the donor side of the VLNT flap, making radio-guided surgery one safe option for treating lymphedema with great results in experts' hands. ***Conclusion:*** Radioguided surgery represents an excellent option for surgical treatment of lymphedema, helping to reduce the chances of generating adverse effects. It still requires more studies to make it a first-line treatment. ***References:*** Maldonado AA, Ramos E, García-Alonso P, Jover JJ, Holguín P, Fernández-Cañamaque JL, Cristóbal L. Abordaje multidisciplinar en el paciente con linfedema: de la rehabilitación a la microcirugía [Multidisciplinary approach in the lymphedema patient: From rehabilitation to microsurgery]. Rehabilitacion (Madr). 2022 Apr-Jun;56(2):150-158. Spanish. doi: 10.1016/j.rh.2021.06.003. Epub 2021 Sep 17. PMID: 34538653.

## EP-0965

### Incidentaloma on [18F]FDG PET-CT breast cancer staging - a rare case of Schwannoma

***B. Martins****, P. Lopes, R. Veiga, C. Loewhental, J. L. Passos-Coelho;*
*Hospital da Luz, Lisboa, PORTUGAL.*

***Aim/Introduction:*** We report the clinical case of a 65-year-old woman, without past medical personal history other than a non-recent surgical intervention on the left knee, who was referred to an oncology appointment after a mammogram and breast ultrasound in January 2023, which documented a 28mm nodule in the upper outer quadrant of the right breast with suspicious homolateral axillary lymph nodes (BIRADS 5). The biopsy of the nodule documented an invasive carcinoma (NOS) with positive hormone receptors (ER 100%, PR 90%), HER2 negative and a Ki-67 of 50%) with axillary lymph node involvement. An [$^{18}$F]FDG PET-CT was requested for staging. ***Materials and Methods:*** A whole body study was performed with 3D mode acquisition, approximately one hour after intravenous administration of the radiopharmaceutical. Low-dose CT was obtained for attenuation correction and anatomical referencing. ***Results:*** The breast lesion was observed in the external quadrants of the right breast (31x11mm in the axial planes with SUVmax 3.58), as well as homolateral axillary adenopathies, the largest measuring 18x12mm with SUVmax 3.6. No other suspicious lymph nodes were seen. A previously unknown tumor was seen in the right iliac fossa, between the psoas and iliac muscles, with 54x49x60mm (ApxTxL) and SUVmax 7.6 On further questioning the patient referred a shooting-type pain in the right leg for the previous three years, which had been worsening. A biopsy of the iliac lesion documented a peripheral nerve neoplasm, compatible with Schwannoma. ***Conclusion:*** The patient underwent surgical treatment. A lumpectomy of the right breast, right axillary lymphadenectomy and, in the same operative time, removal of the iliac fossa tumor, were performed. Histology of the latter confirmed the diagnosis of Schwannoma. Although benign, Schwannomas usually present high SUV values. This feature, especially in some territories, can lead to false positives [1]. Schwannomas result from abnormal proliferation of Schwann cells, are usually single lesions, mostlyindolent. They involve more commonly the brachial and lombar plexus, origin of the limb nerves. [1]. Since it is not possible to distinguish a Schwannoma from a malignant lesion on [$^{18}$F]FDG PET-CT, biopsy is mandatory before treatment, to avoid misdiagnosis [1]. ***References:*** [1] Boré P et al. (2018). False positive 18F-FDG Positron Emission Tomography Findings in Schwannoma - A caution for reporting Physicians. Front. Med. 5:275

## EP-0966

### Hepatic Artery Vasculitis: A rare presentation of single-organ vasculitis documented by 2-[18F]FDG PET/CT

***R. T. Ferreira****, I. C. Ferreira, F. Vinagre, S. Carmona, A. Prata, A. I. Santos;*
*Hospital Garcia de Orta, E. P. E., Almada, PORTUGAL.*

***Aim/Introduction:*** Vasculitis are a group of diseases characterized by inflammation and damage to blood vessels, often with systemic involvement. Single-organ vasculitis (SOV) is a rare condition that affects blood vessels in a specific organ. Gastrointestinal SOV, with exclusive involvement of the hepatic artery, is particularly rare, to the best of our knowledge with only 5 cases described in the literature and none of them submitted to Nuclear Medicine techniques. We present a case of vasculitis that exclusively involves the hepatic artery, documented by 2-[$^{18}$F]FDG PET/CT. ***Materials and Methods:*** A 53-year-old man, without prior medical history, presented to the emergency department with recurring epigastric pain, vomiting, non-selective anorexia and constipation for the last 5 days. There was no fever, weight loss, joint pain, or other systemic symptoms reported. ***Results:*** Physical examination revealed only elevated blood pressure. Laboratory tests showed a slightly elevated C-reactive protein level, normal levels of haemoglobin, white blood cells, liver enzymes and amylase, and negative ANA, ENA, ANCA, anti-dsDNA and cryoglobulins. Abdominal X-ray was normal. CT scan showed an unspecific adipose tissue oedema surrounding the celiac trunk. CT angiography revealed narrowing of the common hepatic artery lumen, due to thickening of the vessel, possibly indicative of vasculitis. A 2-[$^{18}$F]FDG PET/CT scan was performed to evaluate other vascular regions and showed intense diffuse hypermetabolism along the common hepatic artery, with no changes in other vascular territories. Blood cultures, viral and bacterial serologies were also conducted, and no changes were detected, ruling out infectious causes. Based on the most likely diagnosis of single-organ vasculitis, corticosteroid therapy was initiated and the patient was discharged. On 3 months follow-up, C-reactive protein values normalized and there was a complete regression of the clinical symptoms. ***Conclusion:*** Vasculitis diagnosis is often challenging and when we face a specific rare subtype as SOV, which affects a specific organ or tissue such as the skin, gastrointestinal tract, or genitourinary system, this challenge rises significantly due to its isolated nature. 2-[$^{18}$F]FDG PET/CT, as an all-body non-invasive exam, can be valuable to assess the extent of involvement, as shown in this case. Although corticosteroid therapy has a favourable prognosis for SOV, long-term follow-up is recommended due to the possibility of progression to systemic disease and, as shown in other types of vasculitis, 2-[$^{18}$F]FDG PET/CT might also have a potential role to monitor therapy and to evaluate the future progression of this disease.

## EP-0967

### 18F-FDG PET/CT findings in a patient with renal angiomyolipoma

***B. Okudan Tekin***[1], *A. S. Erdoğan*[1], *B. Seven*[2];
[1]*Department of Nuclear Medicine, Ankara City Hospital, University of Health Sciences, Ankara, TÜRKIYE,*
[2]*Department of Nuclear Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital, Amasya, TÜRKIYE.*

***Aim/Introduction:*** Renal angiomyolipoma (AML) is a common benign tumor of the kidney. It may occur sporadically, as well as with tuberous sclerosis complex (TSC) or pulmonary lymphangiomyomatosis. Although renal AMLs are benign formations, they can sometimes undergo malignant transformation. It undergoes malignant transformations similar to renal cell carcinoma, especially as a result of various mutations of atypical epithelioid cells. Renal AMLs are usually silent on 18F-FDG PET/CT. However, it may be useful in detecting malignant transformations or malignant masses containing fat. ***Materials and Methods:*** A 22-year-old female patient, who was followed up with tuberous sclerosis and epilepsy, had multiple masses in both kidneys in the tomography taken due to flank pain, and in the abdominal MRI performed both a few suppressed in fat-suppressed sequences and a few AMLs thought to be poor in fat component were consistent with nodular and mass lesions were observed. Minimally increased 18F-FDG uptake, which can be distinguished from physiological urinary activity, in multiple heterogeneous nodular lesions in both kidneys, 40x34 mm in size, the largest in the left kidney upper pole, in 18F-FDG PET/CT imaging performed because the patient was diagnosed with tuberous sclerosis (SUVmax: 2.67) has drawn attention. Trucut biopsy of the left kidney upper pole lesion was consistent with renal AML. ***Results:*** This presentation demonstrates the 18F-FDG PET/CT findings in a patient with renal AML. ***Conclusion:*** Renal AMLs are benign formations with low FDG affinity. When a tumoral tissue containing a fat component is detected on CT, it is important to distinguish AML from a malignant tumor with a fat component. It should be kept in mind that the low FDG affinity of AML in PET/CT can be found in the differential diagnosis of malignant kidney masses containing the fat component.

## EP-0968

### Rare complication in the cholangiocarcinoma treatment - biliary bronchial fistula - localized with cholescintigraphy with SPECT/CT

***P. Gadzicki***, *M. Nowak, A. Dyla, Z. Adamczewski;*
*Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Biliary bronchial fistula is a rare condition characterized by abnormal communication between the biliary tract and the bronchial trees. This case demonstrates the usefulness of cholescintigraphy with SPECT/CT in the localization of biliary bronchial fistula. ***Materials and Methods:*** Previously intensively treated 61 year-old woman with cholangiocarcionoma developed symptoms such as cough, bilioptysis and weakness. The patient was treated oncologically for over four years; the therapeutic process consisted of radiotherapy, chemotherapy, left-sided hemihepatectomy extended to the resection of the segment V and VIII with lymphadenectomy of the hepatoduodenal ligament and cholecystectomy as well as multiple bile ducts stent implementation. Three months before the cholescintigraphy, a biliary-bronchial fistula was diagnosed and excised. Due to persistent symptoms such as expectoration of sputum with bile and progressive weakness, a number of diagnostic tests were performed and the patient was admitted to hospital to check the effects of the treatment. ***Results:*** The persistent biliary bronchial fistula was visualized with the use of cholescintigraphy with SPECT/CT. ***Conclusion:*** The persistent biliary bronchial fistula was visualized with the use of cholescintigraphy with SPECT/CT.

## EP-0969

### SPECT/CT Diagnosis of single adrenal metastasis of differentiated thyroid cancer

***K. Bayardo***, *J. Naula, O. Alonso, R. Ferrando;*
*University of the Repubic, Montevideo, URUGUAY.*

***Aim/Introduction:*** Differentiated thyroid carcinoma (DTC) is the main endocrine neoplasia, and its incidence has increased in recent decades. Distant CDT metastases are not common, but when they are present, 5-year survival drops to 54.9% compared to 98.3% for regional metastases and 99.9% for localized disease. Most common sites are lymph nodes, lungs, and bone. Rare sites include brain, liver, kidneys, adrenal glands, skin, and muscles. They represent less than 1% of the total, making diagnosis difficult. We present a case of a single metastasis of CDT in the adrenal gland diagnosed by SPECT/CT. ***Materials and Methods:*** 64-year-old female patient diagnosed with a 48 mm follicular thyroid carcinoma in the left lobe with vascular invasion. After total thyroidectomy, she was administered 150 mCi of radioactive iodine (RAI). Post operative RAI scanning showed concentration in bilateral thyroid remnants, without abnormal uptake in the rest of the body. RAI scanning performed 1 year later was negative. During next years, Tg values increased and remained in a range of 45-50 ng/ml under hormonal suppression. Twelve years after diagnosis Tg values reached 500 ng/ml without hormonal suppression and RAI scanning detected an area of intense uptake in the lower mediastinum or epigastrium lateralized to the right, which could not be accurately localized on planar images. ***Results:*** Non-contrast CT reported a right adrenal adenoma. Four months later, a new RAI scan with SPECT/CT showed intense uptake in the right adrenal gland, correlated with a nodular lesion on CT images, consistent with adrenal metastasis. Right adrenalectomy was performed with posterior histopathology confirmation and decrease in Tg values. ***Conclusion:*** CDT metastases in rare locations such as adrenal glands are exceptional events that can imply a great diagnostic challenge. SPECT/CT images can be a fundamental tool for the accurate diagnosis and correct management of this type of lesions.

## EP-0970

### Role of [18F]FDG PET/CT in the detection and differential diagnosis of peritoneal tuberculosis

***S. Bondia-Bescós***[1], *V. Carrero-Vasquez*[1], *I. Sánchez-Rodriguez*[1], *A. Palomar-Muñoz*[1], *L. Gràcia-Sánchez*[1], *M. Pudis*[1], *B. Hervás-Sanz*[1], *J. Díaz-Moreno*[1], *M. Santin-Cerezales*[2], *X. Solanich-Moreno*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, Barcelona, SPAIN,* [2]*Infeccious Diseases Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** Peritoneal carcinomatosis (PC) is a relatively common extension for tumors, particularly from abdomen and pelvis origin, however, there are other conditions that may involve the peritoneum like tuberculous peritonitis (TBP), which are often complicated to differentiate since there are clinical and analytical manifestations that can overlap. Various differential characteristics have been described for each of these entities. The mechanisms by which the peritoneum can be involved in TBP are mostly through hematogenous dissemination, by direct propagation or

through the lymphatic route. On the other hand, most frequent routes for dissemination in PC are by direct pelvic invasion and via transceoelomic. Making this affectation clear with imaging tests is crucial in their differentiation.The aim of this study is to evaluate the role of PET/CT in the detection and differential diagnosis of PTB in patients whose initial suspicion was occult neoplasia with PC. ***Materials and Methods:*** Retrospective study of a 3 case series with presence of peritoneal disease showed on [$^{18}$F] FDG PET/CT, and clinical suspicion of occult neoplasia in which the definitive diagnosis was PTB.Selection of 3 cases with [$^{18}$F]FDG PET/CT and confirmed peritoneal carcinomatosis from different primary neoplasms (ovary, endometrium, gallbladder).Analysis of the morphometabolic characteristics, pattern of the peritoneal involvement and presence of extraperitoneal involvement from these two entities. ***Results:*** In PTB patients (2 women, mean age 42.67 years) the form of presentation was similar in the three cases, highlighting en extensive and uniform parietal peritoneal involvement with slight associated glucose activity, mild uniform hypermetabolic thickening of the greater omentum, and ascites without FDG avidity. Active extraperitoneal involvement was detected in all patients, without clinical suspicion.Among PC patients (2 women, mean age 76.33 years), the involvement distribution was heterogeneous, but the pattern had common findings including focal thickening and major nodularity of the implants. ***Conclusion:*** In our case series the involvement observed in PET/CT had a fundamental role in the diagnosis of TBP, evaluating its extension and detecting other foci of active infection not visualized in conventional imaging techniques.The recognition of these morphometabolic patterns is very useful since it allows guiding the clinical diagnosis and assessing the extension, facilitates biopsy guidance, and reduces treatment initiation time. ***References:*** Ahmed Khan FY. Peritoneal tuberculosis: Advances and controversies. Libyan J Med Sci 2018;2:3-7 Wang SB, He H, Xv DD, et al. Visual PET/CT scoring of mesenteric fdg uptake to differentiate between tuberculous peritonitis and peritoneal carcinomatosis. Diagn Interv Radiol. 2020;26(6):523-530.

## EP-0971

### Dual-tracer PET/CT imaging to determine tumor heterogeneity in a patient with liver metastatic neuroendocrine neoplasm: A case report.

***R. Moreira***, *I. Gottlieb, D. S. Lobo, H. A. Guenka;*
*Casa De Saude Sao Jose, Rio De Janeiro, BRAZIL.*

***Aim/Introduction:*** We present a case of a patient with neuroendocrine neoplasm with biologic heterogeneity between a primary tumor and hepatic metastases.The diagnosis was obtained and multidisciplinary management was conducted with magnetic resonance imaging (MRI) and a positron emission tomography/computed tomography (PET/CT) scan with Fluor-18 [18F]-AlF-NOTA-octreotide ([18F]-OC) and Fluor-18 [18F]-fluorodeoxyglucose ([18F]-FDG). ***Materials and Methods:*** An MRI showed a primary lesion in the terminal ileum with adjacente lymphadenopathy and six suspicious hepatic lesions. A biopsy of the largest hepatic lesion revealed neuroendocrine carcinoma and then PET/CT was performed. A PET/CT scan revealed a difference between [18F]-OC and [18F]-FDG uptake in primary tumor and liver metastases. PET/CT showed lack [18F]-FDG uptake and high [18F]-OC uptake in the primary tumor and adjacente lymphadenopathy, whereas no [18F]-FDG uptake and lack [18F]-OC uptake were identified in the hepatic metastases. ***Results:*** PET/CT imaging with two tracers demonstrated a biologic heterogeneity between a primary tumor and metastases. By providing a noninvasive means of evaluating tumor biology, dual tracer PET/CT offered a practical alternative to multiple biopsies, facilitating clinical decision-making and improving patiente outcomes. ***Conclusion:*** Tumor heterogeneity is a known predictor of aggressive disease and dual tracer PET/CT is a noninvasive imaging technique that enables the evaluation of tumor biological status and impacts patient management strategies.

## EP-0972

### 18 FDG PET/CT imaging in anaplastic thyroid carcinoma : a case report

***F. Chaltout***, *K. Ben Ahmed, M. Ouachem, T. Bint Mohamed, M. Maaloul, S. Charfeddine, K. Chtourou, F. Guermazi;*
*Department of Nuclear Medicine, Habib Bourguiba University Hospital of Sfax, Tunisia, Sfax, TUNISIA.*

***Aim/Introduction:*** Anaplastic thyroid carcinoma (ATC) is an aggressive form of thyroid cancer characterized by uncontrolled growth of cells in the thyroid gland. It shows a rapid growth and local invasion. This form of cancer carries the worst prognosis among all thyroid cancers due to its relenless progression and resistance to cancer treatments. ***Materials and Methods:*** We present a case of 65 year old patient having anaplastic thyroid carcinoma not yet treated. As part of the initial evaluation, a whole body scan was done, which showed a huge thyroid mass with signs of skin invasion reaching the cervical spine . this mass engages the primary carotid artery and compresses the internal jugular vein which remains permeable. The scan showed also some bilateral jugulocarotid nodes and a hepatic nodule which can be an atypical angioma or a metastasis. Consequentely, FDG PET/CT was requested to disocver the metabolic behavior of these lesions. ***Results:*** 18 FDG PET / CT showed an intense hypermetabolic cervical mass ( SUVLbm max =28.38) centrered by an hypometabolic necrosis, associated to bilatreal hypermetabolic jugulocarotid and left supraclavicular lymph nodes . There was no evidence of metabolically active lesion elsewhere in the body. Therfore, this tumor was classified IVB . ***Conclusion:*** Anaplastic thyroid carcinoma (ATC) accounts for 1% - 2% of all thyroid malignancies .It's ahighly agressive and results in over 50% of deaths from thyroid cancer with a median estimated survival of 6-8 months. Its managing is challenging and includes rapid diagnosis, adequate staging and multimodal treatments. FDG PET/CT has been useful at many steps in the therapeutic care process. In fact, it's recommended in the primary staging in order to evaluate the lesion resectability and to unveil unkown metastasis. Add to that, it has an important role in the follow up of ATC after primary surgery for detection of residual, recurrent, or metastatic disease. In a series reported by Poisson et al, it was also found that SUVmax and metabolic tumor volume had a prognostic significance . they suggested that SUVmax >18 and a 18F-FDG uptake volume >300 mL had a significantly worse 6 month survival.

## EP-0973

### Sacrococcygeal metastasis revealing a papillary carcinoma of the thyroid . A Case report

***M. Bourouba***;
*Nuclear Medicine Clinique Fatema Al Azhar, Algiers, ALGERIA.*

***Aim/Introduction:*** A 24-year-old girl who underwent neurosurgery with an invasive osteolytic tumor lesion (108x94x66 mm), located at the level of the sacrum , suggestive of a schwanoma, which led to severe pain with right sciatalgy without motor deficit or sphincter disorders. CT examination shows an extension to the

sacroiliac joints and a lysis of the right iliac bone, extending to the posterior L5 process in contact with the L5 roots, infiltrating the pre-vertebral muscles, and reaching anterior to the contact of the internal iliac artery ***Materials and Methods:*** Partial exeresis performed by posterior route was performed. The pathological study revealed a metastasis of papillary carcinoma of the thyroid in its vesicular form. (Immunohistochimestery : Anti CK7, Anti TTF1 and Anti Tg positive) .The exploration of the thyroid gland shows a cystic lesion of 13 mm diameter lying in the left lobe. A total thyroidectomy was performed, as well as a bilateral dissection of the lymph nodes, revealing a lack of malignancy of the samplings.For the purpose of therapeutic complement the patient is addressed to us for iratherapy. Bone scintigraphy shows an intense uptake (sacrum and coccyx) without evidence of other localizations.The thyroglobulin level is greater than 5000ug/l without replacement therapy since the intervention, greater than one month.The patient receives 6,30 GBq of Iodine 131 capsule (CAPSION CURIUM), ***Results:*** The post-therapeutic scan confirms the uptake of the pelvic focus which appears intense and of large volume.The level of thyroglobulin remains high 3 months after the first iratherapy (> 5000 ug / l) The patient is followed for a second course of iratherapy and surgery are planned, after noting the reduction of the tumor volume ***Conclusion:*** The presence of such a location is quite rare. Its fortuitous discovery, evokes most of the time a neurological problem (schwanome) or tumoral type teratoma of the ovary with bone extension. Moreover, the analysis of the thyroidectomy specimen can evoke a papillary microcarcinoma of the thyroid. Indeed, a replay of the blades could be desirable.

