angiogenesis. In this study, the theranostic role of $^{89}$Zr- and $^{177}$Lu-labeled aflibercept was investigated for PET imaging and treatment in breast cancer murine models. ***Materials and Methods:*** Aflibercept was conjugated with desferrioxamine (Df) and 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling with $^{89}$Zr ($t_{1/2}$ = 78.4 h) and $^{177}$Lu ($t_{1/2}$ = 6.65 d). After the breast cancer 4T1 tumor-bearing mice model was established, PET imaging and biodistribution studies were performed for 7 days after injection of $^{89}$Zr-Df-aflibercept. Further, six groups were employed for the treatment study, including PBS, aflibercept, $^{177}$Lu-only, $^{177}$Lu-DOTA-IgG (human non-specific), $^{177}$Lu-DOTA-aflibercept-low, and $^{177}$Lu-DOTA-aflibercept-high. Tumor sizes and body weight were measured within 16 days post-injection (n = 5-8). Mice injected with Cy5.5-aflibercept (n=4) and Cy5.5-IgG (n=4) were imaged for optical imaging. Finally, histological analysis was performed to examine VEGF expression in tumors. ***Results:*** PET imaging of $^{89}$Zr-Df-aflibercept showed an increased tumor uptake with the maximum SUVmax of 5.61±0.92 at 120 h post-injection for 4T1 tumors (n = 3). After being labeled with Cy5.5 in optical imaging, the uptake of tumors in the experimental group was higher obviously than control IgG. The tumor-to-blood and tumor-to-muscle ratios increased over time. The above results suggest the high uptake of tumors from radiolabeled aflibercept. We further labeled $^{177}$Lu with aflibercept. The results showed that for the treatment group of $^{177}$Lu-DOTA-aflibercept-high, significant inhibition of tumor growth was observed. Within 16 d, the standard tumor volume of $^{177}$Lu-DOTA-aflibercept-high was significantly less than other groups. Therefore, the effectiveness of the treatment was demonstrated in our study. Besides, the body weight of $^{177}$Lu-DOTA-aflibercept-high did not change significantly, indicating the safety of radiolabeled aflibercept in vivo. ***Conclusion:*** $^{89}$Zr- and $^{177}$Lu-labeled aflibercept displayed a significant VEGF positive tumor affinity and effective tumor therapy without significant toxicity. Therefore, radiolabeled aflibercept could be further investigated in the theranostic field of breast cancer.

### OP-623

**Comparison of lesion detectability in Whole-Body Bone Scan images: A Monte Carlo study of CdZnTe- and NaI(Tl)-based Gamma Cameras**

***R. Madru***[1], *N. Karindotter-Borgendahl*[2], *M. Dahlbeck*[2], *M. Ljungberg*[3];
[1]*Skane University Hospital, Lund, SWEDEN,* [2]*Skane Sjukhus Nordost, Kristianstad, SWEDEN,* [3]*Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** Whole-body-bone-scintigraphy (WBBS) is a high-sensitive imaging method to detect metabolic changes at the early stages of the disease. Here, we study the detectability of the lesions by simulating the modern Cadmium-Zinc-Telluride (CZT) gamma camera (high energy resolution) and compare it to the conventional NaI(Tl) camera (high sensitivity) by using SIMIND Monte Carlo simulations with XCAT virtual patients. The aims were to a) create patient-like WBBS images with realistic activity distribution, including "tumors" of different sizes and intensities in the skeleton and b) simulate a WB scanning situation for CZT- and NaI(Tl)-gamma camera and compare detectability of tumors from these images to ground truth. ***Materials and Methods:*** Whole-body images of ten virtual patients with increased metabolic activity situated at 7-10 different locations in the skeleton (volume range 0.5-8 cm$^3$) were simulated. The intensity of the metabolic activity was randomly altered between five different values in the different locations, based on clinical experience, to mimic bone-scintigraphy images of prostate cancer patients. The bone-to-kidney activity concentration ratio was set to 3:1 and bone-to-background to 30:1. Virtual patient images were simulated for CZT- and NaI(Tl) gamma camera with specific parameters regarding the different collimators (WEHR/LEHR), energy resolution (5.9%/9.2% FWHM), intrinsic spatial resolution (2.46/3.8 mm), measured sensitivity (83/90 cps/MBq), pixel size (2.46/2.39 mm). To obtain a realistic noise level as obtained in clinical images, Poisson noise was added to the simulated images (assuming 570 MBq injected activity and scanning speed 15 cm/min). Two experienced physicians visually evaluated the images using third-party software and graded metabolic changes as 1) possibly-, 2) probably-, and 3) certainly positive. The results were compared with the expected findings. The inter-rater reliability was determined and a p-value<0.05 was considered statistically significant. ***Results:*** A lower percentage true positive lesions was detected in CZT-images compared to conventional NaI(Tl) gamma camera (39% vs 50%). The lesions in the spine and sacrum regions were found more difficult to detect for both types of cameras. The inter-rater reliability showed no significant differences between the two readers (p-value=0.003; K=0.185). ***Conclusion:*** According to preliminary results, WBBS images simulated for CZT-camera show a slightly lower sensitivity compared to conventional NaI(Tl). In a clinical setting, the CZT-camera may include contrast enhancement and advanced noise filtering, which was not considered in this study. Further studies regarding the noise and its impact on lesion detectability is ongoing.

### OP-624

**CZT swiveling-detectors ring SPECT enables 3D dynamic acquisitions**

***M. Hesse****, F. Dupont, R. Lhommel;*
*Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.*

***Aim/Introduction:*** CZT detector ring cameras (CZTR) with their PET-like design including a dozen of swiveling detectors set around the patient enable fast SPECT acquisitions. In pure swiveling motion, sampling resolution down to 5 seconds is achievable, allowing fast dynamic SPECT scans, which is still out of reach with conventional rotating-heads SPECT. However, more developments and validations are required before a potential clinical implementation. This study aims at validating 4D scans on CZTR with the help of a dedicated phantom setup. ***Materials and Methods:*** The phantom consisted in a hermetic bottle filled with 100ml of water to which two entries and one output lines were connected through the rubber stopper. One entry was connected to a 50ml perfusion bag filled with about 3mCi of $^{99m}$Tc and the other one to a water tank. The later allowed a continuous infusion to maintain the water volume in the phantom leading to an exponential total activity decrease. This setup typically simulates a $^{99m}$Tc-MAG3 dynamic kidney study. Fifteen minutes dynamic acquisitions were performed first as a 3D SPECT on a CZTR in pure swiveling mode, then in 2D on a conventional gamma camera with 5-15 seconds frames. The CZTR SPECT list file was sorted to produce different SPECT bin durations that

were then reconstructed to a dynamic SPECT image. Total and partial bottle counts kinetic curves were generated. ***Results:*** As expected the corresponding reconstructed SPECT images become noisier the smaller the frame duration. However, total counts in the bottle could still be extracted and used to create low noise kinetic curves down to 5 seconds sampling resolution. The dynamic SPECT curve displayed the usual uptake phase and slower exponential decrease associated to the $^{99m}$Tc release. When normalized, the dynamic SPECT curve nicely fit the 2D dynamic curve with a mean square deviation lower than 2.5%. Very similar values were found for the time to reach the curve maximum and the release half-life between the planar (178 s and 92 s) and SPECT (165 s and 94 s) dynamic images. From 4D-SPECT, release half-life for the six 8mm-thick coronal slices of the bottle was 94.6 ± 6.2 seconds. ***Conclusion:*** Dynamic SPECT imaging is feasible on CZT swiveling-detectors ring cameras and provides dynamic curves in good agreement with planar dynamic images on conventional gamma camera. 4D-SPECT also enables kinetic modeling of specific organ region. Further in vivo testing is required to confirm these promising results.

## OP-625

### SPECT image reconstruction from sparse projection data using deep learning model trained by randomly generated training phantom

***R. Yano***[1], *Y. Okura*[2], *M. Yamamoto*[2];
[1]*Graduate School of Medical Technology and Health Welfare Sciences, Hiroshima International University, Higashihiroshima, JAPAN,* [2]*Department of Clinical Radiology Faculty of Health Sciences, Hiroshima International University, Higashihiroshima, JAPAN.*

***Aim/Introduction:*** In general, the acquisition time of whole-body single photon emission computed tomography (SPECT) is long. One of the methods to shorten acquisition time is to reduce the number of projection data at SPECT acquisition. However, a small number of projection data affect the quality of resultant SPECT images. On the other hand, deep learning technology made remarkable progress in recent years. In general, deep learning techniques require a large number of images for training the model. However, the number of available SPECT images is limited. This study aims to develop a method to obtain sufficient quality SPECT images from sparse projection data and image data other than SPECT images by deep learning and to evaluate the quality of the resultant SPECT images. ***Materials and Methods:*** We constructed a deep learning model by modifying 3D U-Net model so that the number of output frames is twice the number of input frames. To train the model, we used two types of data sets. One was a projection image obtained by Radon transforming CT images available as open data. The other data set was a projection image created from a random point image. Using the trained model, by inputting sparse projection data, we obtained the output image consisting of twice the frame as interpolated projection images. SPECT images were reconstructed by OSEM using the obtained projection images. To evaluate the SPECT images, we used three numerical phantom data from viewpoints of spatial resolutions, image noise, and Image quality. SPECT images by developed methods were compared with reference SPECT images using %CV, FWHM, and PSNR/SSIM. ***Results:*** SPECT image noise by the developed method was approximately 10% lower than that of the reference SPECT image. However, spatial resolutions were not improved so clearly. PSNR and SSIM were comparable between the CT image trained model and the random point trained model. ***Conclusion:*** We constructed the method to reconstruct SPECT images from sparse projection data using deep learning trained other than the projection images. We found that the deep learning model trained by random point data is available for improvement SPECT images. It was suggested that projection images of sufficient quality could be obtained without using SPECT images. ***References:*** Ryden T, Van Essen M, Marin I, Svensson J, Bernhardt P. Deep-Learning Generation of Synthetic Intermediate Projections Improves 177Lu SPECT Images Reconstructed with Sparsely Acquired Projections. J Nucl Med. 2021;62(4):528-35.

## OP-626

### Assessing the Efficacy of the Relative Difference Prior for SPECT Dosimetry

***L. Polson***;
*University of British Columbia, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Radiopharmaceutical therapies (RPTs) are gaining interest due to the promising results in prostate cancer and neuroendocrine tumor treatment. However, current approaches follow a "one size fits all" paradigm that does not account for physiological differences between patients. An alternative to this approach requires quantitative images and standardization of SPECT imaging and reconstruction protocols. The aim of this work was to test if the Bayesian BSREM algorithm with relative difference prior (RDP) could improve accuracy and reduce the variability in image quantification. ***Materials and Methods:*** The XCAT phantom was used to generate 8 different realistic activity uptake scenarios of $^{177}$Lu. Lesions of different size (2-16mm diameter) and locations were included. SPECT scans were simulated using the SIMIND Monte Carlo code with a medium energy collimator, 120 projections, and a 0.3x0.3cm$^2$ pixel size. The OSEM and the BSREM algorithms were used with 8 subsets and a varying number of iterations (1 to 120). Recovery coefficients (RC) vs. noise curves were created, where image noise was computed from the variance in the liver, and RCs were estimated as the ratio of the measured and true activity for both organs and lesions. While organs were segmented using the true mask from XCAT, a 40% threshold was used for lesions to account for some of the spill out due to their small size. Statistical significance between different algorithms was determined using the paired t-test. ***Results:*** Qualitatively, images reconstructed using the BSREM algorithm were smoother (i.e., less noise) compared to OSEM generated ones after 120 iterations. For both algorithms, the bias is reduced with increasing iteration number, but OSEM resulted in increased image noise. In the kidneys, for example, 120 iterations of OSEM and BSREM led to RCs of -4.4±0.8% and -10.4±0.7% respectively (significant difference, $p<10^{-7}$), while the difference in image noise was 35.7±4.6% and 19.6±4.1% respectively (significant difference, $p<10^{-5}$). Lesion quantification was less dependent on iteration numbers for BSREM than OSEM. For example, in 16mm lesions, OSEM yielded RCs of 55.4±10.4% (40 iterations) and 76.2±9.6% (120 iterations) while BSREM yielded RCs of 35.4±7.7% (40 iterations) and 36.8±7.6% (120 iterations). ***Conclusion:*** Usage of BSREM tended to decrease image noise but resulted in worse RCs for all organs and lesions. The invariance of BSREM with respect to iteration number when measuring lesion RCs, however, could be used to reduce the variability in image quantification. Future work should explore alternative parameter configurations for BSREM.

## OP-627

### Head-to-head comparison of SPECT and MRI based holmium-166 dosimetry

***L. E. L. Westlund Gotby***[1], *Y. X. Mak*[2], *N. J. M. Klaassen*[1], *J. Roosen*[1], *M. W. M. van Wijk*[1], *M. W. Konijnenberg*[1,3], *M. Abayazid*[2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Robotics and Mechatronics, University of Twente, Enschede, NETHERLANDS,* [3]*Department of Radiology and Nuclear Medicine, Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Both SPECT/CT, acquired during free-breathing, and MRI, acquired during breath-hold, can be utilized for quantifying the dose distribution in the liver after transarterial radioembolization (TARE) with holmium-166 ($^{166}$Ho) microspheres (MS). In the clinic, the true $^{166}$Ho-MS biodistribution in a patient is unknown, which makes it difficult to assess the accuracy of the estimated dose distribution, the discrepancies between the two imaging modalities, and the impact that respiratory motion has on the quantification. We aim bridge this knowledge gap by modelling a known dose distribution in a liver after TARE and perform a head-to-head comparison of the image based dose information acquired using SPECT/CT and MRI. ***Materials and Methods:*** A mock-up for the liver phantom was created by adding (non-radioactive) $^{165}$Ho-MS to agarose gel that was put in a plastic container (1500 mL). Tumors were modelled by three agarose gel spheres (14, 35, and 112 mL) also placed in the container. A $^{165}$Ho-MS sphere-to-background concentration ratio ($S:BG_{ratio}$) of 4:1 was used. The mock-up phantom was imaged using MRI and the integrity of this model was evaluated based on the $S:BG_{ratio}$ and the homogeneity of the distribution. A pneumatically driven, MRI compatible, robotic phantom [1] will be used to simulate the respiratory induced liver motion. This robotic phantom moves in the superior-inferior, as well as in the anterior-posterior directions and is programmable to match the patient population characteristics. Both phantoms ($^{166}$Ho-MS liver and robotic) will be positioned in the SPECT/CT and MRI scanner, respectively, and imaged for optimal conditions (no motion, both scanners), for free-breathing (SPECT/CT only), and various breath-hold disturbances (MRI only). Dose distributions are evaluated using Q-suite and MATLAB. ***Results:*** MRI based results for the $^{165}$Ho-MS phantom showed $S:BG_{ratio}$ of 4.29, 4.41, and 4.44 for each sphere, respectively. The $^{165}$Ho-MS distribution in the background region is deemed to be sufficiently homogenous based on a mean±SD of 0.252±0.038 mg/ml. Experiments with the $^{166}$Ho-MS liver and robotic phantoms are ongoing. ***Conclusion:*** With this phantom setup we will be able to simulate a known activity distribution after TARE, and quantify the measured dose based on SPECT/CT and MR imaging. This experiment will indicate which image modality should be considered the state-of-the-art for evaluating $^{166}$Ho-MS TARE, and whether any of these two imaging modalities yields dose information that is accurate enough to pursue voxel-based dosimetry. ***References:*** [1] Naghibi, H. et al. Proc. IEEE RAS EMBS Int. Conf. Biomed. Robot. Biomechatronics 2018-Augus, 577-582 (2018)

## OP-628

### Holmium-166 SPECT/CT imaging for dosimetry: a multi-center optimization study in the Netherlands

***L. E. L. Westlund Gotby***[1], *M. Stella*[2], *C. D. E. van Speybroeck*[1], *D. Lobeek*[1], *D. M. V. de Vries-Huizing*[3], *B. J. de Wit-van de Veen*[3], *E. J. Rijkhorst*[4], *R. Wierts*[5], *M. K. Stam*[6], *F. H. P. van Velden*[6], *P. Dibbets-Schneider*[6], *R. van Rooij*[2];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of Radiology and Nuclear Medicine, University Medical Center Utrecht, Utrecht, NETHERLANDS,* [3]*Department of Nuclear Medicine, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [4]*Department of Medical Physics and Technology, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [5]*Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, Maastricht, NETHERLANDS,* [6]*Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS.*

***Aim/Introduction:*** Reliable dosimetry based on SPECT/CT imaging is essential to achieve personalized $^{166}$Ho radioembolization planning and post-treatment evaluation. This study quantitatively evaluates image quality of $^{166}$Ho SPECT/CT reconstructions performed at five Dutch centers with the purpose of optimizing acquisition and reconstruction parameters for $^{166}$Ho SPECT/CT dosimetry. ***Materials and Methods:*** At each center, a cylindrical (~6.7 or 9 L) and a NEMA IEC phantom were filled with ~250 MBq of $^{166}$Ho-chloride. An 8:1 sphere-to-background activity concentration ratio and a cold lung insert were used for the NEMA phantom. The phantoms were imaged using SPECT/CT scanners from two vendors; one Discovery NM/CT 670 Pro and one Discovery NM/CT 870 DR (GE HealthCare), two Symbia Intevo Bold and three Symbia T (Siemens Healthineers). Data were acquired for 20 minutes with a photopeak window at 81 keV (15% width). Two adjacent scatter windows (8% width), and an upper scatter window at 118 keV (12% width) were used for triple energy window (TEW) and dual energy window (DEW) scatter correction, respectively. The TEW and DEW reconstructions were performed with vendor specific software. A vendor neutral software (Hermes Medical Solutions) was used to reconstruct the data with Monte Carlo (MC) based scatter correction. All images were reconstructed using 10 iterations and 8 subsets without post-reconstruction filtering. The image quality was evaluated by quantifying the coefficient of variation (COV; noise) in the cylindrical phantom, and contrast recovery coefficients (CRCs) and contrast-to-noise ratios (CNRs) measured in the NEMA phantom. ***Results:*** The COV increased for TEW compared to DEW but was reduced for MC reconstruction (GE DEW range: 38-44%, Siemens DEW range: 17-20%, GE TEW range: 48-50%, Siemens TEW range: 20-24%, MC range: 16-35%). The CRCs for the largest sphere were higher for TEW compared to DEW reconstruction for all scanners (GE DEW range: 0.36-0.42, Siemens DEW range: 0.43-0.47, GE TEW range: 0.40-0.48, Siemens TEW range: 0.54-0.58). Additionally, MC reconstructions consistently yielded the highest CRCs for the largest sphere of all datasets (range: 0.50-0.68). The CNRs for the largest sphere were similar for DEW and TEW, while on average 43% higher for MC. ***Conclusion:*** TEW and MC reconstructions improved image quality compared to DEW for all scanners, which enables more accurate $^{166}$Ho SPECT/CT based dosimetry. Additionally, implementing the TEW protocol is more straightforward than DEW and this, in combination with the better image quality, facilitates comparison of SPECT/CT based $^{166}$Ho dosimetry after radioembolization in multi-center, multi-scanner studies.

## OP-629

### Quantitative $^{177}$Lu SPECT/CT imaging with a ring-shaped CZT-based camera: 208 vs 113 keV photopeak

***R. Danieli***[1], *M. Stella*[2], *C. Marin*[1], *J. Tran Gia*[3], *J. Leube*[3], *C. Uribe-Munoz*[4], *M. Hesse*[5], *H. Levillain*[1], *B. Vanderlinden*[1], *N. Reynaert*[1], *P. Flamen*[1];
[1]*Institut Jules Bordet, Bruxelles, BELGIUM,* [2]*GE HealthCare, Diegem, BELGIUM,* [3]*University Hospital Würzburg, Würzburg, GERMANY,* [4]*University of British Columbia, Vancouver, BC, CANADA,* [5]*Cliniques Universitaires Saint-Luc, Bruxelles, BELGIUM.*

***Aim/Introduction:*** Quantitative $^{177}$Lu SPECT/CT with NaI-based gamma cameras is commonly performed using the 208 keV photopeak, as it contains less scatter than the 113 keV. However, when using CZT-based systems, the use of the 113 keV photopeak might be reconsidered. This study aims to find the most suitable photopeak for quantitative $^{177}$Lu SPECT/CT imaging with a ring-shaped CZT-based camera by assessing the stability of the calibration at multiple activity concentrations. ***Materials and Methods:*** A cylindrical phantom (filling volume: 5.4L) filled with 640MBq of $^{177}$Lu was used to calibrate the camera. For verification, a similar phantom (5.8L) was prepared and acquired for nine times over two months (activity concentrations from 920 to 2kBq/ml). All acquisitions were performed on a StarGuide (GE HealthCare), with energy windows centred at 208 keV(±6%) and 113 keV(±10%), and scatter windows centred at 185 keV(±5%), 129 keV(±3.5%) and 97 keV(±4.5%). Acquisition duration was set at 15 minutes. Each photopeak was reconstructed separately using the vendor protocol, including attenuation correction, scatter correction (SC) and resolution recovery (SmartConsole V.1.0.10). SC for the 113 keV photopeak was performed with a standard triple-energy window method. For the 208 keV photopeak, a dedicated dual-energy window SC taking into account the "tailing effect" typical for CZT detectors was used. A large volume of interest (VOI) encompassing the whole phantom was drawn on each SPECT reconstruction. For the two reconstructions of the 5.4-L phantom (113 and 208 keV), a calibration factor (CF) was computed by dividing the total counts inside the VOI by the acquisition duration and by the nominal activity. For all eighteen reconstructions of the 5.8-L phantom, the error in the activity quantification was computed as percentage difference between measured and nominal activity. Measured activities were obtained by dividing the total counts inside the VOI by the acquisition duration and by the CF corresponding to the same photopeak. ***Results:*** CFs for the 208 and 113 keV photopeaks were 94.6 and 86.3cps/MBq, respectively. For the 208 keV photopeak, acceptable errors of less than 4% were measured. For the 113 keV photopeak, similar errors were measured for activity concentrations higher than 40kBq/ml. As the activity concentration in the phantom decreased, errors in the activity quantification increased, reaching the maximum value of 70% at 2kBq/ml. ***Conclusion:*** Our results suggest that quantitative $^{177}$Lu SPECT/CT imaging with StarGuide for a clinically realistic range of activity concentrations is currently best performed using the 208 keV photopeak.

## OP-630

### Hyperthyroidism Etiological Diagnosis: a Multilabel Classification using Convolutional Neural Networks on Thyroid Scans

***M. Abdi***[1], *Q. Naili*[1], *M. Habbeche*[1], *M. Bourouba*[2], *S. Berrani*[3];
[1]*Centre d'imagerie scintigraphique Blida, Blida, ALGERIA,* [2]*Clinique Fatema Al Azhar, Alger, ALGERIA,* [3]*National Polytechnic School of Algiers (Ecole Nationale Polytechnique), Algiers, ALGERIA.*

***Aim/Introduction:*** Primary hyperthyroidism has diverse causes and treatments, but it is difficult to diagnose the specific etiology due to overlapping imaging features[1]. A new approach is proposed to identify the main etiologies from thyroid scans, even when more than one disease is present in the same scan. This approach is based on a multilabel classification using convolutional neural networks (CNN). Previous work used a multiclass approach[2]. ***Materials and Methods:*** 1482 thyroid scans have been collected between 2016 and 2023 (patients with hyperthyroidism). The scans were labeled with three classes: Graves' disease, thyroiditis, and hot nodules, based on the interpretation of two experienced nuclear medicine physicians (taking into account clinical, ultrasound, and biological findings [1]). To evaluate the performance of this approach, Two test sets have been collected. The first test set (test 1) consisted of 132 scans from the same department (with documented Thyrotropin Receptor Antibodies). The second test set included 185 scans from another department. Using a transfer learning approach, different CNN architectures have been compared. A 5-level cross-validation was used, and the results are displayed as mean values, with standard deviation (95% confidence level). Each model acted as a multi-label classifier, predicting each etiology independently. We evaluated the precision of the models based on their ability to classify the scans into their respective etiologies. ***Results:*** Multiple CNNs have been trained, and evaluated on two test sets (internal and external). The Xception architecture outperformed the other CNNs in terms of training speed, and precision. On test 1, the CNN achieved a loss value of 0.3911±0.0061 and precision scores of 83.58%±3.57%, 72.64%±1.75%, and 94.57%±6.83% for Graves' disease, thyroiditis, and hot nodules, respectively. The CNN was particularly effective in recognizing the features associated with hot nodules, achieving a precision of 93.43%±3.22% on the test 2 set (external). The CNN also performed well for thyroiditis and Graves' disease, with precision scores of 87.64±2.52% and 70.6%±4.71%, respectively. ***Conclusion:*** This study demonstrated that a multilabel approach based on Xception architecture is effective in identifying the main etiologies of hyperthyroidism from thyroid scans. The use of a multilabel classifier can improve the precision of the diagnosis of hyperthyroidism. This can provide better targeted treatment options. ***References:*** 1: Intenzo, Charles M., et al. "Scintigraphic features of autoimmune thyroiditis." Radiographics 21.4 (2001): 957-964. 2: Ma, Liyong, et al. ## OP-631

### Fundamental study on brain SPECT denoising using deep image prior

***T. Zeniya***[1], *A. Yabe*[1], *Y. Aita*[1], *K. Matsubara*[2], *K. Koshino*[3], *H. Watabe*[4], *T. Yuasa*[5];
[1]*Hirosaki University, Hirosaki, JAPAN,* [2]*Akita Prefectural University, Yurihonjo, JAPAN,* [3]*Hokkaido Information University, Ebetsu, JAPAN,* [4]*Tohoku University, Sendai, JAPAN,* [5]*Yamagata University, Yonezawa, JAPAN.*

***Aim/Introduction:*** We are developing a high spatial resolutiion SPECT system, but the image becomes noisy when sufficient counts are not obtained. Recently, it has been reported that deep image prior (DIP), a deep learning method that does not require prior learning, is effective for PET image denoising. The aim of this study was to evaluate the effects of DIP, and the combination of DIP and total variation (TV) regularization on noise reduction

in SPECT images. Futhermore, the possibility of shortening the imaging time is investigated. ***Materials and Methods:*** A brain phantoms filled with Tc-99m solution were scanned by high-resolution SPECT under development, and similar simulations were performed. After DIP processing the projection data, the images were reconstructed with MLEM (DIP+MLEM) and EMTV (DIP+EMTV). Image quality was evaluated by PSNR and SSIM in addition to visual evaluation.Quantitative accuracy of images was also evaluated by ROI value. In addition, we investigated the possibility of short-time imaging by reducing amount of data. ***Results:*** The images reconstructed with non-DIP+MLEM, with DIP+MLEM and with DIP+EMTV had PSNRs (dB) of 32.09, 41.68 and 41.98, respectively, and SSIMs of 0.856, 0.948 and 0.951, respectively. DIP greatly the image quality of SPECT, and the combination of DIP and EMTV further improved the image. The error between the reconstructed image using DIP and the original image was 2.7 %, demonstrating high quantitative accuracy. The evaluation results of the images reconstructed from the reduced amount of data suggested the possibility of short-time imaging by the proposed method. ***Conclusion:*** This study suggested that DIP was effective in reducing noise and improving the image quality for brain SPECT.

## Clinical Oncology Track - TROP Session: Lung

### OP-632

**Residual total metabolic tumor volume, assessed on post-therapeutic 18F-FDG PET/CT, is a game-changer in the early monitoring of patients with metastatic non-small cell lung cancer treated with immunotherapy.**

***P. Tricarico****;*
*Centre Antoine Lacassagne, Nice, FRANCE.*

***Aim/Introduction:*** Because of atypical progressive imaging patterns in patients with metastatic non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICPIs), new biomarkers are needed for a better monitoring of treatment efficacy. The aim of this prospective study was to evaluate the prognostic value of volume-derived PET parameters on baseline and follow-up 18FDG-PET exams, and to compare their performance to conventional PERCIST criteria. ***Materials and Methods:*** Patients with metastatic NSCLC were included in two different single-center prospective trials. 18FDG-PET exams were performed before the start of immunotherapy (PETbaseline), after 6-8 weeks (PETinterim1) and after 12-16 weeks (PETinterim2) of treatment, using PERCIST criteria for tumor response assessment. Different metabolic parameters were evaluated : absolute values of SUVmax of the most intense lesion, total metabolic tumor volume (TMTV), total lesion glycolysis (TLG), but also their percentage changes between PET studies (ΔSUVmax, ΔTMTV and ΔTLG). For tumor segmentation, a fixed threshold of SUV4.0 was applied. The median follow-up of patients was 19.3 [7.6-32.2] months. Prognostic values and optimal thresholds of PET parameters were estimated by ROC curve analysis of 12-month overall survival (12M-OS) and 6-month progression-free survival (6M-PFS). Tumor progression needed to be confirmed by a multi-disciplinary tumor board. ***Results:*** 119 patients were prospectively included. On PETbaseline, TMTV and TLG were predictive of 12M-OS (AUC=0.65; 95%CI=0.55-0.75 and AUC=0.63; 95%CI=0.52-0.73, respectively); whereas SUVmax was not (AUC=0.52). On PETinterim1 and PETinterim2, all metabolic parameters, excepted ΔTLG on PETinterim2, were predictive for 12M-OS and 6M-PFS, the residual TMTV on PETinterim1 (termed TMTV1) being the strongest prognostic biomarker (AUC=0.82; CI=0.74-0.90, for both 12M-OS and 6M- PFS). Using the optimal threshold by ROC Curve to classify patients into three TMTV1 subgroups (0cm3; 0-57cm3; >57cm3), TMTV1 prognostic stratification outperformed PERCIST criteria. Subgroup analysis demonstrated that TMTV1 remained a strong prognostic biomarker of 12M-OS for both responding (p<0,0001) and non-responding patients (p=0.0003) according to PERCIST criteria. In the specific group of patients with PERCIST progression on PETinterim1, low residual tumor volume (<57cm3) was associated with a still very favorable patients' outcome (6M-PFS=69%; 24M-OS=54%). ***Conclusion:*** Residual metabolic tumor volume, assessed 6-8 weeks after the start of ICPI, is a strong prognostic biomarker in patients with metastatic NSCLC, surpassing and complementing the conventional PERCIST criteria. Its clinical value is to identify, among patients with a first PERCIST progression on PETinterim1, those who maintain a very favorable outcome. ICPI should be maintained beyond the first PERCIST progression for these patients.

### OP-633

**Predictive value of primary tumor metabolic heterogeneity of $^{18}$F-FDG PET/CT for lung cancer progression**

***X. Li***[1,2]*, M. Hou*[3]*, X. Wang*[1,2]*, C. Cui*[1,2]*, Z. Wu*[1,2]*;*
*[1]Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, Shanxi, CHINA, [2]Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan, Shanxi, CHINA, [3]Department of Respiratory, First Hospital of Shanxi Medical University, Taiyuan, Shanxi, CHINA.*

***Aim/Introduction:*** To compare the metabolic heterogeneity of primary lung cancer foci of different histological types based on $^{18}$F-FDG PET/CT and analyze its correlation with Ki67, staging and disease progression. ***Materials and Methods:*** A retrospective analysis of consecutive cases with pre-treatment $^{18}$F-FDG PET/CT whole-body examination and pathologically confirmed primary lung cancer was performed. The primary tumors with SUVmax 40%-90% percent threshold were outlined and different MTVs were obtained. A correlation straight line of MTV-threshold (40%-90%) function was fitted and the absolute value of the slope of the straight line was defined as the Heterogeneity Factor (HF). Differences in HF between histological types were compared and correlations with Ki67, staging and disease progression were analyzed. ***Results:*** A total of 116 lung cancer cases were included, including 98 NSCLC and 18 SCLC. 73 cases in the disease progression group and 32 in the non-progression group. Mann-Whitney U-test analysis yielded a difference between NSCLC and SCLC of HF (U=462.00, P<0.001). At each percentile, HF was higher in SCLC than in NSCLC. The best cut-off value for HF to discriminate NSCLC or SCLC was 0.700 [95% CI=0.624, 0.874]. However, HF did not differ between squamous carcinoma (SQCC) and Adenocarcinoma (ADC) (U=1011, P=0.670). HF was positively correlated with Ki67 ($r_{Spearman}$=0.267, P=0.008) only in NSCLC. Further analysis of the histological subtypes of NSCLC revealed a positive correlation between HF and Ki67 only in ADC ($r_{Spearman}$=0.482, P=0.008). Multivariate ordered logistic regression analysis was performed by dividing all cases of HF

into four grades according to quartiles, with lung cancer T-stage and overall stage as dependent variables, respectively, and HF quartiles were independent risk factors for both stages ($\chi^2$=84.039, P<0.001; $\chi^2$=10.790, P=0.029). The highest quartile of HF (Q4) was associated with ORs for T-stage and overall staging risk compared with the lowest quartile (Q1) were 5.225 [95% CI=3.834, 6.616] and 1.507 [95% CI=0.426, 2.588], respectively. When the proportion of tumors in T-stage versus overall stage was stratified by quartiles of HF, trend analysis showed a positive correlation between HF and both T-stage and overall stage (P=0.011; P=0.009).Spearman correlation analysis showed a positive correlation between HF and disease progression (r=0.295, P=0.001). The best cut-off value for HF in primary tumors of lung cancer to predict disease progression was 0.7634 [95% CI=0.586, 0.786]. ***Conclusion:*** HF was positively correlated with disease progression, suggesting that metabolic heterogeneity of primary lung cancer tumors assessed by pre-treatment $^{18}$F-FDG PET/CT could predict disease progression.

## OP-634

### Prognostic role of pre-operative 18F-FDG PET/CT in surgically treated patients with early-stage non-small-cell lung cancer

***S. Taralli***[1], *F. Vocaturo*[1,2], *E. Perrone*[1,2], *P. C. Pafundi*[3], *S. Ricciardi*[4], *G. Cardillo*[4], *M. L. Calcagni*[1,2];
[1]*Nuclear Medicine Unit, Diagnostic Imaging, Radiation Oncology and Hematology Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [2]*Nuclear Medicine Institute, University Department of Radiological and Hematological Sciences, Università Cattolica del Sacro Cuore, Rome, ITALY,* [3]*Epidemiology and Biostatistics Research Core Facility, GEMELLI GENERATOR, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [4]*Thoracic Surgery Unit, San Camillo Forlanini Hospital, Rome, ITALY.*

***Aim/Introduction:*** Even after curative surgery, patients with early-stage (I-II) non-small-cell lung cancer (NSCLC) still present unsatisfactory prognosis, with >50% developing disease-recurrence. Early prognostic stratification is essential to improve outcome, as high recurrence-risk patients might benefit from more aggressive treatments. In this setting, literature on the prognostic role of pre-operative 18F-FDG PET/CT reported heterogeneous and no definitive results. We thus aimed to investigate, among pre-operative 18F-FDG PET/CT parameters, potential predictors of disease-recurrence in a highly-selected early-stage NSCLC population. ***Materials and Methods:*** We retrospectively analysed 320 consecutive patients (68.2±8.6 years;59.7% males) with surgically-treated early-stage NSCLC (IA-IB=291/320, IIA-IIB=29/320; all pN0 with negative surgical-margins) undergone pre-operative 18F-FDG PET/CT for staging between 2005-2017. The following PET, anatomical, histopathological and clinical parameters were evaluated: 1) tumour activity (SUVmax, SUVmean, SUVpeak, MTV, TLG); 2) tumour size, lung-side, lobe-site, peripheral/central-location, T-stage; 3) histotype, grading, lymphatic and vessel angioinvasion, pleural infiltration, necrosis; 4) patients' age, gender, adjuvant therapy. Potential predictors of recurrence-free survival (RFS) were assessed by Cox regression models and plotted into a nomogram scoring-system. After dichotomization, PET parameters were analysed by Kaplan-Meier survival analysis. A subgroup-analysis was performed in adenocarcinoma-subtype patients (246/320). Statistical analyses were performed with R-software v4.2.2 (statistical significance: p<0.05). ***Results:*** At diagnosis: 246/320 tumours showed peripheral-location, 129/320 high-grade, 110/320 lymphatic-angioinvasion, 140/320 vessel-angioinvasion, 85/320 pleural-infiltration, 107/320 necrosis; 24/320 patients received adjuvant therapy (AT). Disease-recurrence occurred in 71/320 patients (22.2%; median RFS=49.0months from surgery). At univariable analysis, in overall and adenocarcinoma patients: higher SUVmax, SUVmean, SUVpeak and TLG values were significantly associated with disease-recurrence (HR>>1;p<<0.05), alongside AT and histopathological aggressive-features; female-gender and peripheral-location were positive prognostic predictors. At multivariable analysis: AT was independent negative predictor of RFS in overall (HR=1.98;95%CI=1.02-3.84;p=0.043) and adenocarcinoma patients (HR=2.38;95%CI=1.03-5.52;p=0.043); SUVpeak was independent and stronger negative predictor of RFS in adenocarcinoma-subgroup (HR=1.50;95%CI=1.07-2.11;p=0.018). At predictive-model represented by nomogram: SUVpeak showed the highest impact on individual RFS-probability at 1, 3 and 5-years from surgery. At Kaplan-Meier analysis: patients with SUV-parameters and TLG above cut-offs showed a significantly lower RFS, with major RFS-differences in adenocarcinoma-subgroup for SUVpeak (34.7months if >2.84 vs 61.0months if ≤2.84) and SUVmean (23.1months if >6.06 vs 54.7months if ≤6.06). ***Conclusion:*** Tumour metabolic parameters at pre-operative 18F-FDG PET/CT are valuable prognostic predictors in selected early-stage NSCLC population candidate to surgery, able to identify higher recurrence-risk patients. Pre-operative unfavourable metabolic parameters could be considered as additional prognostic risk-factors to practically tailor/guide the planned surgical strategy and decide for adjuvant therapy need.

## OP-635

### The variability and diagnostic value of respiratory-gated 4D PET/CT based radiomics features in lung lesions compared to ungated PET/CT

***S. Huang***[1], *C. Cao*[2], *L. Guo*[1], *C. Li*[1], *W. Mu*[2,3], *Y. Liang*[1,4];
[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, CHINA,* [2]*School of Engineering Medicine, Beihang University, Beijing, CHINA,* [3]*Key Laboratory of Big Data-Based Precision Medicine, Ministry of Industry and Information Technology of the People's Republic of China, Beijing, CHINA,* [4]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

***Aim/Introduction:*** To assess the impact of respiratory motion artifact on tumor heterogeneity using radiomics features in PET/CT is essential for quantitative characterize and diagnosis of lung lesions. The purpose of this study was to investigate the variability of respiratory-gated (RG) 4D PET/CT based radiomics features compared to ungated (UG) PET/CT, as well as their diagnostic value in the differentiation between non-small cell lung cancer (NSCLC) and benign lung lesions. ***Materials and Methods:*** 117 patients with suspected lung lesions underwent ungated PET/CT and chest respiratory-gated 4D PET/CT were prospectively included. 6 patients failed RG PET/CT. A total of 209 lung lesions in 111 cases were segmented manually using ITK-SNAP by two nuclear medicine physicians. For each lesion, 377 Image Biomarker Standardization Initiative (IBSI) radiomics features were extracted from PET images of each scan, including 71 histogram-related features, 89 shape-related features, 62 textural features and 155 wavelet features. We firstly perform variability comparison via t-test. The subgroup of 126 non-metastasis lesions in 91 patients without treatment before PET/CT were included for diagnosis

analysis and were randomly distributed in training and validation sets. We compared the diagnostic efficiencies in feature-level by ROC curves. Then we selected and developed two radiomics models with UG features (i.e. UGModel) and RG features (i.e. RGModel). And the model-level comparison was performed by comparing the diagnostic value of logistic regression models developed with different scans using five-fold cross-validation. ***Results:*** For the variability analysis, 101/377 (26.8%) RG features showed significant difference compared to UG features ($p < 0.05$). As for the diagnosis analysis, 55 benign lesions of 27 cases and 71 malignant lesions of 64 cases were analyzed. For the feature-level comparison, 61/377(16.2%) RG features showed better discriminant ability in malignant recognition ($p < 0.05$). As for the model-level comparison, the average AUC, accuracy, sensitivity, specificity, PPV and NPV of the two radiomics-based models were 0.80, 79.4%, 73.2%, 87.3%, 88.1%, 71.6% for RGModel, and 0.75, 65.9%, 57.7%, 76.4%, 75.9%, 58.3% for UGModel, respectively. ***Conclusion:*** Respiratory-gated PET/CT improves image quality and quantitative characterization of lung lesions by reducing respiratory motion-related artifacts. Compared to ungated PET/CT, respiratory-gated 4D PET/CT based radiomics features showed incremental diagnostic value in both feature-level and model-level for differentiation of NSCLC and benign lung lesions.

## OP-636

### Improved imaging of small lung nodules using LAFOV [$^{18}$F]FDG-PET and data-driven motion compensation method

***C. Bregenzer***[1], *C. Mingels*[1], *M. Viscione*[1], *H. Sari*[1,2], *K. Shi*[1], *A. Rominger*[1], *T. Pyka*[1];
[1]*Department of Nuclear Medicine, Inselspital, University Hospital Bern, University of Bern, Bern, SWITZERLAND,* [2]*Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, SWITZERLAND.*

***Aim/Introduction:*** Detection and characterization of lung nodules with PET has traditionally been imposed a size limit (e.g. ≥8mm) due to decreasing sensitivity of former analogue PET scanners in smaller lesions. The newly introduced long axial field of view (LAFOV) PET scanners have been shown to be superior to traditional standard axial field of view (SAFOV) scanners in term of system sensitivity. In order to improve imaging of lung lesions, data driven gating-based motion correction algorithm (DDG-MC) is available to compensate for respiratory movement. Herein, we present the first data evaluating LAFOV PET for lung lesions compared to simulated SAFOV (sSAFOV) acquisitions with and without motion correction. ***Materials and Methods:*** At the time of writing, 24 consecutive patients with a total of 40 lung lesions which had undergone [$^{18}$F]FDG-PET/CT on a LAFOV PET/CT scanner (106 cm FOV) were included. Data for both ultra-high sensitivity mode (UHS, maximum ring difference (MRD) 322) and sSAFOV acquisition (120 s per bed position, high sensitivity (HS) mode, MRD 85) with and without data driven gating-based motion correction were reconstructed. Lesions were measured in three dimensions (diagnostic inspiratory CT if available, else low-dose CT). Standard uptake values $(SUV)_{mean/max/peak}$ of liver, blood pool and lung background, likewise tumor volume and lesion uptake were calculated with a volume of interest using a 40% isocontour approach. SNR and CNR with lung background were calculated. ***Results:*** Median largest lesion size was 7 mm (Q25: 5mm, Q75: 10 mm). Lesion signal intensity above liver was found in 8/22 small lesions (<8 mm, $SUV_{max}$ 2.15±1.84; ≥8 mm in 15/18, $SUV_{max}$ 7.01±5.25) and above blood pool in 12/22 (≥8 mm in 15/18). SNR and CNR were significantly increased in LAFOV compared to sSAFOV mode (p≤0.01; HS 2 min 53.43±73.75/50.0±73.43, HS 2 min+DDG-MC 63.21±82.19/59.8±81.9, UHS 6 min 62.45±87.03/58.11±86.67, UHS 6 min+DDG-MC 73.68±98.0/69.35±97.58). sSAVOF 2min with DDG-MC was comparable to UHS 6 minutes without motion correction (SNR: p=0.41, CNR: p=0.30). ***Conclusion:*** UHS acquisition on LAFOV PET/CT with DDG-MC motion correction showed significantly higher SNR and CNR in small lung lesions. Higher detection rates compared to SAFOV PET/CT for lung lesions in PET/CT even <8 mm can be achieved. Further correlation with the final diagnosis is planned. LAFOV PET/CT might be of clinical advantage in the assessment of small lung lesions, possibly pushing the lower size limits for reliable characterization.

## OP-637

### Predicting survival of metastatic non-small cell lung cancer (NSCLC) patients treated by anti-PD-1 by combining clinical and radiomic features

***J. Auriac***[1], *N. Captier*[1], *E. Woff*[1,2], *M. Luporsi*[1,3], *C. Nioche*[1], *N. Girard*[4], *I. Buvat*[1], *F. Orlhac*[1];
[1]*Institut Curie, Inserm, Université Paris-Saclay, U1288-LITO, Orsay, FRANCE,* [2]*Université libre de Bruxelles, Jules Bordet Institut, Department of Nuclear Medicine, Bruxelles, BELGIUM,* [3]*Institut Curie, Department of Nuclear Medicine, Paris, FRANCE,* [4]*Institut du Thorax Curie-Montsouris, Paris, FRANCE.*

***Aim/Introduction:*** To determine whether the combination of clinical and radiomic features could predict overall survival (OS) in metastatic patients with non-small cell lung cancer (NSCLC) treated by anti-PD-1 immunotherapy. ***Materials and Methods:*** Baseline FDG-PET/CT images and clinical data were retrospectively collected for 74 metastatic NSCLC patients treated by pembrolizumab. All lesions were segmented with a threshold set to 4 SUV. The Total Metabolic Tumor Volume (TMTV) and the distance between the 2 most distant lesions (Dmax) were extracted using LIFEx [1]. Advanced lung cancer inflammation index (ALI) [2-3] was calculated based on body mass index, serum albumin and neutrophil-to-lymphocyte ratio. For each feature, the optimal cut-off (i.e. giving the lowest p-value in log-rank tests) to distinguish two different groups of patients based on OS was determined. Risk categories were defined based on the presence of risk factors: low ALI, high age, high TMTV and/or high Dmax. Then, different combinations of these 4 binarized features were tested. To compare these combinations, survival analyses were performed for each using the Kaplan Meier method with the log-rank test and Cox proportional hazard regression model, including calculation of adjusted hazard ratios (HRs) with 95% confidence intervals (CI) and Harrell's C-index. ***Results:*** Four univariate models (ALI; age; TMTV; Dmax) and 11 multivariate models (M1 to M11) were tested. High ALI values (>42.4) were significantly associated with longer OS (C-index=0.575, log-rank: p=0.0270). Similarly, young age (<60 yo, C-index=0.600, p=0.0052), low TMTV values (<90 mL, C-index=0.589, p=0.0170) or low Dmax values (<28.4 cm, C-index=0.624, p=0.0008) were associated with longer OS. Comparing the C-index of multivariate models, M4 (ALI+Dmax+Age) outperformed other models to predict OS (C-index=0.708, log-rank: p<0.0001) using 3 risk categories: low (0 or 1 risk factor, n=20), intermediate (2 risk factors, n=33) and high (3 risk factors, n=21). M4 was significantly better than ALI (Z-test [4]: p=0.0001), Dmax (p=0.0009), TMTV (p=0.0042) or age (p=0.0007), and better than 3 multivariate models: M3 (ALI+Dmax, p=0.0106), M5 (ALI+TMTV, p=0.0199) and M6 (ALI+age, p=0.0235). ***Conclusion:*** The performance of ALI can be improved by combining it with simple radiomic features and age. The

combination of ALI, Dmax and age yielded the best performance on predicting OS for metastatic NSCLC patients treated with immunotherapy, and warrants further evaluation. ***References:*** [1] Nioche et al. Cancer Res 2018. [2] Jafri et al. BMC Cancer 2013. [3] Mountzios et al. ESMO Open 2021. [4] Kang et al. Stat Med 2015.