## EP-0974

### Gastric Empty and Esophagus Transit Scintigraphy Imaging of Long Term Tip 1 Diabetic Patient accidentally consuming Formic Acid

***D. Yüksel****, U. Moran, M. Yücel, S. Demirezen, A. Çelik;*
*Pamukkale Universitesi Tip Fakültesi, Denizli, TÜRKIYE.*

***Aim/Introduction:*** Gastroparesis can result from autonomic (vagal) neuropathy, intrinsic neuropathy affecting xcitatory and inhibitory intrinsic nerves or interstitial cells of Cajal, or a combination of extrinsic and intrinsic neuropathic or myopathic disorders(1). In some cases, GES is ordered in patients with known GERD to determine whether some component of gastric stasis may contribute to GERD. Gastric distention may induce GER by triggering lower esphageal sphincter (LES) relaxation (2). In this case report, we present a type 1 Diabetus Mellitus patient and a case who drank formic acid because there are two pathologies that can cause esophageal and stomach motility disorders together. ***Materials and Methods:*** Solid and liquid gastric emptying scintigraphy(4) and esophageal passage scintigraphy(5) were performed according to the consensus report and guidelines. ***Results:*** The patient had type 1 diabetus mellitus for 30 years and drank half a glass of 50% formic acid 3 years ago and vomited. He has hypoglycemia and hyperglycemia attacks because dysphagia and insulin blood sugar regulation could not be achieved. Although the patient has epigastric pain, he does not have any complaints of burning in the throat or retrosternal. On the esophagus scintigraphy, when the esophagus transit time is normal in examinations with liquid, the passage speed of the esophagus lower 1/3 segment slowed. In our examinations made for gastric empty, it was found to be delayed as 964 minutes for liquid. For the solid, it was extended to 422 minutes. ***Conclusion:*** In this patient with type 1 diabetes and a history of drinking formic acid, a delay in esophageal passage and a significant prolongation in gastric emptying were detected. ***References:*** 1.Triadafilopoulos G, Nguyen L, Clarke JO. Patients with symptoms of delayed gastric emptying have a high prevalence of oesophageal dysmotility, irrespective of scintigraphic evidence of gastroparesis. ## EP-0975

### FDG PET/CT imaging in intra-abdominal round cell desmoplastic tumors: a case report

***N. Abaouz****, A. Guensi;*
*Department of Nuclear Medicine, University Hospital Ibn Rochd, Casablanca, MOROCCO.*

***Aim/Introduction:*** Desmoplastic small round cell tumor, according to the International Classification of Diseases for Oncology (2020), is classified as malignant tumor of uncertain differentiation. This tumor usually develops in the abdominal cavity. It is a very uncommon soft tissue tumor in children and young adults. It has an aggressive evolution and its survival is usually poor. In general, the assessment of tumor burden and response is based on CT or MRI. However, these tumors are often metabolically active and can be assessed by FDG PET/CT. In this case, we present the potential usefulness of PET/CT in the evaluation of distant metastases at the time of staging. ***Materials and Methods:*** The patient was 15 years old and was diagnosed with a histologically confirmed intra-abdominal round cell desmoplastic tumor. The patient was admitted to the department of nuclear medicine, CHU IBN ROCHD Casablanca, for a PET/CT scan prior to induction chemotherapy for staging. ***Results:*** Diagnostic abdominal and pelvic CT showed peritoneal masses, the largest one was at the pelvic level (19x13mm) and associated with a right pelvic cystic formation and secondary hepatic and splenic lesions suggesting peritoneal carcinosis.The FDG PET/CT scan revealed, in addition to abundant ascites associated with intensely hypermetabolic thickening of the peritoneal sheets, hypermetabolic liver lesions as well as a hypodense pelvic mass without a metabolism and a hypometabolic splenic lesion. On the same examination, supra-diaphragmatic adenopathies uptake (cervical, mediastinal, and axillary) were identified as secondary lymph node extensions. At the bone level, the uptake was heterogeneous with hypermetabolic foci (C2, right humeral head) suspected of secondary extension. ***Conclusion:*** Although FDG PET/CT is rarely indicated in intra-abdominal round cell desmoplastic tumors, it has its place as an initial extensional examination to determine distant extensions for appropriate treatment.

## EP-0976

### Interest of FDG PET/CT Compared to Bone Scan in the Detection of Lytic Bone Metastasis in Breast Cancer

***N. Abaouz****, A. Guensi;*
*Department Of Nuclear Medicine, University Hospital Ibn Rochd, Casablanca, MOROCCO.*

***Aim/Introduction:*** Breast cancer is one of the most osteophilic cancers and bone is the most frequent distant location in this pathology. In fact, PET-CT can be used to identify lymph node invasion and distant metastasis in a single examination. In addition, PET-CT is more sensitive and specific than CT or bone

scans in the detection of lytic or mixed bone metastasis, or osteomedullary invasion. Our purpose, in this case, is to compare the accuracy of PET/CT with bone scintigraphy for the detection of lytic bone metastasis in a patient followed for breast cancer. ***Materials and Methods:*** The patient was 55 years old and was followed up for a lobular carcinoma of the right breast classified as Luminal B associated with homolateral lymph node extension. She was admitted to the nuclear medicine department of the CHU IBN ROCHD of Casablanca for the initial assessment of extension, firstly for a bone scan, and then for FDG PET/CT. ***Results:*** The planar bone scan performed showed 3 hours after injection of 17 mCi of 99mTc-labelled HMDP a homogeneous and symmetrical distribution of the radiotracer over the entire skeleton explored without any clearly identifiable hyperfixing lesion. On the other hand, FDG PET/CT showed 60 minutes after injection of 250 MBq 18FDG, in addition to the hypermetabolic right breast process and homolateral axillary adenopathies, a hypermetabolic lytic bone lesion of the left sacroiliac, which is consistent with a single bone metastasis. ***Conclusion:*** This case illustrates the superiority of FDG PET/CT over planar bone scans in the detection of lytic bone metastasis in breast cancer.

## EP-0977

### Unexpected 131I iodine scintigraphy finding

***A. Aulich****, B. Stefański, Z. Adamczewski;*
*Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Radioactive iodine 131I is the oldest radiopharmaceutical used in the theranostics concept. It allows the application of the same vector in diagnostics as well as therapy of both benign and malignant thyroid conditions. Radioiodine (RAI) scintigraphy is an invaluable tool for assessment of thyroid diseases including the detection of thyroid cancer metastases. Although extrathyroidal foci of abnormal 131I uptake are highly suggestive of disseminated thyroid cancer, other infrequent causes should be taken into consideration. Warthin's tumor (cystadenoma lymphomatosum) may be one of them, possibly on account of unsatisfactory excretory mechanism in comparison with physiological function of salivary glands and sodium/iodide symporter (NIS) expression in the tumor. ***Materials and Methods:*** An 81-year old woman with toxic nodular goiter was referred for 131I iodine scintigraphy in order to measure thyroid iodine uptake before planned radioiodine treatment. The radiotracer was given orally in a standard protocol, using 4 MBq sodium iodide 131I. The value of thyroid uptake was 22%, which was measured 24h after administration. ***Results:*** Radioiodine scan revealed unexpected accumulation of the radiotracer in the right parotid gland, significantly exceeding physiological level of salivary glands' uptake. The patient had no history of thyroid malignancy. Upon further inquiry she admitted having been diagnosed with Warthin's tumor, confirmed previously by fine needle aspiration biopsy. Surgical treatment was excluded due to significant comorbidities. Radioiodine uptake within the tumor was 4%. Ultrasound scan of the right parotid salivary gland showed an ovoid, hypoechoic, heterogeneous lesion, which measured 26x36x45mm. The image of a solid lesion can be observed in multiple conditions, including Warthin's tumor, although it is not specific. In addition, 99mTc-pertechnetate salivary gland scintigraphy was performed and showed an increased uptake of the radiotracer within the tumor, which is typical for Warthin's tumor. ***Conclusion:*** Although extrathyroidal foci of abnormal 131I uptake are highly suggestive of disseminated thyroid cancer, other infrequent causes should be taken into consideration. Warthin's tumor may be one of them due to NIS overexpression.

## EP-0978

### Incidental finding of pulmonary tumour in lung ventilation and perfusion SPECT: the importanceof a combined low-dose CT scan

***J. Carvalho****, J. R. Duarte, A. Marques, F. Abreu, S. Pintão;*
*Centro Hospitalar de Lisboa Ocidental, Carnaxide, PORTUGAL.*

***Aim/Introduction:*** Lung imaging with SPECT is commonly indicated in patients with suspected pulmonary embolism. The introduction of integrated multimodality SPECT/CT cameras has enabled the simultaneous acquisition of lung ventilation and perfusion SPECT ($V/P_{SPECT}$) with a combined low-dose CT scan, which confers slightly improved specificity for pulmonary embolism, as it may be helpful in identifying nonthromboembolic parenchymal abnormalities. ***Materials and Methods:*** We report a case of a 64-year-old woman with suspected pulmonary embolism with findings suggestive of infarction on chest radiography. The patient underwent lung ventilation and perfusion SPECT in order to quantify the infarcted lung area. ***Results:*** $V/P_{SPECT/CT}$ demonstrated a matched V/P defect in the lower lobe of the left lung, with an associated peripheral opacification in the low-dose CT scan. Due to the suspicion of malignancy, a high resolution CT scan of the thorax was promptly performed, which showed a peripheral spiculated nodule not present in previous exams, highly suggestive of a primary malignant lesion. PET/CT scan with 2-[$^{18}$F]FDG confirmed the presence of a metabolically active lesion in the left lower lobe. A transthoracic biopsy was performed in order to histologically characterize the nodule. ***Conclusion:*** The added value of a low-dose CT scan in lung scintigraphy has been validated in patients with COPD, but not in other subgroups of patients. Despite the additional radiation dose, it can be useful in patients with suspected pulmonary embolism with other concomitant parenchymal abnormalities, not only by increasing diagnostic accuracy, but also by detecting incidental findings that require urgent care, such as pulmonary neoplasms.

## EP-0979

### An adrenal nodule with very high 18F-FDG uptake

***S. Fontão de Castro****, J. Ferro, I. Próspero, D. Barbosa, D. Silva, L. Violante, G. Ferreira, I. Lucena e Sampaio;*
*Portuguese Institute of Oncology - Porto, Porto, PORTUGAL.*

***Aim/Introduction:*** Benign adrenal adenoma with high metabolic uptake is rare. We present a case of a 40-year-old-women, succinate dehydrogenase subunit B (SDHB) mutation carrier, with a previous adrenalectomy due to a paraganglioma, presented with a fast growing adrenal node. Computed tomography (CT) and magnetic resonance imaging (MRI) scans were suggestive of benign adenoma, however, 2-[$^{18}$F]FDG positron emission tomography / computed tomography (PET/CT) showed a very high metabolic uptake (SUVmax 15.5; tumor-to-liver (T/L) SUVmax ratio: 4.9). The adrenal node was resected and pathology revealed a benign adenoma. ***Materials and Methods:*** A forty-year-old woman, asymptomatic, SDHB mutation carrier, with history of a previously treated metanephrine-producer paravertebral paraganglioma (left adrenalectomy and radiotherapy), presented with new node in the right adrenal gland. The patient underwent a CT scan that showed a growing low density lesion (10*15mm to 25*19mm in 20months; Hounsfield Units <10). MRI demonstrated a homogeneous signal drop on opposed-phase images, suggesting a fat lipid-rich adenoma. Notwithstanding, it was a fast growing lesion in a patient with history of paraganglioma, and further investigation was conducted. In order to exclude a new pheochromacytoma, the patient underwent [$^{68}$Ga] Ga-DOTANOC-PET/CT however the adrenal node did not show

significantly increased somatostatin receptor expression. Patient also underwent a 2-[18F]FDG-PET/CT scan, demonstrating a very high uptake in the adrenal node: SUVmax 15.5 and T/L SUVmax ratio: 4.9. Fine needle biopsy aspiration was inconclusive. The case was discussed in a multidisciplinary group meeting and based on the continuous growth, very high 2-[18F]FDG uptake and patient preference, it was decided to performed a right adrenalectomy. ***Results:*** Histology revealed an encapsulated lesion compatible with an adenoma (Weiss score: 0). 2-[18F]FDG PET/CT has been pointed as a tool to distinguish adrenal adenomas from malignant lesions. Among the several papers, it is concordant that tumor-to-liver ratio is a more accurate and reliable parameter than SUVmax to predict malignancy. Kunikowsska analyzed 102 nonsecreting adrenal tumor and concluded that T/L SUVmax ratio of 3.7 has a 95% sensibility (CI 85-96%) and a 90% specificity (CI 84-96). In another study a best diagnosis accuracy cut-off point was 2.5 T/L SUVmax ratio. About 5% of adrenal adenomas have a 2-[18F]FDG uptake greater than the liver, and the reason for this is unknown. ***Conclusion:*** To best of our knowledge, a benign adrenal adenoma with such high uptake and T/L SUVmax ratio has never been described and it is important to have in mind this possible pitfall.

## EP-0980

### Detection of a right ventricle cardiac metastasis from lung adenocarcinoma in a 18F-FDG PET/CT study

***S. Pacella***[1], *M. Mangano*[2], *L. Venegoni*[3], *M. Cergnul*[3], *A. Calcagno*[3], *R. Ferrara*[4], *C. Migliorisi*[3], *M. Carletto*[3], *L. Maffioli*[5];
[1]*IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico, Milano, ITALY,* [2]*ASST Valle Olona, Saronno, ITALY,* [3]*ASST Ovest Milanese-Ospedale Civile di Legnano, Legnano, ITALY,* [4]*ASST Ovest Milanese-Ospedale di Magenta, Magenta, ITALY,* [5]*ASST Sette Laghi, Varese, ITALY.*

***Aim/Introduction:*** Primary cardiac tumours are extremely uncommon, while secondary tumours or cardiac metastasis are not. The incidence of cardiac metastasis is of 1.5%- 20% of autopsies of cancer patients. Primary lung cancer represents about one third of cardiac metastasis followed by breast cancer and haematologic malignancies. 18 F-fluorodeoxyglucose positron emission tomography/computed tomography (18 F-FDG PET/CT) is a very important imaging tool in oncology for tumor staging, restaging, detection of recurrence and monitoring treatment response. Due to the high physiological FDG uptake in the myocardium , it's very challenging the detection of a suspected focal cardiac uptake. ***Materials and Methods:*** 18F-FDG PET/CT for the detection of a right heart metastasis in a patient with a non small-cell lung cancer. ***Results:*** A 78-year-old male underwent 18F-FDG PET/CT for staging his lung tumor. Whole-body 18F-FDG PET/CT demonstrated an increased uptake in the lung mass located in the upper left lobe and showed intense uptake in an enlarged lymph node in the aortopulmonary window. Another intense focal uptake was in the right ventricle. A contrast-enhanced MRI performed after our FDG PET/CT study showed late Gadolinium enhancement in the antero-basal wall of the right ventricle, suspected for a secondary localization ***Conclusion:*** 18F-FDG PET/CT was an important tool in the diagnostic setting of a patient with a lung adenocarcinoma for the detection of metastatic sites, like the cardiac involvement, that is a rare phenomenon. ***References:*** 1) Jiang JY, Lee M, Kang C, Wong VCK, Mansberg R. Atypical metastatic lung cancer of the right ventricle on FDG PET/CT. Radiol Case Rep. 2021 Sep 16;16(11):3569-3573. doi: 10.1016/j.radcr.2021.07.092. PMID: 34567334; PMCID: PMC8449183. 2) Orcurto MV, Delaloye AB, Letovanec I, Martins Favre M, Prior JO. Detection of an asymptomatic right-ventricle cardiac metastasis from a small-cell lung cancer by F-18-FDG PET/CT. J Thorac Oncol. 2009 Jan;4(1):127-30. doi: 10.1097/JTO.0b013e318189f60e. ## EP-0981

### Expect the unexpected- a rare case of incidentally detected recurrent bone invasive giant meningioma on F-18 FDG PET/CT, in a patient with stomach neoplasm

***S. Chausheva***, *B. Chaushev, T. Stoeva, M. Dyankova, T. Yordanova, Z. Dancheva;*
*University Hospital St Marina Varna, Varna, BULGARIA.*

***Aim/Introduction:*** Meningioma is a primary neoplasm of the central nervous system. Up to 3% of people over 60 are thought to be at risk for asymptomatic meningioma. However, even after perfect resection, there is between 9% and 32% risk or recurrency in the 15 years post-surgery. Still, the extent of bone involvement, caifications and the giant size of the reccurent meningioma reported in this paper are of much lower incidence. ***Materials and Methods:*** A 53-year-old male patient was diagnosed with gastric carcinoma and underwent subtotal gastrectomy. He presented at the Department of Nuclear medicine for a scheduled staging F-18 FDG PET/CT and did not report any symptoms regarding his nervous system. According to the clinical history the patient had a meningioma 24 years earlier which was completely removed. Whole-body PET/CT was performed using i.v. F-18 FDG at a dose of 3.5 mCi, where the images were obtained 65 minutes after injection. ***Results:*** The scan showed a large calcified mass with the characteristics of a meningioma, parasagittally, in the left parieto-occipital region. The mass was extra-axial, with lobulated sharp margins and large dimensions - 56/57/64mm. It had low 18F-FDG uptake, probably because of the massive calcifications or the histological type of the tumor. The structure of the mass was inhomogeneous due to predominantly calcium-dense components with a density of around 800HU. There were also several oval, relatively low-dense areas with soft-tissue density. The finding was located mainly along the left surface of the cerebral falx with a small contralateral component at its most parietal point with bone invasion of the parietal bone in the left. Dorsally, the mass expands into the inner cortical layer of the parietal bone as well as partially into the outer cortical layer. There was evident mass-effect with contralateral shift of the ventricular system, approximately 7mm from the mid-line. Ventral dislocation of the posterior horn of the left lateral ventricle was noticed, but no evidence of ventricular dilatation. ***Conclusion:*** Unexpected findings, often without increased uptake, are not infrequently encountered in PET/CT imaging. However, the dimensions and complicity of the meningioma described here are quite rare. Although this is a "can't miss finding" it comes to remind us that underneath any oncological condition there could be additional lesions which are sufficient enough to prompt a systematic review of the CT images obtained during the PET/CT study. Check your CT imiges twice, print your report once!

## EP-0982

### 99mTc-antigranulocite antibody scintigraphy in mycosis fungoides

***A. Velidaki***, *S. Episkopopoulou, I. Sevaslidou, N. Prosotsianiotis, E. Dagrakis, A. Kolindou;*
*Laiko General Hospital of Athens, Athens, GREECE.*

***Aim/Introduction:*** Mycosis fungoides (MF) is a non-Hodgkin's lymphoma of T-cell origin, primarily involving the skin. $^{99m}$Tc anti-granulocyte monoclonal antibody is used by Nuclear Medicine Physicians mainly for the detection of bone infection but it has also the ability to reveal infection in soft tissues and internal organs. In our study, we present a case of highlighting multiple foci throughout the skin during whole-body $^{99m}$Tc anti-granulocyte monoclonal antibody scintigraphy in a woman with MF. ***Materials and Methods:*** A 34-year-old woman was hospitalized due to fever. She had a history of MF with patches and plaques all over her skin. Her blood culture was positive for MRSA. She presented to our Nuclear Medicine Department for investigation of suspected osteomyelitis after surgical debridement of a tibial ulcer. She underwent a $^{99m}$Tc anti-granulocyte monoclonal antibody scintigraphy. ***Results:*** The study ruled out any discrete focus of infection in tibia or other bones and internal organs, but it revealed multiple skin foci throughout the body. Skin radiopharmaceutical uptake seen on scintigraphy, seemed to correspond to the patient's skin lesions. ***Conclusion:*** Skin manifestations of mycosis fungoides are patches, plaques and tumors. The diagnosis of MF can be difficult. Obtaining adequate tissue for biopsy can often be a problem. Literature shows FDG PET-CT may be inferior to clinical examination in mapping the extent of cutaneous lesions, especially when there are macules or thin plaques, but it offers the advantage of characterizing the metabolic activity in the lesions and guide for biopsies. F-18 FDG uptake in disease-involved lesions due to co-existing inflammation is something that limits its specificity. When skin lesions ulcerate, they accumulate inflammation cells and they can be imaged by labeled WBCs scintigraphy. This is the first-to our knowledge- case of MF imaging with 99mTc anti-granulocyte antibody. The demonstration of multiple uptake foci of the radiopharmaceutical, probably implies the presence of another uptake mechanism beyond the presence of inflammation. $^{99m}$Tc anti-granulocyte monoclonal antibody scintigraphy may be an easy and effective way to assess the extent, activity and severity of the disease and may also contribute to disease monitoring.

## EP-0983

### Incidental increased Ga-68 FAPI Uptake in Calcified Meningioma

***A. Namazova***, *A. Kibar, L. U. Beşli, O. E. Sahin, K. Sönmezoğlu;*
*Istanbul University-Cerrahpasa, Cerrahpaşa Faculty of Medicine, Department of Nuclear Medicine, ISTANBUL, TÜRKIYE.*

***Aim/Introduction:*** Meningioma is the most common type of primary brain tumor, accounting for approximately 30 percent of all brain tumors. Most meningiomas are benign, slow-growing lesions. They are typically found incidentally. The aim of our study is to present 68Ga -fibroblast activation protein inhibitor (FAPI) PET/CT findings of primary meningioma in a 74-year-old woman. ***Materials and Methods:*** After the patients were injected with 37MBq (0.1 mci)/kg intravenous of 68Ga FAPI, PET/CT images were taken of the vertex-upper thigh were taken at the 45th minute. ***Results:*** We would like to present a 74-year-old patient with ovarian cancer who underwent 18F-FDG PET/CT and FAPI PET/CT. A high 68Ga-FAPI (SUV MAX, 5,5) uptake was observed in the calcified lesion in the anterior of the falx cerebri. According to the location and radiological and clinical characteristics, the diagnosis of meningioma was defined. ***Conclusion:*** Many studies suggested that meningioma can cause increased uptake of various radiotracers, including 18F-FDG, 68Ga-DOTATATE, 68Ga-PSMA, 18F-FLT, 18F-florapronol and 68Ga FAPI. 68Ga-labeled FAPI has recently been introduced as a promising tumor imaging agent, which has shown promising results in the diagnosis of cancer and inflammatory diseases. In this case, we show a case with calcified benign meningioma which showed increased FAPI activity, which may be mistaken for metastasis in oncological imaging.

## EP-0984

### Bilateral Warthin tumour with coexisting metastatic lung cancer: a rare case demonstrated by 2-[18F]FDG-PET/CT

***I. C. Ferreira***, *R. T. Ferreira, I. Oliveira, A. I. Santos;*
*Hospital Garcia de Orta, E.P.E, Almada, PORTUGAL.*

***Aim/Introduction:*** Warthin tumour (WT) is the second most common benign salivary gland tumour, typically originating in the parotid and affecting males aged 50-70. It grows slowly and has low malignant potential. Bilateral and multifocal lesions are uncommon. Lung cancer (LC) frequently metastasizes to other organs. Several benign aetiologies can cause false positive results on PET/CT with 2-[18F]FDG (FDG-PET/CT). Avidity of WT for 2-[$^{18}$F]FDG is variable, but high uptake has been described. Studies show smokers have an increased risk of developing both WT and LC. While coexistence of LC and WT is rare, it is of diagnostic importance because multifocal WT may mimic metastasis. Our aim was to review the role FDG-PET/CT had in managing such an infrequent case. ***Materials and Methods:*** A 69 year-old man with a history of arterial hypertension, dyslipidemia, heavy smoking and bilateral Warthin tumours (awaiting surgery in another hospital), presented to our institution with sudden onset of dysarthria, dysphagia, involuntary movements of the neck and right amaurosis, resolving after 30 minutes. He also reported weight loss and hemoptoic sputum in the previous week. Neurological exam was normal except for right central facial paresis. Cranio-encephalic (CE), cervical and thoracic CT angiography scans showed a lesion in the left frontal region and a suspicious nodule in the right lung. The patient was admitted for investigation and started therapy with Tacosamide and corticosteroids for suspected focal epileptic seizure due to CE metastasis. ***Results:*** CE RM scan confirmed two brain lesions in the left frontal, temporal and parietal lobes. FDG-PET/CT showed intense radiotracer uptake in a bulky lesion of the upper lobe of the right lung, in a small cerebral lesion and in several large nodules in both parotid glands. Transthoracic needle aspiration biopsy revealed extensively necrotic squamous cell carcinoma. Stereotactic radiosurgery was performed on the brain lesions. Lung surgery was proposed, but the subject was readmitted a month after discharge due to recurrence of neurological symptoms and died two days later from complications of acute infarction of the right middle cerebellar peduncle. ***Conclusion:*** Our case highlights the importance of including WT in the differential diagnosis of salivary gland lesions and recognizing them as potential causes of false-positive findings in FDG-PET/CT studies used for tumour staging. Although rarely reported, coexistence of bilateral WT and lung cancer is noteworthy due to their shared association with smoking as a risk factor.

## EP-0985

### Brown tumors mimicking bone metastasis in a woman with a Parathyroid carcinoma. A Case report.

***A. Genova***[1], *F. Porcaro*[1], *I. Annarumma*[1], *M. Prisco*[1], *L. Turchetta*[1], *A. Biasiucci*[2], *M. Catalano*[1];
[1]*Nuclear Medicine Unit, AORN A. Cardarelli, Naples, NAPLES, ITALY,*
[2]*Histopathology Unit, AORN A. Cardarelli, Naples, NAPLES, ITALY.*

***Aim/Introduction:*** Brown tumors are rare skeletal manifestation of hyperparathyroidism. Persistence of high levels of Parathyroid hormon (PTH) causes increase osteoclasts activity with bone demineralization and microhemorrages creating an excess of cortical bone resorption that produces cysts. Parathyroid Carcinoma (PC) is a very rare cause of multiple brown tumors, in about <1% of hyperparathyroidism cases, its clinical, radiological and Nuclear Medicine findings can create a challenging differential diagnosis. ***Materials and Methods:*** A 47-year old female was admitted for a severe anemia (Haemoglobin 4gr/dl), Hypercalcemia(12.6 mg/dl) and severe bone pelvis pain. Patient had no history of cancer. Chest and abdomen computed tomography (CT) revealed multiple osteolytic lesions on the ribs, scapula and the major on pelvis (6x3 cm), with no findings suggestive of a primary tumor. Tc-99m methylene diphosphonate (MDP) bone scintigraphy confirmed the osteolytic lesions showing multiple foci of reducted MDP uptake, whereas the other bone districts presented a global increased pathological uptake. Consequently, extended blood tests and tumor Markers were investigated. Alphafetoprotein (AFP), CEA, CA19-9, CA125 and Bence-Jones protein levels were normal, however Calcium and PTH are severely increased (14.4mg/dl , 1936.7pg/ml, respectively). ***Results:*** Neck ultrasonography showed a 3.5cm solide nodule in right lobe region; parathyroid scan after injection of technetium 99m-methoxyisobutylisonitrile (MIBI) revealed a large area of increased uptake in corrispondence of right lobe nodule, in both early and delayed phases. Meanwhile patient underwent bone biopsy of the pelvis to reach a definitive diagnosis, that showed a framework of giant osteoclast cells with reactive modifications of the bone tissue, in accordance with Brown tumor diagnosis. Resultantly parathyroid tumor was suspected and inferior right parathyroid gland was surgical resected. Pathological examination, with immunohistochemistry analysis that showed positivity for Pancytokeratin, Chromogranin, GATA3 and negativity for TTF1, Synaptophysin. Over-expressed cyclin D1, Proliferation index 5%. The prevailing reports (infiltration of the fibrous capsule, size, presence of some mitoses) oriented for a low-grade PC. After 5 days from surgery, Sierum Calcium levels dropped from 13.5 mg/dl to 11 mg/dl and PTH levels dropped from 1870 mg/dl to 700 mg/dl. ***Conclusion:*** Osteolytic lesions are common in advanced stages of malignant neoplams. However, it is important not to neglect the hypothesis that they may be signs of brown tumors. In differential diagnosis it should be considered that brown tumors, although rare, may have radiological and nuclear medicine aspects similar to metastatic lesions. An accurate global clinical evaluation should be performed in these complex scenarios.

## EP-0986

### An atypical aspect of bone scintigraphy in AL Amyloidosis

***M. Bel lakhdar***, *H. Guerrouj, J. Rahali, I. Ghfir, N. Ben Raïs;*
*University mohamed V, Faculty of Medicine and Pharmacy, RABAT, MOROCCO.*

***Aim/Introduction:*** Bone scintigraphy is actually a tool with a diagnostic and prognostic good value in amyloid transthyretin cardiac amyloidosis. Cardiac uptake is the most frequently studied extraosseous uptake in this disease.We present a rare pattern of altered bone tracer accumulation, which is consistent with AL amyloidosis in a myeloma patient. ***Materials and Methods:*** The patient was a 36-year-old female with a history of bilateral carpal tunnel syndrome who was admitted to the internal medicine department with symptoms of dyspnea, lower limb edema, macroglossia, and polyarthralgia. Echocardiography and CMR imaging indicated a high suspicion of cardiac amyloidosis. Planar bone scintigraphy was performed two hours after the injection of 740MBq of 99mTc- HMDP. ***Results:*** Bone scintigraphy revealed increased uptake around the joints and in the oro-cervical region without skeletal uptake. Serum protein electrophoresis showed hyper alpha 1 and hyper alpha 2 globulin, and the immunofixation demonstrated a band of light chains type Lambda with L/K ratio of 264. The diagnosis of AL amyloidosis was confirmed by a minor salivary gland biopsy. 30% of clonal plasma cells found on myelogram and the presence of related organ or tissue impairment (CRAB) were consistent with the diagnosis of myeloma. ***Conclusion:*** Our case report presents rare findings of altered bone tracer accumulation, indicative of amyloidosis associated with multiple myeloma. The report sheds light on the underlying mechanisms that may cause the altered tracer distribution in such cases. The findings may have significant implications for the diagnosis and treatment of patients with this condition.

## EP-0987

### Uncommon presentation of an aggressive tumor- FDG PET/CT clinching the diagnosis.

***S. Sagar***, *D. Khan, N. A. Damle, M. Tripathi, M. Bhatt, Y. Gupta, N. Tandon;*
*AIIMS, Delhi, INDIA.*

***Aim/Introduction:*** SIADH is a common paraneoplastic syndrome that occurs in patients with lung cancer, particularly SCLC (1). It is characterized by excessive release of antidiuretic hormone (ADH) from the pituitary gland or other ectopic sources, leading to hyponatremia and low serum osmolality (2).PET/CT is a valuable diagnostic tool for the detection of SCLC and other malignancies, with a reported sensitivity and specificity of 90-95% and 80-85%, respectively (3). In our case, PET/CT not only confirmed the presence of a lung mass but also showed hypermetabolic activity, which is suggestive of a malignant process. The patient presented to endocrinologist despite having widespread metastases and a large lung mass, the patient neither presented with chest symptoms nor with pain at metastatic site. ***Materials and Methods:*** the scan was acquired on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE). ***Results:*** We report the case of a 62-year-old female patient who presented with a 6-month history of fatigue, weight loss, and hyponatremia. The patient's medical history was significant for hypertension and hyperlipidemia. Upon admission, laboratory tests showed a serum sodium level of 124 mmol/L and a serum osmolality of 252 mOsm/kg. Her urine osmolality was elevated at 440 mOsm/kg, and her urine sodium was 85 mmol/L. The patient was diagnosed with the syndrome of inappropriate antidiuretic hormone secretion (SIADH) and was referred for FDG PET/CT. PET/CT scan confirmed the presence of a lung mass with hypermetabolic activity in the left pulmonary region with metastases to multiple skeletal sites. Biopsy of the lung mass revealed small-cell lung carcinoma (SCLC).The patient was started on fluid restriction, and her serum sodium levels gradually improved to 135 mmol/L. However, due to the aggressive nature of SCLC, the patient was started on chemotherapy with cisplatin and etoposide. ***Conclusion:*** This case highlights that PET/CT is a useful tool for the detection of SCLC and can also provide valuable

information regarding the metabolic activity of the tumor. FDG PET/CT can help in diagnosis, staging and excluding alternate diagnosis. ***References:*** 1.Grimaldi C, Pasqualetti P, Tognetti F, et al. Small cell lung cancer and hyponatremia: a retrospective study. Intern Emerg Med. 2011;6(6):503-508. 2.Ellison DH, Berl T. Clinical practice. The syndrome of inappropriate antidiuresis. ## EP-0988

### Basal Cell Carcinoma Transformation to Squamous Cell Carcinoma Following Systemic Treatment: Impressive PET/CT Images and Clinical Implications.

***M. Pudis***[1], *P. C. Notta*[1], *B. Hervás-Sanz*[1], *J. R. Ferreras-Riera*[2], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN,*
[2]*Department of Dermatology, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

***Aim/Introduction:*** Basal cell carcinoma (BCC) is the most common type of skin cancer, usually characterized by slow growth and local invasion. However, in some rare cases, BCC may undergo transformation into a more aggressive form of skin cancer, such as squamous cell carcinoma (SCC), which is associated with a higher risk of metastasis and mortality. ***Materials and Methods:*** We present a case of a 66-year-old woman with a more than 20-year-old ulcerative lesion in the right hemiabdomen (Figure 1) that was diagnosed as an infiltrating basal cell carcinoma. An [$^{18}$F] FDG PET/CT (Figure 2) staging scan revealed cutaneous, muscular, and bone involvement with destruction of the right iliac crest (Figure 3). The patient received two lines of systemic treatment with disease progression, as confirmed by follow-up PET/CT scans revealing lung and bone metastasis. Due to the patient's poor condition and disease progression, a new biopsy was performed, which revealed transformation to squamous cell carcinoma. ***Results:*** Due to the patient's general condition, frailty, and tumor-related bleeding and infection, she was not eligible for clinical trials. Furthermore, radiation therapy was ruled out due to the extensive and deep involvement of the lesion, affecting even the subcutaneous fat. The patient is currently under palliative care follow-up. ***Conclusion:*** This case highlights the importance of early diagnosis and prompt intervention in preventing disease progression and improving patient outcomes. In addition, PET/CT imaging can provide valuable information on disease extent and response to treatment, as evidenced by the impressive images obtained in this case. However, the limited treatment options for advanced cases underscore the need for better understanding of the pathogenesis of BCC transformation to SCC and the development of more effective therapies.

## EP-0989

### Case report: Soft Tissue Metastasis in Lung Cancer - The impact of 2-[18F]FDG PET/CT

***R. T. Ferreira***, *I. C. Ferreira, I. Oliveira, D. Canário, S. Carmona, J. G. Santos, J. A. Sequeira, A. I. Santos;*
*Hospital Garcia de Orta, E. P. E., Almada, PORTUGAL.*

***Aim/Introduction:*** Lung cancer is the second most common cancer worldwide, with a high incidence of distant metastasis. Soft tissue metastases (STM) are rare, particularly when compared to cancer spread sites, such as the brain, bones, liver, and adrenal glands. We present two lung cancer cases, in which a correct M1 staging diagnosis was possible due to 2-[$^{18}$F]FDG PET/CT (FDG-PET/CT) visualization of a single STM - in one case detected in the initial staging and in the other after thoracic disease progression. ***Materials and Methods:*** Case 1 was a 54-year-old male smoker (60 pack/year), with history of nephrectomy for renal cell carcinoma and co-infection with HIV/HCV. The patient was asymptomatic and was referred for assessment of a solitary lung nodule detected during a chest CT. Subsequent staging using FDG-PET/CT revealed not only a mild increase in metabolic activity in the nodule located in the left upper lobe of the lung and in a homolateral hilar lymph node, but also an intense focal uptake in a suspicious lesion located in the right thigh. Case 2 was a 62-year-old female smoker (1,5 packs/year) who had previously been diagnosed with lung adenocarcinoma staged T1b N0 M0. The patient underwent left upper lobectomy and mediastinal lymph node dissection and was subsequently put under surveillance. Approximately six months later, thoracic disease progression was detected on chest CT, revealing a large lesion invading soft tissue and ribs within the chest wall. The subsequent restaging using FDG-PET/CT revealed increased metabolic activity within the thoracic lesion, and identified a new suspicious lesion located in subcutaneous soft tissue in the right thigh. ***Results:*** Biopsy of the lesions identified through FDG-PET/CT confirmed the suspicion of STM from lung adenocarcinoma, confirming ineligibility for surgery and thus, modifying the therapeutic approach in both cases. ***Conclusion:*** Approximately 50% of lung cancer cases are metastatic at the time of diagnosis and most patients do progress from the initial stage to a more advanced disease. Distant metastases to soft tissue, defined as metastases to skeletal muscle, skin and subcutaneous tissues, are rarely reported in the literature. Early detection of STMs is challenging due to their nonspecific clinical and radiological manifestations. FDG-PET/CT is a non-invasive whole-body imaging modality that, as shown in these cases, very efficiently identifies previously unknown metastatic sites, including STMs, thereby making it an essential tool for both initial staging and subsequent monitoring of patients, allowing prompt treatment and possible better prognosis.

## EP-0990

### Evaluation of metabolic response with18F-FDG PET-CT in advanced thymic adenocarcinoma

***H. Noamen***, *K. Ben Ahmed, W. Amouri, T. Mohamed, I. Jardak, M. Maaloul, S. Charfeddine, K. Chtourou, F. Guermazi;*
*University hospital of Habib Bourguiba, Sfax, TUNISIA.*

***Aim/Introduction:*** Thymic adenocarcinomas of the mediastinum are extremely rare and aggressive tumors. Patients with advanced or recurrent thymic carcinomas often need several consecutive lines of chemotherapy and radiotherapy. The aim of this case report is to show the utility of $^{18}$F-FDG PET/CT in assessing the metabolic response in a recurrent advanced thymic adenocarcinoma. ***Materials and Methods:*** A 45-year-old male patient was diagnosed three years ago with poorly differentiated thymic adenocarcinoma initially unresectable with lymphatic mediastinal and hilar invasion on both CT scan and $^{18}$F-FDG PET/CT. The patient was treated with neoadjuvant chemotherapy and radiotherapy. CT findings showed one year after treatment progressive cervical, mediastinal, and abdominal lymphatic disease with lymphangitic pulmonary lesions therefore second-line chemotherapy was indicated. After treatment, the disease was considered stable on morphological response criteria. $^{18}$F-FDG PET/CT was requested to assess metabolic response and to better plan radiotherapy of the residual lesions. ***Results:*** $^{18}$F-FDG PET/CT showed high metabolic activity in multiple cervical, mediastinal, and abdominal lymph nodes, high FDG uptake in pulmonary nodules, and unilateral adrenal gland. These findings were suggestive of recurrent advanced disease. Salvage-intensive chemotherapy before radiotherapy has been discussed after these results.

***Conclusion:*** Thymic adenocarcinomas are rarely reported and have usually a poor prognosis. As a promising metabolic imaging method in terms of patient management, $^{18}$F-FDG PET/CT makes important contributions to a therapeutical evaluation in routine clinical practice of thymic carcinomas. Further studies need to be done in order to assess the role of $^{18}$F-FDG PET/CT in thymic epithelial tumors. ***References:*** Kaira K, Murakami H, Miura S, Kaira R, Akamatsu H, Kimura M and al. 18F-FDG uptake on PET helps predict outcome and response after treatment inunresectable thymic epithelial tumors. Ann Nucl Med. 2011;25:247-53.

## EP-0991

### DLBCL mimicking infection on FDG PET/CT - resolving the conundrum

***D. Khan***, *N. A. Damle, M. Tripathi, B. Pridhivi, P. Sethi, N. Wig, S. Sagar, A. Narayan;*
*AIIMS Delhi, Delhi, INDIA.*

***Aim/Introduction:*** Diffuse large B cell lymphoma (DLBCL) is most common type of non-Hodgkin's lymphoma. It primarily presents as generalized lymphadenopathy. Bone involvement in DLBCL is relatively rare, while osteonecrosis is rarer. Here we present a clinically challenging case of DLBCL with unusual presentation. ***Materials and Methods:*** A 46-year-old male presented to medicine OPD with low back ache and bilateral thigh & leg pain since 5 months, progressively worsening in severity. Physical examination, blood tests, ultrasonography, bone marrow biopsy, muscle biopsy, and two FDG PET/CT were performed to investigate cause of symptoms. Finally, guided bone biopsy of left hip performed based on intensely avid lesion as noted in FDG PET/CT and it revealed diagnosis. ***Results:*** Lab investigation of patient revealed pancytopenia and raised inflammatory markers. Also MRI of patient revealed red marrow re conversion changes in visualised vertebrae. Subsequently patient underwent bone marrow biopsy which showed necrotic/infarcted marrow. Bone marrow culture revealed pseudomonas aeruginosa. As cytopenias improved, patient was discharged and advised to continue antibiotics for 2 weeks . However one month later patient was readmitted with aggravated symptoms and physical examination showing splenomegaly and tenderness in lower back region. Repeat MRI revealed multiple vertebral lesions, left psoas collection and multiple muscular hyperintensities. As the muscle biopsy was inconclusive and psoas collection appeared sterile, to solve diagnostic dilemma FDG PET/CT was performed .It showed diffuse marrow uptake with few focal marrow lesions along with increased tracer avid lytic lesions in the bilateral pelvic bones with hypodensities in few lower limb muscles and significant splenomegaly. CT guided biopsy from left iliacus and left iliac bone revealed extensive coagulative necrosis. Patient was treated as a case of infection related myonecrosis, myositis and sacroiliitis and was started on analgesics with significant improvement of symptoms. Repeat FDG PET/CT was advised to look for resolution of symptoms after one month. It demonstrated progression with extensive marrow lesions and few lytic lesions predominantly in bilateral pelvic along with subcentimetric lymph nodes and persistent splenomegaly. We advised biopsy from intensely FDG avid lesion marrow lesion in left anterior superior iliac spine which was ultimately revealed as case of DLBCL. ***Conclusion:*** This clinically challenging case sheds light on unusual presentation of DLBCL, which is typically characterized by generalized lymphadenopathy. Bone involvement in DLBCL is rare. This case highlights importance of considering lymphoma as a potential diagnosis in patients with unexplained back pain and bone lesions.

## EP-0992

### Osteoblastoma like osteosarcoma - diagnostic challenge - a case report

***N. Manevska***[1], *T. Makazlieva*[1], *S. Kostadinova Kunovska*[2], *S. Stojanoski*[1], *A. Gavrilovski*[3];
[1]*Institute of Pathophysiology and Nuclear medicine, Medical Faculty, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA,* [2]*Institute of Pathology, Medical Faculty, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA,* [3]*University Clinic for Orthopedic Surgery, Medical Faculty, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA.*

***Aim/Introduction:*** Osteoblastoma like osteosarcoma is a rare variety of osteosarcoma (1.1%). Although literature presents these tumors as low-grade malignant tumors, the World Health Organization (WHO) Classification classifies these tumors in the group of conventional (high-grade) osteosarcomas. Differential diagnosis between these kind of tumors from aggressive osteoblastoma as well as osteosarcoma is quite challenging and controversial. ***Materials and Methods:*** 20 year-old girl complained of a pain and limited movement in the right shoulder over a year. The pain was especially strong in the evening, there is tingling and shaking in the hand. ***Results:*** Rtg showed on the proximal metaphysis of the neck of the right humerus, an oval lytic defect medially with a sclerotic rim about 15 mm long. On the CT scan in the proximal meta-epiphysis of the right humerus, localized posteriorly, a lytic change was observed affecting the cortex of the bone with cortical swelling and thinning, expansively related to the environment and measuring 19 x 21 mm on axial scans, 24 mm on coronal scans. A discrete, slightly irregular periosteal reaction was observed. Perilesional soft tissue edema was present. Differential diagnosis included osteoblastoma, chondromyxoid fibroma, and an aggressive aneurysmal bone cyst. MRI presented a tumor mass relatively with a homogeneous signal, with a weak hypersignal in relation to the muscles in T1, and with a hypersignal in T2. Significantly larger part of this tumor mass as an exophytic soft tissue component is outside the bone and around it there is a collection of liquid. Differential diagnosis were paraosteal ostesarcoma or chondroblastoma. Bone scan (99mTc-MDP) was also performed with findings of a high vascularity in the pool phase and intensive pathologic accumulation of the tracer in the meta-diaphysis of the right humerus (tumor mass) on the WBS and the SPECT/CT. She was admitted at the Clinic of Orthopedics and after surgical operation the histopathology revealed osteoblastoma like osteosarcoma. ***Conclusion:*** The right diagnosis is of importance in the treatment protocol of patients with a diagnosis of osteoblastoma like osteosarcoma. Wide surgical margins have to be achieved to prevent future recurrence.