## OP-638

### Variables Derived From 18F-FDG PET/CT In Predicting Patterns Of Recurrence In Patients With Non-Small Cell Lung Cancer (Stage I-III)

***G. Jimenez Londoño***[1], *A. M. Garcia Vicente*[2], *J. J. Bosque*[3], *J. Perez-Beteta*[3], *M. Amo-Salas*[4], *A. F. Honguero-Martinez*[5], *E. Noriega Alvarez*[1], *C. Lucas Lucas*[1], *V. M. Perez-Garcia*[3], *A. M. Soriano Castrejon*[2];
[1]*Department of Nuclear Medicine, Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Department of Nuclear Medicine, Complejo Hospitalario Universitario de Toledo, Toledo, SPAIN,* [3]*Department of Mathematics, Mathematical Oncology Laboratory (MOLAB), Universidad de Castilla-La Mancha, Ciudad Real, SPAIN,* [4]*Department of Mathematics, Universidad de Castilla-La Mancha, Ciudad Real, SPAIN,* [5]*Department of Surgery, Hospital General Universitario de Albacete, Albacete, SPAIN.*

***Aim/Introduction:*** This study aimed to analyse the metabolic parameters derived from 18F FDG PET/CT staging that can predict recurrence patterns in non-small cell lung cancer (NSCLC) ***Materials and Methods:*** Retrospective study including NSCLC patients who had a baseline 18F-FDG PET/CT scan. Inclusion criteria required stage I-III, complete surgical resection, absence of neoadjuvant treatment, lung lesions with significant 18FDG avidity, diameter ≥10 mm and clinical/radiological follow-up ≥24 months. Relapse patterns were analysed based on location (Distant vs. local recurrence), lesion number (poly vs. oligometastasic disease) and organ-specific recurrence. Polymetastases involved >3 lesions in one organ, recurrence in ≥2 organs or widespread pleural/pericardial involvement, with mediastinal lymph nodes counted as one organ.Clinical variables such as age, tumour location, stage, histology, lymph nodal infiltration and lymphovascular and pleural invasion were recorded. After semi-automatic lung tumour segmentation, SUV and volume-based metrics, global texture, geometrical variables and textural parameters based on run-length matrices and co-occurrence matrices were obtained. Uni-Multivariate logistic regression were performed ***Results:*** Out of 173 patients, 104 experienced recurrence, with 39 having local recurrence, 42 exhibiting distant recurrence, and 23 presenting both. The mean time between surgery and the appearance of local and distant recurrence was not significantly different (18.80±16.5 months and 18.07±17.82 months, respectively). Furthermore, 43.3% of patients were classified as oligometastatic and 56.7% as polymetastatic, with the lung, regional lymph nodes, brain and bone being the most commonly affected sites of metastasis. In multivariate analysis, adenocarcinoma tumours, LRLGE (Long run low gray-level emphasis) and SRHGE (Short run high gray-level emphasis) were identified as independent variables for distant recurrence. The analysis also found that patient age, number of affected lymph nodes, Sphericity, nSCD (normalized SUVpeak to centroid distance), Entropy, LGRE (Low gray-level run emphasis), and HGRE (High gray-level run emphasis) were independent variables for polymetastatic disease. Regional lymph node recurrence was related to number of affected lymph nodes and Dissimilarity, while lung recurrence was associated with upper lobe tumour, SUVmax, Sphericity, and nSPD (normalized SUVmax perimeter distance). Brain recurrence was related with adenocarcinoma tumours and lymph node invasion at diagnosis, and bone recurrence was related to the number of affected lymph nodes and GLNU (Gray-level non-uniformity). ***Conclusion:*** Metabolic variables obtained from 18F-FDG PET/CT were found to be predictive of recurrence patterns that are closely linked to the overall survival of NSCLC patients. These findings could help in the development of personalized treatment strategies based on an individual's recurrence pattern

## OP-639

### 18F-FDG PET/CT and Coefficient of Variation of Primary Tumors and Metastatic Lymph Nodes To Assess the Heterogeneity of Glycolytic Phenotype in Patients With Advanced NSCLC

***S. Pellegrino***[1], *R. Fonti*[1], *C. Vallone*[1], *A. Catapano*[1], *R. Morra*[2], *S. De Placido*[2], *S. Del Vecchio*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY,* [2]*Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.*

***Aim/Introduction:*** The aim of the present study was to test whether the Coefficient of Variation (CoV) of 18F-FDG PET/CT images of primary tumors and metastatic lymph nodes may predict clinical outcome in patients with advanced non-small cell lung cancer (NSCLC). ***Materials and Methods:*** Ninety-two patients with advanced NSCLC who had undergone 18F-FDG PET/CT scan at diagnosis were studied. Imaging parameters including SUVmax, SUVmean, CoV (SD divided by SUVmean), MTV, TLG were determined in primary tumors and target lymph nodes along with Total MTV ($MTV_{TOT}$) and Whole-Body TLG ($TLG_{WB}$) of all malignant lesions. Univariate analysis of clinical and imaging variables was performed using Cox proportional hazards regression whereas survival analysis was performed using Kaplan-Meier method and log-rank tests. ***Results:*** A total of 150 lesions were analyzed including 92 primary lung tumors and 58 metastatic lymph nodes showing the highest SUVmax value in each patient. Mean SUVmax, SUVmean, CoV, MTV and TLG values were 12.00±5.77, 5.44±2.11, 0.36±0.13, 71.14±117.08 ml and 401.56±618.48 g in primary tumors while they were 11.89±8.54, 4.85±1.90, 0.37±0.16, 46.16±99.59 ml and 256.84±548.27 g in involved lymph nodes. At univariate analysis, overall survival (OS) was predicted by CoV of primary tumors (p=0.0141), SUVmax (p=0.0363), SUVmean (p=0.0200) and CoV (p=0.0139) of target lymph nodes, $MTV_{TOT}$ (p=0.0165) and stage (p=0.0105). Then we performed Kaplan-Meier analysis by using the cutoff values of CoV of primary tumors (0.35) and CoV of target lymph nodes (0.29). OS was significantly better in patients with CoV of primary tumors>0.35 than those with CoV≤0.35 ($\chi^2$=6.6933, p=0.0097), while patients with CoV of target lymph nodes≤0.29 showed significantly better OS as compared to patients having CoV>0.29 ($\chi^2$=5.9570, p=0.0147). Finally, we combined CoV values of primary tumors and target lymph nodes in all possible arrangements for Kaplan-Meier analysis. Patients with CoV of primary tumors≤0.35 and CoV of target lymph nodes>0.29 had the worst prognosis, while the best OS was observed in patients with CoV of primary tumors>0.35 and CoV of target lymph nodes≤0.29 ($\chi^2$=14.3992, p=0.0024). ***Conclusion:*** CoV of primary tumors and CoV of target lymph nodes can predict clinical outcome of NSCLC patients in opposite direction. In fact, heterogeneity of primary tumors derives mainly from the lower percentage of tumor cells having a glycolytic phenotype inside the malignant lesion whereas in metastatic lymph nodes, heterogeneity is due to a higher percentage of tumor cells having a glycolytic phenotype inside the target lesion.

## OP-640

### Use of 18F-FDG PET Imaging after Curative Treatment of Non-Small Cell Lung Cancer Patients: A Nationwide Cohort Study

***K. Guldbrandsen***[1], *L. Sopina*[2], *T. R. Rasmussen*[3], *B. M. Fischer*[1]; *[1]Dept. of Clinical Physiology, Nuclear Medicine & PET, Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK, [2]Danish Centre for Health Economics, DaCHE, Dept. of Public Health, University of Southern Denmark, Odense, DENMARK, [3]Department of Respiratory Diseases and Allergy, Aarhus University Hospital, Aarhus, DENMARK.*

***Aim/Introduction:*** Surveillance imaging is essential for managing non-small cell lung cancer (NSCLC), as it enables early detection of disease recurrence, which remains a significant risk after curative-intent treatment. In recent years, [$^{18}$F]Fluorodeoxyglucose positron emission tomography-computed tomography (18F-FDG PET/CT) has become an essential imaging modality in lung cancer due to its high sensitivity and specificity for detecting malignant lesions and assessing tumour staging. However, little is known about how 18F-FDG PET imaging is utilized during surveillance. This study aimed to investigate changes over time and factors associated with the use of 18F-FDG PET imaging in patients after curative treatment of NSCLC. ***Materials and Methods:*** We analyzed data from 13,746 NSCLC patients diagnosed between 2007 and 2020 in the Danish Lung Cancer Registry who underwent curative-intent treatment. Multivariable regression was used to analyze trends in the use of 18F-FDG PET imaging over time and to identify factors associated with the use of 18F-FDG PET imaging during the first two years of surveillance after curative therapy. ***Results:*** The utilization rate of 18F-FDG PET scans per 100 patients increased from 9.9 per year in 2007 [95% confidence interval (CI), 4.7 to 15.1] to 40.0 per year in 2013 [95% CI, 36.7 to 43.3], followed by a period of stability. The proportion of patients who received at least one 18F-FDG PET scan during the first two years after treatment increased from 23% for patients diagnosed in 2007-08 to 38% in 2019-20. The utilization rate increased with increasing stage (percentage points, +19.0 [95% CI, 11.3 to 26.7] and +30.3 [95% CI, 22.2 to 38.4] for stages II and III, respectively). Additionally, the utilization rate was higher in patients who received definitive chemoradiation or stereotactic body radiotherapy (SBRT) when compared to surgery (pp, +25.5 [95% CI, 18.3 to 32.6]). ***Conclusion:*** There has been a substantial increase in 18F-FDG PET imaging after curative therapy for NSCLC. Notably, the use is increased in patients with advanced stage and after definitive chemoradiation or SBRT. These findings suggest that 18F-FDG PET imaging is increasingly important in managing these patients. Further research is needed to determine how this will impact patient outcomes and healthcare system efficiency.

### Value of Na[18F]F and 2-[ 18F]FDG PET/CT imaging in early stages of aortic valve degeneration assessment after transcatheter aortic valve (TAVI) implantation

***M. Opalinska***[1], *D. Sorysz*[2], *A. Sowa-Staszczak*[1], *A. Grochowska*[3], *A. Dziewierz*[2], *K. Malinowski*[4], *N. Maruszak*[2], *M. Bagieński*[5], *S. Bartuś*[2], *D. Dudek*[6];
*[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, POLAND, [2]2nd Department of Cardiology, Institute of Cardiology, Jagiellonian University Medical College, Krakow, POLAND, [3]Department of Radiology, University Hospital, Krakow, POLAND, [4]Department of Bioinformatics and Telemedicine, Jagiellonian University Medical College, Krakow, POLAND, [5]Intensive Cardiac Care Unit, University Hospital, Krakow, POLAND, [6]Center for Digital Medicine and Robotics, Jagiellonian University Medical College, Krakow, POLAND.*

***Aim/Introduction:*** Severe symptomatic aortic stenosis is often in the elderly, caused by the degenerative process of valve leaflets associated with aging. Nowadays transcatheter aortic valve implantation (TAVI) is a standard, minimally invasive treatment in such cases. Unfortunately, in some of them we observe their fast degeneration, causing limited durability of TAVI. We aimed to investigate the utility of Na[18F]F and 2-[18F]FDG PET/CT in assessment of an early TAVI valve degeneration and the influence of microcalcification and inflammatory processes on TAVI durability. ***Materials and Methods:*** Seventy-one TAVI patients underwent baseline transthoracic echocardiography (TTE), transesophageal echocardiography, and PET/CT using Na[18F]F and 2-[ 18F] FDG. Of these, 30 patients had follow-up examinations, while the remainder were lost to mortality and the COVID pandemic. TAVI valve morphology and function were assessed using TTE and TEE. SUVmax, SUVmean and tissue-to-background (TBR) of Na[18F]F and 2-[18F]FDG uptake in the projection of the aortic valve were measured. Both Na[18F]F and 2-[18F]FDG uptakes were compared between baseline and follow-up PET/CT scans, performed 18.2 (±11.3) and 19.8 (±12.7) months after baseline, respectively. ***Results:*** Na[18F]F and 2-[18F]FDG PET/CT as well as echocardiography data were analyzed for 30 TAVI patients, all who underwent follow-up PET/CT scans. Median age of patients was 84.0 (IQR 80.0-87.0) years. After TAVI implantation, significant improvement in valve function was observed in all patients. During follow-up, valve function, assessed by TTE, remained stable, however PET/CT imaging has demonstrated an increase in TBR value of 2-[18F]FDG uptake in the inner (1.2 (IQR 1.0-1.7) to 1.7 (IQR 1.5-2.1), p = 0.009) and outer (IQR 1.3 (1.1-1.7) to 1.7 (IQR 1.5-2.1), p= 0.012) sites of the TAVI valve stent, while there were no difference in Na[18F]F uptakes in any site of TAVI (inner: baseline 1.4 (IQR 1.1-1.7), follow-up 1.5 (IQR 1.1-2.0), p = 0.17, outer: baseline 1.1 (IQR 0.9-1.2), follow-up 1.2 (IQR 0.9-1.4), p = 0.57). ***Conclusion:*** In average, 2 years after TAVI implementation, an increase of an inflammation marker (2-[18F]FDG) uptake was seen in PET/CT, while the uptake of the calcification marker (Na[18F]F) remained stable. That inflammation process, as evidenced by increased 2-[18F]FDG uptake, may play a pivotal role in the early stages

of TAVI valve degeneration, preceding the onset of calcification detected by Na[18F]F uptake. The possible use of PET/CT imaging for prediction of degenerative process on TAVI, as well as understanding of the pathomechanism of their destruction needs further investigation.

## OP-642

### The relationship between arterial calcification and hypoxia of the arterial wall detected by [18F] F-Fluoromisonidazole Positron Emission Tomography

***J. Bellinge***[1,2], *I. Barry*[3], *R. Francis*[1,2], *F. Picazo-Pineda*[3], *N. Altaf*[3], *C. Schultz*[1,3];
[1]*University of Western Australia, Perth, AUSTRALIA,*
[2]*Sir Charles Gairdner Hospital, Perth, AUSTRALIA,*
[3]*Royal Perth Hospital, Perth, AUSTRALIA.*

***Aim/Introduction:*** Arterial calcification burden is a strong predictor of cardiovascular disease events. Hypoxia within the arterial wall may contribute to the development of arterial calcification. [18F]F-Fluoromisonidazole ([18F]F-FMISO) Positron Emission Tomography (PET) is a novel method for non-invasive detection of hypoxia of the arterial wall(1). We aimed to investigate the relationship between hypoxia of the arterial wall measured on [18F]F-FMISO PET and arterial calcification burden. ***Materials and Methods:*** This is a post-hoc analysis of 3 prospective observational studies investigating [18F]F-FMISO PET for tumoral hypoxia in patients with mesothelioma or pancreatic cancer (2,3). Arterial [18F]F-FMISO activity was quantified by drawing regions of interest around the adventitia of the thoracic aorta on consecutive axial slices. The SUVmax was measured for each slice and the most disease segment (MDS SUV), defined as the average of three consecutive slices centered on the highest SUVmax, was calculated for each territory of the thoracic aorta (ascending, arch and descending thoracic aorta). The MDS SUV was divided by blood pool SUVmean, measured from the right atrium, to result the tissue-to-background ratio (MDS TBR)(4). Arterial calcification was quantified from attenuation correction CT scans using the Agatston score. Imaging modalities were analysed by blinded observers. Spearmans' Rho (r) and independent t-tests were used appropriately, depending on the distribution of the variables tested. ***Results:*** Forty-one individuals underwent [18F]F-FMISO PET between 2009 and 2017 and were included in this analysis. The mean age was 64.3±9.1 and 85.4% were male. The MDS SUV correlated positively with the calcium score in the ascending (r=0.45, p=0.003) and descending aorta (r=0.37, p=0.019) but not the arch of aorta (r=0.29, p=0.06). The MDS TBR did not correlate with the calcium score in the ascending (r=-0.13, p=0.93), arch (r=0.00, p=0.99) or descending aorta (r=0.25, p=0.12). The maximum MDS SUV of the three thoracic aortic territories was higher in patients prescribed antihypertensive therapy (N=13) compared to those who were not (2.40±0.25 v 2.08±4.9, p=0.033). There were no other associations between thoracic arterial [18F]F-FMISO activity and traditional cardiovascular risk factors. ***Conclusion:*** Thoracic aortic [18F]F-FMISO activity is associated with arterial calcification burden, but the relationship is dependent on the method of quantification. Further studies are required to validate [18F]F-FMISO as a measure of hypoxia of the arterial wall. ***References:*** 1. Mateo et al. Circ Cardiovasc Imaging. 2014;7:312-20. 2. Segard et al. ## OP-643

### Morphological and component features of advanced carotid plaque on MRI in correlation with inflammation on PET: a hybrid $^{18}$F-FDG PET/MRI study

***F. Yu****, Y. Zhang, J. Lu;*
*Xuanwu Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** The aim of this study was to exploit the methodological opportunity of hybrid PET/MRI to simultaneously evaluate the morphological, component, and metabolic features of advanced atherosclerotic plaques, observe the relationship among features and explore the incremental value of PET over MRI. ***Materials and Methods:*** The study group comprised 280 patients with advanced plaque in the carotid bifurcation who underwent $^{18}$F-FDG PET/MRI scan. Plaque morphological and component features were determined on MRI. Maximum standardized uptake values ($SUV_{max}$) and tissue to background ratio (TBR) on corresponding PET sections were calculated. Further, all patients were divided into high and low $^{18}$F-FDG uptake group for subgroup analysis. ***Results:*** The degree of luminal stenosis (77.0% vs 59.0%, $p < 0.001$), the prevalence of complicated lesion-MR AHA type VI (50.6% vs 21.9%, $p < 0.001$), and the intensity of $^{18}$F-FDG uptake ($SUV_{max}$=2.30[1.68-2.92] vs 1.93[1.52-2.49], p=0.007; TBR= 2.96[2.35-3.80] vs 2.32[1.81-3.00], $p < 0.001$) were significantly higher in the symptomatic plaques than the asymptomatic plaques. The degree of luminal stenosis and the MR AHA type was corelated with $^{18}$F-FDG uptake separately (r=0.14, p=0.013 and r=-0.25, p=0.018). Subgroup analysis found higher prevalence of complicated plaque for the symptomatic plaques in both $^{18}$F-FDG high uptake group and low uptake group (56.9% vs 27.5% and 41.7% vs 17.3%, p<0.001 and p=0.001 each). However, lower prevalence of MR AHA type IV-V lesion was identified for symptomatic plaques as compared with asymptomatic plaques only in low uptake group (25.0% vs 45.1%, p=0.026). In contrast, lower prevalence of MR AHA type VII lesion was identified for symptomatic plaques only in high uptake group (2.0% vs 6.9%, p=0.006). No significant difference for the prevalence of MR AHA type VIII lesion was found between the symptomatic and the asymptomatic plaques in both high and low uptake groups. ***Conclusion:*** Morphological and component features were associated with metabolic status in advanced atherosclerotic plaques. Moreover, the prevalence of lipid core (MR AHA type IV-V lesion) and calcification (MR AHA type VII lesion) in symptomatic plaques varied under different inflammatory uptake status. Hybrid $^{18}$F-FDG PET/MRI can provide supplementary optimization information for the traditional MR AHA classification to identify vulnerable plaques in atherosclerosis subjects.

## OP-644

### Comparison between Cardiac $^{18}$F-FAPI PET/CT and MRI for Assessment of Myocardial Fibrosis in Hypertrophic Cardiomyopathy

***L. Wang***[1], *Y. Wang*[2], *Y. Zhang*[1], *Z. Dong*[3], *J. Wang*[3], *X. Xi*[1], *B. Chen*[1], *S. Zhao*[3], *M. Yang*[1];
[1]*Beijing Chaoyang Hospital, Beijing, CHINA,*
[2]*Beijing Tsinghua Changgung Hospital, Beijing, CHINA,* [3]*Fuwai Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Myocardial fibrosis could be evaluated by cardiac MRI and fibroblast activation protein inhibitor (FAPI) PET/CT imaging. We aimed to explore the relationship between FAPI imaging and late gadolinium enhancement (LGE) and T1 mapping for assessment of myocardial fibrosis in hypertrophic cardiomyopathy (HCM). ***Materials and Methods:*** In this

prospective study from July 2021 to October 2022, participants with HCM underwent cardiac FAPI PET/CT imaging and MRI, which was performed within a median time of 2 days before or after FAPI imaging. Myocardial FAPI activity was quantified as intensity (target-to-background uptake ratio, TBR), extent (the percent of FAPI-avid myocardium of left ventricle, FAPI%), and amount (FAPI% × TBR). A segment with TBR of 2.3 or greater than was defined as FAPI-avid. LGE and extracellular volume fraction (ECV) by T1 mapping on MRI were employed to quantify focal and diffuse fibrosis, respectively. The extent of LGE was expressed as the percentage of left ventricular mass (LGE%). Segment with the presence of LGE or ECV≥29.6% was defined as abnormal. Univariable and multivariable linear regression analyses were used to identify factors related to the difference (ΔExtent%) in the extent of myocardial fibrosis detected by FAPI imaging and ECV mapping on MRI. ***Results:*** Fifty-three HCM participants (mean age: 46.0 ± 13.3 years, 30 men) with 848 segments were analyzed. Intense but inhomogeneous FAPI uptake was observed in all participants, most of whom were identified as having LGE (90.6%) and ECV expansion (77.4%). FAPI% varied to a greater scale (12.1%-92.2%) and was larger than ECV [49.7 (37.9, 64.5) vs. 32.0 (30.0, 36.9), P<0.0001)] and LGE% [6.6 (1.9, 15.2), P<0.0001]. Log-transformed ΔExtent% had a positive relationship with the log-transformed N-terminal pro-brain natriuretic peptide (NT-proBNP) [0.88 (95% confidential interval (CI): 0.35, 1.40)] and left ventricular mass [1.82 (95%CI: 0.40, 3.24)]. Notably, in segments without the presence of LGE and ECV expansion, there were still 127 segments (15.0%) showing FAPI activity. ***Conclusion:*** Cardiac FAPI PET/CT imaging was capable of detecting more injured myocardium than MRI. NT-proBNP and left ventricular mass were associated with the difference in the extent of myocardial fibrosis detected by FAPI imaging and ECV.

## OP-645

### Coronary microvascular dysfunction: main characteristics and prognostic value

***K. Kopeva****, E. Grakova, A. Maltseva, A. Mochula, A. Gusakova, A. Smorgon, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The objective of this study was to evaluate the main clinical and instrumental features of coronary microvascular dysfunction (CMD) and to assess its prognostic value during 12 months of follow-up period. ***Materials and Methods:*** A total of 118 patients with non-obstructive CAD and preserved LVEF (62 [59; 64]%) were enrolled. Serum levels of biomarkers were analyzed by ELISA. CMD was defined as the presence of MFR ≤2 evaluated by dynamic CZT-SPECT. Two-dimensional transthoracic echocardiography with evaluation of left ventricle diastolic dysfunction was performed baseline. ***Results:*** Patients were divided into groups depending on the presence of CMD: group 1 included patients with CMD (n=45), and group 2 included patients without CMD (n=73). The lateral e' values were lower by 35% in group 1 (p=0.009) than in group 2. The peak rate of tricuspid regurgitation was higher by 12% (p=0.011), the E/e' ratio was higher by 21.4% (p =0.041) and indexed left atrial volume by 51.2% (p=0.038) in group 1 than group 2. In patients with CMD, the value of global longitudinal starin was lower by 29.7% (p=0.005) than in those without it. In patients with CMD, MFR values were lower by 48.3% (p<0.001) than in patients without it. In group 1, rest-MBF was higher by 30.1% (p<0.001) and stress-MBF was lower by 30.1% (p<0.001) compared to group 2. CRP concentrations were higher by 1.8 times (p=0.011), interleukin-10 concentrations were lower by 21.7% (p=0.048) and interleukin-1β was higher by 2.7 times (p=0.046) in group 1 compared to group 2. The levels of NT-proBNP were higher by 2.6 times (p=0.004), soluble ST2 by 18.1% (p<0.001), tissue inhibitor of metalloproteinase-1 by 2.3 times (p=0.011), matrix metalloproteinase-9 by 1.9 times (p=0.012) in group 1 compared to group 2. GDF-23 and tetranectin did not differ between groups. Multivariate regression analysis showed the presence of diastolic dysfunction (OR 3.27; 95% CI 2.26-5.64; p<0.001), the hyperexpression of NT-proBNP ≥ 760.5 pg/mL (OR 1.67; 95% CI 1.12-4.15; p=0.021), and soluble ST2 ≥ 31.4 ng/mL (OR 1.37; 95% 1.08-2.98; p=0.015) were independent factors associated with CMD. Kaplan-Meier analysis showed that the frequency of adverse outcomes were significantly (p<0.001) higher in patients with CMD (45.2%, n=19) than in patients without it (8.6%, n=6). ***Conclusion:*** The presence of CMD was associated with the severe diastolic dysfunction, hyperexpression of the biomarkers of fibrosis and inflammation. Patients with CMD had higher rate of adverse outcomes than those without it. ***Funding:*** MK-4257.2022.3.

## OP-646

### Comparative analysis of multi-modality cardiac imaging for prediction of cardiovascular outcomes in patients undergoing coronary artery bypass grafting

***M. Gao***[1]*, W. Wen*[2]*, J. Meng*[2]*, M. Yun*[2]*, H. Li*[1]*, Y. Yu*[1]*, X. Zhang*[2]*;*
[1]*Department of Cardiac Surgery, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Molecular Imaging Lab, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** Multidisciplinary quantitative analysis has not been well established in outcome studies in patients with ischemic cardiomyopathy post coronary artery bypass grafting (CABG). This comparative study aimed to evaluate coronary stenosis, micro & macro-calcification in predicting short and long-term cardiovascular outcomes in patients after CABG. ***Materials and Methods:*** Patients with three-vessel disease or left main disease underwent cardiac $^{18}$F-NaF PET/CT, coronary angiography (SYNTAX score), and coronary artery calcium (CAC) scoring prior to the CABG procedure. Maximum coronary microcalcification activity ($TBR_{max}$) and global coronary microcalcification activity ($TBR_{global}$), represented the highest and average coronary $^{18}$F-NaF uptake, were calculated. Radiomic features were extracted from PET, CT, and PET+CT fusion images to develop a multiparametric radiomics signature for cardiac events prediction. Perioperative myocardial infarction (PMI) after 7 days of CABG was defined as the primary endpoint. The major adverse cardiac and cerebrovascular events (MACCEs) and recurrent angina as the secondary endpoint. ***Results:*** 101 patients with coronary artery disease (CAD) were enrolled and followed up to 40.0 months. $TBR_{max}$ (odds ratio, 1.445; P=0.011) and $TBR_{global}$ (odds ratio, 1.797; P=0.018) significantly predicted the occurrence of PMI, outperforming SYNTAX score, CAC score, and blood biomarkers. Patients with threshold value of $TBR_{max}$ > 3.0 had a >4-fold increase in PMI independent of age, sex and risk factors, respectively. Interestingly, the occurrence of PMI in the anterior wall ($PMI_{anterior}$) and the inferior wall ($PMI_{inferior}$) was related to the corresponding coronary $^{18}$F-NaF uptake as TBR in the left anterior descending ($TBR_{LAD-max}$) (odds ratio, 2.154, P=0.036) and TBR in the right coronary artery ($TBR_{RCA-max}$) (odds ratio, 2.686; P=0.031). Furthermore, $TBR_{max}$ was a predictor of MACCEs and threshold value of $TBR_{max}$ >3.6 had a >6-fold

increase in the incidence of MACCEs. The Kaplan-Meier estimate of the survival rate for MACCEs decreased with the increase of $TBR_{max}$. $TBR_{max}$ (HR = 1.261; p = 0.016) and $TBR_{global}$ (HR = 1.327; p = 0.016) were significantly associated with the occurrence of recurrent angina in long term after CABG. ***Conclusion:*** Coronary microcalcification activity quantified by $^{18}$F-NaF PET has superior potential in predicting cardiovascular outcomes after CABG compared to conventional coronary macrocalcification burden and stenosis severity.

## OP-647

### Coronary artery calcium score and epicardial adipose tissue from unenhanced whole-body PET-CT imaging in oncological patients with and without standard modifiable cardiovascular risk factors

***C. Vallone***[1], *C. Nappi*[1], *R. Lepre*[1], *L. Basile*[1], *A. Ponsiglione*[1], *C. Ferraioli*[1], *R. Green*[1], *V. Cantoni*[1], *C. Mainolfi*[1], *M. Imbriaco*[1], *M. Petretta*[2], *A. Cuocolo*[1];
[1]*Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [2]*IRCCS Synlab SDN, Naples, ITALY.*

***Aim/Introduction:*** Earlier diagnoses and more effective therapies lead to an improvement in the survival of patients with cancer. Hence, in cancer patients with high probability of long-term survival it is important to consider cardiovascular risk. Whole-body unenhanced PET-CT imaging performed for oncological reasons may provide additional parameters such as coronary artery calcification (CAC) and epicardial adipose tissue volume (EAT) with cost-effective predictive value in asymptomatic people, beyond traditional cardiovascular risk factors. The aim of the study was to investigate the characteristics of cardiac CT parameters (CAC and EAT) obtained from unenhanced whole-body PET-CT imaging in oncological patients with standard modifiable cardiovascular risk factors (SMuRFs) as compared to patients without (SMURF-less). ***Materials and Methods:*** We studied 109 consecutive patients without known CAD undergoing PET-TC with administration of $^{18}$F-FDG in 92 and $^{18}$F-Choline in 17 patients. For each patient, the exposure variable was defined as having at least one of the following SMuRFs: current smoker status, hypercholesterolemia, diabetes mellitus, or hypertension. Unenhanced CT images were retrospectively reviewed for CAC, EAT on a dedicated platform. CAC score was calculated according to the Agatston method with a threshold of ≥130 HU and EAT volume was quantified setting the range of attenuation for EAT segmentation between -30 and -190 HU. The ln(CAC+1) score transformation was used to adjust for the rightward skew of the data and to reduce heteroscedasticity. ***Results:*** From overall population (53 men, 49%), 44 subjects (40%) were SMuRF-less and 65 (60%) had ≥1 SMuRFs. SMURFs patients were older than SMuRF-less (51±17 vs. 62±12 years, p<0.001). ln(CAC+1) (1.8±2.5 vs. 3.3±2.6, p<0.004) and EAT volume (84±45 vs. 109±49 $cm^3$, p=0.006) were higher in SMURFs patients compared to SMuRF-less. EAT volume was also higher in patients with BMI ≥30 kg/m2 compared to those with BMI <30 kg/m2 (122±33 vs. 95±45 $cm^3$, p=0.04). At regression analysis, a significant relationship was detectable between ln(CAC+1) and EAT volume (p<0.001) in the entire population. At logistic regression analysis, ln(CAC+1) (p<0.005) and EAT volume (p<0.008) were significantly associated with the presence of SMuRFs. ***Conclusion:*** This study first demonstrates a strong association between SMURFs, CAC score and EAT in cancer patients, suggesting evaluating in a cost-effectiveness manner these parameters in all patients undergoing whole-body PET/CT imaging. This approach may imply substantial benefits allowing to evaluate cancer disease and atherosclerotic burden in a single test already included in the diagnostic program of oncological patients with radiation dose optimization.

## OP-648

### Immune checkpoint inhibitor treatment may induce abated reactive arterial inflammation in lung cancer patients with history of sysmatic therapy: trained immunity before immunotherapy?

***R. Calabretta***, *L. Beer, H. Prosch, D. Kifjak, P. Binder, S. Grünert, W. Langsteger, M. Mitterhauser, X. Li, M. Hacker;
Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Immunotherapy with immune checkpoint inhibitors (ICI), one of the most effective therapies in oncology today, is related to different immune-related adverse events (IRAEs) affecting also cardiovascular (CV) system, including accelerated progression of atherosclerosis. Positron emission tomography (PET) with 2-[$^{18}$F]fluoro-d-glucose (2-[$^{18}$F]FDG) is a validated imaging modality to study and to quantify inflammation in atherosclerosis, also in oncological patients. ***Materials and Methods:*** 2-[$^{18}$F]FDG PET/CT imaging pre/post ICI therapy of 47 patients with lung cancer were retrospectively analyzed. Maximum 2-[$^{18}$F]FDG standardized uptake values ($SUV_{max}$) and target-to-background ratios (TBRs) were calculated along six arterial segments. We classified the arterial PET lesions by pre-existing active inflammation (cut-off: $TBR_{pre}$≥1.6). 2-[$^{18}$F] FDG metabolic activity pre/post was also quantified in bone marrow, spleen, and liver. Circulating blood biomarkers like high sensitivity C-reactive protein (hsCRP) and neutrophil-lymphocyte ratio (NLR) were additionally collected at baseline and after ICI treatment. ***Results:*** ICI therapy resulted in a significantly increased arterial inflammatory activity, detected by increased TBRs, in all arterial PET lesions analyzed (n= 761; lesional-$TBR_{pre}$=1.73±0.42 vs. lesional-$TBR_{post}$=1.90±0.44; p<0.001). In particular, a significant elevation of arterial 2-[$^{18}$F]FDG uptake was recorded in PET lesions without pre-activating inflammation (n=305; $TBR_{inf(-)\_pre}$=1.35±0.18 vs. $TBR_{inf(-)\_post}$=1.79±0.39; p<0.001), in calcified (n=73; $TBR_{cal(+)\_pre}$=1.75±0.42 vs. $TBR_{cal(+)\_post}$=1.91±0.45; p<0.001) and in non-calcified lesions ($TBR_{cal(-)\_pre}$=1.64±0.43 vs. $TBR_{cal(-)\_post}$=1.99±0.38; p<0.001). Furthermore, a significant increase of arterial 2-[$^{18}$F]FDG meatbolic activity was observed in patients not previously treated with chemotherapy (n=19; $TBR_{CHT(-)\_pre}$=1.64±0.26 vs. $TBR_{CHT(-)\_post}$=1.91±0.36; p<0.001) or radiotherapy (n=25; $TBR_{RT(-)\_pre}$=1.68±0.25 vs. $TBR_{RT(-)\_post}$=1.93±0.38; p<0.001) as well as in those without CV risk factors (n= 29, $TBR_{RF(-)\_pre}$= 1.72±0.28 vs. $TBR_{RF(-)\_no\_post}$= 1.89±0.34,p<0.01). No significant changes were recorded in 2-[$^{18}$F]FDG uptake of bone marrow ($SUV_{mean\_BM\_pre}$=1.17±0.20 vs. $SUV_{mean\_BM\_post}$=1.12±0.27; p=0.34), spleen ($SUV_{mean\_spleen\_pre}$=1.77±0.47 vs. $SUV_{mean\_spleen\_post}$=1.78±0.37; p=0.92), and liver ($SUV_{mean\_liver\_pre}$=1.99±0.33 vs. $SUV_{mean\_liver\_post}$=2.02±0.41; p=0.61) after ICI treatment. No significant modifications were seen in the blood biomarkers. ***Conclusion:*** Cancer immunotherapy with ICI might increase vascular inflammation in lung cancer patients absenting pre-exisiting arterial inflammation, while subjects priorly exposed to anti-ancer treatments or already presenting CV risk factors could have a lower immuno-response and, subsequently, a lower arterial activation after ICI, probably due to trained immunity.

## OP-649

### Leg-muscle perfusion preserve on 99mTc-MIBI stress-rest scintigraphy : the novel use of radionuclide imaging in peripheral arterial disease

***G. Parida***, *T. Singhal, P. Singh, P. Kumar, R. Emerson, K. Bishnoi, A. Rehaman, S. Patro, K. Agrawal;
All India Institute Of Medical Sciences, Bhubaneswar, INDIA.*

***Aim/Introduction:*** Peripheral arterial disease (PAD) is typically believed to be associated with obstructive arteriopathy. However, real-time clinical studies showed a surprisingly weak correlation between the limb hemodynamics and walking capacity. This depicts other factors at play apart from the macrovascular

obstructive disease as initially believed. Thereby necessitating a need for non-invasive imaging that could detect the functional disturbances apart from hemodynamic disturbance and could predict their functional capacity. This study evaluated the utility of lower extremity 99mTc-MIBI imaging as a non-invasive correlate to lower extremity functional capacity (1, 2). ***Materials and Methods:*** Thirty-three patients including eight diabetics with no known history of PAD were included in the study. 99mTc-MIBI perfusion scintigraphy was performed for calf muscles at stress and rest. Counts are assessed on anterior and posterior images and a geometric mean of both was taken. Perfusion reserve (PR) for bilateral calves was calculated as: (average stress counts-average rest counts)/ average rest counts x 100. Correlation of PR of bilateral calves was assessed with respect to functional / exercise capacity (METs and exercise duration). ***Results:*** Thirty-three patients (26 male and 7 female) with median age of 46 (range 28-66) years were included in the study. Mean PR for left and right calf muscles was 75.35±49.1% and 70.57±44.4% respectively. There was significant correlation between functional capacity of the patients (METs achieved and exercise duration) and PR of bilateral calf muscles (Table 1). Besides, among the diabetics, there was mild negative correlation between duration of diabetes with perfusion reserve with a correlation coefficient of -0.3 and p value of 0.09. ***Conclusion:*** Radionuclide imaging with 99m-Tc MIBI may serve as an ideal non-invasive imaging to detect the macrovascular and microvascular perfusion disturbances in patients with PAD and diabetes much before appearance of clinical symptoms and to assess skeletal muscle adaptation in response to exercise therapy or other novel therapies. ***References:***

## Thyroid Committee - TROP Session: $^{18}$F-FDG and Novel Tracers in the Diagnostic Management of Patients with Thyroid Cancers

### OP-650

**Investigating the role of F18-FDG PET/CT and Ga68 DOTATOC PET/CT in the evaluation of differentiated thyroid cancer patients with increased serum thyroglobulin and negative I-131 whole body scan**

***A. Aghaee***, *K. Aryana, M. Esmatinia, V. Roshan Ravan;*
*Nuclear Medicine Research Center,Mashhad University Of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Regarding increasing prevalence and incidence of thyroid cancer, defining a useful diagnostic protocol for choosing the proper treatment is inevitable. in the differentiation of thyroid cancers, the thyroid cancer population may express different receptors, including somatostatin. The aim of this study was to investigate the role of F18-FDG PET / CT and Ga68-DOTATOC PET / CT in these patients. ***Materials and Methods:*** In this retrospective study, 20 patients with differentiated thyroid carcinoma and Tg values above 10 with TSH stimulation by levothyroxine withdrawal or Tg values above 5 on TSH suppression) following surgery, thyroid ablation or iodine therapy along with recent negative whole body scans with I-131 were evaluated in this study. All patients underwent F18-FDG PET / CT scan first and underwent Ga68-DOTATOC PET / CT scan for a maximum period of one week. ***Results:*** 20 patients with TENIS syndrome were examined, The primary pathology of thyroid cancer was PTC in 19 patients and FTC in one case. The total number of positive findings based on the location of the lesions in both scans was 23/27 and based on the patient in Ga-DOTATOC and FDG were 65% (13/20) and 70% (14/20), respectively. Stage of the disease in most patients according to the seventh edition was stage IV (12 patients) and based on the eighth edition (10 patients) was in stage I of the disease. The overall results of both modalities based on discontinuation of the pill or TSH suppression were not significantly different (p-value < 0.999). The statistical relationship between the number of positive and negative findings of patients in the two PET tracers was not significant (p = 1). While there was a significant relationship between Tg levels and FDG findings (p-value = 0.015) there was no significant relationship between Tg levels and FDG positive findings in TSH stimulation state (p = 0.262). Also, there was no significant relationship between Tg levels and pathological subtypes (p-value = 0.602). ***Conclusion:*** Expression of somatostatin receptors by Ga68-DOTATOC PET / CT uptake is observed in significant percentage of TENIS patients . The positive findings of the two modalities are not significantly different and it seems that Ga-DOTATOC is effective in the treatment plan of patients who have a positive FDG PET / CT finding with no change in the management of the disease.

### OP-651

**Exploring the role of new angiogenic tracer, $^{68}$Ga DOTAGA- IAC and comparison of its diagnostic performance with $^{18}$F-FDG PET/CT in patients with radioiodine refractory differentiated thyroid carcinoma**

***S. Ananth Kumar***, *A. Sood, J. Shukla, R. Kumar, P. Aggarwal, B. Rai Mittal;*
*Postgraduate Institute Of Medical Education and Research, Chandigarh, Chandigarh, INDIA.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT has proven to be an advantageous tool to predict the occurrence of recurrent/ residual disease in patients with radioiodine refractory differentiated thyroid carcinoma (RAIR-DTC). However its non-specificity and lack of a suitable theranostic pair has led to search of new molecular agents targeting various processes involved in the metastases. Integrin antagonist carbamate (IAC), a newer αvβ3 integrin antagonist peptidomimetic molecule in the pipeline, makes molecular imaging of tumour angiogenesis amenable. The study aims to investigate the clinical efficacy of $^{68}$Ga DOTAGA-IAC PET/CT in the detection of RAIR-DTC and compare its diagnostic performance with $^{18}$F-FDG PET/CT. ***Materials and Methods:*** This prospective pilot study included RAIR-DTC patients (previously histopathologically proven DTC patients) as defined by ATA guidelines who underwent whole body $^{18}$F-FDG-PET/CT followed by $^{68}$Ga DOTAGA-IAC PET/CT between Jan 2021 and April 2023 in a tertiary care centre. The imaging findings of both PET/CT were interpreted and quantitative parameters like SUVmax, SUVpeak, MTV and TLG were obtained and statistically analysed using SPSS version 26.0. A p value of <0.05 was considered statistically significant. ***Results:*** 27 patients (14 women) with a median age of 48.3 years (interquartile range-25) were included in the study, most of them being papillary carcinoma thyroid (92.6%). Majority

of the patients were risk stratified as intermediate (55.6%) and high (40.7%) initially respectively. Overall, most patients were stage I (51.9%), followed by stage II (40.7%), III (3.7%) and IV (3.7%) according to AJCC 8th edition. Median TSH and thyroglobulin levels of patients were 75μIU/ml and 154ng/ml respectively. The commonest sites of involvement on both PET/CT were locoregional lymph nodes (77.8%), followed by pulmonary nodules (59.3%), thyroid bed (22.2%), with least common site being liver and paracolic deposit (0.04% each). FDG uptake was significantly higher than IAC with median SUVmax and SUVpeak being 7.9 vs 2.5(p value <0.001) and 4.6 vs 1.7(p value <0.001). $^{18}$F-FDG PET/CT performed better than $^{68}$Ga DOTAGA-IAC PET/CT, predominantly in detecting locoregional lymph nodes (median SUVmax 8.9 vs 3.0, p value <0.001) and pulmonary nodules (median SUVmax 6.2 vs 1.5, p value <0.001). Volumetric parameters like median MTV and TLG of FDG outperformed IAC, with values being 6 vs 0.8(p value 0.007) and 24.9 vs 2.3(p value 0.006) respectively. ***Conclusion:*** Angiogenesis imaging with $^{68}$Ga DOTAGA-IAC PET/CT appears to be inferior compared to $^{18}$F-FDG PET/CT in the detection of lesions in patients with RAIR-DTC, retaining the domination of $^{18}$F-FDG PET/CT imaging in clinical practice.

## OP-652

### Lactate dehydrogenase A is associated with glucose metabolism, radioiodine avidity and prognosis in differentiated thyroid cancer

***T. Tian***, *H. Dai, R. Huang;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** $^{18}$F-FDG PET/CT reflects the Warburg effect of tumours. Lactate dehydrogenase A (LDHA) is an enzyme responsible for the conversion of pyruvate to lactate and plays an important role in aerobic glycolysis. The aim of this study was to i) analyse the relationships among LDHA, glycolysis, and radioactive iodine (RAI) avidity and ii) explore the value of these parameters in the prognosis of differentiated thyroid cancer (DTC). ***Materials and Methods:*** DTC patients who underwent $^{18}$F-FDG PET/CT and subsequent total thyroidectomy or metastasectomy at our centre from 2007-2021 were enrolled. The expression levels of LDHA, glucose transporter 1 (Glut1), glucose transporter 3 (Glut3) and Ki67 proteins in tumour tissue were measured using immunohistochemistry (IHC). The maximum standardized uptake value for the whole body (SUVmax), the maximum standardized uptake value for the lesion corresponding to the IHC specimen (lesion SUVmax), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) were measured. A radioiodine whole body scan was used to determine lesion radioiodine avidity. Quantitative PCR and Western blotting were used to study the expression of Glut1 and Glut3 in thyroid cancer cell line (TPC-1) transfected with lentivirus overexpressing LDHA. ***Results:*** A total of 69 DTC patients were included in the study, and LDHA expression levels were correlated with Glut3 expression levels (P=0.003) and lesion SUVmax (P=0.002). 39 patients undergoing RAI therapy for structural disease. The median LDHA and lesion SUVmax of the RAI avidity group were lower than those of the non-RAI avidity group (200 vs. 285, P= 0.036; 3.06 vs. 8.38, P=0.038, respectively). After a median follow-up of 43 months (3-360 months), 53 patients were finally included in the assessment of clinical outcomes. Of these 53 patients, 18 (34.0%) had disease progression, and 5 (11.1%) died. Elevated SUVmax (log rank P=0.004), MTV (log rank P=0.014), TLG (log rank P=0.001) and LDHA expression (Breslow P=0.048) led to shorter time to progression (TTP). Cox regression analysis revealed that TLG (HR: 4.773, P=0.047) was an independent prognostic factor of TTP.In cellular experiments, overexpression of LDHA significantly increased TPC-1 proliferation, migration, and Glut1 and Glut3 expression. ***Conclusion:*** LDHA expression was highly correlated with the non-avidity of RAI and increased glycolysis. High LDHA expression levels are associated with worse progression. Cellular experiments confirmed that LDHA could regulate the expression of glut1 and Glut3, but immunohistochemical staining showed that LDHA was more closely related to Glut3 expression.

## OP-653

### The Complementary Role of PSMA Expression and [$^{18}$F] FDG PET/CT in Predicting Thyroid Cancer Outcome — from Black and White to Shades of Grey, in the Era of Precision Oncology

***C. Pini***[1], *M. Sollini*[2,3], *M. Kirienko*[4], *L. Di Tommaso*[2,5], *F. Gelardi*[2,3], *S. Ariano*[2,6], *C. Landoni*[1,7], *A. G. Lania*[2,6], *G. Mazziotti*[2,6], *G. Mercante*[2,8], *A. Chiti*[2,3];
[1]*School of Medicine and Surgery, University of Milano-Bicocca, Monza, ITALY,* [2]*Department of Biomedical Sciences - Humanitas University, Pieve Emanuele, ITALY,* [3]*Nuclear Medicine – IRCCS Humanitas Research Hospital, Rozzano, ITALY,* [4]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, ITALY,* [5]*Pathology - IRCCS Humanitas Research Hospital, Rozzano, ITALY,* [6]*Endocrinology - IRCCS Humanitas Research Hospital, Rozzano, ITALY,* [7]*Nuclear Medicine Department, IRCCS Monza, San Gerardo Hospital, Monza, ITALY,* [8]*Otorhinolaryngology, IRCCS Humanitas Research Hospital, Rozzano, ITALY.*

***Aim/Introduction:*** The diagnostic and prognostic value of Prostate-Specific Membrane Antigen (PSMA) in thyroid carcinoma (TC) is still largely unknown. We aimed to test the potential complementary role of PSMA and 2-[$^{18}$F]fluoro-2-deoxy-D-glucose ([$^{18}$F]FDG) as biomarkers for TC outcome prediction. ***Materials and Methods:*** From a retrospective cohort of TC patients we selected those fulfilling the following inclusion/exclusion criteria: thyroidectomy in our Institution, available primary tumor tissue PSMA immunostaining, [$^{18}$F]FDG PET/CT and follow-up data. We included 23 subjects. PSMA staining was visually assessed. PET/CT was considered positive in case of [$^{18}$F]FDG uptake higher than the background at the site of TC confirmed by cyto-/histology, and/or follow-up. Disease recurrence, radioiodine refractoriness (RAI-R) and status at last follow-up (LFU) were used as outcome endpoints. ***Results:*** Disease recurrence occurred in 18/23 patients (median time 11 months, range 1-40); among these 12/18 developed RAI-R (median time 28 months, range 2-221), and 13/18 cases had evidence of disease at LFU. Only one out of 11 patients classified at high risk of structural disease recurrence according to ATA Guidelines did not experience recurrence. PSMA expression was negative in 6/23 cases. PET/CT was negative in 11/23 patients (7/11 experienced recurrence). Nine out of 12 RAI-R patients had a positive PET/CT, while 10/13 cases with evidence of disease at LFU had a positive PET/CT. All patients who had a positive PET/CT had a positive PSMA immunostaining. Six out of 11 patients with negative PET/CT were positive at immunostaining. Patients with negative PET/CT exhibited lower PSMA expression (median score of 30%, range 0-80%) than patients with positive PET/CT. The TC samples without PSMA expression belonged to patients who resulted negative also at PET/CT (3 experienced recurrence, 2 were RAI-R, and 1 had disease at LFU). Four out of 11 patients who resulted negative at PET/CT exhibited very high PSMA expression (≥ 70%) and although 3 of them experienced recurrence, none resulted RAI-R, and only 1 had persistent disease at LFU. ***Conclusion:*** Primary tumour PSMA expression and [$^{18}$F]FDG seem to play a complementary role in TC. The majority of patients who expressed PSMA recurred. Patients with intermediate risk and negative PSMA

immunostaining recurred less than patients who belong to the same class risk and expressed PSMA. Notably, although patients with a negative [18F]FDG PET/CT had a favourable long-term outcome, PSMA assessment might be useful to timely identify subjects at higher risk of recurrence.

## OP-654

### Prospective study on the usefulness of 18FDOPA PET-CT in the management of medullary thyroid cancer patients with higt residual calcitonin rate after surgery

***M. Terroir Cassou Mounat***[1], *A. Lusque*[1], *E. Hindié*[2], *D. Taieb*[3], *L. Vija*[1], *J. Sarini*[1], *F. Courbon*[1], *A. Decotte*[4], *S. Grunenwald*[5], *S. Zerdoud*[1];
[1]*IUCT Oncopole, toulouse, FRANCE,* [2]*University Hospital of Bordeaux, Bordeaux, FRANCE,* [3]*La Timone University Hospital, Marseille, FRANCE,* [4]*University Hospital Rangueil-Larrey, toulouse, FRANCE,* [5]*Centre Hospitalier Universitaire de Toulouse, toulouse, FRANCE.*

***Aim/Introduction:*** The reference treatment of medullary thyroid cancer (MTC) is surgery but calcitonin (ctn) remains often detectable postoperatively. In case of ctn level above 150 pg/ml, international recommendations suggest adding 18 fluoro-dopa positron emission tomography (18FDOPA PET) to conventional imaging (CI) workup. The aim of this study was to measure the impact of the 18FDOPA in the management of MTC patients with elevated ctn by determining its ability to identify residual lymph node and distant metastases compared to CI. ***Materials and Methods:*** This prospective, multicenter, open-label study (NCT02856347) evaluated the benefit of 18FDOPA imaging in the detection of metastatic lymph nodes and metastases, compared to CI in operated MTC patients with ctn above 150 pg/ml. The primary endpoint was the relative true-positive rate of metastatic lymph nodes on 18FDOPA compared with the CI in a per lymph node analysis. Secondary endpoints are discordance rate between 18FDOPA and CI in a per metastasis site analysis, changes in patient management after 18FDOPA determined by a multidisciplinary tumor board of experts (SZ, SG, AD and MT) and concordance between the reading of the 18FDOPA PET in the investigating center and a centralized review (MT). ***Results:*** The study prospectively included 24 patients from five French centers between 2017 and 2020. The median ctn was 824 pg/mL (range 176-16418). A total of 60 lymph nodes were detected by 18FDOPA or CI, fifty-three (35 FDOPA+CI, 18 FDOPA) were defined involved and 7 non-involved (2 FDOPA+CI, 4 FDOPA, 1 CI) after clinical examination (Gold Standard). 18FDOPA detected 1.5 (95%CI: 1.25-1.84) times more lymph nodes metastases compared to CI. For metastases, the discordance rate was 46.4% (95%CI 27.5-66.1), 13/28. After a multidisciplinary tumor board of experts, 14 patients (58.3%, 95%CI: 36.6-77.9) had a change in patient management after 18FDOPA results. Six patients would be monitored, seven patients would have had surgery or modified surgery, four patients a fine needle aspiration, two patients local treatment and three patients systemic treatment. The discordance rate for 18FDOPA between expert and local readers was 20.8% (95%CI: 7.1-42.2, 5/24 pts) for metastases. The expert review allowed catching up two metastatic sites. ***Conclusion:*** In this multicenter prospective study, 18FDOPA imaging changed MTC patient management in 58% of cases. These data confirm that 18FDOPA PET is particularly helpful for MTC workup and patient management. The results on the 18FDOPA expert reading suggest the importance of further improving the assessment of MTC with 18FDOPA.