## EP-0993

### Contribution of whole-body bone scan coupled with SPECT/CT in the diagnosis of SAPHO syndrome: case report.

***j. Charfi***, *S. Marwa, O. Ben Hamida, C. Mhiri, I. Slim, A. Mhiri;*
*salah azaiez institute, tunis, TUNISIA.*

***Aim/Introduction:*** SAPHO syndrome (acronym for Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis) is characterized by neutrophilic skin involvement associated with chronic osteomyelitis. It is an autoimmune disease that most often affects young people without sparing older patients. Tc99m bone scintigraphy is very valuable for diagnosis insofar as the fixation of the isotope may precede the clinical and even radiological manifestations, especially since a link between SAPHO and spondylarthropathies has been established. The aim of our report is to present a case of SAPHO syndrome associated with a vertebral expectation discovered by bone scan. ***Materials and Methods:*** We report the case of a 57-year-old patient admitted

to the orthopedic department for chronic anterior thoracic bone pain. ***Results:*** Clinical ecamination revealed a slight deformation of the right sternoclavicular joint. Biological tests showed an inflammatory syndrome.A standard chest X-ray showed a hypertrophic and condensing aspect of the right sternoclavicular junction. A whole-body scan coupled with SPECT/CT showed at the early stage a moderate hypercaptation of the right sternoclavicular joint and the pubic symphisis. At the late stage, the examination showed intense and diffuse hyperfixation of the right sternoclavicular joint and the manubrium-sternal body junction. Moderate fixation of the left hemi-body of L5 was found associated with condensation and erosion of the vertebral body and hyperfixation of the pubic symphysis with condensation of the left pubis. The whole-body bone scan coupled with SPECT/CT has confirmed the diagnosis of SAPHO in the sternoclavicular junction and has showed also a subclinical localization in the 5th lumbar vertebra. ***Conclusion:*** SAPHO syndrome remains a non-disabling condition and its treatment is essentially symptomatic. Early diagnosis is associated with a better prognosis. This confirms the value of bone scintigraphy which is sensitive even before the onset of clinical manifestations.

## EP-0994

### Place of peritoneal scintigraphy in the diagnosis of pleuro-peritoneal communication: A case report.

***K. Ayed****, H. Charfi, M. Nouira, R. Sfar, K. Chatti;*
*Nuclear Medicine Department, Sahloul Hospital, Sousse, TUNISIA.*

***Aim/Introduction:*** Pleuro-peritoneal communication is a rare complication of peritoneal dialysis, affecting 1.6 to 2% of patients. Its diagnosis is suspected in the presence of suggestive clinical symptoms, and currently, there is no consensus on complementary tests that should be performed to confirm it. Through this case report, we emphasize the role of peritoneal scintigraphy using 99mTc-labeled nanocolloids in the diagnostic approach of this complication. ***Materials and Methods:*** We report the case of a 56-year-old patient with a history of chronic kidney failure at the stage of peritoneal dialysis, who presented to the nephrology consultation with recent-onset dyspnea and progressive worsening. Chest X-ray showed a moderate amount of right pleural effusion. Pleural fluid analysis revealed a transudative fluid, low in LDH and high in glucose, suggesting a passage of peritoneal dialysis fluid into the pleural cavity. Based on these findings, the diagnosis of pleuro-peritoneal leak was considered to be the most probable. ***Results:*** A peritoneal scintigraphy was performed for diagnostic and localizing purposes. Immediate dynamic images and SPECT/CT were obtained, showing a positive examination: passage of the radiotracer injected into the dialysate bag (5mCi of 99mTc-labeled nanocolloid) to a moderate amount of right pleural effusion, with the maximum uptake seen in the right posterior-inferior part of the diaphragm. ***Conclusion:*** Peritoneal scintigraphy is a very effective imaging technique in the diagnostic approach of pleuro-peritoneal communications as a sensitive, low-irradiating, and non-invasive imaging modality that can be used for diagnostic and localizing purposes.

## EP-0995

### Is Captopril renography with 99mTc-DTPA still of merit in renovascular hypertension? a case report

***R. Belayouni****, O. Ben Hamida, M. Ben Nasr, M. Somai, I. Slim, i. meddeb, I. Yeddes, A. Mhiri;*
*Salah Azaiez Institute, Tunis, TUNISIA.*

***Aim/Introduction:*** We present a case of unilateral renovascular hypertension (RVH) confirmed by Captopril renography (CRS) with 99mTc-DTPA. ***Materials and Methods:*** A 5-year-old child, with no particular medical history was admitted to a pediatric ward for confirmed hypertension. Blood pressure (BP) ranged from 150-135 mmHg systolic and 70- 95 mmHg diastolic in the setting position. He had a kidney function decline with a glomerular filtration rate at 70 ml/min. Abdominal auscultation and renal ultrasound showed no abnormalities. The patient was then referred to us for CRS with 99mTc-DTPA. This exam was performed according to two-time one-day protocol. At first, a baseline study was fulfilled. Then, renography was repeated 1 hour after the oral administration of captopril (50 mg) with cheking BP every 15 minutes. sequential renal images were acquired by means of a gamma camera at the rate of one frame every 10 sec for 30 minutes in the supine position after a bolus injection of 162 MBq of 99mTc-DTPA. This scintigraphic protocol was the same in all studies. A background-subtracted renogram was obtained after image treatment. ***Results:*** 99mTc-DTPA sequential images and renogram in the baseline study demonstrate a normal pattern of tracer uptake and excretion in the two kidneys with a symetrical renal functions in both sides. Sequential images and the renogram in captopril study showed a dramatic change in the left kidney as is clearly shown by the shift of the nephrogram to the right, the appearance of a left renal stasis and the increase in peak time (16 minutes Versus 3 minutes) and residual activity which argues in favor of hemodynamically significant renovascular disease in the left kidney.There are no significant changes in the renogram of the right kidney. A medical treatment has been prescribed while waiting for renal artery revascularization. ***Conclusion:*** RVH is a potentially curable etiology. CRS with 99mTc-DTPA is a non-invasive, low-radiation procedure which still being an excellent technique tu use in the exploration of patients with renal artery stenoses. it allows the selection of patients who can successfully benefit from a surgical or endoscopic revascularization procedure.

### Implementation of 3D digital SPECT/CT device for clinical workflow in myocardial perfusion imaging - a multidisciplinary collaborative project approach

***J. Kaunisto****, A. Keinänen, H. Gröhn, T. M. Laitinen, M. Hakulinen, S. Koponen, S. Halttunen, T. P. Laitinen;*
*Kuopio University hospital, Kuopio, FINLAND.*

***Aim/Introduction:*** New 3D digital SPECT/CT enables dynamic 3D myocardial perfusion imaging (MPI) which allowed us to include dynamic scans in clinical rest/stress MPI protocol. Efficient implementation of the new protocol to clinical use is a challenging task. Utilization of continuous improvement (Kaizen) is one of the strategic principles in our hospital. Our aim was to use the LEAN methods to recognize the most critical aspects contributing to successful implementation of the new technology and make corresponding actions as a part of clinical workflow. ***Materials and Methods:*** LEAN A3 report was used to summarize the challenges, status and aim of the dynamic

MPI implementation. Ishikawa diagram was utilized for detailed analysis of critical factors affecting the implementation. To follow PDCA (plan-do-check-act) principle, above analyses were updated based on gained experience from first patient studies, in several brainstorming sessions, by multidisciplinary team. To identify wasted time during the MPI protocol, duration of different phases and waiting time was recorded. ***Results:*** By utilizing Ishikawa diagram, Personnel, Methods and Materials were found to be the most critical factors contributing to the development process. To achieve required expertise level of Personnel, two technologists were named as superusers. They received extensive training from manufacturer and made site visit to other hospital which uses the same equipment and performs similar studies. Multidisciplinary team developed orientation plan for all professional groups which included for example schedule and detailed checklists for required knowledge and skills for each profession. As Methods, imaging protocol and data analysis are continuously developed. Imaging protocol from literature was used as a starting point and modified in iterative process. Imaging protocol and data analysis were further improved with help of manufacturer and analysis software company. As Materials, in addition to orientation plan related material, patient information sheets and operation procedures were updated accordingly.As an overall result, our clinical workflow and patient scheduling has been improved compared to both the starting point of the process with the new device and previous MPI protocol. ***Conclusion:*** Using LEAN methods, we were able to focus our efforts to the essential aspects of implementing the new technology including dynamic MPI protocol as part of the clinical workflow. The well-planned, correctly focused training of the personnel was found to be one of the most important aspects for successful implementation. Process required multidisciplinary team committed to continuous development. The next phase is to concentrate on optimizing study protocol.

## EP-0997

### Annual DXA Operator Audit - A single site experience

***D. Teixeira Macarico***, *C. Reilly, A. Nicol;*
*Nuclear Medicine Department, Queen Elizabeth University Hospital, Department of Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** Dual X-Ray Absorptiometry (DXA) is the gold standard method for diagnosis of Osteoporosis. Due to the high levels of precision needed for this technique it is important that routine audits are performed for the operators in order to ensure the accuracy and reproducibility for diagnosis and treatment monitoring. Nuclear Medicine at the South of Glasgow offers DXA scans. In 2022 following review of scanning protocols and implementation of new techniques, a new audit tool was created for quarterly operator checks as per international recommendations. The aim of this study is use the audit tool to perform a review per quarter and per operator, adopting a learning from excellence and training needs approach. ***Materials and Methods:*** Quarterly audits were performed by a senior operator in 10 randomly selected patients per DXA operator (n=5) at the Queen Elizabeth University Hospital in Glasgow. Scanning and analysis parameters (e.g anatomical area centred and straight, femoral box adjusted, vertebral exclusion correctly performed) were scored between 1 (lowest) to 5 (highest) for all scans (Anterior-Posterior Lumbar Spine, Proximal Femur, Vertebral Fracture Assessment and 33% Radius ). The average score per parameter was calculated per each operator as well as the score per anatomical area and the overall department scores. These were used through the year to identify training needs and adjust practice. A final yearly overview was created to assess progression using this audit tool. ***Results:*** A total of 200 patients were included in this audit (5 operators x 4 scan sites x 4 quarters) - AP Spine (n=197), Proximal Femur (n=187), 33% Radius (n=125) and Vertebral Fracture Assessment (n=198). The operator scores were Q1: average 4.7 (4.4 - 5.0); Q2: average 4.8 (4.6-5.0); Q3: average 4.8 (4.6-5.0); Q4: average 4.8 (4.5-5.0). The minimum operator score (33% radius, 3.6) was in Q1 and the minimum thereafter was 4.1 (33% radius). The target score of 4.5 was achieved in Q1: 17/20; Q2: 18/20; Q3: 17/19; Q4: 17/19 datasets. ***Conclusion:*** This was a useful local audit tool undertaken throughout the year. Good practice was celebrated and follow up actions focused on the radius scans which had recent protocol changes, resulting in improving practice. It is also noted that radius scans are less frequently indicated. There were a few limitations including the disparity of the amount of patients each operator scanned.

***Aim/Introduction:*** INCISIVE is an EU-Horizon 2020 project, part of the Artificial Intelligence (AI) for Health Imaging (AI4HI) network, that aims to develop and validate a multimodal AI-based toolbox for the empowerment of imaging analysis related to the diagnosis, prediction, and follow-up of cancer, while also contributing to the development of an open, standard-based, interoperable Federated European Cancer Imaging repository. ***Materials and Methods:*** The project's consortium comprises 27 partners from 9 countries, each covering different expertise. The Italian University of Tor Vergata (UNITOV) acts as one of the major data providers for nuclear medicine (18F-FDG PET/CT) imaging cases of lung, breast, and colorectal cancer. Collection of clinical and imaging data is carried out in both retrospective and prospective settings. Once the patients are identified, an automated data curation and annotation workflow must be followed, ensuring good quality and integrity of the data. Next, aggregation and segmentation through a Machine Learning-aided annotation tool take place. Data are finally uploaded in the Imaging repository for AI training, validation, and feasibility testing and for AI models implementation. The delivery of all services to the healthcare professionals is foreseen through the development of a hybrid infrastructure with intuitive interactive user interfaces. ***Results:*** For the retrospective phase of the study, UNITOV collected,

anonymized, annotated and uploaded 80 lung cancer PET/CT imaging cases, 40 breast cancer cases and 20 colorectal cancer cases. For the currently ongoing prospective phase of INCISIVE, the number of PET/CT exams collected by UNITOV are 135 for lung cancer, 97 for breast cancer, and 127 for colorectal cancer. Data curation and imaging annotation currently are the most time-consuming phases of the process. Performance of the quality check for collected data demonstrated no major issues, with only limited effort needed for tool debugging. A first prototype of the INCISIVE federated repository has been implemented, integrated and delivered. Further training and validation with INCISIVE data is ongoing. ***Conclusion:*** INCISIVE moves towards the exploration of the full potential of AI solutions in cancer imaging, with preliminary results being expected at the beginning of 2024. The AI-based toolbox will improve the accuracy of PET/CT examinations for the detection of primitive cancers and recurrences.

## EP-1000

### NOAR COST Action: Advancing Targeted Alpha Therapy with Astatine-211 for Cancer Treatment

***E. Janevik-Ivanovska***[1], *J. Gestin*[2], *E. Aneheim*[3], *S. Lindegren*[3], *J. Gaschet*[4], *S. Palm*[5], *D. Niculae*[6], *P. Bouziotis*[7], *M. Pruzynski*[8], *P. Kolenc*[9], *A. I. ***Aim/Introduction:*** The aim of the NOAR COST Action CA19114 is to demonstrate the feasibility and efficacy of using Astatine-211 Targeted Alpha Therapy (TAT) as the European standard for treating certain cancerous pathologies. This will be achieved through efficient knowledge exchange and networking among all European stakeholders and partners outside of Europe. ***Materials and Methods:*** The NOAR COST Action will address the following points: Astatine-211 targetry, production, and logistics; correct speciation of At-211 for pharmaceutical production; optimization of vectors for At-211 labeling and development of validated radiolabeling protocols; automation in production of At-211 and At-211 radiopharmaceuticals; development of dosimetry techniques for At-211 TAT; identification of the regulatory environment for TAT using At-211 radiolabeled vectors; investigation of pharmacoeconomics of TAT with At-211; education and communication aspects. ***Results:*** The NOAR COST Action CA19114 is expected to yield the following outputs: a strong capacity to produce At-211 radiopharmaceuticals by bringing together European skills in radiochemistry, chemistry, biology, dosimetry, and preclinical and clinical research; robust partnerships among participants, leading to increased collaboration; training of Early Career Investigators (ECIs) and PhD students through Short Term Scientific Missions (STSMs); establishment of a network that permits innovative technology on At-211 TAT. ***Conclusion:*** The NOAR COST Action will facilitate efficient knowledge exchange and networking among all European stakeholders interested in promoting At-211 for medical applications and will allow association with partners outside of Europe (USA, South Africa, Japan). By joining European and international research efforts, fundamental and applied knowledge on At-211 will be significantly increased, and Europe will take a technology lead in the field of At-211 TAT.

## EP-1001

### Appropriation of hybrid practices in oncological imaging: the situation of PET-CT in France from a management perspective.

***R. Guignard***[1,2], *B. Geffroy*[2], *V. Fernandez*[3];
[1]*Clinique de Genolier, Genolier, SWITZERLAND,* [2]*IMT Atlantique - LEMNA, Nantes, FRANCE,* [3]*TELECOM Paris, Paris, FRANCE.*

***Aim/Introduction:*** As a hybrid technological device, PET-CT changes the practice of nuclear medicine (NM) physicians while introducing professional practices coming from radiology. The management issues of the adoption of health technologies and the appropriation of innovation in hybrid NM practices (hNMp) have never been addressed in qualitative research. ***Materials and Methods:*** Between 1st January 2022 and 30th June 2022, we conducted a series of 24 semi-structured interviews (average interview length: 70.2±17.7 minutes) among French healthcare professionals working in 6 different NM departments. The aim of these interviews was to find out how NM physicians use PET-CT as a hybrid technology in their daily practice. Interview data were collected, coded, analyzed and triangulated by 3 researchers. ***Results:*** 22 NM physicians and 2 chief NM technologists were interviewed (m/f sex ratio: 1.4; 41.3±8.5 years old). 77.3% of professionals reported an initial training in radiology (6 months minimum) and 14.7±6.7 years of experience in NM.In PET-CT imaging, hNMp was divided into 2 continuous parts, in which different types of professional behaviour were observed: the operational part (ie. imaging protocol, mostly managed by technologists) and the intellectual part (ie. medical interpretation). For each part, we actually identified a number of variables that may have an impact on appropriation process of hNMp.The

fundamentals of hNMp can be supported by several parameters, such as the intrinsic features of the technology (i.e. benefit-risk ratio), a complete expertise of the NM teams in radiological practices, or a standardisation of the procedure with a normalised framework that is understandable for all stakeholders. Dynamic of hNMp appropriation can be explained by the intrinsic dynamic of NM itself, by individual levers and barriers, or by the substitution of CTscans for oncological purposes. The legitimisation of hNMp is first of all part of the legitimisation strategies of PET imaging itself. Among adopters of hNMp, acquisition of transversal skills through a specific training leading to functional autonomy and external influences (demand pressure from oncologists) are important levers. ***Conclusion:*** Our study highlights the heterogeneity of PET-CT imaging practices among French NM physicians, who own PET-CT as a capital resource, and then provides some insights into innovative technology adoption.Socio-organisational boundaries between 2 independent medical specialties, defined by their medical competencies and responsibilities, lead to inequalities in the multimodality approach to PET-CT. Our results support the necessity of different organisational approaches for the management of multimodal imaging.

## EP-1002

### Novel approach for the technical implementation of radiowater studies for a pet/ct- scanner in hospital environment

***M. Hakulinen***[1], *P. Poutiainen*[2];
[1]*Diagnostic Imaging Centre, Kuopio University Hospital, Kuopio, FINLAND,* [2]*Cyclotron and radiopharmacy unit, Kuopio University Hospital, Kuopio, FINLAND.*

***Aim/Introduction:*** Oxygen-15 labelled water, i.e. radiowater, is used as a radioactive tracer for perfusion of heart, brain, and tumors. There are several clear benefits for the use of radiowater in particular, such as low effective dose for the patient, it is metabolically inert and passes freely across cell membranes and thus, the distribution and clearance of radiowater depends completely on the rate of blood flow. However, the use of radiowater is limited since it requires on-site cyclotron and technical implementation can be very challenging. E.g. short half-life of oxygen-15 as well as optimization for the oxygen and radiowater flows in long tubing. Good manufacturing practice (GMP) requirements needs to be carefully designed to full fill the quality demands for drug production. In this study, we will introduce a novel approach for setting up oxygen-15 studies in PET facilities at Kuopio University Hospital. ***Materials and Methods:*** The technical plan for the use of oxygen-15 in clinical PET/CT- studies included several different aspects 1) radiation safety 2) reliability of operation, 3) GMP and quality control requirements 4) maintenance/fault repair and 4) practical work considerations while maintaining the transfer line as short as possible. There were several engineers involved in the project related to electric, HPAC, building automation planning as well as construction experts. This project was part of larger relocation project of our nuclear medicine department. ***Results:*** As a results of this project, we developed a novel floor gutter to scanned rooms enabling reliable connections to the transfer lines especially considering practicality and radiation safety. The system allows several endpoints where the radiowater is used. Easy to operate automated system to control the selection of production lines and waste gas lines were build including simple light system to notify users in different areas where the radioactive gas flows. The safety system was designed to notice and control the flow of possible leaked activities and system design allows at least 300meters long transfer lines. The system was designed to fulfill the GMP requirements and make it possible to build the system outside the cleanroom area. ***Conclusion:*** Novel plan for technical implementation of radiowater studies was achieved. The system was especially designed to enable use of radiowater in multiple endpoints while considering radiation safety, practicability and easy to access characteristics of the system. The system was also designed to fulfill GMP requirements.

## EP-1003

### Identifying the unique needs of transgender, non-binary and gender diverse patients in the nuclear medicine department

***A. Cripps***[1], *J. Taylor*[1,2], *R. Salmon*[1];
[1]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM,* [2]*University of Sheffield, Sheffield, UNITED KINGDOM.*

***Aim/Introduction:*** Transgender and non-binary people face significant barriers to healthcare, exacerbated by a widespread lack of knowledge of their unique healthcare needs amongst healthcare providers[1]. In this study, a literature review, staff interviews and surveys were used to identify the aspects of the nuclear medicine patient pathway where transgender, non-binary and gender diverse (TGD) patients have unique needs. After identifying these needs, a training presentation was developed and delivered to nuclear medicine staff, to increase their understanding of how best to care for these patients. ***Materials and Methods:*** A literature review was conducted of TGD experiences in healthcare, focussing on staff-patient interaction, policy and procedures, and radiology-specific experiences. A focus group with senior staff members in a nuclear medicine department was conducted to understand the background and context surrounding TGD patients in the department and identify knowledge-deficient areas. Patient-facing clinical staff were surveyed to identify any situations in which they would struggle to give high-quality care to a TGD patient, or situations that they felt a TGD patient might find uncomfortable. This data was thematically analysed to identify nuclear medicine-specific issues. These issues arose from aspects of the patient experience where gender is used to determine an aspect of care, or where TGD people are especially vulnerable to discomfort. Training on these key issues was written and delivered, then staff were surveyed post-training to provide feedback. ***Results:*** Four key aspects of the nuclear medicine patient experience were identified: pregnancy enquiries; pregnancy and breastfeeding advice post-therapy; genital, chest or breast injection sites; and gendered normal ranges. Each of these has the capability to either cause discomfort for a TGD patient or result in them receiving substandard care due to lack of knowledge amongst staff. The training described these issues and suggested solutions from the literature. This was overarchingly well-received by staff, with the survey results showing that the modal rating was 'very informative', 'very useful', and 'very relevant'. Thematic analysis revealed a strong sense of increased understanding and empathy for TGD patients post-training. ***Conclusion:*** To conclude, a training presentation was created to identify the unique needs of TGD patients in the nuclear medicine department, and present these to staff, alongside suggestions to ameliorate these patients' experiences. This is a step towards removing barriers to healthcare for a marginalised group and was well-received by staff. ***References:*** (1) Hobster K, McLuskey J. Transgender patients' experiences of health care. British Journal of Nursing. 2020;29(22):1348-53.

## EP-1004

### Illuminating actionable practice to improve recall of medical information in nuclear medicine department

***S. Ibba***[1], *P. Gandolfo*[1], *L. Airò Farulla*[2], *D. Zago*[1], *G. Fosci*[1], *S. Papa*[1];
[1]*CDI Centro Diagnostico Italiano S.p.A., Milan, ITALY,* [2]*University of Milan, Milan, ITALY.*

***Aim/Introduction:*** To prepare patients for nuclear medicine examinations, they are usually provided with a written information note at the time of booking, explaining how the examination is conducted and how they should prepare for it (e.g., interruption of medications). However, nuclear medicine patients are often debilitated, anxious or elderly which causes some of them to fail to understand the complex instructions they receive. This results in some patients arriving on the day of the examination unprepared and thus unable to undergo the procedure. Therefore, we aim to increase the recall of information for nuclear medicine exam preparation to improve patient compliance. ***Materials and Methods:*** In addition to written instructions, in 2019 we introduced a telephone structured interview with the patient carried out by a trained operator of our centre able to explain step by step the preparation for PET and DaTSCAN SPECT and how they are conducted. The interview, which is performed a week before the procedure, is tailor-made and based on a structured checklist. ***Results:*** Before introducing the interview, occasionally patients did not fully understand the written instructions given at the time of booking. If the patient was unprepared for examination, he was dismissed causing delayed diagnosis, a sense of frustration for the patient, and a negative impact on the department's productivity. Implementation of the tailor-made interview, in addition to the written information note, has enabled us to significantly reduce the number of patients who did not follow the correct exam preparation protocol, decreasing the drop-out rate from ~30% to ~2%. The second advantage is that we can intercept any potential issue (e.g., claustrophobia, acute bronchitis..) and implement strategies to counteract them without losing the quality of the examination. This allowed us to greatly improve the patient's physical and psychological compliance during procedures. ***Conclusion:*** Our project allowed us to considerably reduce the number of patients who showed up unprepared for examinations confirming that specific information is better recalled than generally formulated information [1] and accurate knowledge improves patient compliance and satisfaction and decreases anxiety [2]. Finally, this activity contributed to improve the quality of the service provided and the productivity of the department. ***References:*** [1] Kessels, R. (2003). Patients' memory for medical information. Journal of the Royal Society of Medicine, 96(5), 219-222.[2] van der Meulen N., et al. (2008). Interventions to improve recall of medical information in cancer patients: a systematic review of the literature. Psychooncology, 17(9), 857-68.

## EP-1005

### Religion, beliefs and needs in thyroid cancer patients

***E. Olariu****, D. Piciu;*
*The Oncology Institute Cluj-Napoca, Cluj-Napoca, ROMANIA.*

***Aim/Introduction:*** There is limited research specifically addressing the impact of religion and beliefs on quality of life in thyroid cancer patients. However, studies examining the influence of religion and spirituality on quality of life in cancer patients more broadly suggest that these factors can have a significant impact on patients' well-being. Patients who have strong religious or spiritual beliefs may have a greater sense of purpose, meaning, and hope, which can contribute to better mental health and a more positive outlook. ***Materials and Methods:*** We underwent a questionnaire based-study on 72 differentiated thyroid cancer patients who were admitted in the nuclear medicine department for radioiodine therapy between November 2022 and February 2023. For assessing the needs, we used Spiritual Needs Questionnaire (Sp NQ) a reliable and valid questionnaire for research and clinical application and for the religious assessing tool we used the System of Belief Inventory questionnaire (SBI-15R). ***Results:*** 72 patients completed the questionnaires (48 female and 24 male) with a medium age of 52 years old. 58/72 pts were married, 31/72 pts employee and 31/72 pts retired, with most of them with university degree (58/72 pts). The most frequent religion declared was orthodoxy (54/72 pts) followed by catholic (6/72 pts) and other (9/72 pts). Patients reported in more than 90% that religion is a very important issue in their life, with a need for praying/meditation, giving them a strong support in copping with the oncological disease, a real need for recovering the inner spiritual health and to strengthen the relationship with their family. ***Conclusion:*** It's important to note that the impact of religion and beliefs on quality of life can vary depending on the individual patient and their specific circumstances. It's important for healthcare providers to recognize and respect the role that religion and beliefs can play in a patient's experience with cancer, and to provide support that is sensitive to each patient's individual needs and preferences. ***References:*** 1. ## EP-1006

### Performance Evaluation of the Incorporation of PET/CT Procedures in the SUS

***B. Prates****, L. Pozzo;*
*Nuclear and Energy Research Institute, IPEN–CNEN/SP, São Paulo, BRAZIL.*

***Aim/Introduction:*** High-complexity technologies, such as PET/CT, should have their incorporation constantly analyzed and enhanced to support their consolidation. The evaluation of the performance of these equipment commits to the understanding of subjects such as the clinical application effectiveness, the usage of these devices in the patient's real life, and the impact of this technology in the different regions where they are applied. Therefore, this work aimed to evaluate the performance incorporation PET/CT equipments and procedures by the Brazilian National Health System (SUS) according to admissibility, economic, innovation, and technical criteria, accordant to the Methodological Guideline for the Elaboration of Studies for the Evaluation of EMA (medical-assistance equipment). Furthermore, the demand for the application of this technology was also considered. ***Materials and Methods:*** The data collection methodology was based on an active search for information, such as the consultation of bibliographies and websites that presented data of interest, such as ANVISA, DATASUS, CNEN, and RHC. ***Results:*** Thirteen records of equipment from seven distinct manufacturers were identified within the validity period. Moreover, there are 110 registrations with at least one PET/CT equipment in the National Registration of Health Facilities (CNES) and 160 registrations of facilities authorized by the National Commission of Nuclear Energy (CNEN). Published by the National Health Fund (FNS), the

value proposed for such equipment in 2022 is BRL 6,405,000.00. Regarding approved financing proposals, seven are registered and distributed in the records of five facilities. The applied taxes observed are IPI, PIS, and COFINS. Per procedure, according to the SUS table records, the amount paid was BRL 2,107.22, and the total amount paid since the incorporation of the technology is BRL 348,446,738.37. ***Conclusion:*** The development of the work led to the perception that, although there was some difficulty in obtaining some data that permeate the PET/CT technology, the incorporation of this technology took place in a satisfactory manner. There was divergence in results such as the number of devices. This fact was due to the way in which information was made available, as many data are self-declared by interested parties. Because it is the incorporation of a high-complexity technology in full use, few studies evaluating its performance were observed. Based on Consolidation Ordinance No. 1/2017 - which adopts the recommendation of one PET/CT unit per 1.5 million inhabitants, it was found that few Brazilian states have available the number of devices to meet the needs of demand.

## EP-1007

### Patient experience at the heart of the implementation of a PET/MRI system in our centre

***J. Vercher-Conejero***, *M. Cortés-Romera, J. Martín Marcuartu, S. Millat Servent, I. Feliu Perez, C. Martínez Ramos, V. Carrero Vasquez, M. Pudis, S. Santamaria Lopez, I. Bonilla Aguilar, M. Fernandez Yuste;*
*Bellvitge University Hospital, L'Hospitalet de Llobregat (Barcelona), SPAIN.*

***Aim/Introduction:*** Our strategy, as an organization, is focused on improving the patient experience. Our hospital wants to take a step forward to incorporate the patient experience into the organization's culture. Our objective was to create a new culture at the service of the patient as a central axis in the project to set up a PET/MR system in our department, incorporating the patients' point of view (expectations and needs) to improve their experience. ***Materials and Methods:*** The methodology used is known as Design Thinking, which starts from an objective (a better future situation), instead of a problem to be solved. This is based on:1.-Identify the most common patient profile, creating "person maps".2.-Identify the Patient Journey Map from the touch points and pain points. This step involves patients and professionals.3.-Transform the pain points into insights (answer to the question of why the pain point occurs) and from this answer, propose an improvement project.4.-Prioritise improvement projects and develop a prototype.5.-Discuss the prototype with a group of patients, patient relatives and professionals.6.-Define the implementation strategy.7.-To measure patient experience through quality indicators. Quality indicators based on patient experience are needed. The average duration of a patient experience project is estimated to be 2-3 months. This generates a report listing the projects derived from the "pain points" reported by patients, with the aim of incorporating these recommendations into the development process to improve the patient experience.This method, which incorporates small group of patients and the interview as techniques, allows to know the needs and expectations of the patients (and their caregivers). ***Results:*** The results were highly satisfactory with the participation of 13 patients/10 healthcare professions.28 improvement projects were generated, with 2 projects prototyped based on patient impact and feasibility.Satisfaction surveys were conducted with the professionals involved:78% gave an overall satisfaction score of 9 to 10 when participating in a project, and 100% considered that patient experience should be considered in projects for the creation of new hospitals or medical services.Finally, participating patients expressed a high level of satisfaction. ***Conclusion:*** This project is applicable to all medical centres and institutions, taking into account the differences and characteristics of each centre.It is easy to implement and allows to know the needs and expectations of the patient, and to measure their participation in the process.Changing the culture of a healthcare organization to improve patient care requires prior collaboration with the different professionals involved.

## EP-1008

### Knowledge, Attitude and Practice towards the Utility of Medical Radioisotopes for Diagnosis and Therapy of Disease used in Nepal

***A. Gupta***, *P. Sah, S. Prasad, D. Baral;*
*B.P. Koirala Institute of Health Sciences (BPKIHS), Dharan, NEPAL.*

***Aim/Introduction:*** In the last few years, medical use of radioisotopes has been increased dramatically in Nepal for both diagnosis and therapy of various diseases including many cancers. Radioisotopes such as Technetium-99m has been used for gamma imaging in Nepal since very long for the diagnosis of many diseases. Recently, PET imaging has been started in Nepal that uses Flourine-18 (F-18) radioisotope for the diagnosis of many cancers at their early stage. This study was conducted to assess the knowledge, attitude and practice (KAP) among the radiation oncology and nuclear medicine personnel towards the utility of medical radioisotopes used in Nepal for the diagnosis and therapy of disease including cancers. ***Materials and Methods:*** This study was conducted after the approval from Institutional Review Committee (IRC) of B.P. Koirala Institute of Health Sciences (BPKIHS), Dharan, Nepal. Data were collected through the questionnaire from thirty-two radiation oncology and nuclear medicine personnel working at different cancer hospitals and nuclear medicine centers in Nepal where radioisotopes are currently being used. The questionnaire included 38 questions (11 questions for knowledge, 11 questions for attitude and 16 questions for practice) to assess the KAP of the participants. The data collected were entered in the MS excel 2013 and analyzed using statistical analysis software package SPSS 11.5. For descriptive statistics, frequency, percentage, mean and standard deviation (SD) were used along with graphical and tabular presentation. Analyses tests used in this study was independent samples t-test and the Chi-squared test. A p-value $<0.05$ were considered statistically significant. ***Results:*** Thirty-two participants (n=32) of age 22-51 years were included in this study for the interview through the questionnaire. Of the total 32 respondent, 26 (82.25%) were man and 6 (18.75%) were female. Results obtained showed that the knowledge regarding the usage of radioisotopes among the participants is inadequate. The overall knowledge among the participants found to be 40.6% only. Similarly, the attitude of the participants toward the application of medical radioisotopes was found to not satisfactory. The overall attitude of the participants was assessed to be 43.75% only. It was also found that the practice of radioisotopes among the participants are very unsatisfactory (18.75%). ***Conclusion:*** The overall knowledge, attitude and practices of the participants towards the utility of medical radioisotopes found to be 40.6%, 43.75% and 18.75% respectively. From this study, it can be concluded that the awareness regarding the application of medical radioisotopes should be improved.

## EP-1009

### Cyclotron production of ultra-pure indium-111 radionuclide using gold-plated capsules in Iran

***P. Ashtari***[1,2], *Y. Fazaeli*[2], *G. Aslani*[1], *S. Feizi*[2];
[1]*Pars Isotope Co., Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Nuclear Science & Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The aim of this study is to introduce a new, rapid, simple, low cost, and innovative method for the production and purification of Indium-111 for use in nuclear medicine. The main advantage is the elimination of chemical electrolysis, as well as the complex chemical dissolution of the metallic target and its copper substrate. ***Materials and Methods:*** Due to the proper selection of the target isotope, cadmium -112 and optimal bombardment energy, only the Zn-65 impurity is observed in the sample solution. After the separation process, the amount of zinc-65 decreased to less than its standard level in the Indium-111 solution. The cadmium content of the In-111 is determined by polarography method. ***Results:*** The cadmium content of the product is less than 0.1 ppm. Due to the chemical and radiochemical purity, it can be used for labeling of the peptides. ***Conclusion:*** Product efficiency is evaluated using it in the project entitled "production and quality control of the Indium octreotide". The labelling efficiency is more than 97%. ***References:*** [1] S. Lahiri, M. Maiti, K. Ghosh, Production and separation of 111In: An important radionuclide in life sciences: A mini review, J. ## EP-1010

### New method for synthesis of HMPAO compound and a novel method for purification of final product for Triple usage

***M. Alizadeh****, v. ghasemi, e. maleki, h. m. mehrabani, f. farajbakhsh, m. ghapanvari;*
*parsisotope, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The main goal of the present research is a new method for the synthesis and purification of the HMPAO compound to produce a radiopharmaceutical kit for the imaging of the tissue involved in the infection, brain scanning and pelacet labeling considering the structure of the desired compound and paying attention to the fact that the desired product in the carbons (3 and 9 positions) is symmetrical. The main purpose of this project is not only synthesis of API but also finding a new method for separation of isomers. l, d HMPAO is synthesized in 2 steps, each step checked by FT-IR and NMR. After purifying the structure and reaching the desired isomers, the final product was used to prepare the kit. ***Materials and Methods:*** 2,3-Butanedione monoxime, 2,2-dimethyl-1,3-diaminopropane, and PTSA refluxed in anhydrous ethanol. The final solution was checked by TLC sheets after finding the new point of intermediate on TLC sheets the reaction continued by adding sodium borohydride to a cooled solution of the reaction mixture. For the separation of isomers, we used green solvent recrystallization process. The final products were utilized for kit preparation, and the radiochemistry check was used to understand the presence of labeled synthesized API with technetium. ***Results:*** synthesis of HMPAO was done in 2 step reaction and many steps of the purification process. The final pure product was checked by FT-IR peaks at the range of 1626 $cm^{-1}$ and 1636 $cm^{-1}$ are related to C=N-OH and N=C, the $^{13}$C-NMR spectrum of pure d, l-hexamethyl propylene amine oxime shows peaks at 159.00, 57.79, 56.23,34.93, 25.06, 24.86, 19.73 and 8.74. and the bio distribution was checked in 2 steps. the first step was done on rat, and the second one, was checked on the human body. ***Conclusion:*** This study provides valuable data showing beneficial results that the labeled HMPAO with Technetium-99m can use for labeling of white blood cells, and monitoring the place of body tissue involved in the infection, and the final product can use for brain scan. The infection and the final product can use for brain scan. Also, one of the interesting results of this research is the unique ability of the HMPAO to mark blood platelets in order to detect the location of internal bleeding.

## EP-1011

### Comparison of diagnostic efficacy of 99mTc-MIBI SPECT/CT and ultrasonography for primary and secondary renal hyperparathyroidism

***M. Jiang****, W. Mei;*
*Ningbo No.2 Hospital, Ningbo, CHINA.*

***Aim/Introduction:*** This study aimed to compare the efficacy of $^{99m}$Tc-MIBI double-phase scintigraphy (DPS), SPECT/CT, and ultrasound (US) in the preoperative diagnosis of PHPT and SHPT. ***Materials and Methods:*** From September 2018 to February 2023, the imaging and clinical data of 113 patients with HPT (including 95 cases of PHPT and 18 cases of SHPT) who underwent $^{99m}$Tc-MIBI SPECT/CT and US before surgery in Ningbo No.2 Hospital were retrospectively analyzed. The postoperative pathological diagnosis of parathyroid hyperplasia, adenoma, and cancer was considered as positive, while the other results were negative. Fisher's exact test was used to compare the diagnostic efficacy of different tests in PHPT and SHPT. ***Results:*** Of the 95 patients with PHPT, 90 were pathologically confirmed as positive and 18 as negative. In 18 patients with SHPT, there were 44 positive lesions and 2 negative lesions. The accuracy of DPS, SPECT/CT, US, DPS + US, and SPECT/CT + US in the diagnosis of PHPT patients was 88.0% (95/108), 92.6% (100/108), 79.6% (86/108), 86.1% (93/108), and 88.0% (95/108), respectively. For patients with SHPT, the rates were 58.7% (27/46), 87.0% (40/46), 71.7% (33/46), 78.3% (36/46), and 84.8% (39/46), respectively. The diagnostic accuracy of DPS in patients with PHPT was significantly higher than that of SHPT ($P < 0.001$), while there was no statistically significant difference in the diagnostic accuracy of SPECT/CT and US in the two types of HPT ($P = 0.357$ and $P = 0.299$). For SHPT patients, the accuracy of SPECT/CT was significantly higher than that of DPS ($P = 0.004$), but

there was no statistically significant difference between SPECT/CT and US, as well as between US and DPS (P = 0.121 and P = 0.274). ***Conclusion:*** The use of DPS, SPECT/CT, and US has high efficiency in the localization diagnosis of HPT, but the diagnostic accuracy of DPS in PHPT is superior to that of SPHT. For patients with SHPT, $^{99m}$Tc-MIBI SPECT/CT is preferred to obtain higher accuracy.

### ATTR Cardiac Amyloidosis and Carpal tunnel syndrome

***S. Giourgouli****, A. Kokkini-Paschou, V. Pantzou, M. Stathopoulou, J. Koutsikos;*
*Henry Dunant Hospital Center, Athens, GREECE.*

***Aim/Introduction:*** The "carpal tunnel" is a narrow passageway that runs from the base of the hand through the wrist. Several tendons and the median nerve, the main nerve of the front forearm, pass through the carpal tunnel. When any of those tendons become irritated from repetitive or strenuous hand motions and overuse, the median nerve gets compressed. Carpal tunnel syndrome (CTS) occurs from excessive pressure on the median nerve. This may cause a variety of symptoms, which typically are mild to start and gradually grow more intense — especially if left undiagnosed. The association between CTS and systemic amyloidosis has been widely described with a high prevalence of CTS in ATTR Cardiac Amyloidosis (ATTR-CA), ranging from 15% to 60%. The aim of our case is to highlight this association and raise awareness of non-specific findings in bone scintigraphy. ***Materials and Methods:*** We present a case of a 78 y.o. male, presenting to our department for bone scintigraphy because of prostate cancer. As to his medical history, he mentioned hypothyroidism and diabetes. His main symptom was transient pain followed by swelling, mainly in dominant hand. Non-steroidal anti-inflammatory drugs (NSAIDs) helped relieve the pain. 20 mci Tc-99m DPD was injected i.v. and 3 hrs later a whole body scintigraphy was performed. ***Results:*** There was no evidence of metastatic disease and the only finding from the skeletal was the unilateral radiopharmaceutical accumulation in the wrists. An unexpected finding was the diffuse accumulation in the left hemithorax. A SPECT study was followed immediately for better evaluation. The study was indicative of ATTR-CA. Further investigation of the patient, revealed increased LV wall thickness in echocardiography, with EF 55%, while CTS was considered as the cause of the symptoms in both hands. ***Conclusion:*** Bone scintigraphy isn't a method of choice for evaluating CTS. Of imaging methods, magnetic resonance imaging (MRI) has shown the greatest sensitivity and specificity. One relatively new finding is that people with bilateral CTS, may be at increased risk for CA. The awareness of this association offers the possibility of an early pre-clinical ATTR-CA diagnosis. Non-specific findings in bone scintigraphy or findings of the WBS in scintigraphy provide further prognostic information.

## EP-1013

### Monitoring Of Adverse Reactions Caused By [99m Tc] Tc-Mibi

***G. Rubio-Fernández****, R. Maestre-Cutillas, L. Baz-Sanz, L. Cebollada-Cameo, R. Castro-Velasco, C. Juan-Piriz, J. Pérez Iruela;*
*Hospital Ramón y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** To evaluate the adverse drug reactions (ADR) observed when administering and reported by the Radiopharmacy Unit, looking in depth at the incidence and possible causes. ***Materials and Methods:*** An observational and retrospective analysis of ADR was produced by [ $^{99m}$Tc]Tc-MIBI reported through the Spanish Pharmacovigilance System for Medicines for Human Use, from 2020 to March 2023. The ADR, the indication of the radiopharmaceutical, and the development of the ADR were collected. It was checked whether it was indicated in the technical data sheet, its frequency and whether it was related to any excipient of the reagent kit or to the radiopharmaceutical itself. ***Results:*** Between 2020 and March 2023, 4042 doses of [$^{99m}$Tc] Tc-MIBI were administered. Among these, 23 (0.57%) ADR have been reported, 18/23 (78.26%) are women. 22/23 (95.65%) ADR were indicated for parathyroid scintigraphy (PS), although only 766/4042 doses were used for this indication, implying 2.87% ADR in PS. The predominant ADR was dysgeusia and its development was the onset within seconds of administration which disappeared spontaneously without intervention. ***Conclusion:*** Dysgeusia is the most frequent ADR observed, mainly caused by the radiopharmaceutical [ $^{99m}$Tc] Tc-MIBI for PS. This may be due to the reagent kit binder [Tetrakis(2-methoxy-2-methylpropyl-1-isocyanide) copper(I) tetrafluoroborate], which contains copper and often produces a bitter taste. Other factors that can be affected are high levels of the radiopharmaceutical in the bloodstream or speed of injection. It is striking that 766/4042 of the doses of [$^{99m}$Tc]Tc-MIBI produced 22/23 ADR; this may be due to the fact that most of the remaining doses were used for cardiac stress scintigraphy, in which the patient, while running on a treadmill, can ignore the reaction. In our population, a higher incidence of ADR was observed in women. The percentage of ADR is low and inconsequential, but it is important that they are reported in order to control them.