## OP-655

### $CCK_2$-receptor targeted PET/CT in patients with medullary thyroid cancer using [68Ga]Ga-DOTA-CCK-66 - First clinical experience

***O. Viering***[1], *T. Günther*[2], *N. Holzleitner*[2], *H. Wester*[2], *A. Dierks*[1], *M. Kircher*[1], *G. Wienand*[1], *C. H. Pfob*[1], *R. A. Bundschuh*[1], *C. Lapa*[1];
[1]*Nuclear Medicine, faculty of medicine, University of Augsburg, Augsburg, GERMANY,* [2]*Chair of Pharmaceutical Radiochemistry, Technische Universität München, Munich, GERMANY.*

***Aim/Introduction:*** Medullary thyroid cancer (MTC) is a neuroendocrine tumour arising from the parafollicular cells of the thyroid gland and accounts for approximately 5 % of all thyroid cancers. Since patients with MTC can only be cured by complete resection of the primary tumour and any locoregional or distant metastases, accurate imaging techniques for disease staging are required. Recently, cholecystokinin-2 ($CCK_2$)-receptor has been demonstrated as a suitable target for positron emission tomography/computed tomography (PET/CT) imaging of MTC (1). Here, we report on the first clinical experience with [68Ga]Ga-DOTA-CCK-66, a novel $CCK_2R$ ligand. ***Materials and Methods:*** Eight patients (4 male, mean age 59±13 years) with a history of MTC and elevated tumour marker levels (calcitonin: 125 (13-720) pg/ml, CEA: 2.2 (0.8-6.9) ng/ml) underwent PET/CT imaging with 168±17 MBq [68Ga]Ga-DOTA-CCK-66 for re-staging purposes. In 3 patients additional imaging with [18F]FDG- (n=1) and [18F]F-DOPA-PET/CT (n=2) was available. Tumour detection rates were assessed and compared to tumour marker levels as well as doubling times. ***Results:*** PET imaging was well tolerated by all patients with no adverse effects. $CCK_2$-positive lesions were detected in 3/8 patients (37.5 %) with local recurrence in one patient, lymph node metastases in three subjects and bone and liver metastases in one patient. The median calcitonin level was higher in the PET-positive group (380 pg/ml vs. 120 pg/ml) and the PET-positive patients had a shorter median calcitonin doubling time before PET/CT imaging (10 months vs. 37 months). In comparison to [18F]FDG, additional lymph node, liver and bone metastases could be detected with [68Ga]Ga-DOTA-CCK-66. In comparison to [18F]F-DOPA the same number of lesions was documented. Apart from tumour lesions, [68Ga]Ga-DOTA-CCK-66 was only found in the $CCK_2R$-positive stomach as well as in the ureter and the bladder due to excretion. ***Conclusion:*** $CCK_2$-receptor-directed PET imaging with [68Ga]Ga-DOTA-CCK-66 is feasible, as the compound revealed a favourable biodistribution profile and good detection of tumour lesions. PET positivity is correlated with higher tumor marker levels and shorter doubling times. Further research to investigate a potential diagnostic superiority over already established imaging modalities and to assess the therapeutic option by means of 90Y- or 177Lu-labelled DOTA-CCK-66 are warranted.

## OP-656

### PET/CT imaging of differentiated and medullary thyroid carcinoma using the novel SSTR-targeting peptide [$^{18}$F] SiTATE - first clinical experiences

***S. Kunte***[1], *V. Wenter*[1], *G. T. Sheikh*[1], *M. Unterrainer*[1], *S. Lindner*[1], *J. Toms*[1], *K. Jurkschat*[2], *C. Wängler*[3], *B. Wängler*[3], *R. Schirrmacher*[4], *J. Rübenthaler*[1], *C. J. Auernhammer*[1], *C. Spitzweg*[1], *P. Bartenstein*[1], *A. Holzgreve*[1], *L. M. Unterrainer*[1];
*[1]LMU, Munich, GERMANY, [2]Technische Universität Dortmund, Dortmund, GERMANY, [3]Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, GERMANY, [4]University of Alberta, Edmonton, Edmonton, AL, CANADA.*

***Aim/Introduction:*** The novel $^{18}$F-labeled somatostatin-receptor (SSTR)-directed radiotracer [$^{18}$F]SiTATE demonstrated promising results in the imaging of various SSTR-expressing tumor entities and provides also a theranostic perspective. As thyroid carcinomas (TC) express SSTR, the use of SSTR-PET/CT might be useful with regard to therapeutic decisions beyond standard imaging. Data on [$^{18}$F]SiTATE PET/CT imaging in TC, however, are lacking. This study provides first [$^{18}$F]SiTATE PET/CT data in a patient cohort with histologically proven TC. ***Materials and Methods:*** Patients with either differentiated or medullary TC who underwent at least one [$^{18}$F]SiTATE PET/CT were included as part of a non-interventional, observational study. Mean $SUV_{max}$ and $SUV_{mean}$ of the tumoral lesions and mean total tumor volume (TTV) with their standard deviations (SDs) were determined using a 50%-isocontour-VOI. ***Results:*** Overall, 21 patients (mean age 62.24 ±13.9 years; 13 female / 8 male) with TC (10x medullary, 8x follicular, 2x papillary, 1x oncocytic) were included. 16/21 showed metastatic sites in the $^{18}$F-SiTATE PET/CT scan. Altogether, 89 lesions were included. Three patients with medullary and one patient with follicular and papillary TC respectively showed no SiTATE uptake, which was aligned with no target lesions in CT. Analysis of osseous (31 lesions; $SUV_{max}$ 8.3, SD 7.84; $SUV_{mean}$ 5.6, SD 5.29) and nodal (37 lesions; $SUV_{max}$ 8.7, SD 7.73; $SUV_{mean}$ 5.7, SD 5.28) metastases showed the highest uptakes. Metastases were also localized in the lung (17 lesions; $SUV_{max}$ 4.52, SD 1.82; $SUV_{mean}$ 3.49, SD 1.67) and in the soft tissue (1 lesion; $SUV_{max}$ 4.14; $SUV_{mean}$ 2.35). One patient had not undergone thyroidectomy and in two patients, a local recurrence was present; the local tumoral uptake was markedly increased in all three cases ($SUV_{max}$ 11.97, SD 9.66; $SUV_{mean}$ 7.51, SD 5.61). Mean TTV in patients with differentiated TC was 539.21 ml (SD 1059.90), $SUV_{max}$ 14.63 (SD 14.67) and $SUV_{mean}$ 5.33 (SD 3.02). In patients with medullary TC analysis showed a mean TTV of 76.97 ml (SD 173.05), $SUV_{max}$ 5.48 (SD 4.15) and $SUV_{mean}$ 3.55 (SD 2.41). ***Conclusion:*** Our preliminary data demonstrate that [$^{18}$F]SiTATE PET/CT is highly feasible in patients with differentiated and medullary TC. These results suggest [$^{18}$F]SiTATE as a useful, novel SSTR-radioligand for TC beyond established Ga-labeled radioligands. Additionally, [$^{18}$F]SiTATE PET/CT might be helpful to select patients that could benefit from a SSTR-directed therapy. Further analyses comparing [$^{18}$F]SiTATE PET and standard imaging in correlation to clinical follow up are underway.

## OP-657

### Clinical Impact of Ga68-DOTATATE PET/CT Imaging in Medullary Thyroid Carcinoma, a retrospective single center study

***A. Abdelrahman***, *R. Akinlusi, S. Gavane;*
*Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Medullary thyroid carcinoma (MTC) is a rare form of cancer that arises from neuroendocrine calcitonin-secreting cells accounting for 1-2% of all thyroid cancers, however, the mortality burden is up to 15%. As with other neuroendocrine tumors, MTCs overexpress L-type amino acid transporters as well as somatostatin receptors. Hence, they can be imaged by both by 18F-FDOPA and 68Ga-DOTATATE. FDOPA is not readily available in the US. In this study, we aim to investigate the impact of 68Ga-DOTATATE imaging on the management of patients with MTC and to compare its performance to FDG. ***Materials and Methods:*** From 1/1/2018 to 1/1/2023, all patients who had a biopsy proven diagnosis of medullary thyroid carcinoma and underwent 68Ga-DOTATATE PET/CT imaging were retrospectively reviewed. Imaging studies including 68Ga-DOTATATE and FDG PET/CTs have been independently reviewed by two nuclear medicine physicians. The association between qualitative imaging findings for both DOTATATE and FDG PET/CT and serum calcitonin levels was measured using Fischer's exact test. SUV max values were plotted against calcitonin levels in a linear regression model to measure correlation. ***Results:*** 16 patients have met the inclusion criteria. 14 patients (80%) had their DOTATATE imaging for restaging after surgical resection of the thyroid gland due to rising tumor markers and one patient was imaged for initial staging, and one patient was incidentally found to have increased uptake in the thyroid while undergoing DOTATATE PET/CT for NET. Mean calcitonin levels at the time of scan was 1704 (± 4467 SD, IQR: 15567). DOTATATE was positive in 11/16 patients (70%). It had 78% sensitivity and 100% specificity. 7/16 patients had FDG PET/CT along with DOTATATE PET/CT. In this subgroup, the comparison between the performance of DOTATATE and FDG is shown in table 1. The impact of DOTATATE PET/CT imaging on the management is shown in table 2. There was no significant correlation between calcitonin levels and DOTATATE SUV max values (R2 = 0.06, P value = 0.3). ***Conclusion:*** Our initial results demonstrate that DOTATATE PET/CT imaging had a positive impact on management as well as a clinical benefit particularly in detection of recurrent disease with elevated tumor markers. It detected local disease in 8 patients (50%), resulted in surgical intervention in 4 (25%), and upstaged 3/16 patients (19%). DOTATATE PET/CT was superior to FDG PET/CT in detecting recurrent disease. Additional data is being evaluated to assess lesion and per patient sensitivity and specificity for both tracers.

## OP-658

### 18f tetrafluoroborate-pet in evaluation of thyroid cancer patients: preliminary results

***K. Saglam***, *O. Sahin, E. Karayel, H. Pehlivanoglu, R. Uslu Besli, A. Aygun, S. Asa, K. Sonmezoglu;*
*Istanbul Univercity-Cerrahpasa Cerrahpasa Medical Faculty, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Sodium-iodide symporter (NIS) receptors mediate iodine transport into the thyrocytes. NIS receptors can be monitored by SPECT using radioactive iodine and PET imaging using I-124 PET and also the [18F]tetrafluoroborate ([18F] TFB-PET). PET imaging is known for better resolution comparing SPECT and gamma camera imaging methods. I-124 PET can also be used for diagnostic purposes, but its use is limited due to its expensiveness and higher radiation doses.We aimed to compare [18F]TFB-PET with SPECT for imaging the residual tissue, local recurrences, and distant metastases in thyroid cancer. ***Materials and Methods:*** For that ongoing study, we select patients prospectively, who underwent bilateral total thyroidectomy and have indications for RAI treatment. These patients were on a low-iodine diet and not taking any levothyroxine replacement therapy.TSH levels of patients were >50mIU/L. 3-6 mCi [18F]TFB injected and imaging performed with a 40 minutes delay from the injection. Seven patients were included in the study. Patients

treated with various RAI doses. Post-radioiodine therapy SPECT imaging was also performed. A total ten different lesions were identified from SPECT and PET. ROIs were drawn with a standard threshold of 42% and formulated as lesion/background activity count per volume for SPECT and lesion/background SUVMean for [18F]TFB-PET. ***Results:*** Two of the lesions were seen only in [18F] TFB-PET and one of them was evaluated in favor of temporal bone metastases, while the other one was evaluated as residual tissue. Another lesion, a local recurrence, was only seen in SPECT. 7 of 10 lesions were detected on both methods. While comparing with average of lesion/background activity count per volume in lesions detected by SPECT was 112,35, lesion/background SUVMean lesions detected by [18F]TFB-PET was 1005,64. Volumes of two lesions were also obtained by MRI. The results, which were found 0.258 and 0.212 $cm^3$ in MRI, were found to be 0.358, 0.355 $cm^3$ when measured with [18F]TFB-PET, and 5.26, 3.36 $cm^3$ when measured with SPECT, respectively. ***Conclusion:*** One lesion was not detected in [18F]TFB-PET, while two in SPECT. A markedly higher lesion-to-background ratio detected in [18F]TFB-PET; therefore, it is considered to have a better resolution in the [18F] TFB-PET. In addition, when the volume obtained from the [18F] TFB-PET is compared with the MRI, which has a better resolution than the other methods, it is more accurate than SPECT.

### Role of 68Ga-DOTATATE PET/CT Quantitative Parameters in the Differential Diagnosis of Adrenal Lesions

***D. Denizmen***[1], *D. Has Simsek*[1], *E. G. Isık*[1], *H. Hacısahinogulları*[2], *S. Kuyumcu*[1];
[1]*Istanbul University Istanbul Faculty of Medicine Nuclear Medicine Department, Istanbul, TÜRKIYE,* [2]*Istanbul University Istanbul Faculty of Medicine Endocrinology and Metabolic Diseases Department, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Although most of the adrenal lesions consist of benign,non-functional lesions; adrenal tumors have metastatic potential and show aggressive course in advanced stages such as pheochromocytoma(FEO), paraganglioma(PGL), adrenal cortex carcinoma(ACC) [1] .In addition to clinical and laboratory findings,molecular-correlative imaging plays an important role in final diagnosis.[2]This study investigated the contribution of quantitative parameters defined by 68Ga-DOTATATE PET/CT(DOTAPET) in the differential diagnosis of adrenal gland lesions. ***Materials and Methods:*** Patients who referred for characterization of adrenal lesions or had adrenal insidentaloma in DOTAPET included to the study.Additionally, a control group was identified for comparison of normal adrenals by including normal DOTAPET scans verified by correlative CT/MRI.Final diagnosis of adrenal lesions was confirmed with histopathology results,initial or follow up CT/MRI findings.SUVmax values of liver,normal adrenal gland and adrenal lesions in addition to quantitative parameters such as SSTR-TV and SSTR-TL which demonstrates total tumor volume and SSTR expression of the lesions were documented.Diagnostic role of quantitative parameters examined by Mann-Whitney U and Kruskall Wallis tests, and the threshold was determined by ROC curve if parameters were significant. ***Results:*** A total of 85 patients were included to study.41 patients(46 lesions) had adrenal lesions, while 44 patients were in normal control group.25 lesions (n:3 bilateral) were evaluated for adrenal lesion characterization and 21 lesions(n:2 bilateral)were incidentalomas.The final diagnosis was confirmed by histopathology in 22 patients while remaining lesions were determined by MRI(n:18) or follow-up CT(n:6). Of the 46 lesions, 24 lesions were adenoma,14 lesions were FEO,two lesions were ACC and remaining lesions were other pathologies(Table 1).Only FEO and adenoma cases were included to the statistical analysis due to the limited number of other pathologies.Median SUVmax of normal adrenal,FEO and adenoma were calculated as 14.95, 22.27 and 11.45 respectively(p:0.003). SSTR-TV and SSTR-TL of FEO were 18.64 cc and 264.77 while 1.65 cc and 13.35 for adenoma which were significantly higher in FEO(p=0.003).ROC curves showed that SSTR-TV had the highest diagnostic power among all parameters in differentiation of FEO and adenoma(Table 2).The sensitivity and specificity of DOTAPET were found to be 93% and 96% respectively when threshold was 4cc for SSTR-TV(p:<0.001,AUC:0.927-1)(Table 3). ***Conclusion:*** This study indicates that volumetric parameters of DOTAPET had promosing results in differential diagnosis of FEO/adenoma with high diagnostic performance.Further research is required for inclusion in routine clinical practice. ***References:*** 1. ### Role of $^{68}$Ga-PSMA-11 PET/CT in staging metastatic renal cell cancer: A pilot study

***P. Aggarwal***, *H. Singh, C. K. Das, R. S. Mavuduru, A. Lal, N. Kakkar, R. Kumar, U. Gorsi, B. R. Mittal;*
*Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.*

***Aim/Introduction:*** The role of Prostate-specific membrane antigen (PSMA) based positron emission tomography (PET) tracers is well known in the management of prostate cancer. However, it is also an angiogenic imaging marker with a potential role in the imaging of hypervascular tumours like Renal cell cancer (RCC). Our study aims to assess the potential role of $^{68}$Ga-PSMA-11 PET/CT in the staging workup of metastatic RCC and compare it with the current imaging standard (CECT) and $^{18}$F-FDG PET/CT. ***Materials and Methods:*** Biopsy-proven RCC patients with known or suspected distant metastases underwent $^{68}$Ga-PSMA-11 PET/CT for staging/restaging. Those patients who had undergone $^{18}$F-FDG PET/CT within six weeks of $^{68}$Ga-PSMA-11 PET/CT were also included. A patient-based and lesion-based analysis was done to compare the lesion detection rates of CECT, $^{18}$F-FDG and $^{68}$Ga-PSMA-11 PET. Additionally, PET-based quantitative parameters were compared between both the PET modalities. The degree of agreement between different imaging modalities was evaluated using Kohen's kappa and disagreement using the McNemar test. Statistical analysis was done using SPSS v26.0 (IBM Corp, Armank, NY). A p-value of <0.05 was considered significant. ***Results:*** Thirty-seven patients with median age 60 years ± 13 years (range = 26-76 years) were included in the final analysis. Twenty-seven patients had clear cell (cc) RCC, six had papillary RCC (pRCC), and one each had an eosinophilic variant

of ccRCC, collecting duct RCC, translocation RCC and poorly differentiated RCC. Fifteen patients also underwent $^{18}$F-FDG PET. Overall, $^{68}$Ga-PSMA-11 PET/CT identified more lesions than CECT in 27% of patients with lesion-based analysis showing higher lesion detection (568 vs 527, p = 0.215), especially for bone lesions (18.8% vs 9.1%, p <0.001). In ccRCC, there were 51 discordant PSMA+ CT- lesions (tumor thrombi and marrow-based lesions) and 11 discordant PSMA- CT+ liver lesions. $^{68}$Ga-PSMA-11 PET was also superior to CECT in differentiating tumor thrombus from bland thrombus. It was also superior to $^{18}$F-FDG PET/CT in lesion detection (312 vs 202, p < 0.001) with a significantly higher SUVmax (6.9 vs 5.2, p<0.001), SUVpeak (4.4 vs 3.8, p = 0.004) and TBR (5.7 vs 3.8, p <0.001), especially in ccRCC. ***Conclusion:*** $^{68}$Ga-PSMA-11 PET/CT was superior to CECT and $^{18}$F-FDG PET in metastatic clear cell RCC for lesion detection and baseline tumor burden assessment. Its potential role as an angiogenic imaging agent in managing RCC needs to be explored further.

## EPS-191

### Incremental value of $^{68}$Ga-FAPI-04 to dual-tracer PET/CT for the evaluation of hepatobiliary masses with indeterminate CT/MR findings

***I. Ho***[1,2], *S. Chen*[2], *K. Cheng*[2], *K. Wu*[2], *C. Ho*[2];
[1]*The Chinese University of Hong Kong, Hong Kong, HONG KONG,* [2]*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

***Aim/Introduction:*** Dual-tracer (DT) PET/CT with $^{11}$C-acetate (ACT) and $^{18}$F-FDG (FDG) has been widely used for the evaluation of hepatobiliary masses in localities with high liver cancer prevalence. In the past 2 decades, we have confirmed DT-PET/CT highly valuable in most primary liver tumors but may still encounter difficulties in some rare or complicated hepatobiliary pathologies such as hilar tumors (Klatskin tumors) that are non-avid for FDG. $^{68}$Ga-FAPI-04 (FAPI-04) is a rapidly evolving PET tracer recently found useful in a number of tumors; we therefore aimed to evaluate the incremental value of FAPI-04 over DT-PET/CT for the evaluation of hepatobiliary masses with indeterminate CT/MR findings. ***Materials and Methods:*** During Jan-2022 to Feb-2023, 20 patients (M:14, F:6; age range:34-77 years, mean=58.7±14.0 years) underwent FAPI-04 PET/CT for evaluation of suspicious hepatobiliary lesions with indeterminate CT/MR And negative/atypical DT-PET/CT findings. Whole-body FAPI-04 PET/CT was performed within one week after DT-PET/CT. Imaging started at ~60 minutes post FAPI-04 injection (dosage:117±20 MBq, range:76-151 MBq). The $SUV_{max}$ was measured for a maximum of 3 lesions per patient using MIM software. The gold standard for diagnosis was histopathology. One-way ANOVA analysis was performed to evaluate the semiquantitative FAPI-04 uptake among various types of malignancies and benign diseases. ***Results:*** 16/20 patients (M:13, F:3; age range:37-77 years, mean=59.1±12.9 years) with pathological confirmation were finally included for analysis. 12/16 patients were confirmed hepatobiliary malignancies: 5 intrahepatic cholangiocarcinoma (ICC: small-duct and Klatskin), 1 gallbladder adenocarcinoma (GBC), 3 well-differentiated hepatocellular carcinoma (HCC), 1 scirrhous HCC with fibrous features of bile ducts, 1 hepatic-angiosarcoma and 1 hemangioendothelioma. FAPI-04 PET/CT was strongly-avid in 9/12 (75%) hepatobiliary malignancies having negative ACT-PET/CT with/without mild FDG uptake, but completely non-avid in 3 well-differentiated HCC purely-avid for ACT. All "5 ICC+1 GBC" (6 patients: $SUV_{max}$=10.13±3.96, range:6.3-16.3) showed significantly greater intensities than the remaining 3 rare hepatobiliary malignancies (3 patients: $SUV_{max}$=4.40±1.40, range:3.3-6.3). 4/16 patients were confirmed benign but with little to mild uptake on FAPI-04 PET/CT ($SUV_{max}$=2.08±0.74, range 1.2-3.0): 1 FNH, 1 carvernous hemangioma, 1 dysplastic nodule and 1 steatosis. One-way ANOVA analysis showed significant differences among ICC+GBC, rare liver primary, well-differentiate HCC and benign diseases. ***Conclusion:*** FAPI-04 PET/CT has incremental value over FDG PET/CT in evaluation of hilar or small-duct ICC that are non-avid or minimally-avid for FDG, but cannot exclude well-differentiated HCC with pure avidity for ACT. False positive FAPI-04 for the above benign hepatobiliary entities have low uptake but need more cases for ROC differentiation.

## EPS-192

### Utility of CT-free attenuation and scatter correction in dual-tracer PET/CT for Evaluation of Gastric Cancer

***S. Xue***[1], *Y. Miao*[2], *M. Viscione*[1], *H. Wang*[2], *A. Rominger*[1], *R. Guo*[2], *B. Li*[2], *K. Shi*[1];
[1]*University of Bern, Bern, SWITZERLAND,* [2]*Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Ionizing radiation exposure is a major concern in PET/CT imaging, particularly for dual-tracer PET/CT studies where redundant anatomic imaging may add to the radiation burden. This study aims to explore the utility of CT-free deep learning (DL)-based methods for attenuation and scatter correction in the practice of gastric cancer diagnosis using dual-tracer PET/CT. ***Materials and Methods:*** Thirty-three patients with histopathologically confirmed gastric cancer underwent whole-body dual-tracer PET imaging ($^{18}$F-FDG and $^{68}$Ga-FAPI, with an interval of less than 3 days) for pre-treatment evaluation [1]. We trained our previously developed CT-free Decomposition-based DL method [2] using 18F-FDG PET images from 1532 patients and applied it to 33 68Ga-FAPI PET images for attenuation and scatter correction. CT-corrected PET was used as a control. Two nuclear medicine physicians evaluated image quality using a 5-point Likert scale: 1-poor, 2-reasonable, 3-good, 4-very good, and 5-excellent quality. Clinically or pathologically confirmed lesion sites were counted to assess lesion detection sensitivity. ***Results:*** DL-corrected PET imaging achieved higher clinical utility scores (4.85) than CT-corrected PET imaging (4.30). DL-corrected PET imaging had less noise, better contrast, and sharper patterns, resulting in higher scores. Moreover, the number of detected lesions was identical in both datasets. ***Conclusion:*** The CT-free DL-based attenuation and scatter correction may enhance the potential of clinical translation in the dual-tracer PET/CT, which may largely ease the radiation burden for patients.

## EPS-193

### $^{68}$Ga-NY104 PET/CT in patients with recurrent/metastatic clear cell renal cell carcinoma suspicion: a comparative study with $^{18}$F-FDG

***W. Zhu***, *X. Li, Y. Zhang, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** $^{68}$Ga-NY104 is a novel small molecule tracer targeting carbonic anhydrase IX (CAIX), which is overexpressed in clear cell renal cell carcinoma (ccRCC). The purpose of this study was to compare $^{68}$Ga-NY104 PET/CT with $^{18}$F-FDG in patients

with recurrent/metastatic ccRCC suspicion. ***Materials and Methods:*** The study was approved by the institutional review board of Peking Union Medical College Hospital (approval NO. ZS-3089). Patients with recurrent/metastatic ccRCC suspicion were prospectively recruited in the study. All patients received an intravenous injection of $^{68}$Ga-NY104 (200Mbq ± 20%) and underwent whole body PET/CT scan at 45-75 min after injection. Comparative $^{18}$F-FDG PET/CT was performed within a week. The efficacy of $^{68}$Ga-NY104 and $^{18}$F-FDG PET/CT scan was calculated at patient level and lesion level using a final diagnosis as ground truth, which was based on pathological results or comprehensive clinical evaluation. The SUVmax and tumor-to-background ratio (TBR) was also calculated using blood pool as background. ***Results:*** Fifteen patients were recruited in the study. Ten of them were later confirmed as recurrent/metastatic ccRCC while the other 5 patients were confirmed as non-ccRCC (2 inflammation, 2 adenocarcinoma, 1 papillary RCC). The final diagnosis in 12 patients (7 with ccRcc and 5 with non-ccRCC) were confirmed by pathological results and through comprehensive clinical evaluation in other 3 ccRCC patients. The patient-level sensitivity, specificity, and accuracy were 90% (9/10), 100% (5/5), and 93% (14/15) for $^{68}$Ga-NY104 PET and 70% (7/10), 0 (0/5), and 46% (7/15) for $^{18}$F-FDG, respectively. The lesion-level sensitivity, specificity, and accuracy were 88% (66/75), 100% (19/19), and 90% (85/94) for $^{68}$Ga-sNY104 PET and 61% (46/75), 0 (0/19), and 49% (46/94) for $^{18}$F-FDG, respectively. The SUVmax and TBR of matched lesions were significantly higher with $^{68}$Ga-NY104 compared to $^{18}$F-FDG (SUVmax, 17.5 ± 11.4 vs. 8.3 ± 5.3, TBR, 13.5 ± 11.1 vs. 3.7 ± 2.3 P<0.05). ***Conclusion:*** $^{68}$Ga-NY104 PET/CT has better efficacy than $^{18}$F-FDG in patients with recurrent/metastatic ccRCC suspicion.

## EPS-194

### First-in-human validation of enzymolysis clearance strategy for decreasing renal radioactivity using modified 68Ga-HER2 Affibody

***M. Zhang****, T. Xing, J. Wang, T. Ma, G. Li, Z. Quan, W. Yang, F. Kang, J. Wang;*
*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** Enzymolysis clearance strategy is verified a safe and effective way to reduce the renal radioactive accumulation in mice. However, the effectiveness of this strategy in humans remained unknow. Human epidermal growth factor receptor 2 (HER2) is overexpressed in various types of tumors, and radiolabeled HER2 Affibody is believed to be an attractive tool for HER2-targeted theranostics. However, its wide application is limited by the high and persistent radioactivity accumulation in kidney. In this study, we intend to validate the effectiveness of enzymolysis clearance strategy in reducing the renal accumulation by using modified HER2 Affibody. ***Materials and Methods:*** A new HER2 Affibody ligand, NOTA-MVK-$Z_{HER2:2891}$, containing with a cleavable Met-Val-Lys (MVK) linker was synthesized and labeled with $^{68}$Ga. The microPET imaging study was performed in SKOV-3 tumor mice to assess the uptake in tumor and kidney both for the control ligand and the MVK one. Seven healthy volunteers were included for biodistribution and dosimetric studies with both the control and MVK ligands performed one week apart. Urine and blood samples from healthy volunteers were collected for in vivo metabolism study of the two ligands. Four HER2-positive and two HER2-negative patients were recruited for $^{68}$Ga-NOTA -MVK-$Z_{HER2:2891}$ PET/CT imaging at 2 and 4 h post-injection (p.i.). ***Results:*** MicroPET images showed that the tumor uptake of $^{68}$Ga-NOTA-MVK-$Z_{HER2:2891}$ was comparable to that of the control at all the time points, while the kidney uptake was significantly reduced after 40 min p.i. (p = 0.01). The biodistribution study in health volunteers showed that the kidney uptake of MVK ligand was extremely significantly lower than that of the control ligand after 1 h p.i. (p = 0.005), while the uptake of the two ligands in other organs showed no significant difference. The effective dose of the MVK ligand and the control one was 26.1 and 27.7 μSv/MBq, respectively. The enzymolysis fragment of $^{68}$Ga-NOTA-Met-OH was observed in the urine samples of healthy volunteers injected with the MVK ligand, indicating that the enzymolysis clearance strategy worked in humans. The PET/CT study of patients showed that the range of $SUV_{max}$ of HER2-positive lesions were 9.4-21, while that of HER2-negative lesions were 2.7-6.2. ***Conclusion:*** We for the first time demonstrated that enzymolysis clearance strategy can effectively reduce renal radioactivity accumulation in humans. This strategy is expected to decrease renal radiation dose of peptide and small protein-based radiotracers, especially in the field of radionuclide therapy.

## EPS-195

### Biodistribution of Monoclonal Antibodies: Defining New Baselines for $^{89}$Zr-Immuno-PET-Derived Target Engagement In Vivo.

***H. J. Sebus****[1,2], J. E. Wijngaarden[3,2], I. H. C. Miedema[1,2], J. J. Eertink[1,2], I. Bahce[4], A. J. De Langen[4,5], E. F. Smit[6], M. Cleveland[7], D. J. Vugts[3], G. J. C. Zwezerijnen[3,2], M. C. Huisman[3,2], C. W. Menke - van der Houven van Oordt[1,2];*
*[1]Amsterdam UMC location Vrije Universiteit Amsterdam, Medical Oncology, De Boelelaan 1117, Amsterdam, NETHERLANDS, [2]Cancer Center Amsterdam, Imaging & Biomarkers, Amsterdam, NETHERLANDS, [3]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Radiology and Nuclear Medicine, Boelelaan 1117, Amsterdam, NETHERLANDS, [4]Department of Pulmonary Diseases, Cancer Center Amsterdam, Amsterdam University Medical Centers, Amsterdam, NETHERLANDS, [5]Department of Thoracic Oncology, NKI-AvL, Amsterdam, NETHERLANDS, [6]Department of Pulmonology, Leiden University Medical Center, Leiden, NETHERLANDS, [7]Bioimaging, Platform Technology and Science, GlaxoSmithKline, Stevenage, UNITED KINGDOM.*

***Aim/Introduction:*** Using $^{89}$Zr-immuno-PET, the biodistribution of monoclonal antibodies (mAb) can be studied in vivo to assess target engagement. However, quantification with standard uptake values cannot separate reversible from irreversible uptake ($K_i$), which can be done using Patlak linearization. Additionally, $K_i$ comprises non-target and target-specific uptake. To discriminate these, a baseline-$K_i$ must be defined. We assume baseline-$K_i$ equals the $K_i$ of mAbs without target expression in the tissue ($mAb_{neg}$), and can also be derived through saturating all targets with unlabelled mAb (high mass dose) alongside $^{89}$Zr-mAb (saturation effect). This study aims to determine baseline-$K_i$ for tissues of interest in immune oncology treatments (e.g., the adrenal glands, bone marrow, inguinal lymph nodes, pituitary gland, spleen, thyroid and, tonsils) to identify target-specific uptake of (new) mAbs. ***Materials and Methods:*** This retrospective study analysed PET-scan series acquired in clinical trials with $^{89}$Zr-anti-HER3 (N=5, NCT02345174), $^{89}$Zr-cetuximab (N=5, NCT01691391), $^{89}$Zr-durvalumab (N=4, EudraCT2019-004284-51), $^{89}$Zr-ipilimumab (N=5, NCT03313323), $^{89}$Zr-nivolumab (N=3, EudraCT2015-004760-11) and $^{89}$Zr-pembrolizumab (N=3, NCT03065764), with multiple scans 24 hours (e.g. 48 and 144) after injection. Following manual volume of interest delineation, $K_i$ were calculated using

Patlak linearization. Using the Human Protein Atlas, organ target expression was determined ($mAb_{neg}$ and $mAb_{pos}$). When given an increased mass dose, e.g., 2 mg in cycle 1 versus 200 mg with the second tracer administration (N=15/25 series), saturation effects were evaluated to confirm target engagement. Baseline-$K_i$ (reported as medians with interquartile ranges (IQR)) were reported per organ, using $K_i$ of $mAb_{neg}$ from both cycles, and $mAb_{pos}$ in the second cycle. ***Results:*** Baseline-$K_i$ (µL/g/h) in the inguinal lymph nodes (0.27 (IQR 0.18-0.34)), palatine tonsils (0.78 (IQR 0.58-0.98)), spleen (0.51 (IQR 0.42-0.58)), and thyroid (0.46 (IQR 0.39-0.58)) were identified. Baseline-$K_i$ of the other tissues were heterogeneous (IQR > 0.5). Of all $K_i$ (N=302), 79 were unreliable and excluded from analysis, due to small size and activity spill from neighbouring tissue, most frequently the case for the pituitary gland (N=32). The anti-PD-1 mAbs (2-4 mg in cycle 1) showed target engagement in the bone marrow, inguinal lymph nodes (0.56 (IQR 0.22-0.92)), palatine tonsils (1.05 (IQR 0.78-1.24)), spleen (3.12 (IQR 2.59-3.32)) and thyroid (0.90 (IQR 0.65-0.90)). Ipilimumab exhibited no saturation effect, possibly due to cycle 1's relatively high mass dose (10 mg). ***Conclusion:*** This study reports baseline-$K_i$ for the inguinal lymph nodes, palatine tonsils, spleen and thyroid, to help identify target engagement of mAb in vivo using $^{89}$Zr-immuno-PET.

## EPS-196

### Smouldering multiple myeloma: progression to symptomatic disease predicted by 18F-FDG PET-CT

***C. Caldarella***[1], *S. Taralli*[1], *F. Cocciolillo*[1], *T. Za*[2], *V. De Stefano*[2,3], *M. L. Calcagni*[1,4];
[1]*Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, UOC di Medicina Nucleare, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY,* [2]*Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, UOC Servizio e Day Hospital di Ematologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY,* [3]*Dipartimento di Scienze Radiologiche ed Ematologiche, Istituto di Ematologia, Università Cattolica del Sacro Cuore, Rome, ITALY,* [4]*Dipartimento di Scienze Radiologiche ed Ematologiche, Istituto di Medicina Nucleare, Università Cattolica del Sacro Cuore, Rome, ITALY.*

***Aim/Introduction:*** Smouldering multiple myeloma (MM) is characterized by 10-60% bone marrow (BM) plasma cell infiltration in absence of MM-related symptomatology or MM-defining events. Despite its indolent course, the 2-year risk of progression to symptomatic MM may be as high as 73% in patients with unfavourable cytogenetics. In patients with smouldering MM, diffuse 18F-FDG uptake in BM may occur without focal active disease and/or lytic lesions on CT. Aim of this study is to determine whether diffuse 18F-FDG uptake in BM predicts progression to symptomatic MM. ***Materials and Methods:*** Thirty-eight patients (16M/22F), median age 64.98 y (range 43-87), with recently diagnosed smouldering MM and diffuse 18F-FDG uptake in BM on PET-CT, without focal active disease or lytic lesions on CT, were selected retrospectively from a 4-years interval (February 2017 - February 2021). Volumes of interest were placed on dorsal-lumbar spine (D10-L3), iliac crests and femoral diaphyses to obtain SUVmax and SUVmean. A second cohort of 22 patients (13M/9F) with smouldering MM and no significant 18F-FDG uptake was selected from the same time interval. Plasma cell % BM infiltration and M-component at the time of PET-CT were determined. Progression to symptomatic MM was based on IMWG criteria, and minimum 2-year follow-up. Possible differences in progression according to SUVmax or SUVmean (Mann-Whitney), and correlation between SUVmax or SUVmean and laboratory tests (Spearman) were assessed. Youden's Index extrapolated from Receiver Operating Characteristic (ROC) Curve allowed to discover a SUVmax or SUVmean cut-off for progression vs non-progression. ***Results:*** Progression to symptomatic MM was observed in 10/38 (26%) patients with BM diffuse 18F-FDG uptake, 22 months (median) after PET-CT, and in 2/22 (9%) patients with no significant 18F-FDG uptake in BM, 35 and 41 months after PET-CT, respectively. A trend to higher plasma cell % infiltration (median 19% vs 15%; P=0.067) was observed in patients with diffuse than in patients with no significant 18F-FDG uptake. SUVmax cut-off 3.79 for D10-L3 predicted progression to symptomatic MM which occurred in 50% patients with SUVmax > 3.79 (vs 12.5% patients with SUVmax < 3.79; P=0.032), with sensitivity 70% and negative predictive value 87.5%. No robust correlations were evident between SUVmax or SUVmean of selected BM districts and laboratory tests (Spearman's rho < 0.6). ***Conclusion:*** Degree of diffuse 18F-FDG uptake on PET-CT in dorsal-lumbar spine may identify patients with smouldering MM at higher risk of progression to symptomatic MM, with an expected impact on surveillance and treatment.

## EPS-197

### A novel prognostic index for diffuse large B-cell lymphoma combined baseline metabolic tumour volume with clinical and pathological risk factors

***T. Yuan****, X. Chen, Y. Zhang, M. Wei, H. Zhu, Z. Yang, X. Wang;*
*Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** This study aimed to develop a novel prognostic index integrating baseline metabolic tumour volume (MTV) along with clinical and pathological parameters for diffuse large B-cell lymphoma (DLBCL). ***Materials and Methods:*** The prospective trial enrolled 289 patients with newly diagnosed DLBCL (clinicaltrials.gov identifier: NCT02928861). The predictive value of novel prognostic index was compared with Ann Arbor staging and National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). We used the concordance index (C-index) and a calibration curve to determine its predictive capacity. ***Results:*** Multivariate analysis revealed high MTV (>191 $cm^3$), Ann Arbor stage (III-IV) and MYC/BCL2 double expression lymphoma (DEL) to be independently associated with inferior progression-free (PFS) and overall survival (OS). Ann Arbor stage and DEL could be stratified by MTV. Our index, combining MTV with Ann Arbor stage and DEL status, identified four prognostic groups: group 1 (no risk factors,), group 2 (one risk factor), group 3 (two risk factors), and group 4 (three risk factors). The 2-year PFS rates were 85.5%, 73.9%, 53.6%, and 13.9%; 2-year OS rates were 94.6%, 87.0%, 67.5%, and 24.2%, respectively. The C-index values of the novel index were 0.697 and 0.753 for PFS and OS prediction, which was superior to Ann Arbor stage and NCCN-IPI. ***Conclusion:*** The novel index including tumour burden and clinicopathological features may help predict outcome of DLBCL.

## EPS-198

### Lung dose prediction in radioembolization: $^{166}$Ho-microspheres scout for $^{166}$Ho-microspheres treatment vs. $^{99m}$Tc-MAA scout for $^{90}$Y-microspheres treatment

***M. Wagemans****, R. van Rooij, A. J. A. T. Braat, M. L. J. Smits, R. C. G. Bruijnen, H. W. A. M. de Jong, M. G. E. H. Lam;*
*Department of Radiology and Nuclear Medicine, UMC Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Radiation pneumonitis is a rare, but serious complication of radioembolization, mostly described in patients with hepatocellular carcinoma (HCC). Treatment with

$^{166}$Ho-microspheres can be preceded by a lower scout dose consisting of the same microspheres. As individualized treatment planning improves overall patient selection and outcomes, a strong agreement between the scout and therapeutic dose distribution becomes increasingly important. It remains unclear how the predictive value of $^{166}$Ho-microspheres scout compares to that of $^{99m}$Tc-MAA for $^{90}$Y-microspheres. The accuracy of lung mean dose (LMD) prediction was compared for $^{166}$Ho-microspheres scout and treatment versus $^{99m}$Tc-MAA and glass yttrium-90 ($^{90}$Y)-microspheres, in HCC patients. ***Materials and Methods:*** The $^{166}$Ho-microspheres cohort was derived from the prospective HEPAR PRIMARY study.[1] Patients were retrospectively selected for the $^{90}$Y-microspheres cohort (February 2012 to September 2020).[2] LMD for $^{166}$Ho-microspheres scout, $^{166}$Ho-microspheres treatment and $^{99m}$Tc-MAA scout were assessed by SPECT/CT imaging, while $^{90}$Y-microspheres treatment was assessed by PET/CT imaging. The Mann-Whitney U test was used to compare both groups, while Wilcoxon signed rank test was applied to analyse paired data. ***Results:*** In total, 78 HCC patients were included ($^{166}$Ho-microspheres cohort; 21, $^{90}$Y-glass cohort; 57). The median absolute difference between $^{99m}$Tc-MAA predicted LMD and $^{90}$Y-microspheres LMD was 1.84 Gy (range: 0.09-79.38) and was found to be significant (p<0.01). No significant difference was found between the $^{166}$Ho-microspheres scout predicted LMD and $^{166}$Ho-microspheres treatment LMD; median absolute difference 0.16 Gy (range: 0.03-1.26). The Mann-Whitney U test revealed a significant difference in the median absolute differences between the cohorts (U = 140, p<0.01). ***Conclusion:*** Prediction of LMD by $^{166}$Ho-microspheres scout for $^{166}$Ho-microspheres treatment was significantly better than $^{99m}$Tc-MAA LMD prediction for $^{90}$Y-microspheres treatment. Despite inherent limitations in the comparison, these results support the use of $^{166}$Ho-microspheres scout for treatment planning in HCC patients. ***References:*** 1. Reinders MTM, van Erpecum KJ, Smits MLJ et al. Safety and Efficacy of $^{166}$Ho Radioembolization in Hepatocellular Carcinoma: The HEPAR Primary Study. J Nucl Med. 2022;63(12):1891-8. 2. Stella M, Rooij R van, Lam M. et al. Lung dose measured on post-radioembolization $^{90}$Y-PET/CT and incidence of radiation pneumonitis. J Nucl Med 2022; 63:1075-1080.

## EPS-199

### Comparison of response evaluation criteria in diffuse large B-cell lymphoma: Lugano versus RECIL, and PERCIST

***P. Tang****, R. Tian, M. Su;*
*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** The objectives of this study were (1) to compare the interobserver agreement of the Lugano criteria, RECIL criteria, and PERCIST criteria in the response evaluation of DLBCL; and (2) to compare their performance in predicting patients' prognosis. ***Materials and Methods:*** 335 patients diagnosed with diffuse large B-cell lymphoma (DLBCL) were retrospectively analyzed. All patients underwent baseline 18F-FDG PET/CT and interim PET/CT (I-PET/CT) or end-of-treatment PET/CT (EoT-PET/CT). Scans were interpreted by two nuclear medicine physicians using Lugano, RECIL and PERCIST, and the agreement of two observers was compared. Those with inconsistent evaluations reached an agreement by discussion. Then, the RECIL and PERCIST were compared with Lugano for predicting progression-free survival (PFS) and overall survival (OS). Survival curves were estimated with Kaplan-Meier analysis and compared using the log-rank test. The discrimination of different response evaluation criteria was evaluated with C-index and compared using compare C. P < 0.05 was considered statistically significant. ***Results:*** The median follow-up was 47 months. 18F-FDG PET/CT-based response evaluation according to Lugano, RECIL, and PERCIST was determined at interim or end-of-treatment restaging. In the interobserver agreement comparison, the weighted kappa for Lugano, RECIL, and PERCIST were respectively 0.887, 0.798, and 0.740 in I-PET/CT and respectively 0.831, 0.781, and 0.807 in EoT-PET/CT. All three response criteria were significantly associated with PFS (P<0.001) and OS (P<0.001). In I-PET/CT, the C-index of Lugano criteria in predicting PFS and OS was higher than RECIL criteria (both P=0.043) and PERCIST criteria (P=0.008 and P=0.034). In EoT-PET/CT, the C-index for predicting PFS and OS according to Lugano was equal to RECIL, but not significantly different from PERCIST (P = 0.597 and P = 0.231). ***Conclusion:*** With Lugano, RECIL, and PERCIST interpretation, I-PET/CT and EoT-PET/CT were predictive of PFS and OS. But Lugano criteria showed greater interobserver agreement and better prediction of PFS and OS, highlighting the importance of Lugano in DLBCL response evaluation in I-PET/CT and EoT-PET/CT.

## EPS-200

### Voxel-Based Dosimetry with Integrated Y-90 PET/MRI Following TARE with Glass Microspheres and Dose-Response Relationships - Preliminary Results

***B. Demir***[1]*, E. C. Celebioglu*[2]*, C. Soydal*[1]*, N. O. Kucuk*[1]*, D. Kuru Oz*[2]*, M. S. Bilgic*[2]*, K. M. Kir*[1]*;*
[1]*Ankara University School of Medicine Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara University School of Medicine Department of Radiology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** During transarterial radioembolization (TARE) planning, multi-compartmental dosimetry is now recommended by multiple studies and guidelines, but the value of dose-volume histograms and dosimetry with Y-90 PET/MRI has yet to be determined. In this study we aimed to show feasibility of using integrated PET/MRI for an accurate voxel-based dosimetry. ***Materials and Methods:*** Patients who were treated with Y-90 glass microspheres and imaged with Y-90 PET/MRI between February 2021-May 2022 were retrospectively included in the study. Also, the patients who were treated after May 2022 included prospectively to this ambispective study. A total of 55 treatments of 46 patients were included in the study. For dosimetry, acquisition with respiratory gating enabled for most patients with 256 matrix, 1 iteration/16 subsets was employed. In a total of 245 perfused lesions, 165 lesions which could be delineated on pre-treatment PET were included in analysis. Individual average tumour doses(Davg) and dose-volume histograms were calculated. Response to treatment was evaluated with FDG or Ga-68-DOTATATE PET depending on histopathology. Response types were categorized as complete(CR), partial(PR), stable(SD) and progressive(PD). ***Results:*** Of the treatments 27 were for colorectal carcinoma, 12 for hepatocellular carcinoma and the remainder tumours were neuroendocrine, breast, cholangiocellular, pancreatic, thyroid carcinomas and uveal melanoma. Mean Davg values(in Gy) were calculated as 402.57, 201.29, 150.06 and 79.08 for CR, PR, SD and PD. Davg values for responder(CR+PR) lesions(mean:331.44/median:195.7) were significantly higher than non-responding(SD+PD) lesions(mean:96.82/median:79.90). Furthermore, for colorectal carcinoma Davg for responder lesions(mean:183.51/median:161.00) were significantly higher than non-responding(SD+PD) lesions(mean:88.12/median:69.50).

Additionally, CR lesions had significantly higher Davg compared to PR lesions. Also, for colorectal carcinoma lesions D70, D80, D90 and D99 were all significantly higher for responder lesions than non-responder lesions. Between CR and PR lesions D70 and D80 did not differ significantly but D90 and D99 were significantly higher in CR lesions compared to PR lesions. ROC analysis was performed for Davg, D70, D80, D90 and D99 values in colorectal responder and non-responder lesions. AUC for Davg, D70, D80, D90 and D99 were 0.814, 0.862, 0.867, 0.875 and 0.829. High specificity cut-offs were determined as 160.75, 96.50, 71.50, 42 and 29.50; for Davg, D70, D80, D90 and D99 respectively. ***Conclusion:*** In addition to average absorbed dose, D values from dose-volume histograms are also successful in predicting tumour response to TARE treatment. High resolution from PET/MRI with high soft tissue contrast of MRI may yield better registration and segmentation of tumours for Y-90 dosimetry.

## EPS-201

### Dose Distribution Pattern of Fractionally Administered Transarterial Radioembolization Holmium Microspheres in Non-Tumorous Human Liver Tissue

***A. van den Brekel***[1], *T. J. Snoeijink*[1], *J. Roosen*[1], *S. J. S. Ruiter*[2], *V. E. de Meijer*[2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of HPB Surgery and Liver Transplantation, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Transarterial radioembolization (TARE) is a local treatment modality for patients with hepatocellular carcinoma or liver metastases who are not eligible for curative-intent treatment. During TARE, radioactive microspheres containing a high energy beta emitter are injected into the hepatic artery via a microcatheter. High mean absorbed doses in the non-tumorous liver tissue are relatively well tolerated in TARE, which is hypothesized to be a result of a heterogeneous dose distribution in the non-tumorous liver tissue. This study investigated the dose distribution pattern in non-tumorous liver tissue after fractional administration of TARE microspheres using an experimental setup of ex situ perfused human livers, and compared this with patient data. ***Materials and Methods:*** TARE using non-neutron-activated holmium-165 loaded microspheres ($^{165}$Ho-MS) was performed during MRI in three discarded human donor livers under continuous dual hypothermic machine perfusion. Four fractions of 250 mg $^{165}$Ho-MS with different fluorescent dyes were administered centrally in the hepatic artery using a microcatheter. Holmium-sensitive MRI scans were obtained after each fraction, enabling MRI-based dosimetry using a fictional specific activity. Tissue samples were obtained for histopathological analyses with both conventional and fluorescence microscopy. These data were compared to MRI dose distribution patterns of three patients who underwent TARE with holmium microspheres administered in four fractions. ***Results:*** The MRI-based dose maps of the three TARE-treated perfused human livers and the three TARE-treated patients were comparable upon visual inspection, and revealed a heterogeneous dose distribution pattern of several hotspots throughout the non-tumorous liver tissue, where each new fraction of $^{165}$Ho-MS resulted in an increase of the already present hotspots. Histopathological analyses of the machine perfused human livers revealed accumulation of $^{165}$Ho-MS of one or more fractions in the larger arterioles and arteries. ***Conclusion:*** TARE holmium microspheres distribute heterogeneously in non-tumorous liver tissue, where the injection of multiple fractions of microspheres from the same catheter position generally does not result in a more homogenous dose distribution. This implies that part of the non-tumorous liver tissue remains unexposed to lethal doses of ionising radiation during TARE, even when increasing the amount of administered microspheres. Together with the regenerating ability of the liver, this may explain why a relatively high mean absorbed dose can be given to the liver during TARE without inducing liver failure. Future (dose-escalation) studies are needed to investigate the safety of increasing the mean absorbed dose in the non-tumorous liver tissue during TARE.

## EPS-202

### Can Circulating Angiogenic Factors Predict $^{90}$Y Microsphere Treatment Outcomes ?

***M. Mavi***[1], *B. Volkan Salancı*[2], *I. Lay*[3], *F. G. Eldem*[4], *B. Peynircioğlu*[4], *S. Yalçın*[5], *Ö. Uğur*[2], *M. F. Bozkurt*[2];
[1]*Karaman Training and Research Hopital Nuclear Medicine Department, Karaman, TÜRKIYE,* [2]*Hacettepe University Nuclear Medicine Department, Ankara, TÜRKIYE,* [3]*Hacettepe University Medical Biochemistry Department, Ankara, TÜRKIYE,* [4]*Hacettepe University Interventional Radiology Department, Ankara, TÜRKIYE,* [5]*Hacettepe University Medical Oncology Department, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Tumor angiogenesis plays a crucial role in cancer growth, invasion, and metastasis. Despite extensive research on the prognostic value of circulating angiogenic factors in transarterial chemoembolization, limited data are available on their relationship with $^{90}$Y microsphere treatment response. This study aimed to investigate whether circulating angiogenic factors could have an impact to predict Y-90 microsphere treatment outcomes. ***Materials and Methods:*** A total of 22 patients with primary or metastatic liver cancer were included in this study. Blood samples were collected at different time points (on the day before the treatment and days 1,7 and 30 after treatment), and the levels of various angiogenic factors were measured. The patients underwent anatomic (CT and/or MRI) and molecular ([$^{18}$F]FDG PET-CT) imaging to assess early treatment response and overall survival. Response in treated liver region, non-target and extrahepatic progression status were assessed with mRECIST and PERCIST criteria, along with clinical follow-up. ***Results:*** The patients with non-target progression had significantly lower levels of Ang-2 on Day 1 (p=0,019) and Day 7 (p=0,02), while patients with extrahepatic progression had significantly higher levels of osteopontin on Day 30 (p=0,041) . The change in Ang-2 levels from the day before treatment to Day 1 (p=0,029) and from Day 1 to Day 30 (p=0,041), as well as the change in PDGF-BB levels from the day before treatment to Day 1 (p=0,017), were significantly different between patients with and without non-target progression. Patients with target (13,05±1,05 vs 8,15±0,94 months, p=0,028), non-target (14,38±0,66 vs 7,15±1,02 months, p<0,001), and extrahepatic (14,12±0,90 vs 8,49±1,01 months, p=0,012) progression had significantly shorter overall survival. ***Conclusion:*** This study suggests that serum Ang-2, PDGF-BB, and osteopontin levels, as well as the amount and trend of the change in levels after 90Y microsphere treatment, may have a predictive role in prognosis. Furthermore, early target, non-target, and extrahepatic progression after $^{90}$Y microsphere treatment strongly predict shorter survival for patients. This information may be useful in patient management by enabling closer follow-up and/or combining $^{90}$Y microsphere treatment with other possible treatments, such as antiangiogenic treatments, for these patients.

## EPS-203

### Improvement of minimally invasive parathyroidectomy through the introduction of radioguided surgical approach.

***A. Alomar***, *I. Blanco, I. Saura, J. Cruz, A. Barrera, P. Salvador, E. Anda, N. Rudic, F. Lozada, M. Ribelles, A. Camarero, E. Goñi;*
*Hospital Universitario de Navarra (HUN), Pamplona, SPAIN.*

***Aim/Introduction:*** To demonstrate if the implementation of radioguided surgical procedure improves the conventional minimally invasive parathyroidectomy technique. ***Materials and Methods:*** A prospective study was carried out consecutively including 129 minimally invasive radioguided parathyroidectomy (MIRP) procedures between February 2020 and December 2022. This group was compared with 129 selective parathyroidectomy procedures prior to the introduction of radioguided surgery between March 2017 and January 2020. All the surgeries (258) were conducted at the same tertiary center on 254 patients with surgical indication of primary hyperparathyroidism. All of them underwent preoperative morphofunctional confirmation with US and Scintigraphy ± PET-CT. The MIRP group included 112(86.8%) MIBI procedures (i.v. injection of 185MBq of 99mTc-Sestamibi) 60min before surgery and 17(13.2%) MAA procedures (US-guided lesion injection of 18,5MBq of 99mTc-Macroaggregates) 6h before surgery. The intraoperative localization was accomplished with a portable gamma camera and gamma probe. Surgical success was evaluated through intraoperative biopsy. Criterion for cure was based on normal calcemia at 6 months. ***Results:*** The mean age was 61.5±11.7 with 101(78.2%) women in the MIRP group and 60.4±14.1y/o with 103(79.8%) women in the non-radioguided group. No significant differences (p>0.05) were found between the two groups in terms of preoperative calcemia, sex, age, BMI, excised gland weight, preoperative location of the pathological gland on MIBI and US or neck surgical history. The success rate in the surgical localization of the parathyroid glands was identical in both groups; 126(97.7%). Cure rate was slightly higher in the MIRP group [125(97.7%) vs. 120(93.7%), p=0.108 - one patient was lost to follow-up]. However, MIRP provides a significant reduction in surgical time (45min vs. 55min, p=0.005) with lower requirement for initial incision enlargement [4(3.2%) vs. 15(11.6%), p=0.008] and lower percentage of post-surgical complications [8(6.2%) vs. 20(15.5%), p=0.013]. In addition, a greater number of ectopic glands were removed in MIRP [30(23.2%) vs. 14(10.8%), p=0.008]. ***Conclusion:*** Radioguided surgery significantly reduced surgical time as well as the rate of initial incision enlargement with fewer surgical complications and a higher efficacy in the excision of ectopic glands. These benefits without compromising the high success and cure rate of the conventional minimally invasive parathyroidectomy. Moreover, the high percentage of localization and the ex vivo confirmation of radiotracer uptake in the excised gland may obviate the need for intraoperative pathological confirmation, leading to shorter surgical times.

## EPS-204

### $^{188}$Re-N-DEDC lipiodol trans-arterial radionuclide therapy (TART) in HCC patients: Modification in lung Shunt fraction (LSF) criteria and clinical implication on therapeutic dose estimation using scout dose of $^{188}$Re-N DEDC lipiodol

***N. Kumar***, *P. Gupta, S. A. Shamim, S. Gamanagatti, S. Shalimar, C. Bal;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Accurate hepatopulmonary shunt assessment, typically performed by planar scintigraphy, is critical in dose planning and delivery of $^{188}$Re-N-DEDC lipiodol TART. High lung shunt fractions (LSFs) may alter treatment and may induce pulmonary toxicity if radiation absorbed dose to lungs >30Gy. Thus, this study is aimed to modify the LSFs calculation criteria and to describe the potential clinical implications on therapeutic dose estimation based on partition model using transarterial injection of scout dose of $^{188}$Re-N-DEDC lipiodol. ***Materials and Methods:*** The study included 20 patients (18 male; 2 female; mean age, 54 ±11 years) who underwent 5mCi scout $^{188}$Re-N-DEDC lipiodol injected in each tumor artery. The planar and SPECT/CT scintigraphy was performed for artery mapping, LSF calculation and therapy dose planning. LSF using planar imaging (PLSF) was compared with LSF using SPECT/CT (SLSF) via automatically generated volumetric ROIs on Interview fusion imaging software around the lungs and liver with subsequent manual adjustments. The partition model was used to calculate the therapeutic activity to be injected transarterially in super selective artery of tumor. The LSFs values derived from planar and SPECT/CT data were compared using paired-t test. ***Results:*** Of 20 patients, 7 patients had Barcelona Clinic Liver Cancer-stage B (BCLC-B), while 13 had BCLC-C staging. Thirteen out of 20 patients had Child Pugh score A, while 7 had Child Pugh score B. Mean PLSF, 23.2±5.28%, was greater than mean SLSF, 7.4±4.06% ($p < 0.001$). In BCLC-C HCC patients, SLSF is significantly lower compared to PLSF, with a greater discrepancy among patients with a PLSF ≥ 10%, tumor size ≥ 8 cm, and child Pugh score B.None of patient had PLSF <10%, 5/20 patients had %PLSF between 10-20% and remained had >20% PLSF. All except 3 of 20 patients had SPECT/CT LSF was >15% and remained have qualified for standard radionuclide therapy as the estimated absorbed dose to lung was <20Gy in all patients when desired dose to tumor was kept >200Gy on calculated with partition model. ***Conclusion:*** LSF calculation is a subjective criteria, thus appropriate method must be used. The estimated absorbed dose to lung, liver and tumor also varies with LSF calculation and dosimetry method used. SPECT/CT should now be considered for clinical LSF calculations prior TART in HCC patients.

## EPS-205

### A controlled administration device for MRI-guided holmium-166 transarterial radioembolisation: MR-safe and fractional microsphere administration

***M. W. M. van Wijk***[1], *G. van Wolfswinkel*[2], *J. Roosen*[1], *M. J. Arntz*[1], *M. J. R. Janssen*[1], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud university medical center, Nijmegen, NETHERLANDS,* [2]*R&D TIO, Quirem Medical B.V. - a Terumo company, Deventer, NETHERLANDS.*

***Aim/Introduction:*** Transarterial radioembolisation (TARE) is a treatment modality for palliative treatment of liver tumours. Current results from clinical trials show no added overall survival of TARE compared to or combined with systemic therapies, but clinical studies demonstrated the added value of reaching a high tumour dose to the overall and progression free survival of patients [1,2]. Dosimetry is therefore often stated as an important element of optimizing TARE, however, current clinical implementation is limited. Holmium-166 ($^{166}$Ho) microspheres facilitate quick, high resolution MRI-based dosimetry. This is currently used as an evaluation measure, however, it could also be used for intraprocedural dosimetry to optimize tumour and healthy liver dose to improve treatment outcome. MRI-guided

TARE requires accurate, controlled microsphere administration, which is not possible with the current administration systems used for TARE. Therefore, a controlled administration device (CAD) was developed and the safety and feasibility of using this device for fractional administration during MRI-guided TARE was investigated. ***Materials and Methods:*** The CAD system is an MR-safe device containing a rotating syringe to keep the microspheres in a homogeneous suspension, a control unit to set rotational speed and a battery pack for the power supply. The CAD was firstly tested ex-vivo, to determine the optimal settings for microsphere suspension homogenization, MR-safety and administration accuracy. After ex-vivo testing a clinical study (CONTROL) was performed to validate the use of the device in-vivo in an MRI-guided setting. Included patients got a holmium-scout procedure as normally performed to determine administration positions and lung shunt. During the treatment procedure, fluoroscopy was used to place the catheter, after which the patients were transferred to an adjacent 3T MRI system. Patients were positioned in the MRI and $^{166}$Ho microspheres were administered in five fractions. After each fraction a multigradient echo was acquired for MRI-based dosimetry. MRI-based activity maps were used to validate the activity administration in-vivo. ***Results:*** Ex vivo validation of the CAD resulted in accurate, equally concentrated administration fractions of a total dose divided in 10 fractions. Preliminary results of three CONTROL study patients show no device or procedure related (S)AE's. The total activity on the MRI-based activity maps increases consistently with every fraction administered by the CAD. ***Conclusion:*** Preliminary results of in-vivo validation show a good usability of the new controlled administration device which enables MRI-guided TARE with personalized dose administration in a future clinical study (expected to start in June 2023). ***References:*** 1. 10.1148/radiol.2020191606

### NOBLE (Nobody Left Behind) Registry: Initial Experience of [$^{99m}$Tc]Tc-HYNICiPSMA Imaging in the Detection of Prostate Cancer

***S. Martina***[1], *P. Tually*[2], *V. Garcia Quinto*[3], *Y. Omar*[4], *R. Yudistiro*[5], *M. Sathekge*[6], *G. Currie*[7], *P. Galette*[1], *N. Patel*[1], *T. Brown*[1], *G. Bolland*[8], *R. Lo bue*[8], *C. Hayward*[1];
[1]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [2]*TeleMed Nuclear Imaging, Kalgoorlee, AUSTRALIA,* [3]*Hospital Galenia, Cancun, MEXICO,* [4]*Misr Rediology Center, Cairo, EGYPT,* [5]*Siloam International Hospitals, Tangerang, INDONESIA,* [6]*University of Pretoria, Pretoria, SOUTH AFRICA,* [7]*Charles Sturt Univeristy, Wagga Wagga, AUSTRALIA,* [8]*Oncidium Foundation, Brussels, BELGIUM.*

***Aim/Introduction:*** [$^{68}$Ga]Ga-PSMA-11 PET/CT has emerged as the standard of care for prostate cancer (PC) imaging; however, accessibility to PET/CT can be limited by socioeconomic status, geographic factors, or health care structure and funding models. A PSMA-targeted tracer labelled with $^{99m}$technetium ($^{99m}$Tc) that has a long half-life, is more abundant than PET/CT tracers, and could be used with SPECT may have substantial global health benefits. We present preliminary results from a global registry that aims to collect [$^{99m}$Tc]TcHYNIC-iPSMA SPECT images and patient-associated relevant clinical data. The primary and secondary objectives, respectively, are to assess the safety and tolerability of [$^{99m}$Tc]Tc-HYNIC-iPSMA administration and determine the clinical relevance of [$^{99m}$Tc]Tc-HYNIC-iPSMA SPECT in detecting disease at different stages of PC. ***Materials and Methods:*** This is a prospective, observational, multicenter registry; 100 patients with prostate cancer between 18 and 80 years old will be enrolled. Patients receive [$^{99m}$Tc]Tc-HYNIC-iPSMA intravenously prior to imaging (suggested dose for 70-kg patient is 555-740 MBq (1520 mCi) and 50 µg of HYNIC-iPSMA). Patient data are to be analyzed descriptively. An interim analysis is planned when data from 40 patients is collected. ***Results:*** As of abstract submission date, 40 patients have been enrolled in 6 countries (Australia, Azerbaijan, Egypt, Indonesia, South Africa, Mexico) and have received [$^{99m}$Tc]TcHYNICiPSMA tracer administration followed by planar and SPECT imaging. Preliminary data on patients are reported here. Demographics and disease information were collected prior to enrollment: age (mean 69 y), race (27 Caucasian, 4 Latino, 6 Asian, 2 Black/African American, 1 American Indian), rationale for [$^{99m}$Tc]Tc-HYNIC-iPSMA imaging (involving several indications including initial clinical staging, restaging of disease, therapy response assessment, biochemical recurrence) and PSA (average per indication at enrollment; initial clinical staging 67 ng/mL, restaging of disease 54 ng/mL, BCR 256 ng/mL, therapy response assessment 23 ng/mL). In 40% of subjects, a change in treatment due to the [$^{99m}$Tc]Tc-HYNIC-iPSMA imaging was reported . No adverse events have been reported. This study is still enrolling, and an interim analysis is underway. ***Conclusion:*** [$^{99m}$Tc]Tc-HYNIC-iPSMA is promising to identify PSMA-positive PC on SPECT and could enable improved patient access to PSMA imaging worldwide.Disclosure: The sites are sponsoring the registry, through the Principal Investigator/s, who are responsible for the initiation and conduct of the Registry. Telix is providing IP and, with Oncidium Foundation, providing clinical and operational support. Virginie Kinet and Carolina Mena (Telix Pharmaceuticals) provided operational/project management and editorial support.

## EPS-207

### BPH-related False Positive of [$^{68}$Ga]Ga-PSMA PET/CT in the Diagnosis of Prostate Cancer: the Achilles' Heel of Biopsy-free Radical Prostatectomy?

***Y. Tang***, *L. Xiao, J. Yang, J. Hou, B. Chen, S. Hu;*
*Xiangya Hospital Central South University, Changsha, CHINA.*

***Aim/Introduction:*** Radical prostatectomy (RP) is the primary treatment for localized clinically significant prostate cancer. Generally, its application is based on prior biopsy and pathological diagnosis. [$^{68}$Ga]Ga-PSMA PET/CT has been considered in recent years to be effective in biopsy-free RP. However, the expression of PSMA in benign prostatic hyperplasia (BPH) and its related positive reaction are crucial concerns for no biopsy strategy. Currently, no large-scale study has explored the BPH-related false positive of [$^{68}$Ga]Ga-PSMA PET/CT in the detection of prostate cancer. Furthermore, the influence of SUVmax and PI-RADS on biopsy-free RP is also poorly characterized. ***Materials and Methods:*** Patients who received mpMRI and [$^{68}$Ga]Ga-PSMA PET/CT because of clinical suspicion of prostate cancer based on elevated prostate-specific antigen or abnormal digital rectal examination, subsequently were confirmed to be BPH or prostate cancer by pathological examination after systematic/targeted biopsy or/and RP. The mpMRI images were evaluated in accordance with the PI-RADS v2.1 and score ≥ 3 was considered positive. The PET/CT images were interpreted using a five-point Likert scale and those with a score of 3-5 were categorized as positive. The SUVmax value and PI-RADS score of the dominant lesion was recorded. The highest SUVmax in the prostate gland was also collected for negative cases with low-level radiotracer uptake. The Spearman rank correlation analysis was performed to estimate the correlation between the SUVmax and ISUP grade

group. The receiver operating characteristic curve was generated for SUVmax values, from which the area under the curve (AUC) and the Youden index was calculated. Sensitivity and specificity were calculated based on the cutoffs. ***Results:*** 89 BPH and 94 prostate cancer patients were included. 27 of the 89 BPH cases were considered PET/CT-positive, and were regarded as BPH-related false positive (30.3%). SUVmax could effectively distinguish BPH and grade group 1 patients with an AUC of 0.8562, the optimal SUVmax cutoff value was 9.750 with a sensitivity of 64.71% and a specificity of 97.22%. Considering the importance of specificity in biopsy-free RP, the optimal SUVmax cutoff value with 100% specificity was 14.60, with a sensitivity of 41.18%. Notably, using stringent PET and PI-RADS scores criteria (both ≥ 4) could exclude all positive BPH patients. ***Conclusion:*** In summary, our results revealed, for the first time, the BPH-related false positive rate of [$^{68}$Ga]Ga-PSMA PET/CT in the primary diagnosis of prostate cancer. Using SUVmax values or stringent PET and PI-RADS scores in biopsy-free RP can effectively exclude positive BPH patients.

## EPS-208

### FDG-PET/CT for lymph node staging prior to radical cystectomy

***M. Markus***[1], *V. Pihl*[2], *F. Liedberg*[2], *E. Trägårdh*[1];
[1]*Clinical Physiology and Nuclear Medicine, Malmö, SWEDEN,* [2]*Department of Urology, Malmö, SWEDEN.*

***Aim/Introduction:*** $^{18}$F-Fluorodeoxyglucose positron emission combined with computed tomography (FDG-PET/CT) has been proposed to improve preoperative staging in patients with bladder cancer subjected to radical cystectomy (RC). Our aim was to assess the accuracy of FDG-PET/CT for lymph node staging ascertained at the multidisciplinary tumor board (MDT) compared to lymph node status in the surgical lymphadenectomy specimen obtained at RC, and to explore potential factors associated with false positive FDG-PET/CT results. ***Materials and Methods:*** Consecutive patients with bladder cancer undergoing RC with extended lymph node dissection between 2011 and 2019 without preoperative chemotherapy in a tertial referral cystectomy unit were included in the study. Sensitivity, specificity, positive and negative predictive values, and likelihood ratios were calculated. Potential factors investigated for association with false positive FDG-PET/CT were; bacteriuria within four weeks prior to FDG-PET/CT, Bacillus Calmette-Guerin (BCG) treatment within 12 months prior to FDG-PET/CT and transurethral resection of bladder tumor (TURB) within four weeks prior to FDG-PET/CT. ***Results:*** Among 159 patients included for analysis, 46 (29%) were clinically node positive according to FDG-PET/CT. The sensitivity and specificity for detection of lymph node metastasis were 50% and 82%, respectively, and the corresponding positive predictive and negative predictive values were 59% and 76%. Positive and negative likelihood ratios were 2.8 and 0.6, respectively. No association were found between bacteriuria, previous BCG treatment or TURB within 28 days and false positive FDG-PET/CT results. ***Conclusion:*** Preoperative FDG-PET/CT prior to RC had a clinically meaningful high specificity (82%) but lower sensitivity (50%) for detection of lymph node metastases compared to lymph node status in an extended pelvic lymphadenectomy template. We could not identify any factors associated with false positive FDG-PET/CT outcomes.

## EPS-209

### One-day dual-tracer PET/CT protocol with [68Ga]-DOTA-FAPI-04 for negative orequivocal [18F]FDG

***H. Li****, Z. Xiao, C. Li, Y. Tian, N. Lu, J. Chen, D. Xing, Y. He;*
*Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** [68Ga]-FAPI is a tumor-stromal imaging agent that has shown complementary values to [18F]FDG in cancer imaging. We aimed to investigate the feasibility of a One-day dual-tracer PET/CT protocol with [68Ga]-DOTA-FAPI-04 following [18F]-FDG-PET/CT in patients presenting with negative or equivocal [18F]FDG. ***Materials and Methods:*** [68Ga]-DOTA-FAPI-04 was injected following the [18F]-FDG-PET/CT in patients presenting with negative or equivocal [18F]FDG on the same day (The interval between injection of the two tracers was 4-8 hours). The maximum tracer concentration (TCmax) of lesions (Bq/mL) was measured. The tumor-to-blood ratio (TBR), tumor-to-liver ratio (TLR), and tumor-to-cerebellum (TCR) were recorded and compared between the two imaging modalities. The standard for the final diagnosis was histopathologic findings and/or follow-up imaging (at least 3 months). ***Results:*** We prospectively recruited 15 patients (11 males and 4 females, mean age 55.7 ± 13.8). Of them, 5 (33.3%) for detection of the unknown primary site in biopsy-proven or conventional imaging highly suspected of metastatic malignancy with negative [18F]-FDG-PET/CT, 3 (20.0%) for the initial staging, and the other 7 (46.7%) for postoperative recurrence and metastasis detection. The TBR, TLR, and TCR of dual-tracer were significantly higher than those of [18F]FDG for detecting primary lesions and postoperative recurrence (TBR:10.0 vs. 2.8, P=0.006; TLR: 11.8 vs. 2.3, P=0.027; TCR: 8.4 vs.0.89, P=0.013), lymph node (TBR:12.2 vs. 6.9, P=0.042; TLR: 9.7 vs. 5.2, P=0.025; TCR: 4.9 vs. 1.9, P=0.008), and peritoneal metastases (TBR:6.2 vs. 2.0, P=0.012; TLR: 6.0 vs. 1.7, P=0.026; TCR: 4.8 vs. 0.7, P=0.005) in dual-tracer PET/CT than did [18F]FDG. In addition, dual-tracer PET/CT detected the primary site in 2/5 patients (40%) with unknown malignancy. Two patients (2/5) were eventually diagnosed with multiple myeloma or primary peritoneal carcinoma, respectively. Besides, dual-tracer PET/CT upgraded tumor staging in 1/3 of patients (33.3%) and detected more disease recurrence and metastatic lesions in 4/7 patients (57.1%). ***Conclusion:*** Dual-tracer PET/CT showed great potential for detecting primary tumors, postoperative recurrence and metastasis in patients with negative or equivocal for [18F]FDG findings. We will recruit a larger number of participants to further confirms our conclusion in the future.

## Technologists Oral Presentations 3: NM Technologists: Competencies and Training

## OP-659

### Technologists´ interests and barriers toward healthcare research.

***C. H. Led***[1], *C. Baun*[1,2], *M. G. Hildebrandt*[1,2];
[1]*Department of Nuclear Medicine, Odense C, DENMARK,* [2]*Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.*

***Aim/Introduction:*** Clinical and preclinical research is a growing field in healthcare organizations. In the field of nuclear medicine, clinical research is often performed by nuclear medicine physicians or academia. Although technologists often have the primary contact to patients participating in clinical studies, their

role and voice is less defined. This study aims to gather knowledge of the technologists' interests and attitudes toward clinical and preclinical research. Furthermore, to identify incentives and barriers for technicians to participate in research projects. ***Materials and Methods:*** An electronic survey (SurveyXact, Rambøll) was carried out, in October 2022, at the Department of Nuclear Medicine, Odense University Hospital. The questionnaire was developed iteratively by a collaborative team comprising two nuclear medicine technologists and one senior nuclear medicine physician. The questionnaire underwent several pilot tests before the primary survey. The final digital questionnaire included 21 questions (19 forced multiple choice and two open-ended questions) and took approximately 10 minutes to complete. The survey was divided into five main sections; 1) Descriptive background, 2) General interest and visibility of research projects, 3) Interest in a collaborative role in research, and 4) interest in performing own projects. 5) Barriers and suggestions for improvements. The survey was shared by email, with a 14-day response time. After seven days, a reminder email was sent. ***Results:*** 1) Forty-one (76%) technologists completed the survey, of whom 24 (53%) had been employed at the department for >10 years. 2) All responders (100%) found clinical research interesting in general, but 38 (90%) reported that the information level about the ongoing and new projects in the department was insufficient. 3) Twenty-two (52%) of the respondents would like to take a collaborative role in a clinical research project, whereas only 10 (24%) were interested in preclinical projects. 4) Seventeen responders (41%) would like to perform their own research and quality assurance projects. 5) Twenty-six (62%) believe that a dedicated contact person for the technologist group would be beneficial. Finally, twenty-nine (71%) responders listed uncertainty about time, payment, and the priority of clinical tasks were potential barriers. ***Conclusion:*** Based on the results, we conclude that the technologist group in our department has a considerable interest in healthcare research in general. Furthermore, a dedicated subgroup of technicians would like to participate in collaborative- and own research projects. Improvements in visibility, information, and clear, practical framework are needed to ensure that research for technologists becomes more easily accessible.

## OP-660

### Framework for Online Radiographer Clinical Education (FORCE): results of students' evaluation of the Nuclear Medicine strand

***P. Costa***[1], *J. Lemos*[1], *R. Strudwick*[2], *P. Bezzina*[3], *N. Dalen*[4], *J. T. Huhtanen*[5], *M. Jaronen*[6], *T. Saila*[6], *C. Kamp*[7], *L. Rainford*[8], *K. Matthews*[8];
[1]*Nuclear Medicine Department, School of Health - Polytechnic Institute of Porto (ESS|P.Porto), Porto, PORTUGAL,* [2]*School of Health and Sports Sciences - University of Suffolk, Suffolk, UNITED KINGDOM,* [3]*Faculty of Health Sciences - University of Malt, Msida, MALTA,* [4]*Department of Health and Functioning - Western Norway University of Applied Sciences, Bergen, NORWAY,* [5]*Health and Well-being, Rehabilitation, Oral Health Care and Diagnostic Services - Turku University of Applied Sciences, Turku, FINLAND,* [6]*Social Services and Health Care - Tampere University of Applied Sciences, Tampere, FINLAND,* [7]*University of Applied Sciences FH Campus Wien, Wien, AUSTRIA,* [8]*School of Medicine - University College Dublin, Dublin, IRELAND.*

***Aim/Introduction:*** The FORCE project is focused on the use of simulation in education and in such context it is being developed a set of virtual web-based learning resources where Radiography undergraduates can engage in interactive, problem-based development of knowledge, ability and professional awareness within the fields of Nuclear Medicine, Radiology and Radiotherapy. The project was already presented and disseminated in scientific events as well as with academic partners and professional associations and societies. The aim of this novel presentation is to present the current development of the project and to share feedback from students that already tested the first complete case of the specific strand of Nuclear Medicine. ***Materials and Methods:*** An original online questionnaire, based on SurveyMonkey, was developed and face-validity together with pilot tests were implemented to validate such data collection tool. A total of 36 students of the third year of a Medical Imaging and Radiotherapy degree course answered the questionnaire. ***Results:*** The complete simulation case is focused on a patient with an high-risk Prostate Carcinoma that was sent to the Nuclear Medicine Department with a referral for Bone Scintigraphy. Students revealed that time spent to explore the whole case was between 30 minutes and 2 hours (86%, n=31), and the majority of students considered the case as clear in terms of learning objectives and content (94%, n=34 and 92%, n=33, respectively). Global results showed that majority of students (86%, n=31) agree or strongly agree with the idea that studying these cases will improve their clinical learning. Other specific results related with the case structure and content, questions and interactivity, technical e-learning and navigation, multimedia, overall experience, and strengths/weaknesses analysis will be shared. ***Conclusion:*** The presentation will summarise the development process to date and provide a complete presentation of the case here evaluated together with global feedback from students already obtained. These results allowed the validation of the evaluation questionnaire, the collection of data related with students' feedback about the case and revealed very good acceptance of the learning resources that are being developed along this project.

## OP-661

### The evolution of our PSMA PET imaging service

***L. Thomas***;
*St Vincent's Hospital Melbourne, Melbourne, AUSTRALIA.*

***Aim/Introduction:*** Over the past 7 years of our Prostate PET/CT service we have evolved the scanning procedure to be what it is today. ***Materials and Methods:*** We are a single PET/CT scanner department in a tertiary public hospital in Melbourne, Australia. The small size of our hotlab and having no radiopharmacist onsite does not allow us to have a Gallium generator, so we had to source our own supply externally. We were only able to source Gallium once a week and then we had to pick either PSMA or DOTATATE for that run (only 1-3 patient doses). In 2017 we jumped at the opportunity to utilise 18F-DCFPyL as our Prostate PET/CT imaging agent of choice. After starting to scan with 18F-DCFPyL we made quite a few protocol variations with our physicians and referrers. To start with, we performed dual time point half body scans at 1 and 2 hours. Then we moved to a half body scan at 1 hour and Modified CT IVP with 2 PET pelvis beds at 2 hours - logistically this was very hard to schedule. Finally we have settled on a protocol where we hand inject 50 mls of CT contrast and then get the patient walking around for 20 minutes. ***Results:*** Our current protocol has saved patients the extra CT dose along with significant scanner time, resulting in the ability to increase patient numbers. This protocol not only helps us to differentiate between ureters and lymph nodes but also bladder and recurrence in the prostate bed. ***Conclusion:*** Our current Prostate PET/CT protocol with ureteric contrast enhancement produces excellent

diagnostic PET/CT images along with efficient use of our limited scanner time. ***References:*** • Szabó, Z. et al. ## OP-662

### Comparison of calculated Left Ventricular Ejection Fraction (LVEF) from F-18 FDG dual-gated PET/CT, single-gated PET/MRI, and cardiac MRI

***P. Toompong***, *A. Jantarato, D. Siripongsatian, P. Panperee, C. Promteangtrong, A. Kunawudh, P. Kiatkittikul, P. Lerdsirisuk, S. Sombon, C. Chotipsnich;*
*National Cyclotron and PET Centre, Bangkok, THAILAND.*

***Aim/Introduction:*** Left Ventricular Ejection Fraction (LVEF) is a critical parameter in evaluating cardiac function and guiding treatment decisions in breast cancer patients undergoing chemotherapy. Positron Emission Tomography (PET) with F-18-FDG uptake has emerged as a promising alternative to Multi-Gated Acquisition (MUGA) scan. This study aims to compare LVEF assessment using PET/CT, PET/MRI, and Cardiac Magnetic Resonance Imaging (MRI) as the gold standard. ***Materials and Methods:*** Ten breast cancer patients meeting inclusion criteria fasted for 12 hours before undergoing a glucose load of 60 mg and an injection of 18F-FDG. The uptake time was 60 minutes, after which patients underwent PET/CT using three different reconstruction techniques: Dual gating with Electro Cardiac Gated (ECG) and Respiratory gated (Dual Gated), Dual gated with AI-assisted list mode respiratory compensated PET/CT (List mode Dual gating PET/CT), and Single-gated (ECG) PET/CT. Additionally, the single-gated PET/MRI and cardiac MRI were performed for data collection on end-diastolic volume (ED), end-systolic volume (ES), and ejection fraction (EF). Statistical analysis was conducted using Stata, with $p < 0.05$ as statistically significant. ***Results:*** Statistical analysis revealed no significant difference in EF among cardiac MRI, dual-gated PET/CT, list mode PET/CT, single-gated PET/CT, and single-gated PET/MRI (F-ratio = 1.4273, $p = 0.240436$, $p < 0.05$). Dual-gated PET/CT showed the lowest average percentage difference when compared to cardiac MRI (6.45%). ED and ES showed no significant difference among PET-based methods ($p < 0.05$). However, MRI-based methods had significant differences in ED and ES when compared to all PET-based methods, with consistent percentage differences ranging from -37.64% to -39.38% for ED and -43.68% to -45.32% for ES. Intraclass correlation showed moderate to good reliability, and Pearson correlation coefficients indicated good to strong correlations between cardiac MRI and PET MRI-based methods, as well as among PET-based methods. ***Conclusion:*** PET-based methods may offer comparable results to MRI cardiac-based methods for the evaluation of LVEF in breast cancer patients undergoing chemotherapy. Utilizing PET-based methods may offer advantages in terms of convenience, accessibility, and cost-effectiveness, as a promising alternative for assessing LVEF in this population. ***References:*** Li Y, Wang L, Zhao S-H, et al. Gated F-18 FDG PET for Assessment of Left Ventricular Volumes and Ejection Fraction Using QGS and 4D-MSPECT in Patients with Heart Failure: A Comparison with Cardiac MRI. Lipinski M, ed. PLoS ONE. 2014;9(1):e80227. doi:10.1371/journal.pone.0080227

## OP-663

***A. Resende Geao***, *A. Santos, P. Colarinha;*
*Hospital Cuf Descobertas, Lisboa, PORTUGAL.*

***Aim/Introduction:*** 68Ga -PSMA (Prostate-Specific Membrane Antigen) is currently a tool with high clinical application in prostate cancer. In 2023, EANM provided updated guidance and standards of 68Ga-PSMA for prostate cancer imaging. In addition to the guideline recommendations in the available literature can be seen the clinical impact of acquiring an initial dynamic study. The aim of this project is to present the evolution of the technique of acquisition of the dynamic study in a nuclear medicine department. ***Materials and Methods:*** The NM department started to perform 68Ga-PSMA studies since 2018 and many changes have been implemented in the procedure. The timing of the injection and the applied technique has been changing throughout the years. Table 1 summarizes the major modifications implemented in technologists practice.The implementation of the dynamic study in these studies has several challenges, including defining the best technique for injection and determining the optimal image acquisition timing. One challenge is the timing of the injection of the radiopharmaceutical. Injection too early may result in incomplete uptake of the radiopharmaceutical in the tumor and surrounding tissues, while injection too late may result in excessive urinary excretion of the radiopharmaceutical, leading to reduced tumor-to-background contrast. Therefore, it is important to find the optimal time for injection. ***Results:*** The impact of protocol customization on the clinic can be significant, leading to improved imaging results, patient experience, and clinical efficiency. The dynamic study offers several advantages in the visualization of prostate cancer. The early images acquired during the dynamic study can provide information about the initial uptake and clearance of the radiopharmaceutical, allowing for improved visualization of the pelvic area and accurate staging of the disease. It is important for the multidisciplinary team to continually review and adapt protocols to meet the specific needs of patients and equipment, ensuring that the best possible outcomes are achieved for each individual case. ***Conclusion:*** The implementation in routine of the acquisition of a dynamic study in 68Ga-PSMA studies lead to the challenge of defining the best technique for injection of the radiopharmaceutical and image acquisition timing. Advantages and disadvantages can be found however, the advantages of early imaging and improved visualization of the pelvic area make it a valuable tool for diagnosis and management of prostate cancer. ***References:*** Fendler WP, Eiber M, Beheshti M, et al. PSMA PET/CT: joint EANM procedure guideline/SNMMI procedure standard for prostate cancer imaging 2.0. Eur J Nucl Med Mol Imaging. 2023;50(5):1466-1486.

## OP-664

### Short and long-term outcomes prediction using baseline FDG PET imaging in mCRPC patients treated with $^{177}$Lu-PSMA radioligand therapy

***Q. Shagera***, *C. Broeckaert, T. Guiot, E. Barraco, S. Albeaini, L. Taraji, I. Karfis, P. Flamen, C. Artigas;*
*Jules Bordet Institute, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.*

***Aim/Introduction:*** Optimal selection of patients for radionuclide therapy is essential to obtain the expected results. Regarding $^{177}$Lu-PSMA radioligand therapy (PSMA-RLT), it has been proposed to use the so-called dual tracer imaging approach, combining both the analysis of the target expression (PSMA-PET) together with the metabolic activity (FDG-PET). Those patients with mismatching lesions (FDG+/PSMA-) are not to be selected for

PSMA-RLT due to its poor outcome. On the other hand, patients without mismatch but with metabolically active metastatic lesions (FDG+/PSMA+) are still accepted for PSMA-RLT. Therefore, we aimed to evaluate the relationship between baseline FDG-PET imaging characteristics with short-term (PSA response and progression-free survival) and long-term outcomes (OS) in metastatic castration-resistant prostate cancer (mCRPC) patients treated with $^{177}$Lu-PSMA-RLT. ***Materials and Methods:*** For this retrospective analysis, patients with dual tracer imaging (FDG-PET and PSMA-PET) performed within 8 weeks before $^{177}$Lu-PSMA-RLT initiation were included. For each scan, all lesions were contoured using SUV=3 threshold for PSMA and liver SUVmean+2SD for FDG-PET. Quantitative parameters were measured, including the highest SUV (SUVmax), the total tumor volume (Vol), and the ratio FDG/PSMA-TV. Patient outcomes were calculated, including PSA response (decline of 50%) after 2 cycles, PSA-PFS (PCWG3 criteria), and overall survival (OS). The Mann-Whitney test was used to assess the association between baseline parameters and PSA response. The Cox regression model and Kaplan-Meier method were used for survival analysis. ***Results:*** A total of 87 patients were analyzed. 30 patients (34%) died, and 58 (67%) presented disease progression. The FDG-SUVmax, FDG-Vol, and FDG/PSMA-Vol ratio were significantly associated with PSA response (p=0.037, p=0.019, and p=0.001, respectively). PSA response was significantly associated with OS (HR 5.2, p=0.003). Regarding PFS, FDG-SUVmax and FDG/PSMA-Vol ratio presented significant associations (HR 1.06, p=0.006; and HR 2.6, p=0.001, respectively). For OS, FDG-SUVmax, FDG-Vol, and FDG/PSMA-Vol ratio (HR 1.09, p=0.004; HR 1.001, p=0.027 and HR 2.9, p=0.011, respectively). ***Conclusion:*** Our study findings show that baseline FDG-PET quantitative parameters may be used as factors predicting short- and long-term outcomes of patients with mCRPC treated with $^{177}$Lu-PSMA-RLT. Those patients presenting with high glycolytic activity and high metabolic tumor volume compared to PSMA tumor volume are associated with lower response rates and shorter PFS and OS.

## OP-665

### Comparison of non-specific bone uptake of [$^{18}$F]AIF-PSMA-11 in prostate cancer patients acquired at different time intervals.

***I. Cordero***[1,2], *K. Suanes*[1,2], *P. Duarte*[1], *O. Alonso*[1,2];
[1]*Centro Uruguayo de Imagenología Molecular, Montevideo, URUGUAY,* [2]*Unidad Académica de Medicina Nuclear e Imagenología Molecular, Facultad de Medicina, Universidad de la República, Montevideo, URUGUAY.*

***Aim/Introduction:*** Among many $^{18}$F-labeled prostate-specific-membrane-antigen (PSMA) targeted PET/CT tracers, the novel [$^{18}$F]AIF-PSMA-11 produced in our center has demonstrated to be a good alternative for the diagnostic evaluation of prostate cancer (PCa). However, the limited time-dependent in vitro stability and consequently non-specific bone tracer uptake might hamper the visualization of small PCa bone metastases.To compare bone uptake of [$^{18}$F]AIF-PSMA-11 in different regions of interest at 30 minutes and 60 minutes post-administration of the radiotracer. ***Materials and Methods:*** From March 2018 to July 2021, 233 patients (median age: 68 years, range 49-89; median PSA: 24.2 ng/mL, range 0.11-834) at initial staging (21%) or with biochemical recurrence (79%) underwent $^{18}$F-ALF-PSMA-11 PET/CT after the i.v. administration of 4.0 MBq/kg.Studies were performed with a 64-slice PET/CT scan with TOF correction and acquired at 60 minutes or at 30 minutes after injection (Group A and B, respectively).We measured the maximum SUV (SUVmax) and the SUVmax ratio (SR), defined as SUVmax bone/SUVmax background) in the following sites: shoulders, sternoclavicular joints, L5 and sacroiliac joints, in both groups. We selected femoral diaphysis as background. T-test for independent samples was performed using a significance level of 5%. ***Results:*** Abnormal foci were seen in the following sites: prostate gland (n=130), lymph nodes (n=68) and bone (n=74). We found a significantly higher SUVmax for group A (60 min) compared to Group B (30 min), in all studied regions as follows: SR Shoulders 60 vs 30 min: 1.77 (0.5 - 5.8) and 0.98 (0.38 - 2.5), median (range), for each group, respectively (P=0.000042).SR Sternoclavicular joints: 1.7 (0.7 - 3.5) and 1,28 (0, 56-2,8), for each group, respectively (P=0.000716). SR L5: 2.16 (0.4 - 4.0) and 1.72 (0.75 - 4.4), P=0.00002; SR Sacroiliac joints: 1.8 (0.8-3.3) and 1.48 (0.48 - 3.48), for each group, respectively (P< .00001). ***Conclusion:*** [$^{18}$F]AIF-PSMA-11 is a promising imaging technique for the evaluation of PC patients.However, it has demonstrated a time-dependent increase of radiotracer uptake in bone that may influence the accuracy of lesion detection in the skeleton and difficult image interpretation.

## OP-666

### The relentless pursuit for the best compromise between image quality and dose reduction - a single center experience with pediatric patients undergoing 18F-FDG PET/CT with long axial field of view scanner

***A. Cardoso****, A. Mendes, C. Bregenzer, K. Krieger, H. Sari, K. Zeimpekis, N. Gözlügöl, A. Rominger, A. Afshar-Oromieh; Department of Nuclear Medicine, Inselspital, University Hospital Bern, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Children are particularly sensitive to radiation exposure. Besides a cautious indication for nuclear medicine diagnostics, efforts should be made to reduce the radiation dose. Currently, guidelines recommend a dose of 3.7-5.2 MBq $^{18}$F-FDG per kg body weight (BW). Recently, PET/CT-scanners with long axial field of view (LAFOV, also called "whole-body" scanners) have entered the market. They demonstrate a significantly improved performance compared to standard PET/CT-scanners. The aim of this evaluation was to assess the image quality of scans conducted with a whole-body PET/CT-scanner after injection of reduced doses of $^{18}$F-FDG in pediatric tumor patients. ***Materials and Methods:*** From October 2020 until March 2023 a total of 27 $^{18}$F-FDG-PET/CT scans were conducted in 21 children and adolescents (age limit 18 y/o) at our institute with a LAFOV-PET/CT-scanner (FOV: 105cm). Amongst them, three groups were identified depending on the injected activity: 1 MBq/kg, 2 MBq/kg and 3 MBq/kg. Acquisition started at 1h post injection and lasted for 10 minutes in all patients. In addition to the before-mentioned three groups, a fourth group was created simulating 0.5 MBq/kg BW by artificially reconstructing the images obtained with 1 with MBq/kg. The quality of all scans was assessed in a blinded read by the first and the last author using a 5-point Likert scale, with 5 being the best and 1 the worst quality. ***Results:*** Average age was 11.8 ± 5.6 years and average body weight 42.3 ± 22.1 kg. The Likert scales of the four groups were as follows: 2.7 **±** 0.6 for 0.5 MBq/kg (n=10 scans); 3.4 **±** 0.8 for 1 MBq/kg (n=10); 4.5 ± 0.4 for 2 MBq/kg (n=9) and 4.9 ± 0.2 for 3 MBq/kg (n=8). There was a significant association between higher doses and higher Likert scales: p=0.005 for the comparison between group 0.5 MBq/kg vs. group 1 MBq/kg, p=0.002 for the comparison between group 1 MBq/kg vs. group 2 MBq/kg and p=0.018 for the comparison between group 2 MBq/kg vs. group 3 MBq/kg. ***Conclusion:***

Although acquired with a lower dose than recommended by the guidelines, the image quality of scans conducted with 3 MBq/kg $^{18}$F-FDG and the whole-body PET/CT-scanner was outstanding. As expected, the image quality decreased significantly with lower doses. Our results indicate that scans with 0.5 MBq/kg might not be suitable with a 10-min acquisition duration since the quality was lower compared to the other doses.

## OP-667

### Measuring GFR Using $^{51}$Cr-EDTA: a Clinical Case Requiring Gamma Ray Spectra Analysis

***P. Geleijnse***, *S. Jentjens, K. Goffin, W. Deckers, K. Baete; Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM.*

***Aim/Introduction:*** Glomerular filtration rate (GFR) can be estimated from serum parameters, but in specific populations, such as children, or persons with obesity or cachexia, results are less accurate. For these populations, $^{51}$Cr-EDTA clearance from blood plasma can provide a more accurate GFR measurement. The clearance can be assessed using 4 blood samples, taken one hour apart after $^{51}$Cr-EDTA administration. The radioactivity in plasma samples, and reference samples derived from the administered activity concentration, can then be measured using a gamma counter (GC). The count rate measurements allow for a bi-exponential regression analysis of the data, estimation of the distribution volume and GFR computation using the Bröchner-Mortensen correction method. ***Materials and Methods:*** A 9-year-old girl was referred for GFR determination using $^{51}$Cr-EDTA after $^{131}$I-mIBG treatment for a stage 4 neuroblastoma. The paediatric oncologists requested an accurate GFR determination before starting chemotherapy 8 weeks after 2 cycles of $^{131}$I-mIBG therapy, and 4 weeks after the last treatment cycle. Naturally, a considerable amount of $^{131}$I radioactivity in plasma was suspected. In fact, the GC measurement procedure initially did not pursue inspection of the sample gamma ray spectra, besides the determination of the count rate. However, the low yield (9.9%) gamma rays of $^{51}$Cr (320 keV) are near the high (81.2%) and low (6.1%) yield gamma rays of $^{131}$I (364 and 284 keV, respectively). Moreover, factory GC energy window settings for $^{51}$Cr (198 - 360 keV) are influenced by $^{131}$I. Therefore, long-term GC measurements were performed, storing the gamma ray spectra for each sample. The spectra were corrected for background and a gaussian function was fitted to the 320 keV peak to determine its height and derive the $^{51}$Cr activity concentration. The 284 keV peak of $^{131}$I was ignored. ***Results:*** Initial sample count rate results showed very low plasma clearance and determined an unreliable GFR (28 ml/min/1.73m$^2$) due to significant influence of the $^{131}$I activity concentration in blood. Using physical decay and long-term GC measurements, a more accurate $^{51}$Cr activity concentration could be determined, leading to a more reliable GFR determination (65 ml/min/1.73m$^2$). Finally, a measurement of 18 hours per sample was performed 40 days after administration. ***Conclusion:*** This clinical case shows that it is possible to estimate the $^{51}$Cr activity concentration in blood samples, containing other radionuclides, using advanced gamma ray spectra analysis. It also revealed potential pitfalls when using count rate results without thorough inspection of the sample energy spectra.

## Theranostics Track - TROP Session: What's New in Neuroendocrine Tumors?

## OP-668

### Primary tumor resection followed by PRRT in the treatment of patients with metastatic neuroendocrine ileal cancer: preliminary data from a retrospective single center study.

***F. Mattana***[1], *G. A. Zuccotti*[1], *A. Barone*[1], *E. Pisa*[2], *N. Fazio*[3], *U. Fumagalli Romario*[4], *C. M. Grana*[1], *F. Ceci*[1,5], *E. Bertani*[4]; *[1]IEO European Institute of Oncology, Nuclear Medicine, Milano, ITALY, [2]IEO European Institute of Oncology, Pathology, Milano, ITALY, [3]IEO European Institute of Oncology, Division of Gastrointestinal Medical Oncology, Milano, ITALY, [4]IEO European Institute of Oncology, Division of Digestive Surgery, Milano, ITALY, [5]Department of Oncology and Hemato-Oncology, University of Milan, ITALY.*

***Aim/Introduction:*** A low volume disease is an independent positive prognostic factor for the evaluation of response to peptides-radiolabelled-receptor-therapy (PRRT). Data from a previous study[1] in patients with pancreatic-neuroendocrine-cancer (P-NET) showed that resection of the primary tumor before PRRT improves response to therapy and increases progression-free survival (PFS), namely in liver metastatic patients. Primary aim was to evaluate the PFS in two cohorts of patients (surgery + PRRT vs. PRRT alone) affected by ileal neuroendocrine neoplasm (ileum-NEN). Secondary aim was to evaluate the safety of this approach in clinical setting. ***Materials and Methods:*** this is a retrospective single-center study. Inclusion criteria were: 1) patients with histopathological diagnosis of G1-G2 ileum-NEN with synchronous liver metastasis; 2) not eligible for radical surgery; 3) eligible for PRRT. Exclusion criteria were: 1) not eligible for PRRT; 2)<18yo. Two match-comparison cohorts with a comparable total volume disease were identified: patients underwent resection of primary cancer followed by PRRT (group A) and patients underwent PRRT alone (group B). Progressive Disease (PD), Stable disease (SD) and Partial Response (PR) have been defined according clinical and radiological criteria (RECIST 1.1). PFS was evaluated in the two cohorts. ***Results:*** From 2000 to 2016 a total of 25 patients have been evaluated with an over-all median follow-up of 60 months (range 6-132 months). 13 patients were included in group A and 12 in group B. For group A, an average PFS of 52 was found vs. 44.33 months for group B. For group A 7 (54%) patients had PD, 4 (31%) SD, and 2 (15%) PR; in group B, the number of patients with PD, SD, and PR respectively was 9 (75%), 3 (25%) and 0 (0%). No adverse events have been reported in the two groups. ***Conclusion:*** Primary tumor resection prior to PRRT can be safely proposed in patients with G1-G2 metastatic ileum-NEN, as it seems to significantly improve PFS. However, more data deriving from a larger cohort of patients are needed to confirm these preliminary results. ***References:*** Bertani E, Fazio N, Radice D, Zardini C, Grana C, Bodei L, Funicelli L, Ferrari C, Spada F, Partelli S, Falconi M. Resection of the Primary Tumor Followed by Peptide Receptor Radionuclide Therapy as Upfront Strategy for the Treatment of G1-G2 Pancreatic Neuroendocrine Tumors with Unresectable Liver Metastases. Ann Surg Oncol. 2016 Dec;23(Suppl 5):981-989. doi: 10.1245/s10434-016-5550-3. Epub 2016 Sep 9. PMID: 27613553.