## EP-1014

### Assessment of agreement between three creatinine-based GFR predicting equations and 99mTc-DTPA plasma clearance GFR in adult Caucasian patients : a single-center study

***G. Arsos***[1]*, D. Katsampoukas*[1]*, A. Kalaitzoglou*[1]*, E. Manou*[2]*, E. Moralidis*[1]*;*
[1]*3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen. Hospital, Thessaloniki, GREECE,* [2]*Nephrology Clinic, Papageorgiou Gen. Hospital, Thessaloniki, GREECE.*

***Aim/Introduction:*** Serum/plasma Creatinine (SCr) and/or Cystatin C-based equations incorporating age, sex and race variables, are widely used for clinical GFR estimation (eGFR). The CKD-EPI Creatinine Equation 2009 (CKD-EPI 2009), applicable to both black and non-black adults, has been followed by the unifying, race variable-free CKD-EPI Creatinine Equation (CKD-EPI 2021) and the European Kidney Function Consortium equation (EKFC) has been introduced in 2021 for full age spectrum non-black patients. Recently, 99mTc-DTPA has emerged as the dominant radiotracer for plasma clearance GFR measurement (mGFR-DTPA) in Europe. We explore the agreement between the three above equations and mGFR-DTPA in adult Caucasian

patients. ***Materials and Methods:*** GFR was measured for clinical purposes in 515 adult Caucasian patients (age 18-88 years, 42.3% females, 9.7% prospective kidney donors) by the 99mTc-DTPA plasma clearance (bolus i.v. injection, 3 blood samples at 2, 3 and 4 hours post-injection and monoexponential modeling according to BSNM). SCr was measured (mg/dL) with an ID-LC/MS calibrated Jaffe method. eGFR-CKD-EPI 2009, eGFR-CKD-EPI 2021 and eGFR-EKFC were estimated by the CKD-EPI 2009, CKD-EPI 2021 and EKFC equations, respectively. All GFR values were expressed in ml/min/1.73 m2. Agreement between each eGFR and mGFR-DTPA was assessed by the Bland-Altman statistics, with the mean of eGFR-mGFR differences showing the bias and their standard deviation the imprecission). Accuracy was expressed as the percentage of eGFR within ±10% (A10) and ±30% (A30) of mGFR-DTPA values. The correlation between each eGFR and mGFR-DTPA was assessed by the Lin's Concordance Correlation Coefficient (LCCC). One-sample and Paired t-tests, Repeated-measures ANOVA with Bonferroni correction for multiple comparisons, Cochrane Q test and Levene's test for equality of variance were applied as appropriate. ***Results:*** SCr and mGFR-DTPA (mean±SD) were 1.8±1.0 mg/dL and 54.8±27.0. The differences between eGFR-CKD-EPI 2009, eGFR-CKD-EPI 2021, eGFR-EKFC and mGFR-DTPA (mean±SD) were 5.0±12.4, 8.0±12.9 and 2.3±11.2, respectively. All the means differed significantly in comparison to 0 ($p<0.001$) and to each other in all pairwise comparisons ($p<0.001$) as did their variances ($p<0.05$). A10 was 33.0%, 31.3% and 37.1% and A30 77.7%, 73.6% and 83.7% ($p<0.001$ for both) and LCCC was 0.895 (poor agreement), 0.872 (poor agreement) and 0.916 (moderate agreement) for eGFR-CKD-EPI 2009, eGFR-CKD-EPI 2021 and eGFR-EKFC, respectively. ***Conclusion:*** Among the GFR prediction equations CKD-EPI 2009, CKD-EPI 2021 and EKFC, the later shows the best agreement with GFR measured by 99mTc-DTPA plasma clearance in adult Caucasian patients.

## EP-1015

### Development of a boronic acid targeting fluorescent sensor for evaluation of intracellular localization and quantification of blood concentration of boronoagents for BNCT

***S. Takada***[1,2], *N. Kondo*[2], *T. Temma*[2], *M. Hagimori*[1];
[1]*Laboratory of Analytical Chemistry, Faculty of Pharmaceutical Sciences, Mukogawa Women's University, 11-68 Koshien Kyubancho, Nishinomiya, Hyogo, JAPAN,* [2]*Department of Biofunctional Analysis, Graduate School of Pharmaceutical Sciences, Osaka Medical and Pharmaceutical University, 4-20-1 Nasahara, Takatsuki, Osaka, JAPAN.*

***Aim/Introduction:*** In BNCT, the intratumor concentration and intracellular localization of [$^{10}$B]boron are strongly related to therapeutic efficacy. In general, boron concentration in tumors is calculated from blood boron concentration measured by ICP analysis, but it has problems in simplicity. Intracellular boron localization is observed by fluorescence microscopy using the boronic acid targeting fluorescence sensor "DAHMI", but the reaction is slow and the fluorescence produced is weak. Therefore, developing a boronic acid targeting fluorescence sensor with excellent fluorescence properties would enable not only to visualize the boron localization in cells but also to quantify the blood boron concentration. We here designed a novel boronic acid targeting sensor BITQ and evaluated its effectiveness. ***Materials and Methods:*** Emission spectra of BITQ (1 μM) were measured in 0.5% DMSO-$H_2O$ before and after adding p-boronophenylalanine (BPA, 100 μM). Temporal change in fluorescence intensity of BITQ after the addition of BPA was examined for 30 min. The relative quantum yields were measured in EtOH before and after mixing with phenylboronic acid.The results were compared with DAHMI. A microscopic fluorescence observation using BITQ (10 μM) was performed on T3M-4 cells treated or untreated with BPA-Fructose (1 mM) beforehand. BPA-fructose solution (0-900 μM) was added to blood collected from mice, and after deproteinization, BITQ (5 μM) was added, and fluorescence intensity was measured after 15 minutes. The results were compared with the ICP-MS method. ***Results:*** BITQ showed strong fluorescence at 480 nm for the maximum emission wavelength after the addition of BPA. The fluorescence intensity of BITQ stabilized within 1 minute after BPA addition, while DHAMI did not plateau until 30 min after BPA addition. The quantum yield of BITQ after adding phenylboronic acid was 0.53, which was ten-fold larger than that of DAHMI (0.053). The microscopic observation revealed a higher fluorescence in the BPA-treated T3M-4 cells compared to the BPA-untreated group. Boron concentrations measured from BITQ fluorescence method was linearly correlated with those evaluated from ICP-MS analysis with a slope of 1 ($r=0.99$). ***Conclusion:*** In this study, we developed a boronic acid targeting fluorescence sensor, BITQ, showing high quantum yield, rapid reactivity, and high quantitative scope for BPA. BITQ had excellent fluorescence properties, visualized intracellular BPA, and quantified BPA in the blood samples. Therefore, BITQ is an excellent fluorescence sensor for analyzing boronoagent for BNCT.

## EP-1016

### Introducing a method for increasing yield and removing the harmful and toxic solvents during the synthesis process of Sestamibi and labeling it by 99mTc to investigate its applications in vascular imaging.

***V. Ghasemi****, m. alizadeh, h. m. mehrabani, e. maleki, m. ghapanvari, f. farajbakhsh, E. Lohrasbi, J. Aghamohammadi; parsisotope, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** $^{99m}$Tc-Sestamibi (MIBI) is an agent increasingly used for vascular tissue imaging. Yet, toxic and harmful solvents are usually used extensively to synthesize Sestamibi. Therefore, this paper aims to introduce an approach for removing these harmful solvents during the synthesis process of Sestamibi and labeling it by $^{99m}$Tc to investigate its applications in vascular imaging. ***Materials and Methods:*** The synthesis of Sestamibi began with 2-Methylallylamine hydrochloride salt as the starting material and after 3 steps, the 2-Methoxyisobutylisonitrile was successfully obtained. Each step was monitored by TLC sheets and FT-IR spectroscopy. The final crude was synthesized by reacting Tetrakis (acetonitrile) copper (i) tetrafluoroborate with 2-Methoxyisobutylisonitrile. The synthesized API agent was characterized through FT-IR, HPLC, NMR, CHNX, and mass spectrometer. Additionally, the radiochemical purity of $^{99m}$Tc-Sestamibi was confirmed by Gamma-ray spectrometry. ***Results:*** The yield of the product was optimized and improved by up to 80%. The main purpose of this study was to remove toxic solvents such as Benzene and Pyridine and also to produce a pure product. To determine the pure product HPLC was used and accordingly, a single sharp peak in the HPLC diagram was observed proving that the product was pure. To confirm the structure of the product FT-IR, NMR, and Mass spectrometer were utilized. The results confirmed the structure of Sestamibi. The radiochemical study showed that the synthesized API had been properly labeled. Eventually, the biodistribution of the prepared kit was checked on the rat and the results showed high cellular uptake in the coronary tissues.

***Conclusion:*** This method proves that Sestamibi can be synthesized with high yield and purity. The preclinical studies of the prepared kit show high cellular uptake in the Coronary tissues. Considering the wide diagnostic applications of $^{99m}$Tc-Sestamibi and its complex production process in which harmful solvents are usually used, this approach not only has removed the said toxic solvents but also has proved a high yield.

### EP-1017

**Implementation of the new national directive to reduce radioactive waste disposal costs in nuclear medicine and radiometabolic therapy departments**

***M. Anelli***[1], *M. Nicoletto*[2], *A. Zambelli*[3], *A. Di Nicola*[1];
[1]*Azienda Sanitaria Locale di Pescara, Pescara, ITALY,*
[2]*Policlinico di Abano Terme, Abano Terme (PD), ITALY,* [3]*Azienda Ospedaliera Universitaria di Padova, Padova, ITALY.*

***Aim/Introduction:*** This study concerns the compliance of nuclear medicine departments with the new ministerial directives provided for by Legislative Decree No. 101 dated July 31st, 2020 (Directive 2013/59/EURATOM). This act aims to explain and regulate proper management of radioactive waste that is generated in nuclear medicine and radiometabolic therapy departments, also according to national standards. The regulation adjustment provided a new internal protocol concerning radioactive waste management, which was edited on 31st January 2023 in collaboration with the medical physics department. In the relevant case, new storage areas have been identified and new tools for residual radiation counting have been acquired. ***Materials and Methods:*** Nuclear medicine and metabolic therapy use unsealed radioactive substances for diagnostic and therapeutic purposes, thus producing:- solid waste consisting of vials with residual solutions, needles, syringes, disposable gloves, absorbent cotton, paper towel, patient disposal items and belongings that have been in contact with contaminated excretions;- Tc99m generators;- solid waste consisting of protecting equipment used by the staff for radiation protection purposes such as gloves and shoe covers. Generally, radioactive isotopes found in waste are F18, Tc99m, I131, I123, In111, Ga67, Tl201, characterized by a half-life (T/2) lower than 60 days. ***Results:*** The new ministerial directive has brought to significant improvements in the management of radioactive waste. As a result, radioactive waste must go through three steps before being disposed of:1. First, the waste is placed in shielded containers and maintained in temporary storage areas with shielded walls until the containers are filled.2. Once the containers are filled, they are placed in biohazard containers, then sealed, labelled and transported to a new storage area where waste will be listed and divided depending on the isotope. 3. Finally, when it is no longer radioactive (less than 1 kBq/kg), it will be delivered to hospital waste management operators. ***Conclusion:*** Management of radioactive waste has been simplified through the identification of a storage area (see point 3) which is located outside the department, allowing waste to lose radioactivity far from operators and patients. Once radioactivity has decreased enough, the waste can be disposed of, as it is done with ordinary hospital waste. According to first estimates, this method will allow savings of 36% in disposal costs on an annual basis. Furthermore, a first CME course was held by a qualified expert in March 2023, with the purpose of updating all department members. ***References:*** Legislative Decree No. 101/2020, Directive 2013/59/EURATOM

### EP-1018

**Usefulness of simplified respiratory motion freeze devise (IKI-TOMEHIRO-KUN) in myocardial perfusion SPECT**

***H. Ichikawa***[1,2], *T. Kato*[1], *H. Kondo*[3], *T. Shibutani*[2], *H. Shimada*[1], *M. Onoguchi*[2];
[1]*Toyohashi Municipal Hospital, Toyohashi, JAPAN,*
[2]*Kanazawa university, Kanazawa, JAPAN,* [3]*Nagoya University Hospital Department of Cardiology, Nagoya, JAPAN.*

***Aim/Introduction:*** Patient and organ motion occurs in 25-36% of cases in myocardial perfusion SPECT and contributes to artifact generation, and artifact can lead to an inaccurate diagnosis [1, 2]. The purpose of this study was to assess a usefulness of a simplified respiratory motion freeze (RMF) devise (IKI-TOMEHIRO-KUN, ITK). ***Materials and Methods:*** ITK is a pentagonal shape with a length of 20 cm, a width of 20 cm, and a thickness of 10 cm, constructed of Styrofoam. ITK was wrapped around the patient's abdomen during deep exhalation with a gamma camera belt to effectively suppress cardiac motion associated with respiratory motion. We retrospectively evaluated 91 patients who underwent 1-day load/rest or early rest/delayed MPS with $^{99m}$Tc-labeled agents for suspected or known CAD at our institution. SPECT of all patients were scanned on one day in two phases; early (stress or rest) and delayed (rest). All projected data were classified into four levels of degree of cardiac motion: absent (0), mild (1), moderate (2), and severe (3), based on observation of cinematic displays, sinograms, and linograms. The degree of artifacts in SPECT images was visually assessed by motion artifact and overlapping hot spots due to activity in the gastrointestinal tract. ***Results:*** The degree of motion in the control group was absent 10.3%, mild 51.7%, moderate 34.5%, and severe 3.4%, and in the RMF group 39.7%, 38.1%, 19.0%, and 3.2%, respectively, in the same order. In the projection data, the degree of heart motion in RMF group was significantly smaller than that in the control group. The frequency of cardiac bounce in RMF and control groups was identical, whereas the frequency of cardiac shift and creep in RMF group was markedly lower than that in the control group. The degree of motion artifact in SPECT images of RMF group was significantly smaller than that of the control group. ***Conclusion:*** ITK may be a useful device in myocardial perfusion SPECT to reduce patient and organ motion and prevent artifact generation. ***References:*** Germano G. Technical aspects of myocardial SPECT imaging. J Nucl Med. 2001;42(10):1499-507.Wheat JM, Currie GM. Incidence and characterization of patient motion in myocardial perfusion SPECT: Part 1. J Nucl Med Technol. 2004;32(2):60-5.

### EP-1019

**Does high Radiochemical purity obviate the need for a biodistribution whole body image in 68Ga-NOTA-UBI PET/CT?**

***S. Maurya***, *N. Damle, S. Ballal, A. Singhal, V. Tiwari, C. Bal, N. Singh, Y. Dharmashaktu, D. Khan, S. Sagar, A. Gawande;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** $^{68}$Ga-NOTA-UBI is a PET based infection imaging agent with evolving interest. Biodistribution of the tracer is in liver, kidneys and bladder and sometimes spleen. Abnormal biodistribution however can lead to false results. Since it is a relatively new tracer synthesized in house each time, we acquire

a wholebody image to confirm appropriate biodistribution before attempting to interpret the scans. We aimed to study if the whole-body image can be done away with and only a regional spot view taken when normal biodistribution is repeated. ***Materials and Methods:*** NOTA-UBI was procured from ABX, Germany. 300ug of peptide was used in each synthesis. $^{68}$Ga-Cl3 was eluted from the generator and sodium acetate buffer was added followed by addition of the peptide The contents were heated at 95degrees C for 10 minutes. After cooling, it was passed through a C18 Sep Pak cartridge. The product was eluted with 50% ethanol. Quality control was performed by paper chromatography with sodium citrate as the solvent. ***Results:*** We synthesized the tracer a total number of 12 times. Time for synthesis after elution of $^{68}$GaCl3 was 16±2 minutes (range 14-20min). Starting activity of $^{68}$Ga was 13.8±1.5 mCi (range 8-17.9mCi). Final tracer synthesized was 7.05 ± 0.95 mCi (range 4-11mCi). Quality control revealed Radiochemical purity of 98.28 ± 2.25 % (range 96.26-99.45). Images were analysed qualitatively by three independent Nuclear Medicine physicians. Biodistribution was satisfactory in all 23 patients and images were considered interpretable. Delayed imaging of region of interest revealed similar uptake in suspicious lesions with no qualitative difference as assessed by visual analysis. ***Conclusion:*** In the setting of high radiochemical purity, it is adequate to perform only a limited imaging over the region of interest and get satisfactory images. A whole body image to confirm biodistribution seems unnecessary and may be omitted to decrease the radiation exposure to the patient as well as time for completion of the scan. This is especially important in a busy department with high patient volumes.

## EP-1020

### Evaluation of 68Ga-NOTA-Ubiquicidin (29-41) PET/CT with early and delayed imaging through qualitative and quantitative analysis.

***N. Singh***, *N. Damle, S. Maurya, A. Singhal, S. Ballal, V. Tiwari, A. Gawande, P. Kumar, C. Bal, S. Sagar, J. Jaleel;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Radiolabelled Ubiquicidin (UBI) 29-41 shows preferential binding of cationic peptide with the anionic microbial cell membrane at the site of infection. This peptide can be chelated with a bifunctional chelating agent (BFCA) NOTA to allow complexation with 68Ga to form 68Ga-NOTA-UBI [1]. We aimed to evaluate whether delayed imaging is better for interpretation as compared to routine imaging performed at 45-60 min [2]. ***Materials and Methods:*** Seventeen patients with suspected periprosthetic, soft tissue, and lung infections were included in the study.148 MBq of 68Ga-NOTA-UBI-29-41 were administered intravenously to the patients. PET imaging (whole body) was performed at 45-60 min (early) and repeated at 1.5 h (delayed) only at the region of interest. A qualitative and semi-quantitative evaluation was performed. Qualitative analysis was performed by three independent nuclear medicine physicians who evaluated the image quality and their scan interpretation was noted. Image quality was classified as excellent, good, and acceptable. The semi-quantitative analysis was performed by comparing the target-to-background ratio (TBR) in early and delayed imaging. The target-to-background ratio (TBR) was calculated by dividing the maximum standardized uptake value (SUVmax) of a positive lesion by its contralateral side. ***Results:*** Out of 17 patients (mean age, 46.1 years; range, 23-67 years), 14 were males and 3 were females. In qualitative analysis, out of 17 scans, 14 were graded excellent, 2 were good and 1 was satisfactory in image quality. Delayed imaging was better in 2/17 cases by one of the physicians. On the visual score, the target-to-background contrast (T/B) of the lesion was perceived to be almost similar in both sets of images. In semi-quantitative analysis, the mean value of TBR of the region of interest in the early image was 3.12 ± 1.54 & in the delayed image it was 3.948 ± 1.91. There was no statistically significant difference between the TBR of early and delayed images (p=0.2). ***Conclusion:*** We conclude that single time point imaging at 60 min is sufficient to achieve acceptable diagnostic confidence & delayed imaging may not have an additional benefit. ***References:***

## EP-1021

### The impact of multi-bed SPECT-CT misregistration on routine clinical service delivery

***L. Wason***, *R. Williamson, J. Dixon, C. Reilly, A. Nicol;*
*NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.*

***Aim/Introduction:*** Many centres perform multi-bed SPECT-CT to localise areas of radiopharmaceutical uptake indicative of disease. Commissioning of a new SPECT-CT gamma camera identified misregistration of the SPECT and CT data for multi-bed acquisitions that did not occur for single bed acquisitions. Further investigations confirmed the artefact on another system in the department. Modifications are required to our acquisition and reconstruction techniques for both systems utilising multi-bed acquisition mode. Precise SPECT-CT registration is necessary for localisation of radiopharmaceutical uptake and accurate reconstruction (e.g. attenuation correction, scatter correction), this work outlines the practical solutions implemented across two different systems within our department. ***Materials and Methods:*** New image reconstruction workflows were developed for multi-bed SPECT-CT acquisitions. Hardware and software differences between each system required implementation of different image reconstruction workflows. Upgraded software options available on the new system allows reconstruction of the multi-bed SPECT data as one dataset, with minimal misregistration, to be viewed fused with the single CT acquisition, covering the whole field of view. Technologist staff review this registered image, comparing high intensity landmarks (e.g. liver/kidneys on $^{99m}$Tc-Tektrotyd scans) to relevant CT anatomy to check for misregistration. On the older system, where this upgraded software is not available, the SPECT data from each bed position must be reconstructed and checked individually, to prevent significant misregistration occurring. This means the benefit of multi-bed acquisitions is lost from a reporting perspective, but there is still a benefit from the acquisition viewpoint in that there is a dose saving from not overlapping CT between each SPECT bed position. ***Results:*** The detection of this fault prevents misregistration of the SPECT and CT data occurring on a patient acquisition. Collaboration with the manufacturer confirmed the existence of the fault in other systems, improving understanding of the cause leading to development of new image reconstruction workflows across all affected systems that included a registration quality check. Implementation of these workflows has enabled multi-bed acquisition, resulting in a time saving for the patient and staff, as well as a dose saving from not overlapping CT exposures. ***Conclusion:*** This investigation demonstrates there may be technical challenges associated with reconstructing

multi-bed SPECT-CT acquisitions. The technique increases patient throughput, reduces waiting times, and through use of a single CT acquisition, helps to reduce the patient's CT exposure to as low as reasonably practicable. Further work on this will include raising operator awareness and developing an ongoing quality assurance programme.