## OP-669

### First results from IEO 676 clinical study of PRRT in neuroendocrine tumors: is there still space for Y-90-DOTATOC?

***C. Grana***, *A. Barone, S. Papi, P. Rocca, S. Fracassi, M. Ferrari, F. Botta, F. Mattana, F. Ceci, C. Fodor, F. Spada, I. Clerici, N. Fazio, M. Rubino;*
*European Institute of Oncology, IRCCS, Milano, ITALY.*

***Aim/Introduction:*** IEO 676 is a prospective phase II study of Peptide Receptor Radionuclide Therapy (PRRT) with Y-90-DOTATOC in progressive G1, G2, G3, neuroendocrine patients. PRRT has been in use since the late 1990s, with the introduction of 90Y-DOTATOC, which allowed objective responses in 10-30% of treated patients. There have been numerous studies that have led to the approval of Lu-177-oxodotreotide in G1-G2 GEP NETS. The aim of this phase II study is to evaluate the antitumor activity of 90Y-DOTATOC therapy in patients affected by sst2 positive neuroendocrine tumors, stratified for positive or negative FDG PET/CT. Although the comparison between the two patient populations is not an objective of the study, an analysis of these two groups can be carried out at a later stage, in order to evaluate the therapeutic efficacy based on the different activity administered for stratification obtained following positive-negative disease on 18F-FDG PET/CT. ***Materials and Methods:*** The protocol includes two level of administered activity: 5 cycles of 50 mCi of Y-90-DOTATOC in FDG-PET positive pts and 4 cycles in FDG negative pts. ***Results:*** From February 2020 to April 2023 we enrolled 25 out 29 pts: 13 bronchial NET, 2 unknow primary, 7 pNET G3, 1 G2 GEP NET, 1 ovarian NET, 1 paraganglioma. We have observed 1 CR, 1 PR, 11 SD, 5 PD; 7 patients are still in treatment. Therapy was well tolerated in all pts; no hematological toxicity was observed; 2 sindromic pts presented an increase of the syndrome after PRRT that was resolved with medical therapy. The pt obtaining a complete response was FDG negative. ***Conclusion:*** These first results are in line with literature results of PRRT tolerability, and the answer to the question in the title could be yes: PRRT with Y-90-DOTATOC in clinical trials is a treatment that can be proposed in NET, in particular in those patients that can not receive approved radiopharmaceuticals, but can have a benefit from PRRT

## OP-670

### Intra-arterial PRRT, a Prospective Clinical Study in NET Patients with Hepatic Metastases

***S. Ebbers***[1], *M. W. Barentsz*[1], *D. M. V. de Vries-Huizing*[2], *M. W. J. Versleijen*[2], *L. G. Klompenhouwer*[2], *M. E. T. Tesselaar*[2], *M. P. M. Stokkel*[2], *T. Brabander*[3], *H. Hofland*[3], *A. Moelker*[3], *A. J. A. T. Braat*[1], *M. G. E. H. Lam*[1];
[1]*University Medical Center Utrecht, Utrecht, NETHERLANDS,*
[2]*Netherlands Cancer Institute, Amsterdam, NETHERLANDS,*
[3]*Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** The aim was to investigate whether tumor uptake in liver metastases can be enhanced by intra-arterial (IA) administration of $^{177}$Lu-DOTATATE (Lutathera®, Novartis) via the hepatic artery, in order to improve tumor response without increasing toxicity. ***Materials and Methods:*** In this prospective RCT, a total of 27 patients with grade 1-2 NET, and bi-lobar liver metastases were randomized to receive IA PRRT in either the left or right hepatic artery for four consecutive cycles. The other liver lobe was treated via a 'second-pass' effect and was used as a control lobe. Up to 3 tumors per liver lobe were identified as target lesions at baseline (>3 cm). Tumor-to-normal (T/N) uptake ratios on 24h post-treatment SPECT/CT were calculated for each target lesion using the mean uptake and peak uptake (mean uptake in 1cm diameter sphere around maximum uptake voxel), and compared between IA-treated lobe (IAL) and control lobe (CL) using paired-samples t-test. Furthermore, response was recorded according to RECIST 1.1 at 3 and 6 months post-treatment. ***Results:*** A non-significant increase in both $T/N_{mean}$ and $T/N_{peak}$ uptake ratio was observed in the IAL: $T/N_{mean}$: CL = 16.2 vs. IAL = 17.9 (p = 0.299); $T/N_{peak}$: CL = 32.5 vs. IAL = 38.0 (p = 0.091). The mean relative increase in $T/N_{mean}$ = 1.17 (95% CI [1.00; 1.37]), $T/N_{peak}$ = 1.23 (95% CI [1.06; 1.42]). Overall, 67% of patients showed an increase in $T/N_{mean}$ ratio. Tumor response rates were identical (25% PR and 75% SD at 3 mo; 35% PR, 61% SD and 4% PD at 6 mo in both IAL and CL). ***Conclusion:*** No clinically significant increase in hepatic tumor uptake on SPECT/CT after 24h, and no difference in response at 3 or 6 months follow-up could be identified after intra-arterial administration of $^{177}$Lu-DOTATATE.

## OP-671

### Diagnostic Performance of [$^{18}$F]F-meta-fluorobenzylguanidine ([$^{18}$F]MFBG) PET/CT in Patients with Pheochromocytoma and Paraganglioma

***P. Wang***[1], *F. Li*[1], *J. Zhang*[2], *H. Jing*[1], *Y. Zhang*[1];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,*
[2]*National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** 123I-metaiodobenzylguanidine scintigraphy has demonstrated high specificity but low sensitivity for imaging pheochromocytoma and paraganglioma (PPGL) due to limited spatial resolution. 18F-meta-fluorobenzylguanidine ([$^{18}$F]MFBG) is a novel norepinephrine transporter (NET) -targeting PET tracer may address this limitation and enhance PPGL staging and restaging. ***Materials and Methods:*** We assessed the sensitivity, and specificity of 18F-MFBG PET in 17 patients with suspected PPGL using histopathology (n=10) and clinical validation (n=7) as reference standards. Additionally, we compared the detection rate of [$^{18}$F]MFBG PET/CT with [$^{68}$Ga]Ga-DOTATATE PET/CT on a per-patient and per-lesion basis in 31 patients with metastatic PPGL. Tumor uptake measured as tumor-to-background ratio (TBR) were compared between [$^{18}$F]MFBG PET/CT and [$^{68}$Ga]Ga-DOTATATE PET/CT. ***Results:*** [$^{18}$F]MFBG PET/CT was positive in 11 of 17 patients with suspected PPGL, with PPGL confirmed in 11 of 17. Sensitivity and specificity of 18F-MFBG PET/CT were 100% each. In 31 patients with metastatic PPGL, [$^{18}$F]MFBG PET was positive in 29 (93.5%). Two MFBG-negative patients exhibited multiple high-uptake foci on 68Ga-DOTATATE; both were on medications affecting NET during the exam. Combined [$^{18}$F]MFBG PET/CT and [$^{68}$Ga]Ga-DOTATATE PET/CT detected 691 lesions, with 676 (98%) and 658 (95%) visible on [$^{18}$F]MFBG PET/CT and [$^{68}$Ga]Ga-DOTATATE PET/CT, respectively. For matched lesions, [$^{18}$F]MFBG had a higher TBR for liver lesions (5.0 ± 1.8 vs. 3.8 ± 2.0; P=0.133). ***Conclusion:*** [$^{18}$F]MFBG PET/CT exhibits high accuracy for initial PPGL staging and high detection rate for restaging, indicating its potential as a first-line functional imaging modality in this clinical setting.

## OP-672

### $^{225}$Ac-DOTATATE Dosimetry Results from Part 1 of the ACTION-1 Trial

***M. Morris***[1], *G. Ulaner*[2], *T. Delie*[1], *S. Kotiah*[3], *D. Ferreira*[4], *K. Ma*[1], *J. Rearden*[4], *J. Li*[4], *S. Moran*[4], *E. Sneeden*[4], *B. He*[5], *M. Ghaly*[5], *E. Frey*[6], *A. Scott*[1], *C. Huffman*[1], *G. Sgouros*[6];
[1]*Advanced Molecular Imaging and Therapy, Glen Burnie, MD, UNITED STATES OF AMERICA,* [2]*Hoag Family Cancer Institute, Newport Beach, CA, UNITED STATES OF AMERICA,* [3]*Mercy Medical Center, Baltimore, MD, UNITED STATES OF AMERICA,* [4]*RayzeBio, San Diego, CA, UNITED STATES OF AMERICA,* [5]*5Radiopharmaceutical Imaging and Dosimetry, LLC (Rapid), Baltimore, MD, UNITED STATES OF AMERICA,* [6]*The Russell H. Morgan Department of Radiology and Radiological Science, School of Medicine, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** RYZ101 ($^{225}$Ac-DOTATATE) is an alpha-emitting radiopharmaceutical being developed for somatostatin receptor 2-expressing (SSTR2+) solid tumors. ACTION-1 (NCT05477576) is a Phase 1b/3 trial comparing RYZ101 with standard-of-care therapy in SSTR2+, well-differentiated gastro-enteropancreatic neuroendocrine tumors (GEP-NETs) progressing following $^{177}$Lu-labelled somatostatin analogue therapy. A dosimetry substudy was conducted during phase 1b to determine the feasibility of obtaining imaging data with $^{225}$Ac to estimate RYZ101 absorbed doses to critical organs and tumors. ***Materials and Methods:*** Phase 1b primary objective: determine the recommended Phase 3 dose of RYZ101. Seventeen patients were assigned to the highest RYZ101 dose level (120kBq/kg) and observed for dose-limiting toxicities (DLTs) during cycle 1 (8w). Patients receive up to 4 cycles. Nine patients were enrolled in the dosimetry substudy. Dosimetry calculations are performed using SPECT/CT images acquired for Cycles 1 and 4 at 4±1h, 24±2h and 168±24h post-infusion. All SPECT/CT acquisitions utilizing $^{225}$Ac are performed with a High Energy Collimator. Dual-radionuclide quantitative SPECT reconstruction was used to obtain $^{221}$Fr and $^{213}$Bi activity images, including compensation for crosstalk and other physical image-degrading effects. Activity in the liver, kidneys, spleen, red marrow and selected tumors is quantified. Absorbed doses to target organs and lesions are calculated using Medical Internal Radiation Dose (MIRD) Committee S-value methodology (Rapid software package, 3D-RD-S). ***Results:*** As of February 17, 2023, dosimetry results were available for 9 patients (Cycle 1) and 3 patients (Cycle 4). No DLTs were observed. Mean total activity administered in Cycle 1 was 8.9MBq (range 7.3-10.6MBq); mean total activity administered in Cycle 4 was 8.5MBq (range 5.4-11.0MBq). Mean weighted RBE (=5) absorbed dose coefficients for spleen, kidneys, liver, and red marrow in Cycle 1 were 0.88, 0.52, 0.45, and 0.029Gy/MBq and in Cycle 4 were 0.86, 0.42, 0.26, and 0.029Gy/MBq, respectively. Dose coefficients for selected tumors were in the range of 1.0-8.8Gy/MBq during Cycle 1 and 0.95-3.1Gy/MBq during Cycle 4. In general, there is comparable/higher tumor uptake of $^{221}$Fr and $^{213}$Bi in Cycles 1 and 4 compared with that observed in the kidneys and other organs. Imaging and dosimetry are ongoing. ***Conclusion:*** Imaging and obtaining quantitative information for dosimetry of $^{225}$Ac are feasible, where $^{221}$Fr and $^{213}$Bi are imaged directly and simultaneously. This shows, for the first time, that $^{213}$Bi stays mostly with the delivery agent (DOTATATE), with a minor fraction going to kidneys. Overall, initial data from ACTION-1 dosimetry suggest a favorable tumor-to-background profile for RYZ101 in SSTR+ GEP-NETs.

## OP-673

### Early results of$^{212}$Pb-VMT-α-NET Targeted Alpha Therapy in Metastatic Gastro-entero-pancreatic Neuroendocrine Tumors: First in Human Clinical Experience on Safety and Efficacy

***D. Malik***[1], *I. Sen*[1], *P. Thakral*[1], *S. Das*[1], *M. Schultz*[2];
[1]*Fortis Memorial research institute (FMRI), Gurugram, INDIA,* [2]*University of Iowa, Iowa, IA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** There has been an increasing interest in targeted alpha therapy using $^{212}$Pb. $^{212}$Pb-VMT-α-NET, a proprietary molecule from Perspective has shown significantly improved performance in preclinical studies. $^{212}$Pb-VMT-α-NET therapy was effective and well-tolerated in mice, achieving 100% complete response rate in tumor bearing mice. The objective of this study was to investigate the early results on the safety and efficacy of $^{212}$Pb-VMT-alpha NET therapy (TAT) in patients with advanced, progressive, 177Lu-DOTATATE refractory, somatostatin receptor (SSTR) positive, metastatic gastro-entero-pancreatic neuroendocrine tumors (GEP-NETs). ***Materials and Methods:*** This exploratory first in human study was approved by the Institute Ethics Committee (IEC No:2023-002-EMP-40). We recruited 10-patients with well differentiated neuroendocrine tumours. Patients underwent a screening $^{68}$Ga-DOTANOC PET/CT scan to assure high SSTR expression and progressive disease to prior therapies. $^{212}$Pb-VMT-α-NET was administered (25MBq/Kg body weight) at an interval of 8 weeks up to 3 cycles. Hematologic, kidney, and liver function tests were repeated after every cycle of $^{212}$Pb-VMT-α NET therapy at 2, 4 and 8-week intervals. Treatment-related side-effects were assessed every 2 weeks on the basis of physical examination, vital signs, laboratory results and adverse events graded according to the CTCAE v5.0. Efficacy assessment included assessment of clinical response, assessment of objective radiological response measured on the diagnostic contrast-enhanced CT and the receptor expression seen on $^{68}$Ga-DOTANOC PET/CT scans. RECIST 1.1 criteria for changes in size and the changes in uptake of $^{68}$Ga- DOTANOC were used to track response. ***Results:*** The most common adverse effects (AEs) were nausea, alopecia, fatigue and appetite loss. These adverse effects excluding alopecia usually resolved about 7 - 10 days post infusion. None of the patients experienced grade 3 or 4 hemato-toxicity, renal insufficiencies or hepatotoxicity. Morphological response assessment was assessed in all patients which revealed partial response in 9 and stable disease in 1 patient. All patients demonstrated good clinical response with an improvement in their quality of life. There was no treatment related death. ***Conclusion:*** Our initial results indicate $^{212}$Pb-VMT-α-NET therapy as safe with low and transient side-effects. While all patients showed a good clinical response, most showed an objective radiological response to therapy even after a single dose of $^{212}$Pb-VMT-Alpha NET therapy. None of the patients demonstrated a clinically significant grade 3 adverse event. This study is an ongoing trial and we have presented only the preliminary results. Long-term survival data will be derived after a longer duration of follow-up.

## OP-674

### The increase of LutaThera Therapy posology due to dosimetry could be give a better progression free survival (PFS) in GEPNets patients?

***M. Cuomo***[1,2], *G. Argiroffi*[2], *A. Lorenzoni*[2], *G. Aliberti*[2], *M. Bagnalasta*[2], *F. Scalorbi*[2], *M. Kirienko*[2], *C. Chiesa*[2], *E. Seregni*[2], *M. Maccauro*[2];
[1]*University of the study of Milan, Milan, ITALY,* [2]*Istituto Nazionale Tumori Milano, Milan, ITALY.*

***Aim/Introduction:*** The NETTER-1 study demonstrated noticeably increased PFS in GEP-NET treated with 177Lu-DOTATATE respect to cold somatostatine analogs. Aim of our work was to check if

the registered LUTATHERA posology could be increased thanks to dosimetry. ***Materials and Methods:*** Toxicity, radiological responses, dosimetric evaluations and follow-up were collected respectively on 95, 58, 52, 61 patients who completed the 4 injections schedule. Renal toxicity was assessed through creatinine level and eGFR. RECIST responses were measured 3 months after the last administration. Dosimetry was performed after the first and last treatment, with two SPECT/CT scans 1 and 7 days after administration. Red marrow absorbed dose was evaluated encompassing the vertebral body in L2-L3-L4, correcting for the individual volume. The concept of global tumor dose (GTD) was the sum of lesion doses weighted by lesion mass. Cumulative-GTD (CGTD) was calculated as the mean between cycle 1 and 4 multiplied by 4. Patients were followed-up for at least one year, up to a maximum of three, through blood tests and ceCT. ***Results:*** Creatinine toxicity G1 was observed in 19/95 patients, while eGFR G1 in 42/80, and G2 in 18/80. Throbocytopenia G1 occured in 45/95 patients, and 1 G2, 2 G3, 2 G4 occurrences were observed. Anemia was reported as G1: 52/95; G2: 8/95; G3: 1/95. Leucopenia was observed with G1 in 11/95 and G2 in 18/95. No haematological stochastic effect was observed. . Dosimetry agreed with this mild toxicity scenario, with red marrow dose distribution after the first administration spanning from 0.01 to 0.62 Gy, median 0.1 Gy, 25th and 75th percentile at 0.0625 and 0.15 Gy. Cumulative kidney Biologically Effective Dose (BED) ranged from 5 to 32 Gy, median 16 Gy, with 75th percentile at 20 Gy. CGTD ranged from 23 to 650 Gy, median 74 Gy and 75th percentile at 160 Gy,which is the threshold for RECIST response according to Ilan et al 2005. So 75% of our patient got a tumour dose below the efficacy threshold, in perfect agreement with the observed responses. During the follow-up no complete response obtained, only 7/61 partial responses, 44/61 stabilization and 10/61 progression disease were observed. The median PFS of patients was 27.4months. ***Conclusion:*** Clinical outcome and dosimetry demonstrate that 75% of patients got a tumor dose below the efficacy threshold. Probably, increasing number of treatments would increase the rate of PFS, stable disease or tumor regression.

## OP-675

### Personalized, dosimetry-based PRRT therapy in patients with neuroendocrine tumors using [177Lu]Lu-DOTA-TATE or [177Lu]Lu/[90Y]Y-DOTA-TATE mixture - the initial results of DUONEN multicenter study

***M. Opalinska***[1], *G. Kaminski*[2], *M. Dedecjus*[3], *A. Kowalska*[4], *M. Kolodziej*[2], *M. Saracyn*[2], *D. Gasior-Perczak*[4], *W. Lenda-Tracz*[5], *A. Sowa-Staszczak*[1], *A. Borkowska*[6], *A. Budzynska*[7], *A. Kubik*[7], *W. Chalewska*[3], *K. Kacperski*[7], *P. Szubstarska*[7], *P. Garnuszek*[8], *R. Mikolajczak*[8], *A. Hubalewska-Dydejczyk*[1];

***Aim/Introduction:*** Peptide Receptor Radionuclide Therapy (PRRT) is an effective treatment for disseminated neuroendocrine tumors (NETs) with good somatostatin receptors expression. Despite many published studies, the consensus on the optimal PRRT treatment algorithm has not been reached yet.The main objective of the DUONEN multicenter, randomized, phase III study (EUDRACT No: 2020-006068-99) is a development of a dosimetry-based personalized PRRT algorithm. The second goal include the assessment of the efficacy of dosimetry-based personalized therapy with mixture of [177Lu]Lu- and [90Y]Y-DOTA-TATE in comparison with use of [177Lu]Lu-DOTA-TATE in standard doses (7400MBq). The personalized dosimetry is design to deliver the maximal activity to the tumor tissue maintaining the safety of critical organs. ***Materials and Methods:*** Adult patients with advanced, unresectable well-differentiated (G1 and G2) NETs, progressing on long-acting somatostatin analogues are randomized into four arms: A -treated with [177Lu]Lu -DOTA-TATE with constant radioactivity of 7400MBq per cycle B -treated with mixture of [177Lu]Lu-DOTA-TATE and [90Y]Y-DOTA-TATE, initially at a ratio of 3700:1850MBq/MBq. The [177Lu]Lu-DOTATATE activity will be constant in all cycles, the [90Y]Y-DOTA-TATE activity will be adjusted in the second, the third and the fourth cycle, based on bone marrow and kidney dosimetry to obtain the highest radiation dose in tumor tissue.C -analogous to arm B, except that here the activity of [90Y]Y-DOTA-TATE will be constant and the activity of [177Lu]Lu-DOTA-TATE will depend on the results of dosimetry D -initially analogous to arm A and then with an individualized doses based on dosimetry results. The treatment efficacy is evaluated on morphological imaging (TK or MR) according to RECIST 1.1 criteria. The safety of PRRT is assessed by the kidney and bone marrow biochemical function. ***Results:*** 20 patients have been enrolled to the study (arm A-5, arm B-6, arm C-4, arm D-5). 39 cycles of PRTT were given, including 23 fixed doses (firsts doses or arm A). In case of 16 cycles provided for adjustment, the dose of radiopharmaceutical estimated on the basis of personalized dosimetry was increased in 11 and decreased in 5 cases. Four patients were withdrawn due to disease progression or its side effects. Two patients underwent the first post-PRRT evaluation assessed according to RECIST 1.1 criteria achieving 1 partial (arm A) and 1 complete (arm B) response. ***Conclusion:*** Personalized dosimetry allows for the PRRT dose adjustments (more frequently increase) in subsequent treatment cycles maintaining the safety of therapy.Acknowledgements: The study is funded by the Medical Research Agency (Project number 2019/ABM/01/00077-00).

## OP-676

### Quantitative somatostatin receptor image assessment for survival prediction: a full-body, longitudinal, individual lesion analysis of neuroendocrine tumors in patients treated with peptide receptor radiation therapy

***V. Santoro-Fernandes***[1], *B. Schott*[1], *A. Deatsch*[1], *Q. Keigley*[2], *T. Francken*[1], *R. Meeker*[1], *R. Lyer*[3], *F. Christos*[3], *S. Perlman*[2,4], *R. Jeraj*[1,4];
[1]*Department of Medical Physics, School of Medicine and Public Health, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA,* [2]*Section of Nuclear Medicine and Molecular Imaging, Department of Radiology, School of Medicine and Public Health, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA,* [3]*Division of GI Medicine, Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY, UNITED STATES OF AMERICA,* [4]*Carbone Cancer Centre, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Baseline somatostatin-receptor image features (SRIF) are correlated with peptide receptor radionuclide therapy (PRRT) outcomes in metastatic neuroendocrine tumor (mNET) patients[1]. The predictive power of longitudinal SRIF derived from every individual lesion is unexplored. Here, we conducted such an investigation and evaluated how much longitudinal assessment improves the predictive power of SRIF to predict progression-free-survival (PFS) of mNET patients receiving PRRT. ***Materials and Methods:*** We retrospectively collected $^{68}$Ga-DOTATATE PET/CT scans of mNET patients imaged before (baseline) and after $^{177}$Lu-DOTATATE PRRT. PFS was determined based on chart review (median follow-up of 54 months) and used to stratify patients into poor and good responders. All lesions were contoured, and the quantitative features were extracted for every lesion. Lesions were matched between imaging time-points and feature variation was calculated. The lesion-level features were aggregated into patient-level features and separated into baseline and longitudinal sets. Using leave-one-out cross-validation, optimal features in each set were selected by maximum relevance and minimum redundancy. For each set, a multivariate linear regression (MLR) model was fitted for PFS regression and three machine-learning methods (LightGBM, XGBoost, and Random-Forest) were compared to it. Prediction performance was evaluated using RMSE, ROC, Kaplan-Meier, and Proportional-Hazards analyses. ***Results:*** Longitudinal images from 34 mNET patients were acquired. The median PFS was 20 months (min=4, max=54). Eighteen patients were classified as poor responders (PFS<31 months). Altogether, 2521 lesions were identified with median of 38.5 per patient (min=5, max=381). The MLR model using longitudinal SRIFs yielded a better fit than single time-point baseline SRIFs (RMSE=13.5 vs. 14.1). Classification accuracy was also better (AUROC=0.81 vs 0.74). Patient stratification was significant for longitudinal SRIFs and not-significant for baseline SRIFs (p=0.003 vs. 0.06, log-rank test). The hazard ratios showed superiority of longitudinal SRIFs: 0.92 (95% C.I. [0.88, 0.96]; P<0.001) vs. 0.96 (95% C.I. [0.92, 1.00]; P=0.04). Furthermore, the MLR model resulted in better PFS prediction than all machine-learning models. The best-performing machine-learning model (Random-Forest with longitudinal SIRFs) had RMSE of 14.1 vs. 13.5 for longitudinal MLR, and AUROC of 0.71 vs. 0.81 for longitudinal MLR. ***Conclusion:*** This work is the first to investigate the utility of full-body, longitudinal, lesion-wise SRI for clinical outcome prediction. Our results suggest that longitudinal SRIF adds value to PFS prediction when compared to baseline SRIF in mNET patients receiving PRRT. Interestingly, MLR outperformed machine learning models, possibly due to the limited training sample. ***References:*** 1. Haug AR et al. J Nucl Med. 2010;51(9):1349-1356.

**STING-targeted PET Tracer for Early Assessment of CRC Tumor Immunogenicity after Chemotherapy**
***D. Xu***[1,2,3], *X. Lu*[1,3], *F. Yang*[2,3], *D. Li*[3,2];
[1]*Center for Interventional Medicine, the Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, CHINA,* [2]*Department of Nuclear Medicine, the Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, CHINA,* [3]*Guangdong Provincial Engineering Research Center of Molecular Imaging, the Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, CHINA.*

***Aim/Introduction:*** The objective clinical efficiency of immunotherapy for colorectal cancer (CRC) is less than 20%. The combination of chemotherapy and immunotherapy can effectively improve the therapeutic effect, mainly because chemotherapy can promote tumor elimination by activating interferon gene stimulating protein (STING) in immune cells at an early stage and converting CRC to an immunogenic state. However, there is a lack of reliable methods to monitor early tumor immunogenicity changes under the influence of chemotherapy. To standardize the rational use of immune checkpoint inhibitors and to screen the optimal strategy for combination immunotherapy, we used the STING targeted probe to monitor the changes in tumor immunogenicity during chemotherapy in CRC mice. ***Materials and Methods:*** The toluene sulfonate precursor was labeled with $^{18}$F and then reacted with TFA to produce the STING targeted probe—[$^{18}$F]FBTA. [$^{18}$F]FBTA-PET imaging and biodistribution experiments were performed in CRC mice after oxaliplatin (OXA) and cisplatin (CDDP) treatment. CRC mice were also treated with low (CDDP-LD: 1 mg/kg) and medium (CDDP-MD: 2.5 mg/kg) doses of CDDP, PET imaging and biodistribution experiments were performed on the treated mice. The effects of different chemotherapeutic agents (OXA and CDDP) and different doses of CDDP on tumor innate immunity were verified by immunohistochemistry and flow cytometric sorting. ***Results:*** PET imaging of CRC mice showed significantly higher uptake in tumors treated with OXA (3.09 ± 0.25 %ID/g, ***P < 0.001) and CDDP (4.01 ± 0.18 %ID/g, ***P < 0.001), especially in CDDP treated tumors (**P < 0.01). Immunohistochemistry confirmed high levels of STING expression in tumors with high uptake in PET imaging. Flow cytometry results showed that both chemotherapeutic agents led to DC and macrophage infiltration in the tumor and were responsible for the increased level of STING expression. Both CDDP-LD and

CDDP-MD treatment elevated uptake in CRC tumors (***P < 0.001 and ***P < 0.001), especially in CDDP-MD-treated tumors (***P < 0.001). Histocytological experiments also confirmed significantly elevated levels of STING expression in DCs and macrophages after CDDP-LD and CDDP-MD treatment. ***Conclusion:*** In this study, the STING-targeted probe—[$^{18}$F]FBTA was demonstrated to monitor early changes in tumor immunogenicity in CRC mice after OXA or CDDP treatment. And there were differences in tracer uptake in CRC tumors treated with different doses of cisplatin. These studies provide key insights into innate immune activation after chemotherapy and suggest that [$^{18}$F]FBTA will be useful in the screening of chemotherapeutic agents and doses in combination with immunotherapy.

## OP-698

### Targeting PD-1 on Chronically Activated T cells with Radioimmunotherapy as a Novel Therapeutic Strategy for Multiple Sclerosis.

***C. Frank***[1], *H. E. Salapa*[2,3,4], *K. J. H. Allen*[1], *M. C. Levin*[2,3,4], *W. Dawicki*[5], *E. Dadachova*[1];
[1]*College of Pharmacy and Nutrition, University of Saskatchewan, Saskatoon, SK, CANADA,* [2]*Office of Saskatchewan Multiple Sclerosis Clinical Research Chair, CMSNRC (Cameco MS Neuroscience Research Center), College of Medicine, University of Saskatchewan, Saskatoon, SK, CANADA,* [3]*Department of Medicine, Neurology Division, University of Saskatchewan, Saskatoon, SK, CANADA,* [4]*Department of Anatomy, Physiology and Pharmacology, College of Medicine, University of Saskatchewan, Saskatoon, SK, CANADA,* [5]*Department of Biochemistry, Microbiology and Immunology, College of Medicine, University of Saskatchewan, Saskatoon, SK, CANADA.*

***Aim/Introduction:*** Multiple sclerosis is a chronic neurodegenerative autoimmune disease partially characterized by inappropriate immune activation towards myelin proteins[1]. T lymphocytes drive early stages of multiple sclerosis immunopathology. Pathogenic T lymphocytes chronically stimulated by self-antigens develop characteristic "fatigued" receptors such as the programmed cell death protein 1 (PD-1)[1]. Specifically depleting chronically stimulated T lymphocytes by targeting PD-1 may reduce the ability of the immune system to promote the destruction of neurons. Here we report the effectiveness and tolerability of an anti-PD-1 radiolabeled monoclonal antibody in treating mice induced with experimental autoimmune encephalomyelitis (EAE). ***Materials and Methods:*** Female C57Bl/6 mice were induced with EAE and at days 0, 3, 6, 9 and 12 post paralysis development. Animals were euthanized, and spinal cords were stained for CD45, CD3, CD11b, Ly6C and PD-1 to investigate PD-1 expression on infiltrating immune cells. Female C57BL/6 mice were induced with EAE and treated at symptom onset intravenously with 2.22 MBq of [$^{177}$Lu]Lu-DOTA-RMP1-14 (Anti-PD-1), 2.22 MBq of [$^{177}$Lu]Lu-DOTA-Irrelevant Isotype control antibody, "cold" RMP1-14, 2.22 MBq of [$^{177}$Lu]Lu-DOTA-RMP1-14 in combination with 3 mg/kg of fingolimod (FTY720) or saline. Safety and tolerability of the [$^{177}$Lu]Lu-DOTA-RMP1-14 antibody was assessed using total blood counts and blood chemistry to assess liver and kidney toxicity. PET/CT imaging of EAE mice was performed using 3.7 MBq of [$^{89}$Zr]Zr-DFO-RMP1-14 at 0, 24, 48 and 96 hours. Biodistribution of EAE induced mice with 1.85 MBq of [$^{203}$Pb]Pb-DOTA-RMP1-14 on lymph nodes, brain, spinal cord, spleen and kidneys was performed. ***Results:*** PD-1 was expressed and sustained on spinal cord infiltrating T lymphocytes at symptom onset and guided [$^{177}$Lu]Lu-DOTA-RMP1-14 treatment at symptom onset. Administration of [$^{177}$Lu]Lu-DOTA-RMP1-14 significantly reduced the overall disease burden and clinical score in EAE induced animals compared to controls, demonstrated a favorable toxicity profile with no effect on liver and kidney function as well as on bone marrow. PET/CT imaging and biodistribution demonstrates uptake in the lymph nodes and spinal cords of active disease animals. ***Conclusion:*** Here we demonstrate a novel approach using radioimmunotherapy to specifically target and deplete pathogenic lymphocytes in an autoimmune disease animal model. This approach has the potential to be applied to other autoimmune disease to target and deliver cytocidal radiation to pathogenic immune cells. ***References:*** 1) Li, H., Zheng, C., Han, J., Zhu, J., Liu, S., & Jin, T. (2021). PD-1/PD-L1 Axis as a Potential Therapeutic Target for Multiple Sclerosis: A T Cell Perspective. Frontiers in cellular neuroscience, 15, 716747. doi: 10.3389/fncel.2021.716747

## OP-699

### The synthesis of a novel molecular imaging probe$^{68}$Ga-DOTA-PDL1P and applicationin malignant melanoma

***Z. Yang***;
*Fudan University Shanghai Cancer Center, Shanghai, CHINA.*

***Aim/Introduction:*** Based on programmed cell death-ligand 1 targeted peptide (PD-L1P), to synthesize a programmed cell death-ligand 1 (PD-L1) agent on positron emission tomography (PET/CT) imaging and explore the clinical application. ***Materials and Methods:*** DOTA-PDL1P was labeled with gallium 68 (68Ga), and its radiochemical purity and stability were evaluated. Mouse B16-F10 cells were used for cell uptake and blocking in vitro to evaluate its specific targeting performance. Biological distribution and PET/CT tumor imaging were performed in B16-F10 tumor-bearing mice, and the uptake of 68Ga-DOTA-PDL1P in tumors was further evaluated by autoradiography of tumor samples. Finally, the expression of PDL1 in tumor tissues was evaluated by immunohistochemistry. ***Results:*** The labeling rate and radiochemical purity of 68Ga-DOTA-PDL1P were higher than 99% and maintained good stability. Cell uptake results showed that 68Ga-DOTA-PDL1P could be specifically taken up by B16-F10 cells, and this specific uptake could be blocked by PD-L1 antibody. The results of biological distribution indicated that 68Ga-DOTA-PDL1P was excreted mainly through the urinary system. PET imaging results of tumor in tumor bearing mice showed high uptake of 68Ga-DOTA-PDL1P in tumor tissues. The autoradiographic and immunohistochemical results of tumor tissue confirmed that the high uptake sites of 68Ga-DOTA-PDL1P were consistent with the positive areas of PD-L1 expression, which proved that 68Ga-DOTA-PDL1P could specifically screen malignant tumors with positive PD-L1 expression. ***Conclusion:*** The new PET imaging agent $^{68}$Ga-DOTA-PDL1P synthesized in this study has good stability and high tumor targeting specificity, which is a promising new immune PET imaging agent targeting PD-L1 protein.

## OP-700

### A Novel PET Tracer $^{68}$Ga-NOTA-XH05 Targeting LAG-3 for Evaluating the Efficacy of Immunotherapy in Tumors

***P. Yuan***[1,2], *Y. Long*[1,2], *N. Wei*[1,2], *Y. Gai*[1,2], *Y. Zhang*[1,2], *R. An*[1,2], *X. Lan*[1,2];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA.*

***Aim/Introduction:*** Lymphocyte activation gene 3 (LAG-3), which is a novel target for immune checkpoints blocking, is upregulated on activated T cells. Several clinical reports suggested that patients had a better prognosis when LAG-3 expression is observed on

tumor infiltrating lymphocytes, in which LAG-3 can be considered as a biomarker of T cell activation. In this study, a novel peptide PET tracer $^{68}$Ga-NOTA-XH05 targeting LAG-3 was constructed to noninvasively detect LAG-3 expression in tumors after CpG-ODN treatment, in order to evaluate the efficacy of immunotherapy. ***Materials and Methods:*** The tracer $^{68}$Ga-NOTA-XH05 was identified by high performance liquid chromatography (HPLC) after prepared and purified. The expression of LAG-3 in the B16-F10 subcutaneous tumors was monitored by flow cytometry, and its correlation with the uptake of the tracer was analyzed to evaluate the specificity of the tracer. PET imaging and biodistribution were conducted after TLR9 agonist, CpG-ODN, used for the treatment of unilateral or bilateral B16-F10 subcutaneous tumor models, to evaluate the ability of $^{68}$Ga-NOTA-XH05 monitoring the efficacy of immunotherapy and the abscopal effect of CpG-ODN. ***Results:*** After purification, the radiochemical purity of $^{68}$Ga-NOTA-XH05 was over 99%. The mean fluorescence intensity of LAG-3 in tumor cells was detected by flow cytometry and it was positively correlated with the uptake of $^{68}$Ga-NOTA-XH05 ($R^2$=0.5213, P=0.0184), which suggested that the uptake of $^{68}$Ga-NOTA-XH05 could reflect the expression level of LAG-3 in tumor. $^{68}$Ga-NOTA-XH05 PET imaging of the mice with B16-F10 subcutaneous tumors was performed after intratumoral injection of CpG-ODN. The tumor blood ratio (TBR) was 2.234±0.386, which was significantly higher than that of the control (TBR=1.348±0.301, P=0.0001). The result of biodistribution was similar to the imaging result, indicating that $^{68}$Ga-NOTA-XH05 could distinguish therapeutic efficacy. In bilateral subcutaneous tumors model, only the right tumors were treated with intratumoral injection of CpG-ODN. On day 2 after first treatment, $^{68}$Ga-NOTA-XH05 PET imaging showed increased TBR of the right tumors, but no significant difference displayed between the left tumors and the control. On day 8, uptake of the left tumors was also significantly higher than that of the control, and even higher than that of the right tumors, indicating that $^{68}$Ga-NOTA-XH05 can effectively monitor the abscopal effect of CpG-ODN. ***Conclusion:*** $^{68}$Ga-NOTA-XH05 had a good correlation with the expression of LAG-3 in vivo. $^{68}$Ga-NOTA-XH05 could be used to evaluate the immunotherapy response and monitor the abscopal effect of the therapy, which suggests potential clinical translational prospects.

## OP-701

### Preclinical evaluation of a small-molecule carbonic anhydrase IX targeting PET tracer in clear cell renal cell carcinoma

***W. Zhu***, *X. Li, Y. Zhang, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Carbonic anhydrase IX (CAIX) is an isoform of carbonic anhydrases (CAs), which are a family of zinc metalloenzymes that catalyze the reversible hydration of carbon dioxide to bicarbonate and a proton. While CAIX is highly expressed in clear cell renal cell carcinoma (ccRCC), its expression in normal human tissue is limited, making it an ideal target for molecular imaging and precision drug delivery. The purpose of this study was to evaluate 68Ga-NY104, a small molecule CAIX-targeting PET agent, in ccRCC tumor models. ***Materials and Methods:*** 68Ga-NY104 was manually synthesized. The binding affinity (Kd) of $^{68}$Ga-NY104 was measured using surface plasmon resonance. The blood pharmacokinetics were measured in ICR mice. The in vivo and ex vivo biodistribution and blocking study of $^{68}$Ga-NY104 were investigated in CAIX-positive OS-RC-2 xenograft-bearing models. CAIX expression was further confirmed using immunohistochemistry. The binding of the tracer was further validated using autoradiography for human ccRCC samples. ***Results:*** NY104 can be labeled with high radiochemical yield (about 65% for a 30-min radiolabeling process) and purity (>95%). The tracer was stable for at least 3 hours. The binding affinity (Kd) of NY104 to CAIX is 5.75nM. $^{68}$Ga-NY104 quickly cleared through kidney with a biexponential blood clearance: α-half-life, 0.15 h and β-half-life, 6.04 h. Approximately 75% of the administered activity was cleared in the α phase.High tumor accumulation of $^{68}$Ga-NY104 was noted in OS-RC-2 tumors as early as 5 min after injection, which gradually increased until 3 h after injection with ID%/g of 29.29 ± 6.82. Besides, nonnegligible uptake was observed in the heart, lung, liver, stomach, and kidney. After blocking with unlabeled NY104, the tumor showed negligible uptake, confirming the specific binding of $^{68}$Ga-NY104. In PC-3 models, barely any uptake of $^{68}$Ga-NY104 was noted in the tumor. High CAIX expression was observed in OS-RC-2 xenograft tumors. Meanwhile, the PC-3 xenograft tumors were negative for CAIX immunohistochemical staining. Significant binding was detected using autoradiography on sections of human ccRCC tumor, while no significant binding was noted in the pancreatic cancer sample. ***Conclusion:*** $^{68}$Ga-NY104 can efficiently and specifically bind to CAIX and may serve as a biomarker for ccRCC characterization.

## OP-702

### A Radiohapten Capture System for In Vivo CAR T Cell Tracking in Ovarian Cancer

***L. Gajecki***, *L. Eibler, K. Kurtz, S. Lovibond, D. Veach, S. Larson, D. Scheinberg, S. Krebs;*
*Memorial Sloan Kettering, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** CAR-T cell trials have shown remarkable response rates in hematologic malignancies, however, success has been limited in solid tumors. There remains an unmet need to understand why CAR T cell therapy fails, which would be aided through the creation of tools to track the engineered cells' biodistribution, persistence, expansion and functionality in vivo. Here we show that a humanized single-chain variable fragment (scFv) huC825, which specifically binds M-DOTA-haptens (ABD, "Proteus" (Pr)), can be expressed on CAR-T cells directed against the retained portion of MUC16 (MUC16$^{ecto}$) on human ovarian cancer cells. We demonstrate proof-of-principle for huC825 reporter gene function and MUC16 CAR-T tracking in vivo. ***Materials and Methods:*** Transduction of a SFG retroviral vector encoding the huC825 scFv and a second generation MUC16$^{ecto}$-directed CAR (4H1128ζ) into CD3-activated human T cells was confirmed by flow cytometry. In vitro function of the CAR was assessed by bioluminescence cytotoxicity assays on MUC16$^{ecto}$+ human ovarian cancer cells (SKOV3-MUC16$^{ecto}$) expressing firefly luciferase and in vivo functionality was assessed in xenograft mouse models. Flow cytometry using a biotinylated DOTA-probe (Biotin-Pr) in combination with streptavidin–fluorophore anti-biotin verified expression and in vitro functionality of huC825 in huC825-CAR-T cells. The feasibility of in vivo tracking of intravenously administered huC825-CAR-T cells was studied in immuno-deficient mice bearing subcutaneous SKOV3-MUC16$^{ecto}$ xenografts with [$^{86}$Y] Y-ABD PET/CT performed at 16 h post-radiotracer injection. Image-based biodistribution was assessed for tumor ([%ID/g]max) and normal tissue ([%ID/g]mean) to determine tumor-to-normal tissue ratios. ***Results:*** We generated a panel of T cells expressing huC825 and/or CAR (huC825-CAR, CAR). We confirmed cell surface expression of the CAR and huC825 by flow cytometry. The

cytotoxic effector function of huC825 CAR-T was preserved with respect to control CAR-T cells. Using microPET/CT, tumoral uptake of the reporter probe [$^{86}$Y]Y-ABD (3.7 MBq) in mice given 5.0 x$10^5$ huC825-CAR-Ts was observed at day 14 post T cell administration indicating their accumulation (9.8 ± 6.5 [%ID/g]max, n=4). Excellent image contrast with tumor-to-kidney, tumor-to-blood and tumor-to-muscle ratios of 19.2, 127.6 and 205.2 were noted. In contrast, minimal tumoral uptake was observed in control mice (0.2 ± 0.03 [%ID/g]max, n = 4). ***Conclusion:*** CAR-T cell imaging in a solid tumor model was demonstrated in vitro and in vivo through selective DOTA-hapten capture by MUC16 CAR-T cells equipped with huC825 reporter scFv. These cells were tracked in vivo using PET/CT and CAR-T infiltration in SKOV3-MUC16$^{ecto}$ cells was visualized with high contrast. Serial tracking studies are ongoing.

## OP-703

### Discovery and development of high-affinity macrocyclic peptide for PET imaging of human Granzyme-B

***T. Nayak***[1], *J. Schubert*[1], *Z. Zhou*[1], *I. Bennacef*[1], *X. Meng*[1], *M. Stenslik*[1], *K. Getty*[1], *J. Patteson*[1], *H. Zokian*[2], *J. Lee*[2], *E. DiNunzio*[2], *H. Wan*[2], *F. Orvieto*[3], *V. Piacenti*[3], *A. Saldanha*[2], *A. Walji*[1], *E. Hostetler*[1];
[1]*MSD, West Point, PA, UNITED STATES OF AMERICA,*
[2]*MSD, Kenilworth, NJ, UNITED STATES OF AMERICA,*
[3]*IRBM S.p.A, Rome, ITALY.*

***Aim/Introduction:*** Granzyme B (GzmB) is a serine protease secreted by cytotoxic T lymphocytes. GzmB-induced cell death has been traditionally viewed as a primary mechanism used by immune cells to eliminate harmful target cells such as allogeneic, virally infected, and tumor cells. Linear tetrapeptides with moderate affinity have been used for PET imaging of GzmB. However, improvement in affinity and in vivo stability may be required for clinical success.In this study, we report macrocyclic peptides derived from mRNA display screening and selection of a high-affinity lead peptide for clinical translation. ***Materials and Methods:*** An mRNA-display screen against human GzmB yielded 66 macrocyclic peptides hits. Based on binding characteristics and physicochemical properties, two series were identified and peptides from each modified to incorporate a linker and NOTA-based chelator for [18F]AlF chemistry. In vivo PET imaging was performed in healthy mice and rhesus monkeys to assess biodistribution and clearance properties. To assess in vivo binding to human GzmB, xenogeneic Graft-Versus-Host-Disease (GvHD) was generated by engrafting human PBMC cells in NOG mice. Immunohistochemistry was performed on tissues collected after PET scans to confirm GzmB expression. ***Results:*** Despite single-digit nM binding affinity, some peptides were deprioritized due to undesirable off-target biodistribution and clearance properties for clinical translation.A 13 nM binding affinity peptide, and corresponding scrambled peptide (no GzmB binding) were tested in GvHD model. Lung uptake (SUVmean) was significantly greater in GvHD mice than NOG mice (0.23 ± 0.08 vs 0.04 ± 0.08, p = 0.0006). No significant difference in lung uptake was observed between GvHD and NOG mice injected with scrambled peptide, suggesting differences in the GvHD mice are GzmB specific. Similar observations were made in other affected tissues such as liver. GzmB expression measured by immunohistochemistry correlated with observations from PET scans. Based on the encouraging in vivo results, positional scanning mutagenesis and targeted SAR exploration was performed to identify lead peptide with 0.7 nM binding affinity. In vivo PET imaging in GvHD and radiation dosimetry studies were conducted in rhesus monkeys with this 0.7 nM and additional IND-enabling studies are on-going. ***Conclusion:*** High-affinity macrocyclic peptides for PET imaging of human GzmB were discovered and developed though mRNA-display screening and subsequent modifications. In vivo proof-of-concept was achieved in a GvHD model. Clinical studies with the current lead peptide are planned for early 2024.

## OP-704

### Evaluation of Affinity Matured Affibody Molecules for Imaging of Immune Check-Point Protein B7-H3

***M. Oroujeni***[1], *E. Bezverkhniaia*[2], *T. Xu*[1], *Y. Liu*[1], *E. Plotnikov*[2], *E. Ryer*[3], *I. Karlberg*[3], *A. Orlova*[1], *F. Frejd*[1], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION,*
[3]*Affibody AB, Stockholm, SWEDEN.*

***Aim/Introduction:*** B7-H3 is an immune checkpoint protein, which is a promising molecular target for immune therapy of malignant tumours. Sufficient B7-H3 expression level is a precondition for a successful therapy. Radionuclide molecular imaging is a promising technique for visualizing expression levels of molecular targets in vivo. The use of small radiolabelled targeting proteins would enable high-contrast radionuclide imaging of molecular targets if adequate binding affinity and specificity of an imaging probe could be provided. Affibody molecules, small engineered affinity proteins based on a non-immunoglobulin scaffold, have demonstrated an appreciable potential for the use as radionuclide imaging probes. Proof-of principle of radionuclide visualization of B7-H3 in vivo was demonstrated using the [$^{99m}$Tc]Tc-AC12-GGGC Affibody molecule. The aim of this study was to test the hypothesis that the affinity maturation of B7-H3-binding Affibody molecules could improve their targeting properties for imaging of B7-H3-expressing tumours. ***Materials and Methods:*** An affinity maturation of AC12 Affibody molecule enabling selection of clones with higher affinity was performed. The most promising clones were expressed with a -GGGC chelating sequence at the C-terminus and labelled with technetium-99m. In vitro characterization was performed using B7-H3-expressing cell lines. A head-to-head biodistribution of the affinity maturated Affibody binders and the parental variant AC12 (both labelled with $^{99m}$Tc) was studied in mice bearing B7-H3-expressing SKOV-3 xenografts. Uptake in B7-H3-negative Ramos xenografts was used as a specificity control. ***Results:*** Radiolabelling with $^{99m}$Tc resulted in radiochemical yield over 95 % and no further purification was performed. Binding to B7-H3-expressing cell lines was B7-H3-mediated. SYNT-179 showed a 3-8-fold improvement in affinity compared to the parental AC12 Affibody molecule. Biodistribution data 4 h after injection demonstrated that [$^{99m}$Tc]Tc-SYNT-179 showed the lowest blood concentration and uptake in almost all organs and tissues. Tumour uptake was 2.15 ± 1.01 %ID/g. Significantly ($p<0.05$) higher tumour-to-blood ratio for [$^{99m}$Tc]Tc-SYNT-179 (25.7±2.5) compared to [$^{99m}$Tc]Tc-AC12-GGGC (11.0±0.5) was observed. Tumour-to-bone ratio was significantly ($p<0.05$) higher for [$^{99m}$Tc]Tc-SYNT-179 (280.5 ± 50.8) than for [$^{99m}$Tc]Tc-AC12-GGGC (43.6 ± 5.7). ***Conclusion:*** The affinity maturation resulted in an increased affinity and lower hepatic uptake through an affinity maturation step. SYNT-179 could be a promising B7-H3 targeted candidate aiming at clinical application in the future.