## EP-1022

### Image evaluation of different 99mTc/123I ratios for simultaneous dual-isotope myocardial SPECT using D-SPECT cardiac camera

***T. Shibutani***[1], *M. Onoguchi*[1], *H. Yoneyama*[2], *T. Konishi*[2], *K. Nakajima*[3];
[1]*Department of Quantum Medical Technology, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Ishikawa, JAPAN,* [2]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa, Ishikawa, JAPAN,* [3]*Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa, Ishikawa, JAPAN.*

***Aim/Introduction:*** The $^{99m}$Tc images for $^{99m}$Tc/$^{123}$I simultaneous dual-isotope myocardial SPECT with cadmium-zinc-telluride cardiac camera are affected by scattered radiation and crosstalk from $^{123}$I, and scatter correction (SC) is expected for quantitation. However, the image characteristics of the $^{99m}$Tc SC image was influenced by various $^{99m}$Tc and $^{123}$I injection dose settings as experienced in clinical studies. We demonstrated the image quality and correction effect of the $^{99m}$Tc images for different $^{99m}$Tc/$^{123}$I ratios. ***Materials and Methods:*** Three types of myocardial models of normal, anterior, and inferior wall defective myocardium were created using an anthropomorphic myocardial phantom. The $^{99m}$Tc/$^{123}$I ratio was set to 1.0, 3.5, 5 and 6.5, which were determined by possible clinical settings of $^{123}$I-MIBG and $^{123}$I-BMIPP imaging. Energy settings were 105-130 keV for $^{99m}$Tc scatter window, 133-145 keV for $^{99m}$Tc main window, 145-152 keV for $^{123}$I scatter window and 152-168 keV for $^{123}$I main window. SPECT images were acquired by D-SPECT (Spectrum Dynamics Medical), and the scan time was adjusted with a left ventricular count of 1.5 million counts for $^{123}$I. Reconstructed images with no correction (NC) and SC were obtained using Spectrum Dynamics (SD) reconstruction. The parameters of Gaussian filter were set to 1, 3 and 5 as a kernel setting, and 0.25 to 1 as Gaussian standard. The percent coefficient of variance (%CV) was calculated from a 17-segment polar map. Cavity contrast and circumferential profile were analyzed using normal and defect myocardial images. ***Results:*** $^{99m}$Tc SC images in a normal model showed a lower %uptake in the inferior wall compared with $^{99m}$Tc NC images. The %uptake of the inferior wall for the $^{99m}$Tc SC images decreased approximately 5% with decreasing $^{99m}$Tc/$^{123}$I ratio. However, the decrease of %uptake in the inferior wall was improved by adjusting the kernel of the Gaussian filter. The minimum %uptake on the short-axis circumferential profile for $^{99m}$Tc/$^{123}$I ratio of 1.0, 3.5, 5.0 and 6.5 in $^{99m}$Tc SC image was 34.8%, 24.7%, 26.1% and 26.6% for the anterior wall, and 30.5%, 32.3%, 34.3% and 34.5% for the inferior wall, respectively. The %uptake of defect region was independent of $^{99m}$Tc/$^{123}$I ratio. ***Conclusion:*** The normal myocardial distribution of the $^{99m}$Tc SC images was affected by $^{99m}$Tc/$^{123}$I ratio and reduced inferior activity with relatively low $^{99m}$Tc/$^{123}$I ratio could be corrected by appropriate Gaussian filter setting. The dependency of accuracy on $^{99m}$Tc/$^{123}$I ratio needs to be considered when $^{99m}$Tc/$^{123}$I mismatch is relatively small.

## EP-1023

### Assessing glomerular filtration rate through blood sampling via port and arm vein.

***C. H. Led***[1], *L. J. Jeppesen*[1], *O. Gerke*[1,2], *S. Hvidsten*[1], *J. A. Simonsen*[1,2];
[1]*Department of Nuclear Medicine, Odense C, DENMARK,* [2]*Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.*

***Aim/Introduction:*** Glomerular filtration rate (GFR) can be determined accurately from plasma clearance of Tc-99m-DTPA. To avoid recurrent venous punctures in cancer patients, who often have fragile vessels, a subcutaneous port with a catheter extending into a central vein can be installed. The port has a silicone membrane through which drugs can be injected and blood samples drawn. However, the membrane may retain part of the injected tracer biasing calculations and hence GFR. Furthermore, the port has a reservoir in which the tracer may accumulate and eventually be withdrawn by blood sampling. We have previously demonstrated the feasibility of injection of the GFR tracer and blood sampling by port. In the present study, we set out to investigate whether GFR based on blood samples from the port differed from those obtained from a peripheral vein. ***Materials and Methods:*** Patients referred to our department for GFR examination, who already had a port installed, were invited to participate in the trial. Eight patients consented. We administered the tracer into the port through a single-lumen catheter with only one access point. We injected 8 MBq of Tc-99m-DTPA through a three-way stopcock and flushed it with isotonic saline. After three hours we draw two blood samples from an arm vein and four blood samples from the port, the first two portal samples were discarded. The blood samples were processed as in the clinical routine; hence, after centrifugation and pipetting, plasma activity was counted in a well counter (Wizard 2470 gamma counter) and GFR was calculated according to Groth & Aasted. ***Results:*** The mean (range) GFR calculated from peripheral venous blood samples was 59.9 (29-101) ml/min compared to 63.8 (31-108) ml/min for the portal samples. The difference between GFR from the peripheral and portal samples ranged from -7 to -1, and GFR from the arm vein was statistically lower (mean difference: -3.81, 95% CI: -5.86 to -1.77; p-value 0.008, Wilcoxon matched-pairs signed-rank test). ***Conclusion:*** Our concern regarding contamination of the portal samples and thus a falsely reduced GFR was belied since there was consistently lower activity in the portal than in peripheral venous samples. We speculate that this surprising difference stems from a mixture of the central venous blood with filtered blood from the renal veins combined with the longer return time of the peripheral blood. Further, venous stasis from tourniquet placement during venipuncture may delay the return of the peripheral venous blood.

## EP-1024

### Examination of optimum conditions for 99mTc brain perfusion SPECT using a new SZHRX collimator

***T. Nishiyama***[1], *M. Onoguchi*[1], *T. Shibutani*[1], *A. H. Vija*[2], *F. Massanes*[2], *T. Shimizu*[2], *H. Yoneyama*[3], *T. Konishi*[3], *H. Mori*[4], *K. Nakajima*[5];
[1]*Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN,* [2]*Siemens Medical Solutions UNITED STATES OF AMERICA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA,* [3]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa, JAPAN,* [4]*Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, JAPAN,* [5]*Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa, JAPAN.*

***Aim/Introduction:*** A new multi-focal SMARTZoom class collimator with a suitable high resolution and extended magnification volume (SZHRX) is applied to nuclear cardiology and neurology applications. The goal of this study is to investigate optimal counts and reconstruction conditions for brain perfusion SPECT using the SZHRX collimator. ***Materials and Methods:*** The Symbia Intevo 16 (Siemens Healthineers) SPECT/CT scanner was equipped with prototype SZHRX collimators. A Hoffman phantom was filled with $^{99m}$Tc solution. The SPECT data were acquired with 256× 256 matrices, 2.4mm pixel size with a circular brain centered orbit radius of 26cm, and 3 deg./angular step, and the average count in the anterior view of the brain planner image is 2-24 counts/pixel. The SPECT image were reconstructed with a prototype quantitative xSPECT using the ordered subset conjugated gradient method (OSCGM) including system modeling, attenuation, and scatter corrections. The reconstruction parameters were varied from 24 to 60 for the number of updates and from 4.8 to 12mm for a full width at half-maximum (FWHM) of Gaussian filter. For physical analysis, each condition was evaluated by percent-coefficient of variation (%CV), percent contrast (%contrast), normalized mean square error (NMSE). In addition, image uniformity and separation of thalamus were evaluated by visual evaluation. ***Results:*** %contrast was nearly constant for 8 counts or more regardless of Gaussian filter FWHM and the number of updates. On the other hands %contrast varied significantly at lower counts. Similarly, %CV and NMSE showed almost constant values up to approximately 8 counts, while their values were higher at lower counts. %contrast was higher for increasing number of updates and decreasing Gaussian filter FWHM, whereas the %CV was worse. The optimal reconstruction conditions were determined from the physical and visual assessment. ***Conclusion:*** We determined that the optimal reconstruction parameter for brain perfusion SPECT imaging of the SZHRX collimator were Gaussian filter FWHM 7.2mm and number of updates 48 for more than 8 counts, Gaussian filter FWHM 9.6mm and number of updates 48 or more for less than 8 counts.

## EP-1025

### Inter- and intraobserver and the test-retest variability in bone density measurement in vertebral fracture assessment on DXA

***S. Wongjarern****, A. Willemsen, R. Slart;*
*UMCG, Groningen, NETHERLANDS.*

***Aim/Introduction:*** During an audit of the Dual-energy X-ray absorptiometry (DXA) at our department of Nuclear Medicine the variability in bone density measurement (BDM) and vertebral fracture assessment (VFA) was lacking and it was advised to evaluate this. Therefore, the aim of this project was to evaluate the variability in BDM and VFA. ***Materials and Methods:*** In total thirty patients were scanned twice by three technologists. The BDM of the left hip and the mean of the four lumbar spine (L1-L4) was determined. In addition, the VFA (Th4-L4) was scored as normal, crush, wedge or biconcave. The first scans, test (T), were processed by each technologist to determine the interobserver variability. In addition, each technologist processed ten of these scans for the second time, to determine the intraobserver variability. Similarly, each technologist also processed ten of the second scans, retest (RT). The results were compared with the first scan to determine the test-retest variability. For each comparison the mean and standard deviation (SD) were calculated and reported as percentages. As for the BDM, the same approach was used to determine the inter- and intraobserver variability. For the VFA we calculated the concordance as match, mismatch or missing, when a vertebrae could not be evaluated. ***Results:*** The interobserver variability between the three technologists ranged on average for the hip from -0,47% to 0,09% and for the lumbar spine -0,51% to 0,24%, respectively. The intraobserver variability ranged on average for the hip from -0,06% to 0,5% and for the lumbar spine -0,01% to -0,08%, respectively. As expected the mean error was very small indicating there is no bias. The SD were similar for all three observers. On average the intraobserver variability was lower than the interobserver variability. The test-retest variability was somewhat higher than the inter- and intraobserver variability indicating that the scan itself is the major source of variability. For the VFA a concordance 90% was found for both the inter- and intraobserver comparison. The remaining 10% was approximately equally divided between mismatch and missing. ***Conclusion:*** The inter-and intraobserver variability on DXA was lower than the test-retest variability for BDM with an excellent agreement for VFA. For therapy evaluation, taking a difference of two SD as significant, we found a threshold slightly less than 4%.

## EP-1026

### The Advantages of using Nitrogen-13 Ammonia PET Imaging in Flow Quantification of Microvascular Diseases

***G. Daigneault****, M. Balu, M. Menelas;*
*CHUM, Montreal, QC, CANADA.*

***Aim/Introduction:*** Clinical PET myocardial perfusion imaging provides significant improvement in diagnostic performance of myocardial perfusion, in comparison to SPECT imaging. Particularly, it allows assesment of microvascular diseases and accurate blood flow quantification, and other potential applications. ***Materials and Methods:*** 1300 PET N-13-Ammonia myocardial perfusion imaging quantification were performed in our hospital since 2018. All patients were recruited through our open label research protocol. The onsite cyclotron generates from 620 to 800 mCi per beam, so 4 patients can be imaged per batch. In our facility, with the involvement of our technologists, nuclear medecine physicians and cyclotron team, we have established a rigorous onsite protocol, to have an effective way of executing the N-13-Ammonia perfusion imaging. ***Results:*** Considering the limitations of this particular exam (availability of the radionuclide, selective criterias for patient selection in the study, department resources), the contribution in the diagnosis of microvascular diseases has a high specificity and accuracy for cardiologists, especially in hemodynamics. It has been integrated in our Women's Cardiovascular Health Clinic, with a high success rate in diagnosis and prognosis in cases of equivocal SPECT imaging or suspect microvascular diseases. ***Conclusion:*** Quantification of myocardial perfusion using PET N-13-Ammonia provides a high performance level myocardial perfusion imaging, both in accuracy and specificity, and is minimally invasive. It is also a good exam to consider in advanced atherosclerosis, in nonatherosclerosis microvascular diseases, defining prognosis, and evaluation of therapies. ***References:*** Clinical PET Myocardial Perfusion Imaging and Flow Quantification, Daniel Juneau et al., 2016; Assessment of Diagnostic Performance of Quantitative Flow Measurements in Normal Subjects and Patients With Angiographically Documented Coronary Artery Disease by Means of Nitrogen-13 Ammonia and Positron Emission Tomography, Otto Muzik et al., Journal of the American College of Cardiology, Volume 31, Issue 3, March 1998, Pages 534-540; In-house protocol chart.

## EP-1027

### Investigation of volumetric measurements from gated myocardial perfusion Multi-Pinhole SPECT with shortening acquisition time

***M. Alamin***[1], *S. Barna*[2], *V. Bencze Linczerné*[3], *K. Kukuts*[3], *A. Oszlanszki*[3], *J. Varga*[4], *Á. Krizsán*[3], *A. Forgács*[3], *I. Garai*[2];
[1]*University of Debrecen, Debrecen, HUNGARY,* [2]*University of Debrecen, Faculty of Medicine, Department of Medical Imaging, Division of Nuclear Medicine; Scanomed Nuclear Medicine Centres, Debrecen, HUNGARY,* [3]*Scanomed Nuclear Medicine Centres, Debrecen, HUNGARY,* [4]*University of Debrecen, Faculty of Medicine, Department of Medical Imaging, Division of Nuclear Medicine, Debrecen, HUNGARY.*

***Aim/Introduction:*** Triple-headed system equipped with multi-pinhole collimator (MPH-Cardiac) has significantly improved system volumetric sensitivity for cardiac imaging, making possible to reduce acquisition time. The aim of this study was to evaluate how volumetric parameters of gated myocardial perfusion SPECT are reproducible with shorter time. In addition, we have extracted and compared the same parameters from parallel-hole SPECT imaging. ***Materials and Methods:*** 34 patients (median age: 61 years) underwent 46 cardiac gated $^{99m}$Tc- MIBI MPI scans (17 rest, 29 stress). Using 2-days protocol. 40 ± 20 min after the administration of 350 MBq $^{99m}$Tc-MIBI each patient were examined on two systems in randomized order. Image acquisitions were performed with LEHR collimators on a dual-headed SPECT system (AnyScan-SC) in 90° detector configuration, 64 views covering 180° scan arc, and the MPH-Cardiac collimators on a triple head SPECT system (AnyScan-SC-TRIO) in 75° detector configuration, 125° scan arc. Projection images with shorter acquisition time (10, 8, 6, 4, and 2 minutes) were generated from the MPH-Cardiac SPECT list mode. Image reconstructions were performed with Tera-Tomo 3D SPECT using 128 resolution, iterations 8 subsets 3.6 mm voxel size for the MPH-Cardiac, and OSEM with Butterworth pre-filter 6.5 mm voxel size in case of the LEHR. Attenuation and scatter correction was not applied. Ejection fraction (EF), end diastolic volume (EDV) and end systolic volume (ESV) were evaluated by two experienced nuclear medicine experts using dedicated cardiac software (INVIA-Corridor-4DM, 2017). Observer variability were investigated with the calculation of Interclass Correlation Coefficient (ICC) for each parameter (EDV, ESV, EF) and for both acquisitions and for each acquisition time regarding MPH-cardiac SPECT. The presence of differences between the measured volumetric parameters were evaluated with nonparametric paired-sample test (Wilcoxon signed rank test). The statistical calculation was carried out using IBM SPSS, 28. ***Results:*** Observer variability indicates good reliability for parallel hole images (worst ICC = 0.766 for EF) and excellent reliability for MPH cardiac images (ICC > 0.9), even for 4 and 2 minute scans. There was no significant difference between the measured ESV (mean 36.6 ml for MPH and 30.2 ml LEHR, p=0.857) and EF (p=0.065, for MPH 69.9 ml vs 68.6 ml LEHR). The EDV values were significantly bigger for MPH-Cardiac images (p<0.001, mean 110.2 ml for MPH and 90.4 ml for LEHR). ***Conclusion:*** Triple-headed SPECT system equipped with dedicated cardiac multi-pinhole collimator provide reliable volumetric measurements during significantly shorter acquisition time with excellent reader agreement.

## EP-1028

### Overall survival of patients undergoing transarterial radioembolization (TARE) and the influence of additional treatments, injected activity and mean dose to the tumor

***S. Ialuna***[1], *N. Quartuccio*[1], *D. Scalisi*[2], *F. D'Amato*[3], *M. R. Barcellona*[4], *M. G. Bavetta*[4], *G. Fusco*[4], *E. Bronte*[5], *E. Musso*[5], *F. Bronte*[6], *V. Picciotto*[4], *A. Carroccio*[4], *F. Verderame*[5], *G. Malizia*[6], *F. La Gattuta*[7], *A. M. Moreci*[1];
[1]*Nuclear Medicine Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [2]*Health Physics Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [3]*Unit of Interventional radiology, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [4]*Internal Medicine Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [5]*Clinical Oncology Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [6]*Gastroenterology Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY,* [7]*Interventional Radiology Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY.*

***Aim/Introduction:*** To present the preliminary experience of our center with transarterial radioembolization (TARE) with Yttrium-90, with regards to overall survival (OS) in different pathologies. The secondary goals of the study included the influence of additional treatments, injected activity, mean dose to the tumor on OS. ***Materials and Methods:*** The database of our center was interrogated to retrieve patients who had undergone TARE with Yttrium-90 glass or resin microspheres. The following information were searched for the inclusion to the study: 1) type of pathology; 2) sex; 3) age; 4) administered activity; 5) mean dose to the tumor; 6) additional treatments; 7) OS. The OS of the different groups of patients, based on pathology and additional treatment were compared (p<0.05). A bivariate correlation (p<0.05) was used to investigate the association between injected activity and OS, and between mean dose to the tumor on OS. ***Results:*** From a total of 150 patients who had undergone TARE, 39 patients with complete datasets were retrieved (Sex: 27 M, 12 F; mean age: 61.26 ± 14.95 years). The pathologies treated with TARE were hepatocellular carcinoma (HCC; n=23) and liver metastasis from colon cancer (n=16). The median follow-up from TARE to the last available record (April 2023) was 69 months (range: 39-91 months). Mean administered activity was 2.2 ± 0.9 GBq; mean dose to the tumor was 282.68 Gy. Additional treatments included Sorafenib (n=7), Regorafenib (n=2) or both (1). Patients with HCC demonstrated a significantly longer OS than those with liver metastasis (22.66±19.11 vs. 10.41±8.75 months; p=0.022). Patients with liver metastases from colon receiving additional treatment demonstrated a longer OS than patients receiving only TARE (23.50±19.76 months vs. 8.54±5.31; p=0.018); there was a direct correlation between injected activity and OS (R=0.55, p=0.034) and between mean activity reaching the tumor and OS (R=0.812; p=0.008). Patients with HCC receiving additional treatment (n=8) demonstrated a trend for longer OS than patients receiving only TARE (n=15; 31.07±18.20 months vs. 18.20±18.66; p=0.13); there was a trend towards a direct correlation between mean dose to the tumor and OS (R=0.45, p=0.118). ***Conclusion:*** In our experience, patients with HCC receiving TARE achieve a longer OS than those with liver metastases from colon cancer. Additional treatments and increasing injected activity and mean dose to the tumor are beneficial for outcome, especially in patients with liver metastases from colon cancer.

## EP-1029

### Quantitative Parameters of 99mTc-PYP SPECT/CT Correlates with Left Ventricle Diastolic Dysfunction in Transthyretin Amyloid Cardiomyopathy, Not Myocardial Perfusion Reserve

***Y. Chen***[1], *C. Ko*[1], *J. Cheng*[1], *A. Yu*[2], *C. Tsai*[2], *P. Tseng*[3], *C. Chao*[4], *M. Cheng*[1], *Y. Lin*[2];
[1]*Department of Nuclear Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [2]*Department of Internal Medicine, Division of Cardiology, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [3]*Department of Internal Medicine, Division of Gastroenterology, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [4]*Department of Neurology, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN.*

***Aim/Introduction:*** Coronary microvascular dysfunction has been previously documented in cardiac amyloidosis even in the absence of obstructive epicardial coronary artery disease (CAD). $^{99m}$Tc-pyrophosphate (PYP) scintigraphy is used to support the diagnosis of transthyretin amyloid cardiomyopathy (ATTR-CM) when unexplained increased left ventricle (LV) wall thickness is observed on echocardiography. However, the relationship between PYP accumulation, LV morphology, and myocardial blood flow (MBF) remains unexplored. Consequently, our study aims to assess the roles of $^{99m}$Tc-PYP scans, echocardiography, and quantitative $^{201}$Tl myocardial perfusion imaging (MPI)-derived parameters in patients with ATTR-CM. ***Materials and Methods:*** We retrospectively analyzed 34 patients (mean age 65.6±6.8 years, 71% women) diagnosed with ATTR-CM without CAD. All patients underwent quantitative $^{201}$Tl MPI, $^{99m}$Tc-PYP scan, and echocardiography within a 3-month period. Quantitative global stress/rest MBF and myocardial perfusion reserve (MPR) were computed using in-house software. PYP images were analyzed using both planar heart-to-contralateral lung (H/CL) ratio and volumetric heart-to-lung (H/L) ratio from SPECT/CT. These parameters were compared with indices derived from echocardiography (including interventricular septal diameter (IVSd), left ventricular posterior wall diameter (LVPWd), left ventricular end-diastolic diameter (LVEDd), left ventricular ejection fraction (LVEF), and stroke volume) and serum N-terminal pro-B-type natriuretic peptide (NTproBNP) levels through Pearson correlation analysis. ***Results:*** The median serum NTproBNP level and LVEF were 733.8 pg/mL(range, 31.1-3269) and 62.7%(range, 33.3-81.3%). NTproBNP showed a negative correlation with stress MBF (r=-0.667, p<0.0001), MPR (r =-0.532, p<0.005), and LVEF (r =-0.526, p<0.005), but a positive correlation with LVPWd (r=0.644, p<0.0001). Both stress MBF and MPR demonstrated negative correlations with wall thickness (IVSd, LVPWd, r=-0.401, -0.554, and -0.352, -0.339, respectively, all p<0.05). The volumetric H/L ratio was the only parameter that displayed a negative correlation with LVEDd (r=-0.352, p<0.05) and stroke volume (r=-0.447, p<0.01). No significant correlation was found between the volumetric H/L ratio and LV wall thickness or dynamic MPI indices. ***Conclusion:*** The results of our study suggest that a reduced myocardial reserve, as seen in dynamic MPI, has a relationship with elevated cardiac biomarkers and increased LV wall thickness identified in echocardiography. In contrast, the volumetric H/L ratio, obtained from PYP scans, displays a negative correlation with end-diastolic diameter and stroke volume. These findings underline the potential value of PYP imaging in assessing the degree of diastolic dysfunction in ATTR-CM, a condition often first detected in patients with preserved ejection fraction.