## OP-705

### A $^{68}$Ga labelled CD25 targeted cyclopeptide probe for activated T cell imaging

***F. Liu***[1], *S. Wang*[2], *P. Wang*[1], *Z. Yang*[1];
[1]*Peking University Cancer Hospital & Institute, Beijing, CHINA,*
[2]*Peking University Health Science Cente, Beijing, CHINA.*

***Aim/Introduction:*** Immunotherapy and adoptive T cell therapy was developing rapidly in recent years and achieved promising outcomes in the treatment of various cancer. Tumor T cell activation is critical for treatment, and noninvasive imaging of T cell activation can provide early prediction of efficacy. CD25 is the-chain of IL-2 receptor, which shows negligible expression on naive T cells, while upregulated on activated T cells. To track the status of activated T cells in vivo, a cyclopeptide MCDQWERCKW containing DOTA chelating agent targeting CD25 was constructed and named DOTA-TCP. ***Materials and Methods:*** DOTA-TCP was synthesized by solid phase and purified by Pre-HPLC.$^{68}$Ga-DOTA-TCP was radiolabeled with $^{68}$Ga eluted from a $^{68}$Ge-$^{68}$Ga generator. The in vitro and in vivo stability of $^{68}$Ga-DOTA-TCP was determined by Radio-HPLC in saline solution or 5% human serum albumin(HSA) and normal mice. Karpas299 tumor-bearing CB17-SCID mice with high CD25 expression were selected and were intravenously injected with 200 μL of $^{68}$Ga-DOTA-TCP (7.4 MBq), and static Micro-PET/CT imaging was acquired at 1 h post-injection observe the uptake and metabolism of tumor, muscle and other areas of interest. ***Results:*** The purity of DOTA-TCP was > 95% and its structure was identified by ESI-MS. The radiochemical purity of $^{68}$Ga-DOTA-TCP was >95% after purification by C18 cartridge. $^{68}$Ga-DOTA-TCP had good stability in vitro and in vivo, the radiochemical purity can maintain >95% within 30min,The Micro-PET/CT Imaging results of $^{68}$Ga-DOTA-TCP in karpas299 tumor-bearing mice showed that the probe had uptake at the tumor site, the relatively lower background uptake rendered higher tumor-to-background ratio and better PET/CT imaging quality. The tumor ratio of $^{68}$Ga-DOTA-TCP was 3.29. ***Conclusion:*** $^{68}$Ga-DOTA-TCP showed good in vitro and in vivo stability and rapid clearance by the kidney. It also showed sufficient specificity and tumor-background ratio when applied to the imaging of CD25-positive Karpas299 tumor bearing mouse model. Therefore $^{68}$Ga-DOTA-TCP has a certain application prospect in noninvasive evaluation of T cell activation status in vivo.

### Primary prostate characterization in PSMA-11 PET on real quantum computers

***L. Papp***, *C. P. Spielvogel, M. Hacker, W. Drexler, S. Moradi;*
*Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Prostate cancer is one of the most common cancers in men. The routine diagnosis is based on inaccurate biopsy sampling. Radiomics combined with machine learning has shown feasible results regarding primary prostate cancer characterization in vivo. Nevertheless, conventional ML (CML) tends to be architecturally complex which complicates their generalization abilities, especially on small medical data. In contrast, quantum machine learning (QML) has the ability to build robust, algorithmically simple and potentially superior prediction models compared to CML. Nevertheless, existing so-called noisy intermediate scale quantum computers (NISQs) are still challenging to be utilized due to their high noise and error rates. Hence, this study aimed to investigate the feasibility of utilizing error mitigation techniques combined with QML in predicting prostate lesion risk in real NISQ devices. ***Materials and Methods:*** This study involved 121 [$^{68}$Ga]Ga-PSMA-11 (PSMA-11) primary prostate lesions having radiomic features with 60 low (≤ Gleason 3) and 61 high (≥ Gleason 4) Gleason risk as endpoint to predict. Ten-fold cross-validation was utilized with 90:10 train:test ratios to estimate predictive ML performance. Spearman rank reduncandy reduction combined with R-squared feature ranking and selection of 8 radiomic features per-train subset was performed. Multiple QML models were built per-fold in a quantum simulator environment: A simplified quantum support vector machine (qsSVM), a quantum kernel Gaussian process (qGP), and a quantum distance classifier (qDC). For comparison, respective CML models were built: support vector machine (cSVM), Gaussian process (cGP) and k-nearest neighbor (ckNN). Furthermore, quantum error mitigation was employed, followed by evaluating the QML approaches on the real IonQ device in a hold-out validation setting. ***Results:*** Predictive performance evaluation over 10-fold test subsets revealed an average 76% accuracy (ACC) for QML and 72% ACC for CML models in simulator environment, thus, demosntrating quantum advantage. The average test ACC in noiseless simulator environment was 75-83% for qDC, qGP and qsSVM approaches in the held-out validation setting. In contrast, the test ACC on the IonQ device without error mitigation was in the range of 42-75%. Utilizing error mitigation on IonQ yielded identical results to the noiseless simulator test performances in the qDC (77% ACC) and qsSVM (76% ACC) algorithms. ***Conclusion:*** We demonstrated that with error mitigation, quantum advantage can be achieved in real existing quantum computers when predicting low-vs-high risk in clinically-relevant primary prostate PSMA-11 cancer cohort.

## OP-707

### Image-based PSMA PET/MRI deep learning model for automatic prostate cancer grading

***E. Solari***[1], *S. Schachoff*[1], *I. Rauscher*[1], *M. Eiber*[1], *W. Weber*[1], *N. Navab*[2], *S. G. Nekolla*[1];
[1]*Klinikum rechts der Isar, Technical University Munich, München, GERMANY,* [2]*School of Informatics, Technical University Munich, München, GERMANY.*

***Aim/Introduction:*** Gleason score (GS) is fundamental in the decision making process of prostate cancer (PCa) management. Post-surgical GS (psGS) originates from a radical prostatectomy, but patients who are not subjected to this treatment option rely on a biopsy GS (bGS), which is less accurate and only agrees with psGS in around 60% of the cases. Previously, we showed that it is possible to improve this agreement applying PSMA PET/MRI radiomics in a small cohort. In this work, we propose a novel tool to automate and improve psGS predictions from an initial PSMA PET/MRI study, based on a multi-step deep learning pipeline. ***Materials and Methods:*** 185 biopsy planning and primary staging 68Ga-PSMA PET/MR PCa studies from a single scanner were included. An automatic deep learning pipeline was implemented to predict psGS from only images (PET, T2w, ADC). A whole-prostate segmentation tool was trained on 90 T2w

images manually segmented by an expert. The segmentations were later transposed into the other modalities. Three separate convolutional neural networks (CNN) were trained to classify two psGS groups (GS<8, GS≥8) from each image modality (60/20/20 train/validation/test split), with weighted average voting for the final classification. Balanced accuracy (bAcc) was used as the main metric to compare our model vs bGS predictions. ***Results:*** The patient distribution among the two groups was balanced (G<8: 56%, n=103; GS≥8: 44%, n=82). The segmentation showed signs of overfitting, suggesting the necessity of more annotated images (Dice coeff. 75%). The three CNN were trained over 20 epochs to classify psGS. The final model outperformed bGS in the prediction of psGS overall (bAcc, CNN: 90%; bGS: 74%) and in sensitivity and specificity towards the higher GS groups (CNN vs bGS, GS≥8: sens. 92% vs 79%; spec. 87% vs 69% respectively). This explained the reduction in under- and overestimation of psGS groups with respect to bGS (CNN vs bGS, underestimates: 8 vs 20 cases; overestimates: 15 vs 28 cases). ***Conclusion:*** Our work shows that it is possible to automate the prediction of psGS by groups based on PSMA PET/MRI studies, outperforming bGS. Possible clinical implications are the reduction of unnecessary biopsies and the improvement of initial patient management.

## OP-708

### Increased sensitivity for AI-based detection of lymph node metastases on [18F]-PSMA-1007 PET-CT when adding synthetic data to the training data

***E. Tragardh***[1,2], *J. Ulén*[3], *O. Enqvist*[3,4], *L. Edenbrandt*[5], *M. Larsson*[3];
[1]*Skåne University Hospital, Malmö, SWEDEN,* [2]*Lund University, Malmö, SWEDEN,* [3]*Eigenvision AB, Malmö, SWEDEN,* [4]*Chalmers University of Technology, Gothenburg, SWEDEN,* [5]*Sahlgrenska Academy, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Obtaining manually annotated positron emission tomography-computed tomography (PET-CT) images for training artificial intelligence (AI) is laborious. Here we investigated if it is possible to develop a fully automated AI-based method for detecting suspected lymph node metastases in prostate-specific membrane antigen (PSMA) PET-CT images of patients with prostate cancer, by adding synthetic lymph node metastases to the images to expand the training set. ***Materials and Methods:*** Patients referred for clinically indicated [18F]-PSMA PET-CT due to staging of high-risk prostate cancer or recurrence were included. The synthetic data were derived from original training images to which new, synthetic, lymph node metastases were added. Lymph node metastasis templates were gathered from all training images and carefully placed in new images using an aligned lymph node positioning map. In this way, the original training set from a previously published study (ref 1) (n=420), was expanded by one synthetic image for every original image. The resulting training set, with double the size (n=840), was used to train the AI tool. The performance of the AI-method was compared to nuclear medicine physicians and to a previously developed AI in a test set of 120 patients. The human readers were alternately used as a reference and compared to either another reading or AI. ***Results:*** The AI had an average sensitivity of 84% for detecting lymph node metastases, compared with 78% for human readings. Our previously developed AI-method, without synthetic data, had an average sensitivity of 79%. The number of true positive lesions was slightly higher for the new AI compared to human readings and the previous AI, while the number of false negative lesions was lower. The number of false positive lesions increased from 3.3 per patient for the new AI compared to 2.8 for the previous AI. ***Conclusion:*** It was possible to use synthetic data to increase the performance of a fully automated AI to detect suspected lymph node metastases in PSMA PET-CT images. However, the number of false positive lesions increased somewhat. ***References:*** 1. Trägårdh E et al. Freely available, fully automated AI-based analysis of primary tumour and metastases of prostate cancer in whole-body [18F]-PSMA-1007 PET-CT. Diagnostics(Basel) 2022;12:2101.

## OP-709

### Deep learning-based PET Image harmonization improves robustness and discriminative power of quantitative imaging markers in multi-institutional studies

***D. Haberl***[1], *C. P. Spielvogel*[1], *D. Iommi*[1], *I. Buvat*[2], *A. R. Haug*[1], *L. Papp*[3];
[1]*Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [2]*LITO laboratory, U1288 Inserm, Institut Curie, University Paris-Saclay, Orsay, FRANCE,* [3]*Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Quantitative PET/CT imaging has become a promising method providing information regarding diagnosis, prognosis, and treatment response monitoring. However, the sensitivity of quantitative imaging biomarkers (QIB) to different scanners and imaging protocols is a limiting factor in large-scale multi-institutional studies and hampers clinical translation. In response, we developed a deep learning harmonization method that aims to improve the reproducibility and discriminative power of QIB in multicentric studies. ***Materials and Methods:*** A cycle-consistent generative adversarial network (CycleGAN) was used to perform image style and texture translation among different centers and scanners. The capability of processing volumetric images was added to better deal with the 3D nature of tomographic biomedical images and to enable the application to whole-body PET scans. The method was evaluated by applying it on two different datasets and tasks. First, harmonization was performed on a dual-center whole-body lung cancer (LC) cohort where the SUV coefficient of variation (CV) in healthy liver tissue was evaluated. Second, the method was applied to a head and neck (HN) cancer cohort acquired from three centers. Here, the clinical impact of the method was analyzed by predicting the patient outcome (development of distant metastases) using a multivariate logistic regression model incorporating first-order statistics (n=18) and texture features (n=75) from baseline $^{18}$F-FDG PET before and after harmonization. ***Results:*** The high structural similarity (SSIM) of 0.991±0.006 (mean±1sd) and low mean squared error of 0.012±0.015 in the LC cohort indicated successful style and texture transfer without altering global anatomical structures. Site-specific differences (p=0.0003) were observed for the liver CV which became insignificant (p=0.1207) after harmonization. Inter-site reproducibility of QIB in healthy liver tissue increased by 41±12% (GLCM), 38±10% (GLRLM), 37±10% (GLDM), 29±18% (GLSZM), 22±15% (NGTDM), and 16±15% (first-order statistics) on average through the proposed method. In the HN cancer cohort, the clinical outcome prediction improved from AUC=0.68 (95% CI 0.66-0.71) to AUC=0.73 (0.71-0.75) through the GAN-harmonization (p<0.0001). ***Conclusion:*** The proposed method has the potential to improve QIB reproducibility of quantitative PET/CT imaging between centers while retaining the clinically relevant biological information. The approach is - in contrast to existing feature-based PET harmonization methods - operating at the image level, allowing physicians and researchers to have access to the images after harmonization. The clinical relevance of the method was demonstrated by directly linking it to an improved outcome prediction for HN cancer patients.

### [$^{11}$C] CFT PET to [$^{123}$I] FP-CIT SPECT Domain Adaptation:A CycleGAN harmonization approach

***L. Lopes***[1,2], *S. Xu*[1], *J. Lu*[3], *T. Pyka*[1], *K. Krieger*[1], *R. Fahmi*[4], *B. Spottiswoode*[4], *A. Soliman*[4], *R. Buchert*[5], *M. Brendel*[6], *J. Hong*[1,2], *C. Clement*[1,2], *C. Bassetti*[7], *A. Rominger*[1], *P. Wu*[3], *K. Shi*[1];
*[1]Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND, [2]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, SWITZERLAND, [3]Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [4]Siemens Medical Solutions United States Of America, Inc., Knoxville, TN, UNITED STATES OF AMERICA, [5]Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY, [6]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [7]Department of Neurology, University of Bern, Bern, SWITZERLAND.*

***Aim/Introduction:*** Dopamine transporter (DAT) imaging is routinely used in the diagnosis of Parkinson's Disease (PD) and atypical parkinsonian syndromes(APS). While CFT PET is widely accessible in East Asia with a substantial APS database to support AI advancements, DAT SPECT is widely used in Europe with only limited APS data. Cross-modality harmonization is still challenging, which is particularly relevant in longitudinal or multicenter studies. This study aims to develop a deep learning-based cross-modality synthesis to improve interoperability between CFT PET and DAT SPECT. ***Materials and Methods:*** A 3D CycleGAN was trained using unpaired CFT PET (n=705; 66% PD) and DAT SPECT (n=1033; 85% PD) brain images from PD and non-parkinsonian (NP) subjects. The network was used to generate synthetic SPECT from a real PET test set (n=116; 63% PD). A blind visual scoring analysis was performed by two nuclear medicine specialists in a mixed selection of 10 real and 10 synthetic SPECT images. Specialists scored the level of noise, presence of artifacts, confidence in diagnosis, and synthetic/real interpretation on a 3-point Likert scale. Quantitatively, striatal-specific binding ratios (SBR) were calculated in the real PET and real and synthetic SPECT test sets and compared. A convolutional neural network (CNN) for NP vs PD classification was trained with the synthetic SPECT dataset and tested on the real SPECT test set. ***Results:*** Visual assessment showed no significant differences in the mean synthetic/real score between real and synthetic datasets. The synthetic SPECT dataset has a slightly insignificant higher mean noise and artifacts score, and a significantly lower mean confidence in diagnosis score($P<0.05$) compared to real SPECT. The mean diagnostic accuracy of visual interpretation in the synthetic SPECT images was 75%, compared to 90% in real SPECT images. The SBR values of synthetic SPECT were not significantly different from those of real SPECT. Differences were significant between NP and PD in the synthetic SPECT($P<0.05$). The CNN trained with synthetic SPECT achieved a diagnostic accuracy of 97% in the real SPECT test set. ***Conclusion:*** Our CycleGAN successfully generated synthetic SPECT images visually indistinguishable from real SPECT images and preserved disease classification information. The developed PET-to-SPECT translation has the potential to improve the reproducibility of quantitative metrics and classification accuracy across the two modalities, which might facilitate multicenter studies and aid in the challenging differential diagnosis of PD and APS. Further studies with a higher number of visual assessments are needed to validate the approach.

## OP-711

### Estimating the Tumor Localization Performance via Class-Activation Map Explanations of a Slice Classification Neural Network Without Pixel-Level Supervision

***S. Ahamed***[1,2], *C. F. Uribe*[1,3], *A. Rahmim*[1,2];
*[1]University of British Columbia, Vancouver, BC, CANADA, [2]BC Cancer Research Institute, Vancouver, BC, CANADA, [3]BC Cancer, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Explainability of AI models in medical image analysis is important for building trust, ensuring regulatory compliance, facilitating clinical decision support, and beyond. They allow physicians to understand AI-generated results and make informed clinical decisions. We utilized class-activation maps (CAMs)-based explanation methods on our previously trained slice classification network[1]. The network was trained on a multi-centric dataset(n=466) of lymphoma PET axial slices using slice-level annotation (positive vs. negative for tumors). We explored the extent of (pixel-level) tumor localization using explanations on slices and performed localization receiver operating characteristic (LROC) analysis, without explicitly training on pixel-level supervision. ***Materials and Methods:*** The test set performance of our previously trained network was: sensitivity=73%, specificity=96%, precision=79%, F1-score=76%[1]. In this work, CAM-based methods (GradCAM, GradCAM++, EigenCAM, LayerCAM) were utilized for interpreting classification decisions. These methods computed gradients of target class with respect to feature maps of the last convolutional layer, resulting in heatmaps highlighting important regions influencing the model's prediction. An acceptance circle with varying radii R (between 3.12mm and 390mm) centered at the centroid of the explanation heatmap was constructed, and the fraction of tumors (ground-truth) encompassed by the circle was measured. The fraction of tumors localized (averaged over the whole set) was plotted as a function of the circle radius to generate LROC curves for each CAM method. ***Results:*** At a chosen R=6.2 cm on the empirical-LROC curves, the mean fraction of tumor localized on the slices via GradCAM, GradCAM++, EigenCAM, and LayerCAM was 0.537±0.401, 0.502±0.402, 0.560±0.398, and 0.531±0.402, respectively. Area under the LROC curves (AUC LROC) used as surrogates to represent the localization power of these methods were calculated to be 0.529, 0.487, 0.552, and 0.522, respectively. A simulated random localizer on the same set had a mean localization fraction=0.025±0.026 and AUC LROC=0. ***Conclusion:*** Utilizing the explanations of classification models could be an effective way for not just interpreting model predictions, but also localizing tumors without explicit pixel-level training/supervision. In our analysis, the EigenCAM method outperformed all other methods in the task of finding a tumor localization window via explanation. Future work will focus on improving localization performance for smaller window sizes. ***References:*** [1]S. Ahamed, el al, Proc. SPIE 12464, Medical Imaging 2023.

## OP-712

### Early experiences with the use of triplet networks for histological subtype classification in Non-Small Cell Lung Cancer

***F. Gelardi***[1,2], *F. Aksu*[1], *A. Chiti*[1,2], *P. Soda*[3,4];
*[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), ITALY, [2]Department of Nuclear Medicine, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY, [3]Research Unit of Computer Systems and Bioinformatics, Campus Bio-Medico University of Rome, Rome, ITALY, [4]Department of Radiation Sciences, Radiation Physics, Biomedical Engineering, Umea University, Umea, SWEDEN.*

***Aim/Introduction:*** Non-Small Cells Lung Cancer (NSCLC) is one of the leading neoplasms and causes of morbidity and mortality worldwide. Accurate histopathological assessment and disease extent staging by invasive and imaging techniques are essential for individualised patient management and outcome prediction, resulting in delayed treatment and costly procedures. Virtual biopsy through the development of deep learning (DL) methods exploiting routinely collected image scans is a promising strategy to address these issues. However, most well-known DL techniques require a large amount of data, while the available datasets are small, limiting the training of the model. We aimed to test whether triplet networks were able to classify the histological subtype of NSCLC on a small dataset and to compare their performance with plain Convolutional Neural Networks (CNNs). ***Materials and Methods:*** We retrospectively and randomly selected patients with new diagnosis of NSCLC, baseline [18F]FDG PET/CT and surgical intervention performed in the IRCCS Humanitas Research Hospital. We collected demographic data, tumour information and clinical outcome. We segmented semi-automatically primary tumour lesions on PET images using a commercial software (PET VCAR, GE Healthcare, Waukesha, WI, USA) and manually adjusted the volume of interest (VOI) on CT images in case of mismatch between CT and PET images. We performed different experiments using different pretrained CNNs and triplet selection methods on the CT image dataset extracted from PET/CT. We statistically compared performance scores, measured in terms of area under the receiver operating characteristics curve (AUROC) averaged over 25 runs. We considered a p-value ≤0.1 for statistical significance. ***Results:*** We included 87 patients with NSCLC (age 69±8, male-to-female ratio 3:1). The histological diagnosis was adenocarcinoma in 60 patients and squamous cell carcinoma in 27 patients. The triplet network approach was more robust to data scarcity compared to plain CNNs. ResNet-50 and GoogleNet were the best performing networks ($p \leq 0.01$), with an AUROC of 0.651 ± 0.136 in GoogleNet. ***Conclusion:*** Triplet networks outperformed plain CNNs in the classification of the histological subtype of NSCLC in almost all experiments. Triplet networks are a viable option to overcome the limitations of small datasets when applying deep learning techniques in medical imaging.

## OP-713

### Development and Multicenter Validation of an Artificial Intelligence System for the Detection of Cardiac Amyloidosis in $^{99m}$Tc Scintigraphy

***C. Spielvogel***[1], *D. Haberl*[1], *J. Ning*[2], *R. Calabretta*[1], *T. Traub-Weidinger*[1], *R. H. Davies*[3], *I. Pierce*[4], *K. Patel*[4], *K. Kluge*[1], *T. Nakuz*[1], *A. ***Aim/Introduction:*** In Cardiac amyloidosis (CA), misfolded proteins aggregate to amyloid fibrils and accumulate in the myocardium, eventually leading to heart failure and death. The current diagnostic approach relies on difficult-to-standardize, visual interpretation of $^{99m}$Tc-scintigraphy[1]. In addition to the resulting variability in image ratings, CA is sometimes an incidental finding in $^{99m}$Tc-scintigraphy and not always correctly recognized or reported to the referring physician[2]. We developed an artificial intelligence (AI) system to detect CA on $^{99m}$Tc-scintigraphy scans in a standardized and accurate way. Robustness, prognostic value, safety, and clinical applicability of the AI system were assessed by multicenter validation, outcome assessment with two clinical endpoints, a medical algorithmic audit[3], and a multi-case multi-reader (MCMR) study. ***Materials and Methods:*** Overall, 19201 scans from 16059 patients originating from eight centers in Austria, the United Kingdom, and China were included in the study. The AI system was developed using data from a single center and validated on the remaining seven centers. The AI system was trained to detect the presence of a CA-associated pattern (Perugini grade[4] ≥ 2). The system's performance was further compared to the diagnostic performance of five experienced physicians through a MCMR study. Outcome assessment was performed using multivariate Cox regression corrected for relevant confounders (median follow-up time 4.1 years, IQR 1.5-6.5). ***Results:*** The AI system achieved a 10-fold cross-validation performance of AUC 1.000 (95% CI: 1.000-1.000) for the Austrian cohort and independent external validation AUCs of 0.997 (95% CI: 0.993-0.999) and 0.925 (95% CI: 0.871-0.971) for the United Kingdom and China cohorts respectively. The AI system's predictions were prognostic for survival (HR 1.40; 95% CI: 1.04-1.90; p=0.029) and heart failure (HR 1.85; 95% CI: 1.15-3.00 ; p=0.012). Median follow-up was 3.1 years (IQR 1.4-6.5) after which 28% of patients were either affected by heart failure or death. In the MCMR study, disagreement among the physicians occurred in 10.2% of cases (Fleiss kappa 0.88) and with a mean performance of AUC 0.945 (range 0.911-0.970), while the AI system had an AUC of 0.997. The medical algorithmic audit suggested robustness across tracers, scanners, demographic factors and centers. ***Conclusion:*** The developed AI system reaches diagnostic performances comparable with nuclear medicine physicians and provides a standardized and fast approach for reliably detecting CA patients using $^{99m}$Tc-scintigraphy scans. The AI system may be employed for CA screening among patients referred for 99mTc-scintigraphy. ***References:*** 1.Kittleson,-M.-et-al.-2023-ACC-Expert-Con ensus-Decision-Pathway-on-Compre ensive-Multidisciplinary-Care-for-the-Patient-With-Cardiac-Am loidosis.-J.-Am.-Coll.-Cardiol.-81,-1076-1126-(2023).2.Stan,-C.,-Mititelu,-R.,-Adam,-R.-D.-&-Jurcuț,-R.-Awareness-of-Nucler-Medicine-Physicians-in-Romania-Regarding-the-Diagnostic-of-Cardiac-Amyloidosis-A-Survey-Based-Study.-Diagnosics-(Basel)-12,-(2022).3.Liu,-X.-et-al.-The-medical-algorithmic-audit.-The-Lancet-Digial-Health-4,-e384-e397-(2022).4.Hutt,-D.-F.-et-al.-Prognostic-utility-of-the-Perugini-grading-of-99mTc-DPD-scintigraphy-in-transthyretin-(ATTR)-amyloidosis-and-its-relationship-with-skeletal-muscle-and-soft-tissue-amyloid.-Eur.-Heart-J.-Cardiovasc.-Imaging-18,-1344-1350-(2017).

## OP-714

### Deep learning-based image classification in differentiating lymphoma pulmonary involvement and other hypermetabolic pulmonary diseases on $^{18}$F-FDG PET/CT

***R. Cheng***[1], *Y. Peng*[1], *M. Quan*[2], *B. Li*[1], *N. Wen*[2], *J. Hu*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Department of Radiology, Ruijin Hospital Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Lymphoma pulmonary involvement, lung cancer, and hypermetabolic benign pulmonary lesions share similar patterns on $^{18}$F-FDG PET/CT frequently. To address this issue, we developed a deep learning model by utilizing multi-center PET/CT data to realize the auto-segmentation and classification of hypermetabolic pulmonary lesions on images of $^{18}$F-FDG PET/

CT. ***Materials and Methods:*** This study employed two datasets. Dataset I included 1014 FDG PET/CT studies with malignant lymphoma, melanoma, lung cancer and negative controls from the AutoPET competition [1]. All the lesions were manually annotated. The dataset was divided into training and validation sets in a 4:1 ratio for initial model training. Dataset II consisted of 161 cases of PET/CT images (40 lyphoma, 60 lung cancer, 60 benign) acquired from our own institute. Lesion in the thoracic regions in Dataset II was segmented manually by two nuclear medicine physicians and extracted based on a 41% SUVmax threshold, resulting in 620 lesions. Then, it was partitioned into training, verification, and test sets using a 3:1:1 ratio. The images from both datasets underwent thoracic region cropping for model inputs. To train the lesion segmentation model, we employed a 3D UNet network model with ResNet-18 as the backbone [3D UNet (ResNet-18)], which was pre-trained using Dataset I and finetuned on Dataset II. Next, the 3D ResNet-18 was trained to classify the lesions based on the lesion. Subsequently, the lesion classification model was trained on Dataset II using the same 3D ResNet-18 model. ***Results:*** In the segmentation task, the model achieved a Dice coefficient of 0.699, with precision and recall scores of 0.869 and 0.614 respectively in the testing cohort. Meanwhile, in the classification task, the model achieved an area under the curve (AUC) of 0.975, with an accuracy rate of 87.9% (48/48 for lymphoma, 50/54 for benign, and 20/22 for lung cancer). ***Conclusion:*** The proposed deep learning model provides a practical approach for identifying hypermetabolic lung lesions to aid physicians in clinical decision making. Future studies should assess the model's diagnostic performance by comparing it with double-blind diagnoses made by physicians. ***References:*** [1] Gatidis S, Kuestner T. ### OP-715

**Can pre-therapy $^{68}$Ga-PSMA-11 PET SUVs predict absorbed doses across multiple cycles of $^{177}$Lu-PSMA-617 therapy of mCRPC patients?**

***J. Brosch-Lenz***[1], *N. Colpo*[2], *I. Bloise*[1], *X. Hou*[1], *W. R. Parulekar*[3], *C. Dellar*[3], *F. Saad*[4], *K. Chi*[2], *D. Wilson*[2], *F. Bénard*[2], *A. Rahmim*[1], *C. Uribe*[2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA,* [3]*Canadian Cancer Trials Group, Queen's University Kingston, Kingston, ON, CANADA,* [4]*Prostate cancer research, Montreal Cancer Institute / CRCHUM, Montreal, QC, CANADA.*

***Aim/Introduction:*** $^{177}$Lu-PSMA-617 is an approved radiopharmaceutical for the treatment of metastatic, castration-resistant prostate cancer. However, patient-individual therapy response is not yet understood. Therefore, we aimed at investigating how parameters from the pre-therapeutic $^{68}$Ga-PSMA-11 PET/CT imaging may predict the absorbed dose in the total tumor burden (TTB) and kidneys across multiple cycles of $^{177}$Lu-PSMA-617 therapy. This work is based on early experience from the Canadian Cancer Trials Group PR21 trial (NCT 04663997). ***Materials and Methods:*** Pre-therapy $^{68}$Ga-PSMA-11 PET/CT and post-therapy $^{177}$Lu-PSMA-617 SPECT/CT data from four patients with a total of 24 therapy cycles were analyzed. Healthy organs were segmented on the CT images using an AI-model, while tumors were segmented on the SPECT images using the qPSMA approach [1]. Tissue-specific time-activity-curves were fitted to a mono-exponential function for the first therapy cycle, while a single time point dosimetry approach [2] was used for the subsequent therapy cycles. S-value based dosimetry was performed in IDAC-Dose v2.1 using organ/lesion time-integrated activity and mass. A correlation analysis was performed between the TTB and kidneys on PET and TTB absorbed dose (AD) across therapy cycles and between TTB $SUV_{max}$ and $SUV_{mean}$ on PET and the TTB and kidney ADs. ***Results:*** PET-based TTB was 563±726 ml averaged across all patients. $SUV_{max}$ and $SUV_{mean}$ were 66.3±31.8 and 13.5±3.3 for TTB, averaged across all patients. Left and right kidney ADs increased on average by +38% and +36% from cycle 1 to 6. In contrast, ADs for TTB decreased on average by -39% from cycle 1 to 6. Intermediate correlation was found between PET-TTB and kidney AD ($R^2$ from 0.21-0.70) across cycles, while no correlation was found between PET-TTB and TTB AD. For tumors, small ($R^2$=0.20) to intermediate ($R^2$=0.45) correlation was found between $SUV_{max}$ and TTB AD and $SUV_{mean}$ and TTB AD for the 1st cycle. Varying correlation ($R^2$ from 0.00 to 0.98) was found between TTB $SUV_{max/mean}$ and kidney AD across cycles. ***Conclusion:*** Despite the small number of investigated patients, we believe that the TTB $SUV_{mean}$ may be used as a predictor for tumor AD. However, contrary to the global approach in this work, a separate analysis between lesions in soft tissue and bone is advisable and might lead to better correlation. It is planned to expand this analysis to a larger patient cohort of the PR21 trial. ***References:*** [1] DOI: 10.2967/jnumed.118.224055; [2] DOI: https://doi.org/10.2967/jnumed.122.264594

### OP-716

**Safety and efficacy of PSMA-targeted radionuclide therapy with $^{177}$Lu-ITG-PSMA-1 in metastatic castration resistant prostate cancer patients: Update on the prospective, multicentre, Swiss registry study**

***A. Chirindel***[1], *A. Bauman*[1], *M. Fani*[1], *F. Forrer*[2], *A. Afshar-Oromieh*[3], *M. del Sol Pérez Lago*[4], *J. Blautzik*[5], *N. Schaefer*[6], *E. Nitzsche*[7], *D. Wild*[1], *G. Nicolas*[1];
[1]*University Hospital Basel, Basel, SWITZERLAND,* [2]*Kantonsspital St. Gallen, St Gallen, SWITZERLAND,* [3]*Inselspital, Berne, SWITZERLAND,* [4]*Luzerner Kantonsspital, Lucerne, SWITZERLAND,* [5]*Hirslanden Klinik St. Anna, Lucerne, SWITZERLAND,* [6]*University Hospital Lausanne, CHUV, Lausanne, SWITZERLAND,* [7]*Kantonsspital Aarau, Aarau, SWITZERLAND.*

***Aim/Introduction:*** To assess safety and efficacy of $^{177}$Lu-ITG-PSMA-1 ($^{177}$Lu-PSMA I&T) in progressive metastatic castration resistant prostate cancer (mCRPC) patients, implemented in day-to-day clinical practice in Switzerland. ***Materials and Methods:*** Prospective, multicenter national register study (EKNZ 2021-01271) of progressive mCRPC patients treated with $^{177}$Lu-ITG-PSMA-1. The primary endpoint is safety, assessed by biweekly laboratory parameters, adverse events (as per CTCAE v5.0) and xerostomia questionnaire (XQ). Efficacy outcome measures comprise best biochemical ($PSA_{50}$: PSA decrease >50% from baseline) and imaging response (clinical evaluation based on all available imaging modalities: CT, MRI, quantitative PSMA SPECT- or PET-CT), time to progression, overall survival and quality-of-life (EORTC PR25, EORTC QLQ-C30 and Brief Pain

Inventory Questionnaires). Descriptive and comparative statistics will be used to evaluate therapy safety and response. Multivariate analysis and Kaplan-Meier statistics will be used to evaluate time-to-outcome events and prognostic factors. ***Results:*** So far 140 patients (age: 74±8 years, mean±SD)) treated since May 2020 until March 2023 with at least 1 cycle (number of cycles, median [IQR]: 3 [2-5],) and 1 follow-up. The activity per cycle (median [IQR]) was 7.1 [6.5-7.5] GBq. Treatment related ≥G3 anemia, leucopenia and thrombocytopenia were found in 20 (14.7%), 5 (4%) and 4 (3%) patients, respectively. Analysis of the XQ-score (0-80) in the first 75 patients showed an increase from 7±10 to 10±11 (mean±SD) between the first and the last cycle (p=0.009, paired t-test), while an increase ≥10 was observed in 16 patients (21%). $PSA_{50}$ was achieved in 55/135 (41%), whereas any PSA decrease occurred in 89/135 (66%) patients. Partial imaging response (PR) was found in 47/89 patients (53%). PR occurred at cycle 2 in 68% (32/47), while only 6/47 (12%) responded after the 3rd cycle. The median time to progression and OS will be presented. ***Conclusion:*** Our preliminary analysis shows that $^{177}$Lu-ITG-PSMA-1 therapy is safe and efficacious in most progressive mCRPC patients. Anemia appears to be the most frequent and clinically relevant subacute myelotoxicity; while during treatment, a marked XQ-score increase is reported only in a small minority of patients. Biochemical or imaging-based tumor response, was recorded in approximately half of the patients.

## OP-717

### Systematic evaluation of response and adverse events in mCRPC patients treated with different combinations of $^{225}$Ac/$^{177}$Lu-PSMA-therapy

***G. Sheikh***[1], *M. J. Zacherl*[1], *A. Holzgreve*[1], *S. C. Kunte*[1], *V. Wenter*[1], *M. Unterrainer*[2], *W. Kunz*[3], *J. Casuscelli*[4], *C. Stief*[4], *P. Bartenstein*[1], *L. M. Unterrainer*[1];
[1]*Department of Nuclear Medicine, LMU Klinikum, Munich, GERMANY,* [2]*Die Radiologie, Munich, GERMANY,* [3]*Department of Radiology, LMU Klinikum, Munich, GERMANY,* [4]*Department of Urology, LMU Klinikum, Munich, GERMANY.*

***Aim/Introduction:*** $^{225}$Ac-Targeted alpha therapy is a potent and promising option for patients with metastatic castration-resistant prostate cancer (mCRPC) and failure of guideline-based therapies and $^{177}$Lu-PSMA-radioligand therapy. Unfortunately, side effects associated with TAT can significantly affect quality of life. A combination treatment regimen adding $^{177}$Lu and reducing $^{225}$Ac activities may limit side effects while maintaining sufficient anti-tumour effect. We therefore evaluated different combinations $^{225}$Ac-/$^{177}$Lu-PSMA-I&T (ALCT) with regard to response and adverse events. ***Materials and Methods:*** A total of 22 consecutive patients treated with ALCT on compassionate use basis at our department were evaluated. Patients were grouped into three different subgroups, depending on the $^{225}$Ac/$^{177}$Lu-activity administered: group 1 (Gr1) received 4MBq and 4000MBq, group 2 (Gr2) 6MB and 1000 or 2000MBq and group 3 (Gr3) 8 MBq and 1000MBq per therapy cycle, respectively. Laboratory (PSA, ALP, LDH, Hb, Lc, Tc, Crea) and imaging parameters on $^{18}$F-PSMA-PET/CTs (TTV, SUVmax/mean) at baseline and after 2 cycles of therapy were evaluated for the total patient population as well as each therapy subgroup and statistically compared. Adverse events (xerostomia, anemia, leukopenia, thrombocytopenia, weight loss) were recorded. Response evaluation criteria in PSMA-PET/CT (RECIP 1.0) was used for response evaluation. ***Results:*** Gr1 showed RECIP 1.0 response in 4/10 patients and progression in 3/10 patients, Group 2 showed response in 2/3 patients and progression in 1/3 patients and group 3 showed response in 4/8 patients and progression in 2/8 patients. There was no significant difference between the three subgroups in respect to absolute values after therapy or pre- and post-therapy difference in any of the laboratory or imaging parameters evaluated. A positive correlation could be found between $^{177}$Lu-activity and bone marrow events and $^{225}$Ac-activity and xerostomia. After 2 cycles of ALCT the following adverse events developed newly or worsened by at least one grade: anemia in 2/10 patients from Gr1 and 3/9 patients from Gr3; thrombocytopenia in 1/10 patients from Gr1; leukopenia in 4/10 from Gr1, 1/3 from Gr2 and 2/9 from Gr3; weight loss in 1/10 from Gr1 and 2/9 from Gr3 and xerostomia in 3/10 from Gr1, 1/3 from Gr2 and 5/9 from Gr3. ***Conclusion:*** Since there was no significant differences in efficacy between the three therapy groups, ALCT with lower $^{225}$Ac-activity may be a good choice in cases in which conservation of salivary gland function is the main concern, but more careful monitoring of blood values is warranted in those patients.

## OP-718

### ProstACT GLOBAL: A Phase 3 Study of 177Lu-DOTA-rosopatamab (TLX591) With and Without the Best Standard of Care for Patients With PSMA Expressing Metastatic Castration-resistant Prostate Cancer Progressing Despite Prior Treatment with a Novel Androgen Axis Drug

***S. Martina***[1], *C. Hawkins*[1], *N. Patel*[1], *J. Gibson*[1], *T. Brown*[1], *N. Lenzo*[2], *C. Hayward*[1];
[1]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,*
[2]*Genesis Care, Alexandria NSW 2015, AUSTRALIA.*

***Aim/Introduction:*** The treatment of advanced prostate cancer (PC) is challenging, with undesirable side effects that impact patient quality of life. Radioimmunotherapy (RIT) can localize therapy to specific tumor cells in multiple organs to reduce or eliminate damage to normal tissue. The cell surface glycoprotein prostate-specific membrane antigen (PSMA) is an ideal therapeutic target as it is highly expressed by malignant prostate cells. There is a strong rationale for further investigation of the $^{177}$Lu-labeled, chelator-conjugated antibody, $^{177}$Lu-DOTA-rosopatamab, as a potential RIT candidate for the treatment of PC. ***Materials and Methods:*** In this multinational, multicenter, prospective, randomized, open label phase 3 study, 387 patients with PSMA-expressing metastatic castration-resistant PC (mCRPC) that have progressed despite prior treatment with a novel androgen axis drug will be enrolled in a 2:1 ratio to receive either the best standard of care (SoC) or 2 single intravenous (IV) injections of 76 milicuries (mCi) each (equivalent to a 45 mCi/m2 dose in a standard 1.7m2 individual) of $^{177}$Lu-DOTA-rosopatamab, given 14 days apart, plus best SoC. Eligible patients must have received prior therapy with either enzalutamide or abiraterone plus prednisone, and 1 line of prior taxane therapy or have refused or are ineligible for taxanes. Patients must have adequate organ function including at least $150x10^9$ /L platelets, hemoglobin 10 g/dL, and have PSMA-positive disease on $^{68}$Ga-PSMA-11 PET/CT imaging as confirmed by a central reader. Key exclusion criteria include small cell histology, increased risk of hemorrhage or bleeding, known brain or hepatic metastases, or history of stroke, seizure, or treatment with radioisotopes within 6 months prior to randomization. The primary endpoint is radiographic progression-free survival (PFS). Secondary endpoints include 5-year overall survival, tumor objective response rate, time to symptomatic skeletal event, PFS, and participant number with treatment-related adverse events. Effective treatment options for mCRPC with favorable safety and tolerability profiles continue

to be an unmet need. Combining the advantages of targeted radiotherapy and immunotherapy, along with proven patient selection capabilities of $^{68}$Ga-PSMA-11 PET, provides reasonable justification for further evaluation of $^{177}$Lu-DOTA-rosopatamab in a large-scale trial. ***Results:*** This study is ongoing; no results are available at the time of abstract submission. ***Conclusion:*** Effective treatment options for mCRPC with favorable safety and tolerability profiles continue to be an unmet need. Combining the advantages of targeted radiotherapy and immunotherapy, along with proven patient selection capabilities of $^{68}$Ga-PSMA-11 PET, provides reasonable justification for further evaluation of $^{177}$Lu-DOTA-rosopatamab in a large-scale trial.

## OP-719

### [$^{225}$Ac]Ac-PSMA-617 mutational landscape in circulating tumor DNA (ctDNA): early clinical outcome prediction in metastatic castration-resistant prostate cancer

***M. Amghar***[1], *T. Rausch*[2], *T. Hielscher*[1], *H. Ozgur*[2], *M. Roscher*[1], *U. Bauder-Wüst*[1], *M. Schick*[1], *Y. Remde*[1], *G. Bakos*[1], *M. Schäfer*[1], *F. Bruchertseifer*[3], *A. Morgenstern*[3], *V. Benеš*[2], *C. Kratochwil*[4], *M. Benešová-Schäfer*[1];
[1]*DKFZ, Heidelberg, GERMANY,* [2]*EMBL, Heidelberg, GERMANY,* [3]*European Commission, Joint Research Centre (JRC), Karlsruhe, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital, Heidelberg, GERMANY.*

***Aim/Introduction:*** First clinical experiences employing prostate-specific-membrane-antigen (PSMA)-addressing PSMA-617 with the alpha-particle-emitting radionuclide actinium-225 ($^{225}$Ac) exhibited astonishing responses in heavily pre-treated-metastatic castration- and chemo-resistant-prostate-cancer (PCa) patients. Thus, our efforts have been directed toward the investigation of functional predispositions of PCa-related radiation resistance and sensitivity to PSMA-directed targeted alpha therapy (TαT) with [$^{225}$Ac]Ac-PSMA-617. Preclinical and clinical studies reported that DNA-damage repair (DDR)-associated gene mutations can interfere with radiosensitivity of PCa. Therefore, non-invasive liquid biopsies, detecting early clinical outcome, represent an unmet clinical need. Whole-genome circulating tumor DNA (ctDNA) and its matching germline DNA (gDNA) sequencing will address the molecular alpha emitter-based radiation resistance mechanisms. ***Materials and Methods:*** Blood samples from PCa patients undergoing repeated cycles of TαT were collected within an ethical approval (S-882/2020). Digital-droplet-PCR (dd-PCR) was performed using androgen receptor (AR) copy number variation (CNV) assay, including NSUN3 as a reference gene, and ZXDB as a control. CNV analysis was performed using a linear mixed model accounting for repeated measurements and applying log-transformed CNV levels. gDNA and ctDNA whole genome sequencing (WGS) was performed to the requested depths. Targeted sequencing panel of ctDNA comprehended hotspot coverage: AKT1, EGFR (ERBB1), ERBB3, ESR1 (ERα), FBXW7, KRAS, PIK3CA (p110-alpha), SF3B1, and whole coding coverage: BRCA1, BRCA2, ERBB2 (HER-2, NEU), TP53 (p53). ***Results:*** The cohort consisted of 43 metastatic castration- and chemo-resistant PCa patients with a median age of 74 (57-84). Patients were divided into three groups: responders, non-responders and unknowns based on the prostate-specific antigen (PSA) value measured in blood. No significant correlation was observed between CNV estimates and PSA levels (p=0.07). No significant difference in cfDNA CNV levels (p=0.4) was observed between non-responders and responders. WGS data from 15 patients has been performed. Upon radiation resistance filter gene set, 23 genetic alterations were reported in 15 patients, comprising three frame shift, 18 missense mutations and one stop gained as well as three rearrangements. Overall, SIRT1 (100%), BARD1 (67%), and SFRP2 (53%) showed the highest mutation frequency. SIRT1 (100%), FANCD2 (93%), MUS81 (93%), IP6K3 (97%), and BARD1 (87%) were the genes showing the highest mutation frequency rate upon DDR filter gene set. ***Conclusion:*** The unique set of longitudinal patient probes undergoing PSMA-TαT harbors the potential to shed light on mechanisms of congenital and acquired resistances correlating genomic, molecular and clinical data on (progression-free) survival and might enable risk stratification, prognosis and therapy prediction for heavily pre-treated metastatic castration- and chemo-resistant PCa patients.

## OP-720

### Evaluation of labelingparameters of PSMA-617 with $^{213}$Bi for targeted alpha-radionuclide therapy of metastatic castration-resistant prostate cancer

***H. khoshhosn****, M. Davarpanah, H. Khoshhosn*, A. Gravand, Y. Tavakoli, N. Soltani, M. Harati, B. Kalantari, F.Johri;
*Pars Isotope company, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Targeted alpha therapy (TAT) has a great potential for the treatment of metastatic castration resistant prostate cancer. Recent studies have shown that prostate-specific membrane antigen (PSMA) is an important target for radionuclide imaging and therapy of PCa. PSMA is selectively overexpressed in 90-100% of primary and metastatic PCa lesions.[(i),(ii)] The alpha emitter $^{213}$Bi is a generator-based radionuclide and has a half-life of 46 minutes which can be obtained by an $^{225}$Ac/ $^{213}$Bi generator. The objective of this study was to validate a radiolabeling and quality control procedure of $^{213}$Bi labeled PSMA-617 in routine clinical production. Effective parameters on labeling of $^{213}$Bi-PSMA-617 were evaluated. Radionuclide purity was over 99.9%. Labeling yield and radiochemical purity were >99%. The production and labeling process of the $^{213}$Bi-PSMA-617 was reproducible and stable. ***Materials and Methods:*** $^{213}$Bi$^{3+}$ obtained from an $^{225}$Ac/ $^{213}$Bi-generator was provided by ITG Co. without adding any carrier, PSMA-617 peptide was from Arian pazho Co., which was used in preparation of the radiopharmaceutical. The generator was eluted with 0.6 mL 0.1 M NaI in 0.1 M HCl. The generator eluate was transferred into the reaction vial which contains 0.6 mL of 1M sodium acetate buffer, 5 mg ascorbic acid and 20 µg PSMA-617 (19 nmol). The pH of the reaction mixture was determined to be 5.0. The labeling was accomplished after heating the solution for 12 minutes at 95°C. ***Results:*** Using this procedure the incorporation of $^{213}$Bi was 99% with 50 MBq of $^{213}$Bi. The pH of the reaction mixture and the final product was 5.0. After QC, the final product could be used directly without the need for a final purification step. The final reaction volume was about 1.2 mL and can be diluted further for dose administration to any desired volume. ITLC analysis of the final product revealed no evidence of free Bi after 3 hours. ***Conclusion:*** A routinely useful synthesis procedure for the radiopharmaceutical production of $^{213}$Bi-PSMA-617 was validated. This protocol allows a routine production for the treatment of patients with metastatic castration-resistant prostate cancer. ***References:*** [1] Minner S, Wittmer C, Graefen M, et al. ### Safety, Dosimetry and Response of $^{177}$Lu-LNC1003 in Patients with Metastatic Castration Resistant Prostate Cancer

***J. Zang***[1], *G. Wang*[2], *T. Zhao*[3], *Y. Yang*[1], *W. Miao*[1], *Z. Zhu*[2], *J. Zhang*[3], *X. Chen*[3];
[1]*Department of Nuclear Medicine, the First Affiliated Hospital, Fujian Medical University, Fuzhou, CHINA,* [2]*Department of Nuclear Medicine, Peking Union Medical College (PUMC) Hospital, Chinese Academy of Medical Science and PUMC, Beijing, CHINA,* [3]*Departments of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** In our previous studies, to increase tumor accumulation and retention for radioligand therapy, we conjugated a truncated Evans blue (EB) molecule onto PSMA-617, and obtained the first-generation drug $^{177}$Lu-EB-PSMA. To further optimize its pharmacokinetics, we designed and synthesized the second generation of drug $^{177}$Lu-PSMA-EB-01 (or $^{177}$Lu-LNC1003). This translational study is designed to assess the safety, dosimetry and therapeutic response to $^{177}$Lu-LNC1003 in patients with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Following institutional review board approval and informed consent, ten patients with mCRPC were recruited. Patients were divided into 3 groups: group A (n = 4) was treated with about a 1.11 GBq (30 mCi) dose of $^{177}$Lu-LNC1003. Group B (n = 3) was treated with about a 1.85 GBq (50 mCi) dose of $^{177}$Lu-LNC1003. Group C (n = 3) was treated with around a 2.59 GBq (70 mCi) dose of $^{177}$Lu-LNC1003. ***Results:*** $^{177}$Lu-LNC1003 at different doses was well tolerated by all patients. No significant adverse effects were observed up to 2 months after the first cycle of treatment. Two patients in Group B experienced Grade 1 thrombocytopenia, but recovered within 8 weeks. Kidney function and liver function were not significantly changed within 2 months period of observation. The total body effective dose for $^{177}$Lu-LNC1003 was 0.384 ± 0.050 mSv/MBq. The highest estimated radiation dose was calculated for lacrimal glands at 2.65 ± 1.98 mSv/MBq. For the kidneys and red bone marrow, the calculated absorbed doses were 2.09 ± 0.51 mSv/MBq and 0.195 ± 0.0329 mSv/MBq, respectively. The mean absorbed dose for bone metastases and lymph node metastases was 8.74 mSv/MBq and 9.51 mSv/MBq, respectively. After the first cycle of treatment, a decline in the PSA level was observed in 1 (25.0%), and 2 (66.7%) patients in groups A and B, respectively. A decline in the PSA level of greater than 50% (PR) occurred in 0 (0%), and 1 (33.3%) of patients in groups A and B, respectively. After the first treatment cycle, according to the adapted PERCIST 1.0, 0 (0%), 1 (25.0%) patient in group A and 2 (66.7%) patients in group B had PR. Patients in the group C had not yet reached the time for recheck. ***Conclusion:*** This first-in-human study demonstrated that $^{177}$Lu-LNC1003 had higher accumulation than $^{177}$Lu-EB-PSMA and $^{177}$Lu-PSMA-617 in mCRPC and was well tolerated at the administered low dose. Further investigations with increased dose and frequency of administration are warranted.

## OP-722

### Extension of a $^{68}$Ga-PSMA PET-based nomogram for outcome prediction of $^{177}$Lu-PSMA radioligand therapy for the use of $^{18}$F-rhPSMA-7.3

***I. Rauscher***[1], *K. Hansen*[1], *A. Gafita*[1], *W. A. Weber*[1], *M. Eiber*[2];
[1]*Department of Nuclear Medicine, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY,* [2]*Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY.*

***Aim/Introduction:*** Recently, $^{177}$Lu-PSMA radioligand therapy (RLT) has been approved by the FDA and EMA for patients with metastatic-castration resistant prostate cancer (mCRPC). As response to $^{177}$Lu-PSMA RLT is not achieved by all patients, nomograms, including pre-therapeutic $^{68}$Ga-PSMA-PET, were established to predict outcomes. The increasing use of $^{18}$F-labelled PSMA-ligands requires adaptation of these methods. Thus, the aim of this retrospective analysis was the extension of a recently published nomogram for use with $^{18}$F-rhPSMA- 7.3 in a large cohort of patients with mCRPC. ***Materials and Methods:*** A total number of 180 patients were retrospectively included. First, pre-therapeutic outcome probabilities (PSA-progression-free survival (PFS) and overall survival (OS)) for each patient were estimated according to recently published $^{68}$Ga-PSMA PET-based prediction models. (1). Parameters included the same clinical variables and imaging data now derived from $^{18}$F-rhPSMA-7.3 PET (tumor SUVmean, number of lesions, presence of pelvic lymph node, bone and/or liver metastases). The observed and estimated outcome of each patient C-indexes were calculated for OS and PFS. OS and PFS were compared, stratifying patients in high- and low-risk groups based on the cut-off values determined by Gafita et al (1). ***Results:*** The estimated median PFS and OS were 3.7 months and 14.9 months, while the observed PFS and OS were 3.1 months and 12.1 months, respectively. For the OS survival model our data reached a C-index of 0.70 (95%CI 0.66-0.75), which is comparable to the development cohort and the validation cohort of Gafita et al. (C-index of 0.71 and 0.72, respectively). The C-index for PSA-PFS was 0.64 (95%CI 0.60-0.70) and substantially lower compared to a C-index of 0.71 (95%CI 0.65-0.78) in the validation cohort of Gafita et al. Low-risk patients presented with a significantly longer OS than high-risk patients (16.5 months (95%CI 15.1-17.8) vs. 8.8 months (95%CI 7.7-9.9), respectively; p-value < 0.0001). ***Conclusion:*** The use of data from $^{18}$F-rhPSMA 7.3-PET substituting $^{68}$Ga-PSMA in a recently proposed PET-based prediction nomogram performs well for assessing outcome of $^{177}$Lu-PSMA RLT. Its high concordance of the C-indexes confirming the prediction models' ability to determine reliable outcome parameters. As prediction models might be beneficial in patient selection further improvement of the model is warranted. ***References:*** (1) Gafita A, Calais J, Grogan TR, et al., Nomograms to predict outcomes after (177)Lu-PSMA therapy in men with metastatic castration-resistant prostate cancer: an international, multicentre, retrospective study, Lancet Oncol, 2021;22:1115-1125.

## OP-723

### $^{177}$Lu-PSMA-617 therapy in advanced mCRPC patients: preliminary results of the phase 2 prospective trial IRST-185.03

***I. Marini***, *M. Sansovini, G. Paganelli, I. Grassi, F. Matteucci, S. Nicolini, U. De Giorgi, E. F. Giunta, F. Foca, M. Monti, M. Celli, P. Caroli, V. Di Iorio, A. Sarnelli, C. Lolli, G. Schepisi, N. Brighi, S. Severi; IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY.*

***Aim/Introduction:*** IRST-185.03 is an open-label, single-centre, phase 2 prospective study. We report the efficacy and toxicity of $^{177}$Lu-PSMA-617 low dosages therapy, scheduled to identify the optimal cumulative activity to treat advanced mCRPC patients. The study is still ongoing. ***Materials and Methods:*** Progressive mCRPC patients, with positive 68Ga-PSMA PET-CT, were assigned to two distinct treatment groups based on age, prior therapies and risk factors for toxicity: a low-dosage group (LD - range 3.7-4.4 GBq per cycle) and a high-dosage group (HD - 5.5 GBq per cycle), both to

receive 4 (up to 6) cycles of $^{177}$Lu-PSMA-617. The primary objective of this analysis was the assessment of best biochemical response (BR) defined as ≥50% PSA reduction from baseline. Secondary objectives were safety, median progression-free survival (mPFS) and median overall survival (mOS). ***Results:*** From April 2017 to October 2022 we prospectively enrolled 145 patients. We had 3 screening failure and 142 patients who received at least one $^{177}$Lu-PSMA-617 cycle. 43 patients were assigned to the LD-group and 99 to the HD-group. All 142 patients were evaluated for BR, safety, OS and PFS. The median number of cycles was 4 and the median follow-up was 28.8 months. A PSA reduction ≥50% was achieved in 57 patients (40.1%), a reduction ≥30% in 69 patients (48.6%). 73 patients (51.4%) had a PSA increase or a PSA reduction <30%. $^{177}$Lu-PSMA-617 therapy proved to be safe and well tolerated in both groups. Overall only 7 patients had a G3 toxicity, 5 haematological, 2 renal. No G4 toxicity was observed. The most common side effect was G1 anaemia (13.4% of patients). No significant salivary gland toxicity was registered. The mPFS was 6.8 months in the LD-group and 7.0 months in the HD-group (non-significant difference). The overall mPFS was 7.0 months. Overall, the 6-month mPFS rate was 53.9% and the 12-month mPFS rate was 18.9%. The mOS was 13.5 months in the LD-group, 16.4 months in the HD-group and 16.8 months overall. The total 12-month mOS rate was 51.1% for the LD-group and 64.9% for the HD-group. The total 12-month mOS was 60.4%. ***Conclusion:*** Our results, obtained with reduced dosages, are in line with previous literature data and demonstrated an improved tolerance profile. The search for a minimum effective and non-toxic dosage deserves to be pursued with a view to using 177Lu-PSMA-617 in combination with other treatments, within de-escalation protocols and at earlier stages of the disease.

### OP-724

**Prognostic role of coronary microvascular dysfunction in non-obstructive coronary artery disease**

***K. Kopeva****, A. Maltseva, E. Grakova, A. Mochula, K. Zavadovsky;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution «Tomsk National Research Medical Center of the Russian Academy of Sciences», Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** The objective of the study was to evaluate of the prognostic role of coronary microvascular dysfunction (CMD), obtained by dynamic SPECT, in the development and progression of HFpEF in patients with non-obstructive coronary artery disease (CAD) during a 12-month follow-up period. ***Materials and Methods:*** A total of 112 patients (70 men, median age of 62.0 (58.0; 69.0) years) with preserved LV EF and non-obstructive coronary artery disease were enrolled in the study. Dynamic CZT SPECT and coronary computed tomography angiography studies were performed baseline. Impaired Myocardial flow reserve (MFR) was defined as MFR ≤2. Coronary microvascular dysfunction (CMD) was therefore defined as the presence of impaired MFR in the absence of flow-limiting CAD. Serum levels of NT-proBNP were analyzed by ELISA. ***Results:*** All patients were divided into groups depending on the presence of CMD: group 1 included patients with CMD (CFR ≤2; n=42), and group 2 included patients without it (CFR >2; n=70). MFR levels and rest-MBF correlated with the level of NT-proBNP (r=-0.368; p=0.007 and r=0.354; p=0.042, respectively). The values of MFR also correlated with LAVI (r=-0.464; p=0.001) and septal e' (r=0.314, p=0.012), and rest-MBF correlated with E/e' (r=0.512; p=0.002). During 12 months of follow-up, 25 patients had adverse events. The Kaplan-Meier test showed that the frequency of adverse outcomes significantly (p<0.001) differed between groups. Patients with CMD had higher rates of adverse outcomes (8.6%, n=6) than those without it (45.2%, n=19). Based on ROC-analysis, only the levels of MFR ≤ 1.62 (sensitivity 85.7%, specificity 84.7%; AUC=0.884; p<0.001) and stress-MBF ≤ 1.35 ml/min/g (sensitivity 87.5%, specificity 62.5%; AUC=0.750; p<0.001) were identified as cut-off values predicting the adverse outcomes. Based on ROC-curve comparison analysis, MFR values were more significant predictor (p=0.034) of HFpEF development and progression. ***Conclusion:*** The presence of CMD, obtained by dynamic SPECT, helped to identify patients at high risk of developing and progressing HFpEF during the 12-month follow-up period. The values of MFR and stress-MBF can be used as a non-invasive predictor for risk evaluation of HFpEF development and progression in patients with non-obstructive CAD. ***References:*** Funding: MK-4257.2022.3

### OP-725

**Impact of coronary flow reserve on the mortality and major adverse cardiac and cerebrovascular event in hemodialysis patients, regardless of diabetes**

***S. Ohshima****;*
*Nagoya Kyoritsu Hospital, Nagoya, JAPAN.*

***Aim/Introduction:*** Ischemic heart disease (IHD) is still a major problem not only in general patients but also in regular hemodialysis (HD) patients. We have reported about prognostic value of coronary flow reserve (CFR) derived from N13-ammonia PET in HD population for all-cause mortality and major adverse cardiac event (MACE) in prior studies. We investigated the impact of diabetes and low CFR on the mortality in HD population. ***Materials and Methods:*** A total 1,020 HD patients who undergone 13N-ammonia PET for suspected IHD were enrolled. We divided them into four groups according to CFR (cut off value = 2.0) and whether DM or not. We collected and evaluated their all-cause mortality, cardiovascular (CV) mortality and MACE, and analyzed using Kaplan-Meier methods and uni/multivariate cox regression model. ***Results:*** There were inter group differences in all-cause mortality, CV death, non-CV death and MACCE. Whether DM or not, CFR predicted HD patients' prognosis precisely. And HD patients with DM and low CFR had worst prognosis in all prognostic evaluation. Furthermore, multivariate Cox regression model showed CFR (continuous value) was an independent predictor for all-cause mortality (hazard ratio (HR); 0.7744, 95% confidential interval (CI) 0.6056-0.9790, p value=0.0368) and MACCE (HR0.7691, 95%CI0.6295-0.9320, p=0.0087) in DM HD population. Similarly, CFR predicted all-cause mortality (HR0.7313, 95%CI 0.5689-0.9401, p=0.0146) and non-CV death (HR0.6361, 95%CI0.4514-0.8963, p=0.0097) in non-DM HD population. ***Conclusion:*** Low CFR would predict the HD patients' unfavorable prognosis regardless of DM. Moreover, HD patients with DM and low CFR had worst prognosis in all-cause mortality, CV death, non-CV death and MACCE.

## OP-726

### Relationship between monocyte to high density lipoprotein cholesterol ratio and myocardial perfusion imaging findings

***M. Sadic***;
*Division of Nuclear Medicine, Department of Radiology, University of Washington, Seattle, WA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Monocyte to high density lipoprotein ratio (MHR) has been proposed as a novel prognostic indicator of CAD. Myocardial perfusion imaging is a useful non-invasive imaging test to evaluate the suspected or known CAD and to predict the prognosis as well. To the best of our knowledge, relationship between MHR and MPI findings such as TID in patients with suspected CAD has not stated clearly and this is the first study to evaluate the relationship between MHR and MPI parameters. In the light of relation between MHR and CAD, the goal of our study is to investigate the correlation between MHR and MPI findings. ***Materials and Methods:*** A total of 134 patients were included in our study. Patients were divided into groups according to the MPI findings and coronary angiography (CAG) results. They were evaluated due to possible cardiac events by gated single-photon emission computed tomography (GSPECT) MPI and coronary angiography (CA). Evaluations include the assessment of myocardial perfusion, wall motion and wall thickening and the measurement of LVEDV, LVESV, LVEF, SSS, SDS, SRS and TID parameters. We examined on these data to determine the value of TID. Their hematologic and biochemical data were obtained. The monocyte-to-high density lipoprotein ratio was calculated, and the relationship between the groups and the MHR was statistically analyzed. ***Results:*** The MHR was statistically higher in the patients with ischemia detected with MPI, than in patients who had normal MPI values (2.63 ± 1.71 and 2.04 ± 1.05, respectively). Therefore, the MHR was similar between patients who were both CAG positive and had ischemic MPI according to MPI findings. In addition, the MHR was similar for patients who had both normal MPS and CAG negative. MHR was detected as an independent predictor for coronary artery disease on logistic regression analysis (p = 0.005, OR = 1.29, 95% CI: 1.082 - 1.539). ***Conclusion:*** The MHR is an independent predictor for coronary artery disease. a high TID value was found to be well-correlated with the high of MHR in patient with CAD. This novel index is a beneficial identifier to interpret the results of MPI in terms of increasing diagnostic accuracy. This may provide valuable information to select the high-risk patients.

## OP-727

### Analysis of related factors of persistent or recurrent chest pain in patients with coronary artery disease after PCI based on gated myocardial perfusion imaging

***Z. Yang***[1,2], *J. Wang*[1,2], *Y. Wang*[1,2];
[1]*Department of Nuclear Medicine, The Third Affiliated Hospital of Soochow University, Changzhou, Jiangsu Province, CHINA,* [2]*Institute of Clinical Translation of Nuclear Medicine and Molecular Imaging, Soochow University, Changzhou, Jiangsu Province, CHINA.*

***Aim/Introduction:*** We aimed to evaluate the influencing factors of persistent or recurrent chest pain in patients with coronary artery disease after percutaneous coronary intervention (PCI) using gated myocardial perfusion imaging (GMPI). ***Materials and Methods:*** This study prospectively enrolled 201 patients with coronary artery disease who underwent PCI. All subjects underwent GMPI within 1-2 months after PCI, and were followed up by telephone or medical record system at 1 year after PCI for persistent or recurrent chest pain. The clinical characteristics, cardiac Doppler ultrasound, electrocardiogram, GMPI, coronary angiography findings and PCI procedural factors were collected. PCI treatment methods are divided into complete revascularization and incomplete revascularization (incomplete revascularization due to technical reasons such as small coronary artery or preoperative non-culprit vascular functional evaluation). Multivariate logistic regression analysis was performed to define the independent risk factors of persistent or recurrent chest pain after PCI in patients with coronary artery disease. ***Results:*** Persistent or recurrent chest pain after PCI occurred in 59 (29.4%) out of 201 patients. The symptomatic group was significantly older than the asymptomatic group (63.0±9.6 years vs. 59.7±10.4 years, t=2.074, P=0.039). Compared with patients in the asymptomatic group, patients in the symptomatic group had a higher proportion of patients with residual myocardial ischemia and incomplete revascularization (66.1% vs. 49.3%, $\chi^2$=4.743, P=0.029 and 54.2% vs. 35.2%, $\chi^2$=6.247, P=0.012). However, there were no statistically significant differences between the symptomatic group and the asymptomatic group in terms of coronary artery disease type, highest troponin, left ventricular ejection fraction (LVEF), arrhythmia, Gensini score, and coronary collateral circulation (all P>0.05). Multivariate logistic regression analysis showed that residual myocardial ischemia (OR=2.237, 95%CI: 1.140-4.389, P=0.019) and incomplete revascularization (OR=2.117, 95%CI: 1.112-4.031, P=0.022) were independent risk factors for persistent or recurrent chest pain after PCI. ***Conclusion:*** Residual myocardial ischemia and incomplete revascularization are independent risk factors for persistent or recurrent chest pain after PCI. GMPI assessment of residual myocardial ischemia and the therapeutic strategy of complete revascularization have important clinical significance in predicting persistent or recurrent chest pain after PCI.

## OP-728

### Association between myocardial perfusion and peripheral endothelial function in patients with coronary artery disease

***N. Vartiainen***, *J. E. K. Hartikainen, T. M. Laitinen, H. Mussalo, P. Kuikka, T. P. Laitinen;*
*Kuopio University Hospital, Kuopio, FINLAND.*

***Aim/Introduction:*** Hyperemic myocardial perfusion can be assessed quantitatively with $^{15}O$-$H_2O$ PET/CT by infusing intravenous adenosine to induce maximal vasodilation. It has been speculated that adenosine-induced vasodilation is a least partly mediated by coronary endothelial function, but this is still unclear. Impaired adenosine-mediated vasodilatation in coronary arteries has been frequently, but not always seen among patients with coronary endothelial dysfunction. Flow-mediated dilation (FMD) of brachial artery is a marker of peripheral endothelial function and a risk factor for adverse cardiovascular events. Our aim was to assess if there is a relationship between quantitative myocardial perfusion determined with $^{15}O$-$H_2O$ PET/CT and brachial artery FMD. ***Materials and Methods:*** We prospectively studied 56 patients (22 men, 34 women, aged 41-77 years), who had findings consistent with coronary artery disease in coronary CT angiography. Quantitative myocardial perfusion PET/CT was imaged at rest and during adenosine-induced maximal vasodilation by using $^{15}O$-$H_2O$ as a tracer. FMD was measured with ultrasound from the left brachial artery. FMD was determined by the increase in vessel diameter after reactive hyperemia relative to

the baseline diameter. ***Results:*** There was a statistically significant correlation between FMD and global stress perfusion (r=0.311, p=0.020). A statistically significant difference was observed in FMD between the patients grouped to the lowest and the highest tertile by global stress perfusion (3.9% vs. 7.0%, p=0.029). There was no statistically significant difference in FMD between patients with normal (n=40) and patients with impaired (n=16) stress perfusion (5.0% vs. 6.4%, p=0.414). ***Conclusion:*** Our study showed a statistically significant correlation between FMD of brachial artery and global myocardial stress perfusion in PET/CT. This strengthens the idea, that adenosine-induced hyperemic myocardial perfusion can be viewed as a marker of coronary endothelial function. FMD of brachial artery, however, doesn't function as surrogate marker for myocardial ischemia in patients with coronary artery disease.

## OP-729

### Relative stress perfusion deficit is an independent predictor of significant stenosis in a heterogenous population of patients examined with [$^{15}$O]$H_2O$ PET

***P. Mark***[1], *E. Prescott*[2], *L. Marner*[1], *P. Hovind*[1], *M. Krakauer*[1];
*[1]Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital - Bispebjerg Frederiksberg Hospital, Bispebjerg Bakke 23, 2400 Copenhagen, DENMARK, [2]Department of Cardiology, Copenhagen University Hospital - Bispebjerg Frederiksberg Hospital, Bispebjerg Bakke 23, 2400 Copenhagen, DENMARK.*

***Aim/Introduction:*** Myocardial perfusion imaging with [$^{15}$O]$H_2O$ PET can detect coronary artery stenosis with high accuracy in patients with no history of ischemic heart disease. However, recent evidence suggests reduced accuracy in patients with previous ischemic heart disease[1]. We aimed to examine absolute and relative stress perfusion deficits as predictors of significant coronary artery stenosis in subsequent coronary angiography (CAG) in a heterogenous population. ***Materials and Methods:*** From May to December 2022 we retrospectively and consecutively included patients referred to CAG after [$^{15}$O]$H_2O$ PET. The patients were divided into groups with significant vs. no significant stenosis (fractional flow reserve (FFR) ≤0.8 or a coronary artery narrowing of ≥70% when FFR was not available). Total perfusion deficit (TPD) was calculated as a combined continuous measure of the extent and severity of reduced stress perfusion as a percentage of the total left ventricle myocardium. The thresholds for decreased perfusion was <2.4 mL/min/g for absolute TPD (aTPD) and <0.7 relative to the individual highest perfusion for relative TPD (rTPD). Values of aTPD and rTPD are given as median (IQR). A multivariate logistic regression analysis was performed to test the adjusted associations (odds ratio (OR) with 95% CI) with subsequent detection of significant stenosis. ***Results:*** In a total of 144 patients, 78 patients had at least one significant stenosis and 66 patients had no significant stenosis. In groups of no stenosis vs. stenosis, aTPD was 22% (12-46) vs. 37% (16-66) (P=0.007) and rTPD was 9% (4-15) vs. 19% (9-29) (P<0.001). In an adjusted analysis rTPD ($OR_{10\%\ increase}$ = 1.92 (1.34-2.76), P<0.001), previous CABG (OR = 0.13 (0.04-0.41), P=0.001) and reduced LVEF (OR = 0.28 (0.09-0.88), P=0.03) were independently associated with coronary stenosis, whereas the association with aTPD ($OR_{10\%\ increase}$ = 1.15 (1.00-1.32) P=0.06) was borderline. ***Conclusion:*** In the presence of an absolute perfusion deficit, rTPD independently improves the detection of significant stenosis in a heterogenous population of patients examined with [$^{15}$O]$H_2O$ PET. Furthermore, previous CABG and reduced LVEF are associated with non-stenotic perfusion deficiencies suggesting caution when interpreting myocardial perfusion measurements in patients with such confounders. ***References:*** 1. Driessen et al. Functional stress imaging to predict abnormal coronary fractional flow reserve: the PACIFIC 2 study. Eur Heart J 2022 Sep 1;43(33):3118-3128.

## OP-730

### Cardiac $^{15}$O-water PET/CT predicts progression of Cardiac Dysfunction in Patients with Type 2 Diabetes and Diabetic Foot Ulcers

***N. Christensen***[1,2,3], *L. P. Tolbod*[1,2], *K. Bouchelouche*[1,2], *M. A. Madsen*[1], *C. S. Buhl*[3], *J. Sørensen*[1];
*[1]Department of Nuclear Medicine & PET, Aarhus University Hospital, Aarhus N, DENMARK, [2]Aarhus University, Aarhus C, DENMARK, [3]Steno Diabetes Center Aarhus, Aarhus University Hospital, Aarhus N, DENMARK.*

***Aim/Introduction:*** Patients with type 2 diabetes (T2DM) and diabetic foot ulcers (DFU) are at an increased risk for developing cardiovascular disease. Cardiac $^{15}$O-water PET/CT is a non-invasive method for evaluating myocardial blood flow (MBF) in detecting early signs of ischemic heart disease (IHD). Additionally, measurements of ankle-brachial index (ABI) and toe-brachial index (TBI) can provide information on the severity of peripheral artery disease (PAD). This study aimed to investigate the association between MBF and the occurrence of cardiac events in patients with T2DM and DFU. ***Materials and Methods:*** Cardiac $^{15}$O-water PET/CT was performed at rest and during adenosine stress in 21 patients with T2DM and DFU. Peripheral hemodynamic measurements (ABI/TBI) were performed within four weeks prior to PET/CT. The PET scan was considered positive if maximal MBF in one or more vascular territories or globally was <2.3 mL/min/g. Cardiac events were recorded. ***Results:*** Ten (48%) patients had positive PET. Seven (33%) of these had known stable IHD. Five of the PET-positive patients developed chest pain or dyspnoea during follow-up (median 8 months). Cardiac symptoms were associated with lower maximal MBF (p=0.004). TBI correlated with maximal MBF (r=0.56, p=0.009) and coronary flow reserve (CFR) (r=0.68, p=0.0006), and ABI correlated with CFR (r=0.72, p=0.0008). Nine of 10 PET-positive patients had TBI below the reference level for PAD (p=0.0006). ABI measurements were obtained from eight PET-positive patients, of whom six had ABI values below the reference level for PAD (p=0.07). None of the PET-negative patients reported cardiac symptoms. ***Conclusion:*** Our study shows that PAD and significant IHD often coexist in T2DM patients with DFU. We found a significant association between maximal MBF and imminent worsening of cardiac symptoms, as well as a significant correlation between reduced coronary flow reserve and PAD severity, as measured by TBI and ABI. Our results suggest that cardiac PET/CT might be valuable in T2DM patients with DFU.

## OP-731

### Prevalence, characteristics and effect of cardiac motion in $^{13}$N-ammonia PET/CT dynamic acquisitions

***O. Mendoza-Ibanez***[1], *T. S. Martinez Lucio*[1], *F. van der Zant*[2], *C. Hayden*[3], *R. J. J. Knol*[2], *R. H. J. A. Slart*[1], *S. V. Lazarenko*[2];
*[1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Northwest Clinics Alkmaar, Alkmaar, NETHERLANDS, [3]Siemens Medical Solutions, Inc. United States Of America, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Heart-wall motion negatively impacts PET/CT results. For dynamic acquisitions, motion can induce estimation errors up to 500% in myocardial blood flow (MBF) and myocardial flow reserve (MFR) values. Motion can present as inter-frame

motion (interMo) or as intra-frame motion (intraMo), and can differ between different axes and/or phase. A prototype data driven motion correction (DDMC) algorithm allows heart-wall motion tracking for each second of acquisition time in the 3D space what could allow better description of motion. This project aims to depict the prevalence, characteristics, and effect of cardiac motion in 13N-ammonia PET/CT dynamic acquisitions with the use of DDMC. ***Materials and Methods:*** 25 patients who underwent a cardiac PET/CT examination were retrospectively included. Inclusion criteria: no prior CAD, normal PET/CT results, and follow-up without major adverse cardiac events. DDMC was used to retrieve motion information in the later frames, as accuracy for the early frames was suboptimal. Data was retrieved in the left-right tranxial (x), anterior-posterior transaxial (y) and axial (z) directions. IntraMo was defined as the ratio between the sum of absolute differences in heart position and the frame-length for each frame. InterMo was defined as the difference in average heart position from one frame to the previous. Patients were classified with "significant motion" (sigMo) when InterMo >3mm was found. Absolute mean values of IntraMo and InterMo were used for final comparison between patients. Image processing was performed with Cedars Sinai QPET to retrieve values of MBF and CFR and compare them between the lower and upper tertile of motion. Differences were analyzed using Mann-Whitney U and McNemar tests. ***Results:*** Twenty-one patients (84%) had sigMo either in rest or stress. The prevalence of sigMo was significantly higher in z-axis both for rest [48% vs 12%(x) vs 12%(y)] and stress phase [68% vs 4%(x) vs 4%(y)]. InterMo in z-axis was higher in stress than rest, while intraMo was higher for all the axis in stress than rest ($p<0.05$). When comparing between axes, interMo and intraMo in z-axis were significantly higher than for the other axes both in rest and stress. Values of MBF in stress, Cx MFR and RCA MFR were significantly lower for the group with highest interMo in z-axis. ***Conclusion:*** A substantial percentage of patients present significant cardiac motion in PET/CT examinations. InterMo in the z-axis during stress appears highly relevant, as it leads to significantly lower values in stress MBF and CFR parameters.

## OP-732

### Role of motion correction tools in the estimation of microvascular coronary function by $^{13}$N-ammonia hybrid-positron emission tomography

***O. Mendoza-Ibanez***[1], *R. J. J. Knol*[2], *R. H. J. A. Slart*[1], *C. Hayden*[3], *T. S. Martinez Lucio*[1], *S. V. Lazarenko*[2];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Northwest Hospital Group Alkmaar, Alkmaar, NETHERLANDS,* [3]*Siemens Medical Solutions United States Of America, Tenesse, TN, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** PET/CT is considered the gold-standard for the non-invasive determination of microvascular coronary function, by software-based estimations of regional and global values of myocardial blood flow (MBF) in rest and stress, and coronary flow reserve (CFR). The presence of motion artifacts can impact the quantification, leading to estimation errors up to 500% in MBF/CFR parameters. Some motion-corrections (MC) tools are now available, with their specific role yet to be proven. In-software MC tools (ISMC) are available within some commercial packages for PET processing, and, more recently, an innovative data driven motion correction (DDMC) has been developed to correct for motion prior the image reconstruction process. This work aims to elucidate the role of ISMC and DDMC in the determination of MBF and CFR values. ***Materials and Methods:*** Twenty-eight patients that underwent a $^{13}$NH3-PET/CT examinations were retrospectively included. Inclusion criteria: no prior CAD/MI, normal LV-function, normal CFR, and no MACEs during follow-up. Image processing was made in three different software packages, namely Corridor.4DM (4DM), Cedars-Sinai QPET (QPET), and SyngoMBF (Syngo). Values of regional and global MBF in rest and stress and CFR without MC (NMC), with the use of ISMC and after processing with DDMC were acquired for the final analysis. Paired T-Tests, Bland-Altman plots and intraclass correlation coefficients were used for statistical analysis. ***Results:*** Population consisted of 17(65%) woman, all patients >42 yo, and 23(88%) of adenosine stress (12% regadenoson). QPET proved to be more sensitive to MC, as significantly higher values in all regional and global stress-MBF and CFR were obtained after the use of any MC technique ($p<0.001$). For 4DM, the impact of ISMC was higher than DDMC, with significant changes in seven parameters of rest-MBF and stress-MBF compared to only 3 with DDMC. For Syngo, no significant effect was observed by the use of any MC tool (all p-values >0.05). Bland-Altman and ICC plots showed that the use of any MC tool improves the agreement between software. DDMC demonstrated the higher improvements, achieving excellent agreement (ICC >0.9) in the RCA CFR. ***Conclusion:*** The effect of MC tools is related to the software used for image processing. QPET appear to underestimate values of regional and global stress-MBF and CFR when NMC is used, whereas the other packages does not appear that sensitive to motion. In general, the use of a MC technique seems valuable, particularly for DDMC, to improve reliability and agreement between software.

### In Vitro Evaluation of Radiation-induced DNA Damage and Repair within Targeted Radionuclide Therapies in Comparison to External Radiation

***R. Winter***, *U. Bauder-Wüst, M. Schäfer, M. Roscher, R. Lopez Perez, M. Benešová-Schäfer;*
*German Cancer Research Center, Heidelberg, GERMANY.*

***Aim/Introduction:*** For late-stage cancer patients who do not respond to conventional therapies, Targeted Radionuclide Therapy (TRNT) and Targeted Alpha Therapy (TαT) have lately been aroused as highly potent treatment options. Despite the promising outlook, radioresistance development associated with mutations in DNA repair genes has been found in prostate cancer (PCa) patients. However, knowledge and understanding about the mechanism of DNA damage induction and repair after TRNT and TαT is still incomplete. Therefore, this study aims to investigate these mechanisms with the β-emitter $^{177}$Lu as well as the α-emitters $^{227}$Th and $^{223}$Ra. External radiation with photons, as an established therapy, will serve as an alternative for further comparison and calibration. ***Materials and Methods:*** LNCaP was selected as PCa cell line. Cells were incubated with non-complexed radionuclides for 4 h with 100, 500, 1000 and 5000 kBq of [$^{177}$Lu]$LuCl_3$ or with 1, 5, 10 and 100 kBq of [$^{227}$Th]$ThCl_4$ or [$^{223}$Ra]$Ra(NO_3)_2$. After incubation, cells were fixated. The DNA damaging effects were compared to treatment with external radiation using doses ranging from 0.5 to 2.5 Gy in 0.5 Gy increments and fixated 30 min after irradiation. Systematic evaluation of nuclide- and dose-dependence of DNA damage was performed by visualization of DNA double-strand breaks via immunofluorescent staining of γH2AX. ***Results:*** Literature research showed a ratio of 1:700 for activities of α-emitters: β-emitter leading to comparable DNA damage. This observation was in line with our experiments. Calibration with external radiation showed 5000 kBq of $^{177}$Lu equals 1.1 Gy external radiation dose whereas 5 kBq of $^{223}$Ra equals 0.6 Gy. Since the same activity of $^{227}$Th corresponds only to 0.2 Gy, $^{223}$Ra showed higher damaging potential than $^{227}$Th. For all treatments, signal intensity of foci was increasing linearly with dose, while foci area showed a broader size range for α-emitters than gamma and β-emitters. ***Conclusion:*** The results provide a deeper understanding of the DNA damage induction after TRNT and TαT, and highlight differences in β- and α-emitter-based therapies like higher damaging potential of $^{223}$Ra. Hereby the short-lived daughter radionuclides of $^{223}$Ra, namely the α-emitters $^{219}$Rn and $^{215}$Po with a half-life of 4.0 s and 1.9 ms, are increasing the frequency of emitted α-particles. Likewise, the study is setting a baseline for therapeutic dose estimation of different radionuclides. Subsequent experiments with PSMA-617 labelled radionuclides as well as other targets like neurokinin receptor 1 (NK-1) will provide further amelioration of TRNT and TαT.

## EPS-211

### Three-dimensional spheroids as in vitro preclinical model for radiobiology studies: the example of radium-223 in prostate cancer spheroids

***A. Pires Lourenço***[1,2,3], *I. A. Marques*[4,2,5], *D. Cancelinha*[4,6], *G. Costa*[7], *A. M. Abrantes*[4,2,3], *M. F. Botelho*[4,2,3];
[1]*Institute of Biophysics, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of CIMAGO, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL,* [2]*Center for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, Coimbra, PORTUGAL,* [3]*Clinical Academic Center of Coimbra (CACC), Coimbra, PORTUGAL,* [4]*Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Institute of Biophysics, Faculty of Medicine, Coimbra, PORTUGAL,* [5]*Faculty of Pharmacy, University of Coimbra, Coimbra, PORTUGAL,* [6]*Faculty of Science and Technology, University of Coimbra, Coimbra, PORTUGAL,* [7]*Department of Nuclear Medicine, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, PORTUGAL.*

***Aim/Introduction:*** Several radiopharmaceuticals have emerged for diagnostic, therapeutic or theragnostics. Conducting radiobiological studies during radiopharmaceuticals preclinical testing could provide relevant insights to improve the clinical outcomes. Usually, they are not included into this phase neither are done in 3D cell cultures, which better mimics the human tumor microenvironment. The aim of this study is to use and validate 3D spheroids as in vitro preclinical models for radiobiology research. Specifically, we propose prostate cancer spheroids to evaluate the radiobiology of the alpha-emitter radium-223. ***Materials and Methods:*** Prostate cancer (PCa) spheroids were developed using PC3 cells, a human metastatic PCa cell line derived from a bone metastasis. Three techniques for generating 3D spheroids were tested: magnetic levitation, hanging drop and liquid overlay technique (in ultra-low attachment plates). Spheroids with 5000 cells were generated, incubated with increasing volumic activities of radium-233 dichloride (Ra-223, 55-7040Bq/mL) for 24h, and then monitored for 7 days by optical microscopy. Radiobiology studies were done 7 days post-irradiation, namely spheroids' viability (ATP levels) and cell death profile (apoptosis or necrosis). Immunohistochemistry , invasion and migration assays were also performed, as well as dosimetry to correlate the biological effects with doses. ***Results:*** Spheroids generated by liquid overlay technique showed to be faster (48h) to develop and easier to irradiate, with high reproducibility among experiments. Generally, a decrease in spheroid size and integrity was observed with increasing activities of Ra-223 over time. Spheroids' area and viability, 7d post-irradiation with 5280Bq/mL, decreased to 1.27±0.04mm2($p<0.0001$) and 32.2±1.7% ($p<0.0001$), respectively, comparatively to control. These effects were associated with increased cell death, showed by an increasing in morphological features of apoptosis and higher levels of annexin-V staining. Compared to our previous results obtained in conventional 2D PC3 cell cultures, fewer biological effects are obtained in 3D spheroids, when exposed to the same volumic activity of Ra-223. ***Conclusion:*** Our results demonstrate that 3D spheroids may be used as an in vitro preclinical model for radiobiology studies. The advantages include a better mimic of the human microenvironment and, consequently, the radiopharmaceutical's biological effects and, in terms of radiological protection, allows carrying out analyzes easily and safely. Apart from the need to optimize the spheroid model for each cell line, it showed to be easily reproduced for similar assays with other cell lines, as well as, for other radiopharmaceuticals. Institutional funding from FCT strategic projects (UIDB/04539/2020,UIDP/04539/2020) and by COMPETE-FEDER (POCI-01-0145-FEDER-007440).

## EPS-212

### Comparison of biological effects produced by radioactively labeled antibodies in human cancer cells and fungal cells

***J. Bonet***, *M. E. Malo, K. J. Allen, C. Frank, R. Jiao, E. Dadachova; University of Saskatchewan, Saskatoon, SK, CANADA.*

***Aim/Introduction:*** Radioimmunotherapy (RIT) has been used as an effective cancer therapy for decades. Current work includes the translation of this treatment modality into the field of opportunistic fungal infections. The aim of this project is to conduct mechanistic studies to compare the effects of RIT on both cancer and fungal cells. ***Materials and Methods:*** Human pathogenic yeast Cryptococcus neoformans and the human acute myeloid leukemia cell line OCI-AML3 were used as a model in vitro systems. C.neoformans was treated with 3.7 KBq and 2.59 KBq [$^{225}$Ac]Ac-DOTA-400-2 or 3.7 Mbq and 1.85 MBq [$^{177}$Lu]Lu-DOTA-400-2 monoclonal antibodies raised against the 1,3-β-glucan antigen. Cells were incubated with radiolabeled antibodies for 1 hour, washed, and cultured in a minimal medium. OCI-AML3 was comparatively treated with 3.7 KBq and 2.59 KBq of [$^{225}$Ac]Ac-DOTA-HuM195 (lintuzumab) or 3.7 Mbq and 1.85 MBq of [$^{177}$Lu]Lu-DOTA-HuM195 anti-CD33 antibody. Cells were incubated with radiolabeled antibodies for 1 hour, washed, and cultured in a complete medium. Mechanistic studies on the effect of RIT on eukaryotic cells were performed by visualizing DNA double-strand breaks (DSBs) via Gamma-Histone 2Ax (γ-H2Ax) immunofluorescence, cell viability via clonogenic and trypan blue survival assays, antibody internalization assays, and micronuclei formation assays. ***Results:*** Clonogenic survival assay demonstrated that both $^{177}$Lu and $^{225}$Ac-labeled antibodies were effective in killing leukemic and fungal cells, at 24, 48, and 72 hrs post-treatment. $^{225}$Ac-labeled antibodies demonstrated greater potency in vitro and were more cytotoxic towards both fungal and leukemic cells compared to $^{177}$Lu-labeled antibodies. Gamma-H2AX immunofluorescence demonstrated increased DSBs in $^{225}$Ac-labeled antibody-treated fungal and leukemic cells 1 hr post-treatment compared to $^{177}$Lu-labeled antibodies. ***Conclusion:*** Current comparative evaluation of the effect of RIT on fungal and human cells supports the predicted cytotoxic response of both fungal and cancer cell lines towards RIT. The eukaryotic nature of both fungal and human cells makes them respond in similar ways to the effects of antibody-delivered targeted radiation.

## EPS-213

### HDACi Treatment Increases SSTR2 mRNA and Protein Expression in Tumor-Bearing Animals: What is the Effect on Radiolabeled DOTATATE uptake?

***M. J. Klomp***, *L. van den Brink, P. M. van Koetsveld, C. M. A. de Ridder, D. C. Stuurman, L. J. Hofland, S. U. Dalm; Erasmus MC, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Somatostatin type-2 receptors (SSTR2) form a pivotal target for the treatment of neuroendocrine tumors (NET) using [$^{177}$Lu]Lu-DOTATATE. However, treatment responses are suboptimal and improvement is thus required. We aim to increase SSTR2 expression using epigenetic drugs, i.e. histone deacetylase (HDAC) inhibitors (HDACis), to increase the tumoral [$^{177}$Lu]Lu-DOTATATE dose for improved treatment responses. Promising results are described after HDACi treatment in vitro, but encouraging in vivo studies are lacking. Therefore, the objective of this study was to assess the effect of several HDACis on SSTR2 expression and [$^{111}$In]In/[$^{177}$Lu]Lu-DOTATATE uptake in tumor-bearing animals. Our second objective was to gain more insight into the association between HDAC and SSTR2 expression. ***Materials and Methods:*** Human NCI-H69 small-cell lung carcinoma cells and human BON-1 pancreatic NET cells were treated with an HDACi (i.e entinostat, mocetinostat (MOC), LMK235, CI994 or panobinostat (PAN)), and evaluated for SSTR2 mRNA expression levels and [$^{111}$In]In-DOTATATE uptake. Additionally, NCI-H69 and BON-1 tumor-bearing animals were treated with the HDACis, followed by [$^{111}$In]In/[$^{177}$Lu]Lu-DOTATATE injection and biodistribution studies. Tumors were collected to analyze SSTR2 expression. Additionally, HDAC and SSTR2 mRNA expression levels were measured in NCI-H69, BON-1, NCI-H727 (human pulmonary carcinoid) and GOT1 (human midgut NET) xenografts and/or cells. ***Results:*** All HDACis significantly enhanced SSTR2 mRNA expression levels and uptake of [$^{111}$In]In-DOTATATE in vitro. However, no significant increase in tumoral [$^{177}$Lu]Lu-DOTATATE uptake was observed after HDACi treatment in NCI-H69 xenografts, whereas tumoral SSTR2 mRNA expression levels were significantly upregulated after MOC, CI994 and PAN treatment (≤2.1-fold, $p<0.0001$) and SSTR2 protein expression levels after CI994 (1.3-fold, $p=0.0012$). In line with what is observed in PAN-treated NCI-H69 tumor-bearing animals, PAN-treated BON-1 xenografts only demonstrated significantly increased SSTR2 mRNA expression levels (2.0-fold, $p=0.003$). Moreover, BON-1 xenografts showed a significantly higher expression for six out of the eleven examined HDACs in comparison to NCI-H69 tumors. Focusing on these elevated HDACs in cell lines, an inverse correlation was found between HDAC3 and SSTR2 expression (Pearson $r=-0.92$, $p<0.0001$). ***Conclusion:*** Depending on the inhibitor, increased SSTR2 expression levels were observed after HDACi treatment in vitro and in vivo. Despite this, tumoral radiolabeled DOTATATE uptake levels were not significantly enhanced in vivo; not in NCI-H69, nor in BON-1 tumor-bearing animals regardless of higher HDAC expression levels. The discrepancy between the increased SSTR2 expression and unchanged radiolabeled DOTATATE uptake after HDACi treatment indicates the need for further investigations, including a better understanding of the association between HDACs and SSTR2.

## EPS-214

### Preclinical efficacy of novel anti-oxMIF/HSG bispecific antibody for pretargeted radioimmunotherapy

***A. Puchol Tarazona***, *I. Mirkina, M. Thiele, A. Schinagl; OncoOne Research & Development GmbH, Vienna, AUSTRIA.*

***Aim/Introduction:*** This study aimed to evaluate a two-step pretargeting radioimmunotherapy based on an anti-oxMIF x anti-HSG (histamine-succinyl-glycyl) bispecific antibody and a $^{177}$Lu-labelled di-HSG peptide hapten in murine models of colorectal and pancreatic cancer. The antibody targets oxMIF - the "oxidised", disease-related structural isoform of the pleiotropic cytokine MIF (macrophage migration inhibitory factor)[1]. ***Materials and Methods:*** An anti-oxMIF x anti-HSG bispecific antibody (cON-05) in the format Fab-scFv-Fc was designed, recombinantly expressed and purified. Infrared dye-labelled cON-05 was administered to Balb/c mice bearing subcutaneous CT26 cancer syngrafts to assess tumour uptake and retention by infrared imaging and to determine its half-life in circulation. Balb/c mice bearing subcutaneous CT26 tumours or Balb/c nude mice bearing subcutaneous CFPAC-1 tumours were given a single intravenous injection of the antibody (doses 1.0, 2.5 or 5.0 mg/kg). 3-5 days later, the mice received one tenth molar equivalents of a $^{177}$Lu-labeled, di-HSG hapten peptide (3.7, 9.3 or 18.5 MBq). At least one control group given only the radiolabelled hapten

at the highest dose was included. Tumour volume and body weight were monitored for three weeks. ***Results:*** Rapidly growing subcutaneous CT26 tumours almost completely regressed when mice were given the highest treatment dose (5 mg/kg and 18.5 MBq) with a pretargeting delay of three days. Administered with a 5-day pretargeting interval, the highest dose arrested tumour growth in both CT26 and CFPAC-1-derived cancer models, while the lower doses reduced the tumour growth rate. In all cases, the highest treatment dose was well tolerated and resulted in 100% survival at the study endpoint, in contrast to 0% or 50% survival for the control groups in the CT26 and CFPAC-1 models, respectively. ***Conclusion:*** Our pretargeting therapy making use of an anti-oxMIF x anti-HSG bispecific antibody and a $^{177}$Lu-loaded peptide hapten resulted in nearly complete tumour regression or stopped tumour growth in murine models of colorectal and pancreatic adenocarcinoma. The treatment led to 100% survival and was well tolerated. This intervention could prove effective at delivering high radioactive doses safely to tumours in oxMIF-positive patients. ***References:*** 1. Schinagl A, Thiele M, Douillard P, et al. Oxidized macrophage migration inhibitory factor is a potential new tissue marker and drug target in cancer. Oncotarget. 2016;7(45):73486-73496.

## EPS-215

### Combined Treatment with $^{177}$Lu-DOTATOC and Histone Deacetylase Inhibitor s on SSTR2 Expression and Uptake in in vivo

***H. Bakr***[1,2], *A. Al-Awar*[1], *E. Forssell-Aronsson*[1,2];
[1]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Center for Cancer Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN,* [2]*Department of Medical Physics and Biomedical Engineering, Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Patients with metastatic disease from neuroendocrine tumours are often successfully treated with $^{177}$Lu-octreotate, but few are cured. Histone deacetylase inhibitors (HDACis) have been used for a long time in psychiatry and neurology, and have lately been proposed for treatment of cancer, They influence the regulation of gene expression, cell growth pathways, and cell cycle arrest in cancer cells, and have shown cytostatic effect. The aim of this study was to investigate the potentially increased therapeutic effect of combining radiation therapy with the HDACi valproic acid (VPA) in mice bearing the human small-intestine neuroendocrine GOT1 tumours. ***Materials and Methods:*** BALB/c mice bearing GOT1 tumours were divided into five groups of 5-6 animals/group. The mice received either 1) a single i.v injection with 30 MBq $^{177}$Lu-octreotide alone, 2) VPA administered orally once daily for 5 days per week alone, 3) combined treatment 1 and 2, or 4) 2x15 MBq $^{177}$Lu-octreotide 48h apart combined with treatment 2. One group was mock-treated and used as control. The body weight and tumour volume were measured three times per week. Animals were killed when the tumour weight was 10% of the body weight. ***Results:*** The animals in the combination therapy groups with 2x15 MBq $^{177}$Lu-octreotide showed a reduction in relative tumor size during the first week, while there was no reduction in tumour size in the other groups. Furthermore, the animals in that group also had the longest median overall survival of 39 days (max 70 days), while corresponding values for the other groups were 18-32 days and maximal values of 25-44 days. ***Conclusion:*** The results showed that an increased therapeutic effect could be achieved with a combination of $^{177}$Lu-octrotide and the HDACi VPA, both regarding tumour volume reduction and overall survival. Best results were obtained after fractionation of the $^{177}$Lu-.octreotide. Future studies should aim for finding the most optimal treatment schedule including fractionation of both $^{177}$Lu-octreotide/octreotate and the HDACi.

## EPS-216

### Effective treatment of SSTR2 positive small cell lung cancer using$^{211}$At-containing targeted α-particle therapy agent which promotes endogenous anti-tumor immune response.

***F. Yu***, *S. Qin, J. Zhang, M. Yang;*
*Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Small cell lung cancer (SCLC) is a neuroendocrine tumor with a high degree of malignancy. Due to limited treatment options, patients with SCLC have a poor prognosis. ***Materials and Methods:*** We developed and evaluated biological effects of [$^{211}$At]SAB-Oct for targeted alpha therapy. Concurrently, we explored immunogenicity triggered by alpha-emitter $^{211}$At and excavated its potential mechanisms. ***Results:*** We have found, however, that intravenously administered octreotide (Oct) armed with astatine-211 ([$^{211}$At]SAB-Oct) is effective against somatostatin receptor 2 (SSTR2)-positive SCLC tumor in SCLC tumor-bearing BALB/c nude mice. In biodistribution analysis, [$^{211}$At]SAB-Oct achieved a highest concentration in the SCLC tumors up to 3 hours after injection as time proceeded. A single intravenous injection of [$^{211}$At]SAB-Oct (370 kBq) was sufficient to suppress SSTR2-positive SCLC tumor growth in treated mice by inducing DNA double strand breaks. Additionally, a multi-treatment course (370 kBq followed by twice doses of 370 kBq for a total of 1110 kBq) inhibited the growth of the tumor compared to the untreated control group without significant off-target toxicity. Surprisingly, we found that [$^{211}$At]SAB-Oct could up-regulate the expressions of calcreticulin and major histocompatibility complex I (MHC-I) on the tumor cell membrane surface, suggesting that α-particle internal irradiation may activate endogenous anti-tumor immune response through the regulation of immune cells in the tumor microenvironment, which could synergically enhance the efficacy of immunotherapy. ***Conclusion:*** We conclude that [$^{211}$At]SAB-Oct is a potential new therapeutic option for SSTR2-positive SCLC.