### Optimization of Classical Pulmonary SPECT on a Revolutionary Camera

***S. Hirsi***[1,2], *A. E. Pedersen*[3,2], *H. Precht*[3,4,5], *S. Hess*[6,7,8], *R. Horvat*[6,7], *M. H. Vilstrup*[6,7], *P. L. Hansen*[2,4], *T. Q. Christensen*[7,9];
[1]*Department of Nuclear Medicine and PET Centre, Aarhus University Hospital, Aarhus, DENMARK,* [2]*Education of Radiography, UCL University College, Odense, DENMARK,* [3]*Department of Radiology, Lillebaelt Hospital, University Hospitals of Southern Denmark, Kolding, DENMARK,* [4]*Health Sciences Research Centre, UCL University College, Odense, DENMARK,* [5]*Department of Regional Health, University of Southern Denmark, Odense, DENMARK,* [6]*Department of Radiology and Nuclear Medicine, Hospital South West Jutland, Esbjerg, DENMARK,* [7]*IRIS - Imaging Research Initiative Southwest, Esbjerg, DENMARK,* [8]*Department of Regional Health Research, Faculty of Health Sciences, University of Southern Denmark, Odense, DENMARK,* [9]*Department of Clinical Engineering, Region of Southern Denmark, Esbjerg, DENMARK.*

***Aim/Introduction:*** Shorter acquisition times improve throughput and patient comfort. We investigated if a new 12-detector cadmium-zinc-telluride (CZT) SPECT enabled shorter acquisition times for pulmonary ventilation/perfusion (V/Q) SPECT while maintaining image quality. Further, we investigated the potential of utilizing a Block Sequential Regularized Expectation Maximization (BSREM) reconstruction algorithm, which recently became commercially available in SPECT. ***Materials and Methods:*** Eight patients with suspicion of pulmonary embolism were scanned on both a 12-detector CZT SPECT and a 2-detector NaI SPECT. All had Q-SPECT with an acquisition time of 17 minutes after injection of 200 MBq +/-10% Tc-99m macro-aggregated albumin. Four patients further underwent 12 minutes of V-SPECT after inhaling approximately 25 MBq of Tc-99m-technegas. Images from the 12-detector SPECT were reconstructed with list-mode files at reduced times of 33%, 42%, 50%, and 67% using Ordered Subset Expectation Maximization (OSEM) with 5 iterations (i), 8 subsets (s) and 3mm Gaussian post-filter. The BSREM algorithm was investigated at 50% acquisition time with 20i10s using the relative differences for maximum regularization method with gamma of 1 and varying regularization strength factors (beta) of 0.02, 0.05 and 0.08. Three nuclear medicine physicians evaluated image quality through absolute Visual Grading Analysis with regards to visibility of interlobar fissures (VIF), visibility of lung boundaries (VLB), and diagnostic confidence (DQ); the former two and VLB were assessed using a four-point forced-choice scale, whereas VIF was done binarily. Visual grading characteristics curves (VGC) were generated and area under the curve ($AUC_{VGC}$) were calculated. Fleiss' Kappa and Cohen's Weighted Kappa were used to assess interrater/intrarater reliability. ***Results:*** $AUC_{VGC}$ curves on OSEM reconstructions were below 0.5 for all acquisition times for most parameters on the 12-detector SPECT compared to 2-detector SPECT, except for VIF, which had an $AUC_{VGC}$ of 0.507 (CI: 0.375-0.670) when using 100% acquisition time on OSEM. However, when BSREM was used on 50% acquisition time and beta-value of 0.08, $AUC_{VGC}$ increased from 0.037, 0.070, 0.436 and 0.170 to 0.440, 0.473, 0.559 and 0.480 for IQ, DC, VIF and VLB, respectively. ***Conclusion:*** Our study indicates the possibility of reducing acquisition time by 50% for V/Q SPECT without compromising image quality on the 12-detector SPECT when using BSREM 20i10s with beta-value of 0.08. Image quality was lower across all OSEM reconstructions for the 12-detector SPECT compared to the 2-detector SPECT, possibly due to the use of smaller voxel volumes (2.46 mm). These results warrant further investigation.

### Quantitative (FDG)PET/CT - How huge a small error can be

***I. Pestean***, *A. Sabo, M. Cecan, M. Crisan, E. Barbus, D. Piciu; Institute of Oncology, Cluj, ROMANIA.*

***Aim/Introduction:*** The SUV (Standardized Uptake Value) in PET-CT is the one of the greatest achievements of PET-CT technique, having impact on the primary tumor evaluation, disease progression evaluation and treatment response assessment. It is necessary to optimally choose the right SUV normalization type, calculated by the body weight, body surface area, or, as recommended by most specialists, by lean body mass (SUVlbm). The SUV SUVlbm formula depends on the administrated radiopharmaceutical activity, disintegration time, patient weight and height. We evaluated the SUVlbm variation when input data errors occurred due to misregistration. ***Materials and Methods:*** We evaluated three types of malignant lesions findings, 10 with low, 10 with medium and 10 with high SUVlbm values (the median SUVlbm value being 3.78, 6.66 and 20.21). We calculated the SUVlbm of the lesions having an error of 10%, 20%, 30% and 50% in the input data, respectively administrated activity, patient height and weight, named as SUVlbm10, SUVlbm20, SUVlbm30 and respectively, SUVlbm50. We expressed the changings of SUVlbm as percentage of the correct SUVlbm to correlate the impact of the SUVlbm changings with the errors of the input data. ***Results:*** The SUVlbm variations in the case of height errors ranged between 6.08% and 27.63%, the highest error occurring in lesions with medium SUVlbm. The SUVlbm variations when weight errors were simulated ranged between 4.35% and 24.87%, the highest impact being noticed in lesions with low SUVlbm. The SUVlbm variations ranged between -9.16% and -33.48% in the case of administrated activity error simulations, with highest impact in lesions with medium uptake. ***Conclusion:*** The SUVlbm is changed when input data are misregistrated, the changes occur at any type of uptake and at any level of error and the variations are significant in SUVlbm evaluations.SUV is a predictable parameter highly correlated with tumor aggressiveness, commonly used in comparative studies, a specific indicator for treatment response and its standardizations and accuracy is mandatory

### Description amyloid PET (18F-Florbetaben) imaging protocol in patients with suspected Alzheimer's disease

***M. Caballero Vivancos***[1], *M. Pérez Ávila*[1], *F. González Asid*[1], *E. Córdoba Cañete*[1], *R. Sánchez Sánchez*[2]*;*
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [2]*Hospital Universitario Virgen de las Nieves, Maracena, Granada, SPAIN.*

***Aim/Introduction:*** Alzheimer's disease (AD) is a neurodegenerative condition characterized by progressive cognitive decline and memory loss, and is the most common form of dementia. Amyloid plaques with neurofibrillary tangles are a neuropathological hallmark of AD that produces synaptic dysfunction and culminates later in neuronal loss. Amyloid PET is a useful, available and non-invasive technique that provides in vivo information about the cortical amyloid burden. ***Materials and Methods:*** These are studies that do not require special preparation, do not require fasting or withdrawal of the usual medication. The dose is administered as a slow bolus and washing the line with approximately 5-15ml of sterile 0.9% sodium chloride. After a rest period of 45-130 minutes, the images are acquired. It is recommended that the patient empty the bladder to obtain maximum comfort and avoid movement during image acquisition, in addition to reducing local irradiation. The patient, in the supine position, must have adequate and fixed support for the head, avoiding extreme extension or flexion of the neck, including the entire brain in the study. Images should be acquired in three-dimensional mode with appropriate corrections and reconstructed using attenuation correction with a transaxial pixel size of 2-3mm and a slice thickness of 2-4mm. ***Results:*** The application of this protocol in our institution allows the correct interpretation of amyloid PET studies.Nuclear physicians have been able to interpret the study in a binary, positive or negative way for the presence of cortical amyloid plaques. ***Conclusion:*** Amyloid PET is a useful and available technique that provides us with in vivo information on amyloid deposits.

### Evaluation of image quality according to the difference in acquisition methods(SS and CBM) between PET/CT manufacturers in the 68Ga study

***E. Seo***, *J. Ryu;*
*Asan Medical Center, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Each manufacturer has different spatial resolution and image quality as a result of different image acquisition methods (Step-and-shoot method; SS and Continuous Bed Motion; CBM) which can influence diagnostics information in Nuclear Medicine. This study investigated the image quality of each PET/CT scanner using an ACR phantom with $^{68}$Ga. ***Materials and Methods:*** GE and Siemens PET/CT scanners were used. SS method was performed for 1~5 min per bed. CBM (only Siemens) was performed at a speed of 0.9~2.9mm/s). Reconstructed Images were applied with Gaussian 2mm Iteration 2, subset 6, TOF, PSF and then analyzed as spatial resolution, recovery coefficients, contrast-noise ratio (CNR), and signal-noise ratio (SNR). ***Results:*** For the SS method, spatial resolution was improved in proportion to acquisition time, while CNR and SNR did not differ significantly more than 3 minutes for GE and 3.5 minutes for Siemens. For the CBM of Siemens, the spatial resolution decreased by 1 step as the speed increased by 0.4 mm/s, and the CNR and SNR did not have significant values when the speed was 2.1mm/s or faster. ***Conclusion:*** Considering that the patient's movement and breathing artifacts increase as the scan time increases, especially when we perform the $^{68}$Ga study, the maximum level of the scan speed in the CBM method is 1.7 mm/s, and in the SS method, the maximum acquisition time for obtaining adequate image quality is 3 ~3.5 min. ***References:*** - Comparison of image quality and spatial resolution between 18F, 68Ga, and 64Cu phantom measurements using a digital Biograph Vision PET/CT- Continuous bed motion in a silicon photomultiplier-based scanner provides equivalent spatial resolution and image quality in whole body PET images at similar acquisition times using the step-and-shoot method

## EP-1034

### 99mTc Radiopharmaceuticals: Evaluation of Radiochemical Purities in the Last Two Years of Use

***D. Di Martino***, *A. Prisco, F. Rescigno, M. Buonanno, V. Porfidia, A. Esposito, M. Aurilio, S. Lastoria;*
*Istituto Tumori G.Pascale, Napoli, ITALY.*

***Aim/Introduction:*** $^{99m}$Tc radiopharmaceuticals are the most frequently used products in the nuclear medicine and they prepared in the hospital, start from colds kit. The most important quality test, before the administration, is radiochemical purity (RCP) that indicates the ratio of radionuclide contained in the

radiopharmaceutical in the desired chemical form and is expressed in percentage. This parameter aims to determine the produced radiopharmaceutical is in accordance with the summary of product characteristics (SPC). ***Materials and Methods:*** In the hospital radiopharmacy the applicable quality control method is radio-thin layer chromatography (radioTLC). With this technique, the components of the radiopharmaceutical are separated according to the solubility in the solvent and adsorption to the support medium. Moreover, in order to separate and quantify two or more impurity, two or more paper strip can be used with different eluents. A digital autoradiography system was used for the identification and quantification of radioactivity distribution along the chromatographic strips.The time taken for each control range from 5 (1 strip) to 7 minutes (2 strip). ***Results:*** The study was performed over a period of two years (January 1 2021- December 31 2022) and included a total of 1186 radiopharmaceutical preparations and their quality control. The radiopharmaceutical preparations were the following: $^{99m}$Tc-albumin colloid (N=451), $^{99m}$Tc-oxidronate (N=494), $^{99m}$Tc-diethylene triamine-pentacetic acid (N=209) and $^{99m}$Tc-sestamibi (n=32). The mean results of RCP determination are: $^{99m}$Tc-albumin 99,7 % (Min 95%); $^{99m}$Tc-oxidronate 99,08% (Min 96,5%) for strip A and 99,1% (Min 97,9%) for strip B; $^{99m}$Tc-diethylene triamine pentacetic acid 98,9 % (Min 97,5%) for strip A and 98,8% (Min 97,4%) for strip B and 97,8 % (Min 97%) for $^{99m}$Tc-sestamibi. Zero out of the 1186 preparations were non-conforming for clinical use with the RCP limits indicated by manufacturer acceptance. ***Conclusion:*** QC regarding the determination of RCP is mandatory for all $^{99m}$Tc radiopharmaceuticals. Radiochemical impurities actually may cause difficulty in evaluating images and even inaccurate clinical diagnosis. For most radiopharmaceuticals, the lower limit of RCP is 95 percent; that is, at least 95 percent of the radioactive isotope must be attached to the ligand. Correctly following the manufacturer's instructions that can be found in the package insert, all prepared radiopharmaceuticals found to comply with the quality specifications.

## EP-1035

### How to optimize the synthesis of [177Lu]Lu-DOTATOC, from a simple manual operation

***P. Christensen****;*
*Aarhus University Hospital, Aarhus, DENMARK.*

***Aim/Introduction:*** Peptide Receptor Radionuclide Therapy (PRRT) with [$^{177}$Lu]Lu-DOTATOC is used in therapy of neuroendocrine tumours. The Department of Nuclear Medicine & PET-Centre, Aarhus University Hospital, have offered this treatment since 2016. For patients participating in a clinical trial and those not covered by the Lutathera authorization, we have an in-house production of [$^{177}$Lu]Lu-DOTATOC, with an annually average of 66 treatments. ***Materials and Methods:*** All syntheses were carried out using the Eckert & Ziegler Modular-Lab PharmTracer automated synthesis system. Materials and methods were used according to the instructions given by the manufacturer of the system. For all the synthesis, we have used no-carrier added lutetium chloride supplied from ITG. The [$^{177}$Lu]$Cl_3$ have a half-life of 6.7 days and were delivered in a 2 mL v-vial. In 2018 we introduced a manual operation, to optimise the total yield, since much of the [$^{177}$Lu]$Cl_3$ still remains in the delivered v-vial at the end of synthesis. After transfer of the v-vial content, acetate labelling buffer is added to the v-vial, and the v-vial washed by simply turning the vial upside down. This ensures that as much as possible of the radioactivity is transferred to the reaction vial. We have measured the radioactivity in the delivered v-vial before start of the synthesis and the radioactivity in the product vial after synthesis. We have also measured the remaining activity in the v-vial after synthesis and the activity in the bottle containing the waste of the synthesis. By non-decay corrected calculations, we determined the yield and identified where the free [$^{177}$Lu]$Cl_3$ was located. ***Results:*** This poster will show, how this manual operation has some positive effects on overall yield of the synthesis of [$^{177}$Lu]Lu-DOTATOC, thus a more efficient usage of the delivered [$^{177}$Lu]$Cl_3$ radioactivity and hereby cost reduction.

## EP-1036

### Impact of images reconstructed using Bayesian penalized likelihood on ability of [11C]MET-PET to differentiate malignant grades in brain gliomas

***Y. Kamitaka****[1,2], K. Wagatsuma[1,3], M. Inaji[4], K. Ikemoto[3], K. Miwa[5], K. Ishii[1], M. Kobayashi[2];*
*[1]Research Team for Neuroimaging, Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]Division of Health Sciences, Graduate School of Medical Sciences, Kanazawa University, Ishikawa, JAPAN, [3]Radiological Technology, Medical Engineering and Technology, School of Allied Health Sciences, Kitasato University, Kanagawa, JAPAN, [4]Department of Neurosurgery, Tokyo Medical and Dental University, Tokyo, JAPAN, [5]Department of Radiological Sciences, School of Health Sciences, Fukushima Medical University, Fukushima, JAPAN.*

***Aim/Introduction:*** The role of amino acid positron emission tomography (PET) imaging using [$^{11}$C]methionine ([$^{11}$C]MET) is to differentiate between malignant glioma grades. Quantitative parameters such as standardized uptake values (SUVs) are increased when images are reconstructed using the Bayesian penalized likelihood (BPL) compared with conventional ordered subset-expectation maximization (OSEM). The present study aimed to determine whether [$^{11}$C]MET-PET images reconstructed using BPL can differentiate malignant grades in brain gliomas. ***Materials and Methods:*** Thirty-six primary glioma lesions that were assessed in 32 patients by [$^{11}$C]MET-PET imaging were classified as grades 2 and 3 (n = 14) and 4 (n = 18) based on the WHO 2021 classification. We then measured the $SUV_{mean}$ in normal tissues and the $SUV_{max}$ and $SUV_{peak}$ in gliomas from PET images reconstructed using OSEM with time-of-flight (TOF) and BPL with TOF (β200). Tumor-to-normal tissue ratios (T/N) were calculated as $T/N_{max}$ and $T/N_{peak}$. Mean Ki-67 and quantitative values ($SUV_{max}$, $SUV_{peak}$, $T/N_{max}$, and $T/N_{peak}$) were compared between malignant grades (2 and 3 vs. 4) using OSEM and BPL. Relationships between Ki-67 and quantitative values were assessed using Pearson correlations. We then calculated the area under receiver operating characteristic (ROC) curves (AUC) for Ki-67 and the quantitative values. ***Results:*** The means of Ki-67, $SUV_{max}$ in BPL, and $SUV_{peak}$ in OSEM and BPL were statistically higher in grade 4 than grades 2 and 3. Quantitative values increased under BPL reconstruction regardless of the malignant status of gliomas. The correlation coefficients derived using OSEM and BPL were respectively: $SUV_{max}$, 0.344 and 0.392; $SUV_{peak}$, 0.346 and 0.352; $T/N_{max}$, 0.221 and 0.269; $T/N_{peak}$, 0.250 and 0.252. The AUCs derived using OSEM and BPL were respectively Ki-67, 0.97; $SUV_{max}$, 0.69 and 0.72; $SUV_{peak}$, 0.68 and 0.70; $T/N_{max}$,0.63 and 0.66; $T/N_{peak}$, 0.64 and 0.65. ***Conclusion:*** The reconstruction of [$^{11}$C]MET-PET images using BPL differentiated between malignant grades in gliomas using $SUV_{max}$ and $SUV_{peak}$ and led to increased quantitative values regardless of the malignant status of gliomas. The BPL improved the ability to discriminate malignant from benign gliomas on [$^{11}$C]MET-PET images.

## EP-1037

**Nuclear Medicine**

***A. Alshehri***, *T. Wright, K. M Prise, A. Cole;*
*Queens University Belfast, Belfast, UNITED KINGDOM.*

***Aim/Introduction:*** Despite continued advancements into the treatment of PCa, it continues to represent a major burden in men worldwide. This is particularly problematic upon progression to MCRPC which has metastasised to bone. Of the current therapeutics available two agents targeting the androgen receptor pathway: Abiraterone and Enzalutamide are now routinely used as standard of care. These agents have been shown to result in significant increases to OS in MCRPC patients, however, questions still remain to their optimisation and effects when combined with radiation. ***Materials and Methods:*** Colony assays-Cells were pre-treated with 10μM Abiraterone or Enzalutamide one-hour before irradiation and irradiated at dose 0-8Gy.Western Blot and cell cycle.Samples were pre-treated with 10μM Abiraterone/Enzalutamide one or 24hours before irradiation at 2Gy. Samples were harvested 1,24, 48hours post-radiation for western blot and CellCycle analysis. ***Results:*** Radiosensitising effects of Abiraterone and Enzalutamide: Having previously established the cytotoxic potential of Abiraterone and Enzalutamide as single agents and their significant additive impact when combined with 2Gy.The radiosensitising potential of these hormonal agents was investigated.LNCaPs showed increased radiosensitivity when pre-treated 24hours before radiation for both Abiraterone(SER=1.23) and Enzalutamide(SER=1.23).No radiosensitising effects were observed with Enzalutamide across both PC3s(SER=0.96) and SJSA-1s(SER=1.01).However, Abiraterone displayed synergy with radiation regardless of AR status, with PC3s(SER=1.19) and SJSA-1s(SER=1.17).Abiraterone and Enzalutamide inhibit DNA repair through RAD51 suppression:The AR has been linked to the upregulation of key DNA repair genes.Therefore, the impact of AR suppression on DNA repair pathways such as homologous recombination was investigated through investigation of RAD51 expression.AR suppression with Abiraterone and Enzalutamide resulted in total visible reduction in or RAD51 expression, correlated with PSA expression.Importantly, these effects were shown to be conserved with 2Gy co-treatment when Abiraterone and Enzalutamide was administered 24hours before radiation.Cell cycle distribution was also investigated to determine if these impacts were direct or result of cell cycle distribution change.Abiraterone and Enzalutamide results in cell cycle distribution changes. ***Conclusion:*** Results suggest radiosensitisation effect with Abiraterone and Enzalutamide in AR sensitive prostate models, while Abiraterone seems to induce radiosensitisation regardless of AR status. Hinting at alternative mechanism of action.The underlying mechanisms for AR suppression based sensitation involves the reduction of key DNA DSB repair pathways such as HR and NHEJ.With reductions in HR at least partially the result of cell cycle distribution changes. Comparison of Abiraterone against Enzalutamide suggest Abiraterone to be more effective across all in vitro metrics measured, providing a rationale for selection of Abiraterone over Enzalutamide. ***References:*** 1.SgourosG,RoeskeJCM,MichaelR,etal.