## EPS-217

### DOTAGA-modified DB15 mimics for theranostic use in prostate cancer

***P. Kanellopoulos***[1], *A. Mattsson*[1], *A. Abouzayed*[1], *K. Obeid*[1], *B. A. Nock*[2], *V. Tolmachev*[1], *T. Maina*[3], *A. Orlova*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*INRASTES, NCSR "Demokritos", Athens, GREECE,* [3]*INRASTES, NSCR "Demokritos", Athens, GREECE.*

***Aim/Introduction:*** The gastrin-releasing peptide receptor (GRPR) is frequently overexpressed in primary and metastatic prostate cancer. We herein report on three mimics of the neprilysin (NEP)-resistant SPECT radiotracer [$^{99m}$Tc]Tc-DB15 ($N_4$-Ama-Dig-DPhe-Gln-Trp-Ala-Val-Sar-His-Leu-NHEt, $N_4$: 6-carboxy-1,4,8,11-tetraazaundecane, Ama: 4-aminomethylaniline, Dig: diglycolic acid) (1). These analogs carry the DOTAGA instead of the $N_4$ chelator, thus allowing for coordination of trivalent-radiometals, including the theranostic In-111/Lu-177 pair. To compensate for charge changes at the N-terminus, a Arg/DArg was introduced next to DOTAGA, yielding: AU-SAR-M1 (DOTAGA-Ama-Dig-DPhe-Gln-Trp-Ala-Val-Sar-His-Leu-NHEt), AU-SAR-M2 ([DOTAGA-Arg]

AU-SAR-M1) and AU-SAR-M3 ([DOTAGA-DArg]AU-SAR-M1). After labeling with In-111, the respective [111In]In-radiopeptides were compared in GRPR-expressing cell and animal models. ***Materials and Methods:*** After [$^{111}$In]In-labeling (30 min, 85°C), the metal-chelate stability was assessed under 1000x molar excess of EDTA (1 h). GRPR-specificity and cell-uptake over time were tested in PC-3 cells. Metabolic stability was determined in peripheral blood of healthy Swiss albino mice 5 min post-injection (pi), while biodistribution was performed in Balb/c nu/nu mice bearing PC-3 xenografts at 4 h pi. ***Results:*** Radiochemical yields and complex stability were high for all radiopeptides (>97% and >91%, respectively). All radiotracers displayed a sub-nanomolar receptor affinity and a highly GRPR-specific cell binding. Cell associated activity was: 39±2% of added activity for [$^{111}$In]In-AU-SAR-M1, 33±1% for [$^{111}$In]In-AU-SAR-M2 and 48±3% for [$^{111}$In]In-AU-SAR-M3. All radiopeptides displayed metabolic stabilities comparable or higher than [$^{99m}$Tc]Tc-DB15. During biodistribution, [$^{111}$In]In-AU-SAR-M1 (11±1 %IA/g) and [$^{111}$In]In-AU-SAR-M2 (12.7±0.8 %IA/g) displayed almost twice as high tumor uptake vs. [$^{111}$In]In-AU-SAR-M3 (6.7±0.3 %IA/g; $p<0.001$). On the other hand, [$^{111}$In]In-AU-SAR-M3 demonstrated the lowest pancreatic uptake (0.5±0.1 %IA/g), followed by [$^{111}$In]In-AU-SAR-M1 (2±1.2 %IA/g; $p<0.0001$) and [$^{111}$In]In-AU-SAR-M2 (9±2 %IA/g; $p<0.0001$). Renal uptake was lower for the first two radiopeptides (3.1±0.3 %IA/g and 3.4±0.4 %IA/g respectively; $p<0.001$ & $p<0.01$), whereas [$^{111}$In]In-AU-SAR-M2 had higher intestinal uptake than the other two analogs. Interestingly, [$^{111}$In]In-AU-SAR-M1 displayed the highest tumor-to-background ratios, although second in rank in terms of tumor uptake ***Conclusion:*** Three novel DB-15 mimics, coupled to DOTAGA for [$^{111}$In]In-labeling, were successfully prepared, showing higher resistance to NEP than the parent [$^{99m}$Tc]Tc-DB15. The introduction of basic Arg/DArg next to DOTAGA had no considerable impact on their biological performance. [$^{111}$In]In-AU-SAR-M1, lacking a basic Arg/DArg residue next to DOTAGA, displayed the best tumor-to-background ratios in PC-3 tumor-bearing mice. ***References:*** (1) Nock et al. Cancers. 2021; 13: 5093

## EPS-218

### Development and preclinical evaluation of biodistribution and dosimetry of $^{177}$Lu-labelled PSMA targeting therapeutic with optimized linker for treatment of disseminated prostate cancer

***A. Orlova***[1], *A. Abouzayed*[1], *K. Seitova*[2], *F. Lundmark*[1], *V. Bodenko*[2], *M. Oroujeni*[1], *V. Tolmachev*[1], *U. Rosenström*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Prostate specific membrane antigen (PSMA) is highly expressed in metastatic castration-resistant prostate cancer (mCRPC) and is a promising therapeutic target. PSMA-targeting agents for diagnostic and therapy of PC are widely used in patient management and has shown an improved outcomes for patients with mCRPC. Using a computer modelling, we have performed an optimization of a urea-based probe for radionuclide visualization of PSMA expression in vivo[1]. With the purpose to develop a targeting agent equally suitable for radionuclide imaging and therapy, the agent containing DOTA chelator was designed (designated BQ7876). The aim of the study was to test the hypothesis that $^{177}$Lu-labelled BQ7876 possesses target binding and biodistribution properties potentially enabling its use for radionuclide therapy. ***Materials and Methods:*** BQ7876 was synthesized using Fmoc solid-phase peptide synthesis and labelled with Lu-177. Specificity and affinity of [$^{177}$Lu]Lu-BQ7876 to PSMA-expressing PC3-pip cells was evaluated and its processing after binding to these cells was studied. Animal studies in mice were performed to assess its biodistribution in vivo, specificity of its accumulation in PSMA-expressing tumour xenografts and dosimetry. In a number of experiments, [$^{177}$Lu]Lu-PSMA-617 was simultaneously evaluated for comparison. ***Results:*** Peptide was labelled with Lu-177 with radiochemical yield >99%. Its binding to PSMA was specific in vitro and in vivo when tested in antigen saturation conditions and in PSMA-negative tumours, respectively. The binding of [$^{177}$Lu]Lu-BQ7876 to living PC3-pip cells was characterized by rapid association, while the dissociation included a rapid and a slow phase with affinities $K_{D1}$= 3.8 nM and $K_{D2}$= 25 nM. The half-inhibitory concentration for $^{nat}$Lu-BQ7876 was 59 nM that is equal to 61 nM for $^{nat}$Lu-PSMA-617. Cellular processing of [$^{177}$Lu]Lu-BQ7876 was accompanied by slow internalization. [$^{177}$Lu]Lu-BQ7876 was cleared from blood and normal tissues rapidly. Initial elevated uptake in kidneys decreased rapidly, and by 3 h pi, the renal uptake (13±3%ID/g) did not differ significantly from tumour uptake (9±3%ID/g). Tumour uptake was stable between 1 and 3 h followed by a slow decline. The calculated effective dose (0.00423 Sv/GBq) was somewhat lower than the clinical values for [$^{177}$Lu]Lu-PSMA-617 (~0.08 Sv/GBq). The highest absorbed dose was in kidneys, followed by organs and tissues in abdomen. ***Conclusion:*** Biodistribution studies in mice demonstrated that targeting properties of [$^{177}$Lu]Lu-BQ7876 are not inferior to properties of [$^{177}$Lu]Lu-PSMA-617. Phase I clinical study is required to evaluate if [$^{177}$Lu]Lu-BQ7876 offers any advantage in clinics. ***References:*** [1]Lundmark et al. Pharmaceutics. 2022;14:1098.

## EPS-219

### Theranostic approach in CD30 positive cancers with a radiolabeled antibody conjugated to the radiosensitizing antitubulin monomethyl auristatin E payload

***C. Petitot***[1], *J. Frenay*[2], *A. M. M. Dias*[1], *A. Oudot*[1], *A. Helbling*[1], *M. Moreau*[3], *M. Monterrat*[1], *M. Guillemin*[1], *N. Ranjit*[1], *A. Cochet*[4], *P. S. Bellaye*[5], *B. Collin*[6];
[1]*Pirp - Service de Médecine Nucléaire, Centre Georges-François Leclerc, Dijon, FRANCE,* [2]*Icb - Umr Cnrs 6303 / Pirp - Service de Médecine Nucléaire, Centre Georges-François Leclerc, Dijon, FRANCE,* [3]*Icmub - Umr Cnrs 6302, Dijon, FRANCE,* [4]*Icmub - Umr Cnrs 6302 / Pirp - Service de Médecine Nucléaire, Centre Georges-François Leclerc / Chu François Mitterrand, Dijon, FRANCE,* [5]*Pirp - Service de Médecine Nucléaire, Centre Georges-François Leclerc / Lnc - Umr Inserm 1231, Dijon, FRANCE,* [6]*Icmub - Umr Cnrs 6302 / Pirp - Service de Médecine Nucléaire, Centre Georges-François Leclerc, Dijon, FRANCE.*

***Aim/Introduction:*** CD30 is a 120 kDa transmembrane glycoprotein that is the eighth member of the tumour necrosis factor receptor superfamily (TNFRSF8). It interacts with TRAF2 or TRAF5 proteins to activate nuclear factor kappa B (NF-κB), which leads to cellular proliferation and differentiation. CD30 represents an attractive theranostic target since it is overexpressed in many cancers such as lymphomas, melanoma, nasopharyngeal carcinoma or lung cancers. In this context, a theranostic probe based on brentuximab vedotin (BV, antibody drug conjugate approved in CD30 positive lymphomas) might be of great interest, especially for further combination with radiotherapy due to the radiosentization properties of its payload (monomethyl auristatin E, MMAE). Thus, this preclinical study aimed to develop a radiolabeled BV for theranostic PET imaging purposes. ***Materials and Methods:*** KARPAS 299 cell line (anaplastic large cell lymphoma) were used as CD30 positive tumour models. BV was randomly conjugated

to deferoxamine (DFO) to be radiolabeled with zirconium-89 ($^{89}$Zr). The radiochemical purity (RCP) was assessed by instant thin layer chromatography. In vitro binding assays were performed to ensure that bioconjugation and radiolabeling did not alter the affinity and immunoreactivity of the BV radioconjugate. For the in vivo experiments, a total of $10.10^6$ cells were subcutaneously implanted in the right flank of irradiated NOD-SCID mice (n = 6). Finally, $^{89}$Zr-DFO-BV (25 µg, 5 MBq per mouse in 100 µL, n = 3) was injected i.v. in tumor-bearing mice (target volume: 300-500 mm$^3$). In parallel, a blocking group was also performed with the same design plus a 50x excess of « cold » BV. Then, mice underwent PET/CT imaging at 24h, 48h and 72h post-injection and ex vivo gamma counting was performed after the last imaging timepoint. ***Results:*** After radiolabeling, we obtained an RCP systematically > 95% (specific activity of 100MBq/mg). In vitro assays demonstrated good affinity (Kd = 0.15 ± 0.026 nM) and immunoreactivity (about 60%). PET imaging of $^{89}$Zr-DFO-BV showed the highest tumour uptake at 72h post-injection (30.4 ± 1.5 %ID/g) with a good specificity as demonstrated by the blocking group (uptake significantly decreased about 5 times, 6.2 ± 2.0 %ID/g) and confirmed by ex vivo gamma counting. ***Conclusion:*** Our study demonstrated that BV could be a suitable PET companion diagnostic in the frame of targeted therapy of CD30 positive cancers. It could also be of great interest for further association with external and/or molecular radiotherapy since the BV's payload (MMAE) is a well-known radiosensitizer

## EPS-220

### Testing the potential therapeutic use of [$^{188}$Re]Re-maSSS/maSES-PEG2-RM26 as part of a theranostic pair with their [$^{99m}$Tc]Tc-labeled counterparts

***P. Kanellopoulos****, Q. Yu, A. Abouzayed, E. Bezverkhniaia, V. Tolmachev, A. Orlova;*
*Uppsala University, Uppsala, SWEDEN.*

***Aim/Introduction:*** Despite the introduction of new radionuclides in use in nuclear medicine, tracers based on Tc-99m are still on high demand, due to its availability and the paired equipment worldwide. Recently two novel [99mTc]Tc-labeled radioantagonist based on the RM26 motif were reported. These two radiotracers ([$^{99m}$Tc]Tc-maSSS-PEG2-RM26 and [$^{99m}$Tc]Tc-maSES-PEG2-RM26) (1) displayed promising preclinical results, to the degree that the first one became subject in clinical trials (2). Based on the positive results and the lack of a potent GRPR-targeting theranostic pair for clinical use, we aimed to investigate the performance of these two agents after labeling with generator acquired Re-188. ***Materials and Methods:*** Both maSSS-PEG2-RM26 and maSES-PEG2-RM26 were labeled with Re-188, radiochemical yields were determined using iTLC with PBS or pyridine/$CH_3COOH$/water 5:3:1.5 as mobile phases and radiochemichal purity was accessed with reverse-phase radio-HPLC. The complex stability was tested with 1000x molar excess of L-Cystein at room temperature. Cell association and GRPR-specificity were tested in PC-3 (37°C, Cf=0.25nM peptide concentration), while for GRPR-blocking 100x molar excess of DOTAGA-PEG2-RM26 was used. The biodistribution profile of the two resulting radiotracers was accessed in Balb/c nu/nu mice bearing PC-3 xenografts. ***Results:*** Radiochemichal yields were 88±9% and 89±9% for maSSS-PEG2-RM26 and maSES-PEG2-RM26, respectively. The HPLC chromatogram showed excellent radiochemical purity for both compounds. Cysteine challenge show a robust metal-chelate with little to none Re-188 released within 1 h. Both radiotracers had a cell-uptake highly GRPR-specific with values reaching 8.5±0.1% of added activity and 5±0.3% respectively, after blocking these values dropped to 1.14±0.01% ($p<10^{-7}$) and 1.0±0.2% ($p<10^{-4}$). Both radiotracers displayed a typical for antagonist cell uptake pattern, with the bulk of the activity remaining on the membrane and a slow internalization over 24 h continues incubation. Both radiotracers displayed similar biodsitribution pattern with their previously reposted [$^{99m}$Tc]Tc-labeled counterpart (1). Biodistribution results for organ of interest such as liver, kidneys, pancreas and tumors are summarized in the following table. ***Conclusion:*** Despite their rapid washout from other tissues, both [$^{188}$Re]Re-labeled compounds displayed a descent tumor uptake and retention. Unfortunately, both had high hepatobiliary excretion with very high gastrointestinal activity uptake, hindering their potential therapeutic use due to radiotoxicity. ***References:*** (1) Abouzayed A et al Pharmaceutics. 2021;13(2):182. doi:10.3390/pharmaceutics13020182 (2) Chernov V et al. ### Alpha-emitter radium-223 mediates tumor eradication via STING-dependent pyroptosis

***F. Yu****, M. Yang, S. Qin, J. Zhang;*
*Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Radium-223 ($^{223}$Ra) is the first-in-class alpha-emitter to mediate tumor eradication. Radiation emitted from alpha-emitter is usually regarded to reduce tumor burden by directly cleaving double-strand DNA and killing tumor cells. However, the immunogenic characteristics and various cell death modalities triggered by alpha-emitter $^{223}$Ra remain unclear. ***Materials and Methods:*** We evaluated biological effects of $^{223}$Ra in cancer cell lines and mice models by biological endpoints. Concurrently, we explored immunogenicity and cell death modalities triggered by $^{223}$Ra and excavated its mechanisms of pyroptosis induction. Besides, synergistic effect with checkpoint blockade was also assessed. ***Results:*** $^{223}$Ra exhibited efficient therapeutic antitumor effects, which examined by cell viability study and tumor regression. More importantly, the irradiated cells increased the pro-inflammatory damage-associated molecular patterns, including surface-exposed calreticulin, released HMGB1, and secreted HSP70, which actively shaped tumor immunogenicity. Pyroptosis, an immunogenic cell death, was also found to play significant roles in the modulation of cancer progression under the therapeutic $^{223}$Ra. Mechanically, this synergistic effect relied on $^{223}$Ra-induced DNA damage, which activated the STING-mediated DNA sensing pathway, leading to significant increase in the degree of the T cells activation and DCs maturation as well as NLRP3 inflammasome-dependent pyroptosis. Besides, it showed potent therapeutic efficacy in $^{223}$Ra combining with checkpoint blockade anti-CD47 mAb. ***Conclusion:*** These findings reveal that alpha-emitter $^{223}$Ra with high relative biological effectiveness values induces broad antitumor effects and triggers robust tumor immunogenicity mainly through STING-dependent pyroptosis, which may shed light on promising targets for tumor therapeutic interventions.

## EPS-222

### Fractionated therapy of the PSMA-targeted radioligand$^{212}$Pb-AB001 significantly delays tumor growth

***A. Kjoel Tornes****[1,2], V. Y. Stenberg[1,2], A. Repetto-Llamazares[1], R. H. Larsen[3,1], A. Juzeniene[2];*
*[1]ArtBio AS, Oslo, NORWAY, [2]Department of Radiation Biology, Oslo University Hospital, Oslo, NORWAY, [3]Sciencons AS, Oslo, NORWAY.*

***Aim/Introduction:*** Treatment with beta-emitting $^{177}$Lu-PSMA-617 is approved for metastatic castration-resistant prostate cancer expressing prostate-specific membrane antigen (PSMA). Targeted

alpha therapy has resulted in favorable outcomes in patients both naïve or refractory to $^{177}$Lu-PSMA-617. However, $^{225}$Ac ($t_{1/2}$=9.9 days) is not available in high quantities for clinical use and has a long physical half-life compared to the circulatory half-life of anti-PSMA small molecules. Pb-212 ($t_{1/2}$=10.6h) is an in vivo generator of alpha particle emitters whose half-life matches that of small molecules, thereby potentially increasing the therapeutic efficacy of radioligand therapy. Previous studies with the novel PSMA-targeting radioligand $^{212}$Pb-AB001 have shown preclinical efficacy in vitro and in vivo [1]. The current preclinical study aims to optimize treatment effectiveness and safety by investigating the treatment regimen of $^{212}$Pb-AB001. ***Materials and Methods:*** Athymic nude mice with subcutaneous PC-3 PIP-luc xenografts were treated with $^{212}$Pb-AB001 7-10 days post cell inoculation. All groups received a cumulative dose of 0.8 MBq $^{212}$Pb-AB001 injected in 1 to 8 fractions in weekly or biweekly intervals. Tumor size and body weights were measured 2-3 times per week. Blood sampling for hematological and clinical chemistry analysis was performed at euthanasia and organs were collected for histology. Flow cytometry was performed to study cell cycle phase distribution and DNA damage in vitro. ***Results:*** Prolonged median survival and tumor growth delay were observed in all treatment groups receiving a cumulative dose of 0.8 MBq $^{212}$Pb-AB001 compared to the control. Treatments administered as two injections of 0.4 MBq with a two-week interval or four injections of 0.2 MBq delivered weekly, resulted in significant tumor growth delay and improved overall survival compared to the single dose of 0.8 MBq. Weekly injections of 0.4 MBq or 0.1 MBq, or biweekly injections of 0.2 MBq resulted in similar median survival as the group receiving one dose of 0.8 MBq. No significant differences were observed in body weight, hematology or biochemistry parameters in the treatment groups at day 60. $^{212}$Pb-AB001 demonstrated activity-dependent DNA damage (γH2AX), cell-cycle arrest in G2-M phase and apoptosis in vitro. ***Conclusion:*** The current results show that fractionated therapy with $^{212}$Pb-AB001 represents a promising strategy to enhance therapeutic efficacy compared to single-dose treatment. The number of fractions, interval duration between fractions, and administered dose per fraction were identified as crucial factors influencing the treatment outcome. This study emphasizes the importance of determining optimal dosing regimen through further preclinical and clinical investigations of $^{212}$Pb-AB001. ***References:*** [1]doi:10.3390/cancers14112784

## EPS-223

### Biodistribution Study and Pre-clinical Radiopharmaceutical Therapy with a CXCR4-targetted Compound on a Human CXCR4 Positive Multiple Myeloma Orthotopic Model

***I. Bloise****, H. Kuo, N. Colpo, H. Merkens, P. Ng, D. Kwon, L. Escano, F. Kuchenbauer, K. Lin, F. Benard;*
*BC Cancer, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Despite recent treatment advances, Multiple Myeloma (MM) represents 10% of hematological malignancies and remains incurable. The chemokine receptor 4 (CXCR4), overexpressed in MM and other solid tumors and hematological malignancies, is an attractive target for radiopharmaceutical therapy (RPT). We developed an orthotopic model of MM applicable to pre-clinical studies involving CXCR4-targeted radiopharmaceuticals. In this study, we investigate the applicability of such model in RPT, including treatment efficacy, possible side effects and potential toxicity. ***Materials and Methods:*** SPECT/CT images and biodistribution studies were performed on luciferase-transfected AMO1 MM xenograft-bearing NRG male mice with [$^{177}$Lu]Lu-BL34. For RPT, NRG mice were intravenously injected with $10^6$ luciferase-transfected AMO1 cells. Animals were clinically monitored once a week for the following 5 weeks, then divided into groups and injected with saline, 15MBq, 35MBq and 50MBq of [$^{177}$Lu]Lu-BL34 (control n=4/ RPT n=8). Disease engraftment and spread was also monitored weekly by in vivo bioluminescence imaging in a Perkin Elmer's IVIS Lumina 5, starting 3 weeks post-injection until RPT, and once 2 weeks after therapy due to radiation safety protocols. Animals were monitored daily following therapy until reaching humane endpoint criteria and their weights measured and recorded once a week. ***Results:*** Biodistribution study and SPECT/CT images showed high persistent uptake in xenografts and low uptake with quick washout in healthy organs. Limited mobility and hind limb paralysis were the most common symptoms leading to euthanasia in the different groups. No significant weight loss (>10% of body weight) was observed in any of the treatment groups. Extra-marrow tumor growth was observed in 3 mice in the 15MBq group and 1 mouse in the 35MBq, tumors involved the mandible, thorax, hips and lumbar spine. The median survival endpoint was reached by control, 15MBq, 35MBq and 60MBq in 20, 18, 20 and 24 days respectively. Statistical significance was achieved only in the highest activity treatment group (p=0.0158). ***Conclusion:*** Many clinical trials use CXCR4-targeted RPT for marrow ablation, in this pre-clinical study we were able to show potential treatment benefits using a non-myeloablative approach. Treatment was well tolerated, no acute side effects from therapy were evident regardless of the injected activity, and humane endpoint was reached due to disease progression. Further work is needed as many CXCR4-targeted radiopharmaceuticals are highly selective for human CXCR4, which may mask some undesirable effects of RPT in mouse models due to CXCR4 expression in normal hematopoietic stem cells and bone marrow stromal cells.

## EPS-224

### Design and evaluation of a new generation of long-acting SSTR2 antagonists for enhanced radionuclide therapy of NETs

***M. Handula***[1]*, S. Beekman*[1]*, Y. Seimbille*[1,2]*;*
[1]*Erasmus MC, Rotterdam, NETHERLANDS,*
[2]*TRIUMF, Vancouver, BC, CANADA.*

***Aim/Introduction:*** The high expression of the somatostatin receptor subtype 2 (SSTR2) by the neuroendocrine tumors (NETs) makes it an ultimate target for the diagnosis and treatment of the malignancies. Various biovectors were developed to target NETs and among them, DOTA-JR11 a SSTR2-antagonist. Preclinical studies showed that high tumor uptake and favorable biodistribution were observed using the antagonist. However, rapid blood clearance was reported upon injection of the radioligand. Hence, there is a need to improve the bioavailability of the radioligand to achieve higher tumor uptake, and consequently enhance therapeutic efficacy. We report herein the development and evaluation of SSTR2-antagonists bearing palmitic fatty acid to improve the pharmacokinetic properties of DOTA-JR11. ***Materials and Methods:*** DOTA-JR11-Lys($N_3$)-$NH_2$ (1) was synthesized by solid-phase peptide synthesis. Palmitic acid was conjugated either to bicyclononyne (BCN) or aza-dibenzocyclooctyne (DBCO) and coupled to 1 via the strain-promoted azide-alkyne cycloaddition to obtain compounds 2 and 3, respectively. Both peptides were radiolabeled with [$^{177}$Lu]$LuCl_3$ in optimized conditions. Stability studies in PBS and mouse serum, as well as hydrophilicity ($LogD_{7.4}$)

were determined for both compounds. Competitive binding assay as well as cell uptake and internalization were carried out in U2OS.SSTR2 cells. ***Results:*** Compounds 1, 2 and 3 were successfully synthesized and obtained in 15, 55 and 65% chemical yield, respectively. 2 and 3 were radiolabeled with lutetium-177 and obtained in excellent radiochemical yields (> 98%) and radiochemical purities (> 98%). [$^{177}$Lu]Lu-2 and [$^{177}$Lu]Lu-3 exhibited a $logD_{7.4}$ value of 0.63 and 0.56, respectively, and high stability in PBS (> 91%) at 24 h post incubation at 37 °C. However, [$^{177}$Lu]Lu-2 showed higher sensitivity towards peptidase digestion in mouse serum compared to [$^{177}$Lu]Lu-3 (24.2 and 98.7% intact radioligand at 24 h post incubation at 37 °C, respectively). The binding affinity of 2 and 3 was 1.1 and 9.7-fold lower than the binding affinity of the parent peptide DOTA-JR11 (4.1 nM and 37.0 nM vs. 3.8 nM). [$^{177}$Lu]Lu-2 and [$^{177}$Lu]Lu-3 had lower cell uptake compared to [$^{177}$Lu]Lu-DOTA-JR11 (26.3% AD and 16.1% AD, respectively, compared to 54.7% AD). However, uptake could be blocked, confirming the specificity of the binding to SSTR2. ***Conclusion:*** Our new DOTA-JR11 analogs were successfully synthesized and radiolabeled with lutetium-177. They exhibited good binding affinity to SSTR2 and showed acceptable cell uptake. Further optimization of the molecular structure to enhance the hydrophilicity and the pharmacokinetics is underway, as well as in vivo evaluation in tumor bearing mice.

## EPS-225

### DOTA-MGS5, a novel cholecystokinin-2 receptor-targeting peptide analogue for use in targeted therapy, preclinical evaluation for clinical translation

***T. Zavvar***[1], *A. A. Hoermann*[1], *M. Klingler*[1], *J. Hagenbuchner*[2], *L. Joosten*[3], *G. Franssen*[3], *P. Laverman*[3], *M. W. Konijnenberg*[4], *I. Skvortsova*[5], *L. Gruber*[6], *E. von Guggenberg*[1];
[1]*Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA,* [2]*Department of Pediatrics II, Medical University of Innsbruck, Innsbruck, AUSTRIA,* [3]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [4]*Department of Radiology and Nuclear Medicine, Erasmus Medical Center, Rotterdam, NETHERLANDS,* [5]*Department of Therapeutic Radiology and Oncology, Medical University of Innsbruck, Innsbruck, AUSTRIA,* [6]*Department of Radiology, Medical University Innsbruck, Innsbruck, AUSTRIA.*

***Aim/Introduction:*** Cholecystokinin-2 receptors (CCK2R) are overexpressed in medullary thyroid carcinoma (MTC) and some other malignancies. We recently reported on the development of DOTA-DGlu-Ala-Tyr-Gly-Trp-(N-Me)Nle-Asp-1-Nal-$NH_2$ (DOTA-MGS5), a novel minigastrin analogue that exhibits improved stability and enhanced tumour targeting properties. As a result, targeting CCK2R with DOTA-MGS5 provides a potential new theranostic strategy for patients with CCK2R expressing neoplasms. We conducted preclinical studies with the aim of clinical translation of [$^{177}$Lu]Lu-DOTA-MGS5 for peptide receptor radionuclide therapy (PRRT). ***Materials and Methods:*** A431 and AR42J cells expressing CCK2R were used to examine the receptor-specific cellular uptake of [$^{177}$Lu]Lu-DOTA-MGS5 up to 4h after incubation. In addition, confocal microscopy studies were performed using MGS5 conjugated with the fluorescent dye ATTO-488. Biodistribution studies were conducted in A431-CCK2R xenografted female BALB/c nude mice for up to seven days after injection. To investigate the therapeutic effect, cell viability studies were performed on A431-CCK2R cells. The radiation dose response after incubation with ~60 or ~240 kBq (~0.5-2 nM) [$^{177}$Lu]Lu-DOTA-MGS5 was compared to different doses of external beam radiation (2, 4, 8 Gy). ***Results:*** [$^{177}$Lu]Lu-DOTA-MGS5 exhibited a high and specific cell uptake of 68.0±2.3% in A431-cells and 48.6±2.2% in AR42J-cells after 4h incubation. Fluorescence microscopy confirmed a rapid receptor-specific translocation of ATTO-488-MGS5 from the cell membrane to the intracellular compartment in both cell lines. The radiolabelled peptide exhibited a favourable biodistribution profile in animals, with low non-specific radioactivity accumulation in the majority of tissues. The tumour uptake in A431-CCK2R xenografts was remarkably increased (28.9±7.2% and 12.6±3.3% IA/g at 1 and 3 days after injection) combined with a very favourable tumour-to-kidney ratio (13-15). In stomach, with physiological CCK2R expression, a somewhat prolonged retention of radioactivity was observed with a tumour-to-stomach ratio of 4-6. On the basis of the pharmacokinetic data acquired in mice, human dosimetry estimates were calculated. In the cell viability studies a reduction of total viable cells comparable to 4 Gy external beam radiation was achieved. ***Conclusion:*** A high receptor specific cell uptake and favourable tumour targeting properties was confirmed for [$^{177}$Lu]Lu-DOTA-MGS5. Improved tumour uptake and retention was determined in A431-CCK2R xenografted mice. The therapeutic effect observed in vitro and the dosimetry extrapolations from mice to human support the therapeutic use of [$^{177}$Lu]Lu-DOTA-MGS5 in patients with advanced MTC and other CCK2R-expressing tumours.

***References:*** von Guggenberg, Elisabeth, et al. "Preliminary clinical experience of cholecystokinin-2 receptor PET/CT imaging using the 68Ga-labeled minigastrin analog DOTA-MGS5 in patients with medullary thyroid cancer." JNM (2023).

## EPS-227

### Preclinical evaluation of a radiotheranostic single-domain antibody against Fibroblast Activation Protein alpha

***Y. Dekempeneer***[1], *S. Massa*[1], *F. Santens*[1], *L. Navarro*[1], *M. Berdal*[1], *M. M. Lucero*[1], *A. Pombo Antunes*[1], *J. A. Van Ginderachter*[2,3], *T. Lahoutte*[1,4,3], *N. Devoogdt*[1,3], *M. D'Huyvetter*[1,3];
[1]*PRECIRIX NV/SA, Brussels, BELGIUM,* [2]*VIB Center for Inflammation Research, Brussels, BELGIUM,* [3]*Vrije Universiteit Brussel, Brussels, BELGIUM,* [4]*UZ Brussel, Brussels, BELGIUM.*

***Aim/Introduction:*** Fibroblast activation protein alpha (FAP) is highly expressed on cancer associated fibroblasts of epithelial-derived cancers. Breast, colon and pancreatic tumors often show strong desmoplastic reactions which results in a dominant presence of stromal cells. FAP gains interest as a target for molecular imaging and targeted therapies. Single-domain antibodies (sdAbs) are the smallest antibody-derived fragments with beneficial pharmacokinetic properties for molecular imaging and targeted therapy. ***Materials and Methods:*** We describe the generation, selection and characterization of a sdAb against FAP. We assessed in mice its imaging and therapeutic potential after radiolabeling with biomarker dose Iodine-131 ($^{131}$I) and Gallium-68 ($^{68}$Ga) for respectively SPECT and PET imaging, and with Iodine-131 and Actinium-225 ($^{225}$Ac) for targeted radionuclide therapy. ***Results:*** The lead anti-FAP sdAb (=sdAb) was identified with picomolar affinity for a FAP conserved epitope that is away from the catalytic site, and recognized both purified and membrane-anchored FAP protein. The radiolabeled variants [$^{68}$Ga]Ga-DOTA-sdAb, [$^{225}$Ac]Ac-DOTA-sdAb and [$^{131}$I]I-GMIB-sdAb had radiochemical purities >95% and were functional on recombinant human FAP protein and FAP$^+$ GM05389 human fibroblasts. [$^{68}$Ga]Ga-DOTA-sdAb, [$^{225}$Ac]Ac-DOTA-sdAb and [$^{131}$I]I-GMIB-sdAb accumulated fast and specific in FAP$^+$human U87MG glioblastoma tumors upon intravenous

administration. Low but specific uptake (about 2-3 %IA/g) was observed in lymph nodes, uterus, bone and skin. Unbound [$^{131}$I]I-GMIB-sdAb was rapidly cleared from kidneys (<1%IA/g after 24h), while for [$^{225}$Ac]Ac-DOTA-sdAb it is slower (8.07+/-1.39%IA/g after 24h and 2.47+/-0.18%IA/g after 96h). Mice treated with [$^{225}$Ac]Ac-DOTA-sdAb and [$^{131}$I]I-GMIB-sdAb lived longer compared to mice treated with radioactive controls or vehicle solution, and this in a dose-dependent manner. ***Conclusion:*** [$^{68}$Ga]Ga-DOTA-sdAb and biomarker dose [$^{131}$I]I-GMIB-sdAb allow for specific detection of FAP$^{+}$tumors in mice. Therapeutic [$^{225}$Ac]Ac-DOTA-sdAb and [$^{131}$I]I-GMIB-sdAb revealed high and sustained tumor targeting, which translated into dose-dependent therapeutic effect in FAP$^{+}$tumor xenografted mice. This study confirms the potential of radiolabeled anti-FAP sdAb as radiotheranostic for FAP$^{+}$cancers and warrants clinical testing.

## EPS-228

### Auger electron therapy of prostate cancer: a preclinical evaluation of $^{58m}$Co-DOTA-PSMA-617

***C. Baun***[1,2,3], *J. H. Dam*[1], *J. D. Ewald*[4,2], *B. W. Kristensen*[4], *V. S. Laursen*[1,2], *M. G. Hildebrandt*[1,2,3], *B. B. Olsen*[1], *H. Thisgaard*[1,2]; *[1]Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK, [2]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [3]Center for Personalized Response Monitoring in Oncology (PREMIO), Odense University Hospital, Odense, DENMARK, [4]Department of Pathology, Odense University Hospital, Odense C, DENMARK.*

***Aim/Introduction:*** We have previously evaluated the novel theranostic pair [$^{55/58m}$Co]Co-DOTA-PSMA-617 in vitro and in vivo in prostate cancer. These preliminary studies demonstrated promising antiproliferative effects in vitro, while specific tumor targeting was achieved in xenograft mice (1). The current study aimed to evaluate the therapeutic efficacy and adverse effects of [$^{58m}$Co]Co-DOTA-PSMA-617 in vitro and in vivo in prostate cancer xenograft mice. ***Materials and Methods:*** The therapeutic effect of [$^{58m}$Co]Co-DOTA-PSMA-617 in vitro was evaluated by clonogenic assay of PSMA-positive (PC3-PIP) and PSMA-negative (PC3-flu) prostate cancer cells. Increasing activity concentrations (0-60 MBq/ml) of [$^{58m}$Co]Co-DOTA-PSMA-617 diluted in the incubation medium was added to cells followed by 24 h incubation. The therapeutic effect in vivo was investigated in male BALB/c mice (n=12) inoculated subcutaneously with 1x10$^{6}$ PC3-PIP cells. Seven days after tumor inoculation, the mice were divided into two groups with equal visual tumor sizes. One group (n=6) was injected iv with [$^{58m}$Co]Co-DOTA-PSMA-617 (144.0±9.0 MBq, 2.3±0.1 nmol) and the other group (n=6) with saline. One week later, the treatment was repeated. The mice were monitored by body weight and tumor size measurements until the end of the observation period (90 days) or when they reached one of the humane endpoints, after which they were euthanized, and the kidneys and liver were collected for histopathological analysis**.** Two mice from the treated group had to be censored due to hostility between cage rivals, which resulted in terminal lesions. Survival was analyzed by Kaplan-Meyer analysis and log-rank (Mantel-Cox) test. ***Results:*** The clonogenic survival of PC3-PIP cells in vitro was significantly reduced by [$^{58m}$Co]Co-DOTA-PSMA-617 in an activity-dependent manner (2.5 MBq/mL: p<0.001; 5-60 MBq/mL: p<0.0001). In vivo, the treated mice had a significantly improved median survival time of 23 days compared to untreated mice, which only had a median survival time of 11 days (p=0.0014). Hence, a 110% increase in median survival was obtained. Further, 25% of the treated mice had a complete response and long-term survival. The histopathological assessment of liver and kidney tissue showed no signs of inflammation, fibrosis, or necrosis, and no visible differences were observed between the groups. ***Conclusion:*** Auger electron therapy with [$^{58m}$Co]Co-DOTA-PSMA-617 showed promising therapeutic effects in vitro and in vivo and resulted in significant survival benefits for tumor-bearing mice with no toxicities observed. ***References:*** [$^{58m}$Co]Co-DOTA-PSMA-617: A novel radioligand for Auger electron therapy of prostate cancer Thisgaard, H. et al. 2017. J. Label. Compd. Radiopharm. 60, Suppl. 1, S327, P 167.

### Polymeric Micelles as Drug Delivery System for PARP Inhibitor-Based Chemo-Radiotherapy Combination Against Triple-Negative Breast Cancer

***L. Schäfer***[1], *A. Wang*[2], *Q. Peña*[2], *E. Henrard*[1], *T. Lammers*[2], *E. M. Buhl*[3], *M. Frings*[4], *C. Bolm*[4], *A. Morgenroth*[1], *F. M. Mottaghy*[1,5]; *[1]Department of Nuclear Medicine, RWTH Aachen University Hospital, 52074 Aachen, GERMANY, [2]Institute for Experimental Molecular Imaging, RWTH Aachen University Hospital, 52074 Aachen, GERMANY, [3]Electron Microscopy Facility, Institute of Pathology, RWTH Aachen University Hospital, 52074 Aachen, GERMANY, [4]Institute of Organic Chemistry, RWTH Aachen University, 52074 Aachen, GERMANY, [5]Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, 6229 ER Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Poly (ADP-ribose) polymerase inhibitors (PARPi) are commonly used in the treatment against BRCA-mutated (BRCA$^{mut}$) tumors, such as triple negative breast cancer (TNBC). However, PARPi-based monotherapies have some inherent limitations, including the development of resistance. To overcome some of these drawbacks, combinations of PARPi with different chemotherapeutics or other cancer treatments (e.g., radiotherapy) have shown significant promise. We have previously established a therapeutic approach against BRCA$^{mut}$ TNBC, based on combining the DNA damage response inhibition of PARPi with the radiotherapeutic effect of the Auger electron emitter 125-iodine ($^{125}$I). Yet, preliminary preclinical evaluation showed poor biodistribution and chemical instability of the developed $^{125}$I-PARPi tracer. Hence, we here set out to develop a polymeric micelle-based formulation efficiently co-encapsulating non-radioactive and radioactive I-PARPi with the overall aim of improving tracer stability, biodistribution and target-site accumulation for more efficient chemo-internal radiotherapy combination. ***Materials and Methods:*** Radiolabeling was performed using a tributyltin-precursor with chloramine-T as catalyst. Radioactive and non-radioactive I-PARPi co-loaded polymeric micelles were prepared via nanoprecipitation method. Physicochemical and pharmaceutical properties were analyzed by high-performance liquid chromatography (HPLC), dynamic light scattering and transmission electron microscopy (TEM). Drug encapsulation efficiency (EE) and retention inside the micelles were analysed by HPLC. Cell uptake of the tracer was assessed in different TNBC BRCA$^{mut}$ and BRCA wildtype cell lines, and analysed by Gamma-counter measurements. In vitro tracer stability was examined via HPLC. ***Results:*** TEM images of the co-loaded micelles showed a homogenous distribution of spherical particles, with sizes around 70 nm and polydispersity index (PDI) below 0.1, as confirmed by DLS. Radioactive and non-radioactive I-PARPi were efficiently co-encapsulated into the micelles (EE > 80 %), and these were stable over 14 days at 4 °C. Co-loaded micelles showed a similar release profile for both compounds (i.e., 50 % retained after 72 hours). Furthermore, formulation in micelles improved tracer stability about 10-fold by minimizing its deiodination in vitro,

as well as it enhanced tracer uptake in BRCA$^{mut}$ TNBC cell lines. ***Conclusion:*** We have successfully developed a stable radioactive and non-radioactive I-PARPi co-loaded polymeric micelle formulation that holds potential for efficient chemo-radiotracer therapy combination in TNBC. Ongoing work involves in vivo investigation of the nanoformulation in terms of tracer stability in blood, its pharmacokinetics and therapeutic efficacy.

## EPS-230

**Successful treatment of human high-risk neuroblastoma using $^{177}$Lu-octreotide combined with Lorlatinib in a mouse model**

***E. Forssell-Aronsson***[1,2], *A. Romiani*[1], *D. Pettersson*[1], *K. Simonsson*[1], *H. Bakr*[1,2], *D. Lind*[1], *A. Kovacs*[1,2], *R. Palmer*[1], *B. Hallberg*[1], *K. Helou*[1], *J. Spetz*[1];
[1]*University of Gothenburg, Gothenburg, SWEDEN,*
[2]*Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Children with high-risk neuroblastoma (HR-NB) has poor prognosis with less than 40% survival, and new treatment options should be developed. Many human HR-NBs overexpress somatostatin (SS) receptors (SSTRs) to a very high extent, and should be possible to successfully treat with, e.g., $^{177}$Lu-labelled SS analogues. Recent clinical and preclinical studies show, however, unexpectedly low therapeutic effects of such treatment. HR.NBs often have gain-of-function mutations in anaplastic lymphoma kinase (ALK). The aim of this study was to investigate if treatment with $^{177}$Lu-octreotide in combination with the ALK inhibitor lorlatinib would give enhanced effect in a human HR-NB mouse model. ***Materials and Methods:*** Balb/C mice were xenografted with human CLB-BAR HR-NB. Biodistribution of $^{177}$Lu-octreotate and $^{177}$Lu-octreotide were determined, and the absorbed dose was estimated to tumour and selected normal tissues. Initial therapeutic effects were studied in mice administered with different amounts of $^{177}$Lu-octreotate or $^{177}$Lu-octreotide. In the final therapy study, mice were treated with 30 MBq $^{177}$Lu-octreotide, lorlatinib, or a combination of both treatments, and controls received saline. Tumour volume was followed and compared with controls. Tumour samples were analysed by qPCR and immunohistochemical (IHC) analyses for apoptosis. ***Results:*** Biodistribution data showed very high uptake and absorbed dose to tumour tissue for both radiopharmaceuticals. Tumour/Blood $^{177}$Lu activity concentration ratios were 420 and 270 for $^{177}$Lu-octreotide and $^{177}$Lu-octreotate, respectively. Treatment with $^{177}$Lu-octreotide gave somewhat better effects than $^{177}$Lu-octreotate, but still a very low effect on tumour volume. No dose-response effects of $^{177}$Lu-octreotate were obtained. Combination therapy with $^{177}$Lu-octreotide and lorlatinib resulted in clear and synergistic tumour volume reduction, with a relative tumour volume of 0.39 compared with 4.6 and 1.2 for $^{177}$Lu-octreotide and lorlatinib as monotherapy, respectively. Furthermore, more apoptosis-related genes were affected by combination than single-treatment. ***Conclusion:*** The gene regulation suggest apoptosis activation through the extrinsic pathway for both treatments. ALK mutations seems to results in radioresistance. ALK inhibitors may restore radiosensitivity and lead to successful therapeutic effects of $^{177}$Lu-octreotide.

***Aim/Introduction:*** DNA polymerase theta (Pol theta) is essential for DNA double strand break repair through microhomology-mediated end-joining (MMEJ). Pol theta has very restricted expression in normal tissues but is frequently overexpressed in cancer cells and its loss has been shown to sensitise cancer cells but not normal cells to ionising radiation (IR). This highlights Pol theta as a promising drug target for the potentiation of radiotherapy. Artios recently developed potent and highly selective Pol theta inhibitors showing in vitro and in vivo efficacy in cancer models[1]. The aim of this study was to explore the possible therapeutic applications of these inhibitors in combination with radiation. ***Materials and Methods:*** For this purpose a panel of cell lines (n=56) enriched for head & neck, colorectal and lung cancers was treated with either Pol theta inhibitor, X-rays or a combination of Pol theta inhibitor and X-rays then assessed for in vitro viability by colony formation assay and induction of DNA damage response markers by immunofluorescence. ***Results:*** It was observed that Pol theta inhibition sensitised a wide range of cancer cell lines but not normal cells to X-rays. This effect was enhanced with increasing number of X-ray fractions, a modality that closely reflects clinical treatment regimens. Additionally, it was shown that Pol theta inhibition combined with X-rays leads to increased DNA damage foci compared to the X-ray or Pol theta inhibitor treatment alone[2]. The combination of Pol theta inhibitor with X-rays was well tolerated in vivo during xenograft efficacy studies and induced a significant reduction in tumor growth compared to single agent treatment[2]. In studies to identify potential patient selection biomarkers, it was found that loss of the Shieldin

complex component SHLD2, sensitised cells to the combination treatment in vitro, which may have relevance for the treatment of tumors that have mutations in the 53BP1/Shieldin complex. In addition, it was confirmed that Pol theta inhibition potentiates the efficacy of fractionated protons both in vitro and in vivo in mouse xenotransplants, suggesting that Pol theta inhibition has the potential to increase the efficiency of different radiotherapies. ***Conclusion:*** Collectively, our results show that Artios' potent and selective Pol theta inhibitors are effective radiosensitisers in a wide range of cancer models, paving the way for testing Pol theta inhibitors with radiotherapy in clinical trials. ***References:*** 1. ## OP-765

### Dissecting signaling network response to radiolabeled minigastrin analog reveals radiosensitizing targets in CCKBR-positive cancers

***M. Grzmil***[1], *Y. Qin*[1], *A. Blanc*[1], *T. Chiorazzo*[1], *P. Berger*[2], *S. Frank*[3], *R. Schibli*[1,4], *M. Behe*[1];
[1]*Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen PSI, SWITZERLAND,* [2]*Laboratory of Nanoscale Biology, Paul Scherrer Institute, Villigen PSI, SWITZERLAND,* [3]*Division of Neuropathology, Institute of Pathology, University of Basel, Basel, SWITZERLAND,* [4]*Department of Chemistry and Applied Biosciences, ETH Zürich, Zürich, SWITZERLAND.*

***Aim/Introduction:*** Identification of radiation-activated survival mechanisms in cancer cells provides opportunities to develop new therapeutic strategies based on the targeting signaling pathways, which are triggered during radiotherapy. Our recent study explored cancer responses to targeted beta radiation therapy and identified radiosensitizing targets including integrin or epidermal growth factor receptors [1]. In comparison to β-emitters, targeted alpha-particle therapy (TAT) with a relatively short range and high linear energy transfer shows higher toxicity to cancer cells. Nevertheless, the toxicity to healthy organs or cancer radioresistance can limit the efficacy. In the present study, we analyzed signaling network responses to TAT with actinium-225 labeled minigastrin analog [$^{225}$Ac]Ac-PP-F11N to improve the effectiveness of TAT by combinatory treatments. ***Materials and Methods:*** Quantitative phosphoproteomics and proteomics followed by the bioinformatics analysis identified alterations in the signaling networks in response to [$^{225}$Ac]Ac-PP-F11N in A431 cells, which overexpress cholecystokinin B receptor (CCKBR). Western blot (WB) analysis and confocal microscopy verified the activation of the induced pathways. Small-molecule inhibitors were used to validate the radiosensitizing strategies both in vitro and in A431/CCKBR tumor-bearing nude mice. ***Results:*** TAT-induced DNA damage response (DDR), cell cycle regulation, signal transduction, RNA transcription and processing as well as cell morphology and transport. WB analysis and microscopy confirmed increased phosphorylations of p53, p53BP1, histone deacetylases (HDACs), and H2AX. Inhibition of HDAC, ATM, and p38 kinases by TMP269, AZD1390, and SB202190, respectively, sensitized A431/CCKBR cells to TAT. Combination of [$^{225}$Ac]Ac-PP-F11N with HDAC inhibitor vorinostat (SAHA) showed significantly reduced viability and increased DNA damage of A431/CCKBR cells as well as the most pronounced tumor growth inhibition and the extended mean survival of treated tumor-bearing mice. ***Conclusion:*** The present study revealed alterations in cancer signaling networks in response to TAT and verified the radiosensitizing potential of HDAC inhibitors to [$^{225}$Ac]Ac-PP-F11N [2]. This research further recommends the development of radiosensitizing strategies by targeting radiation-activated and survival-promoting signaling pathways. ***References:*** 1. ## OP-766

### p53 Stabilisation Potentiates $^{177}$Lu-DOTATATE Treatment in Neuroblastoma

***H. Berglund***[1], *S. Lundsten Salomonsson*[2], *T. Mohajershojai*[1], *D. P. Lane*[1,3,4], *M. Nestor*[1];
[1]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN,* [2]*Ridgeview Instruments AB, Uppsala, SWEDEN,* [3]*Department of Microbiology, Tumour and Cell Biology, Karolinska Institute, Stockholm, SWEDEN,* [4]*p53Lab, Agency for Science Technology and Research (A*STAR), Singapore, SINGAPORE.*

***Aim/Introduction:*** Targeted radionuclide therapy against somatostatin receptors using $^{177}$Lu-DOTATATE is currently being explored as a treatment option for neuroblastoma. Combining molecular radiotherapy with radiosensitising drugs have been proposed as a viable strategy for enhancing the therapeutic efficacy while minimising adverse effects. p53 has been identified as a potential target for radiosensitisation due to its involvement in DNA damage response. The aim of this study was to investigate the novel wild-type p53-stabilising peptide VIP116 in neuroblastoma, both as monotherapy and together with $^{177}$Lu-DOTATATE in neuroblastoma models in vitro and in vivo. ***Materials and Methods:*** Three neuroblastoma cell lines were characterised in vitro for specific uptake of $^{177}$Lu-DOTATATE and sensitivity towards VIP116. Multicellular tumour spheroids using the IMR-32 cell line were established and subjected to mono- and combination treatment of varying concentrations of VIP116 and $^{177}$Lu-DOTATATE. Biodistribution of $^{177}$Lu-DOTATATE was performed in mice bearing IMR-32 or Neuro 2a tumour xenografts. A monotherapy study using VIP116 was done in mice with IMR-32 or Neuro 2a tumour xenografts. A combination therapy study was conducted in mice bearing IMR-32 tumour xenografts. This study included four treatment groups: control, VIP116 monotherapy, $^{177}$Lu-DOTATATE monotherapy and a combination group. ***Results:*** Two out of three cell lines had a specific uptake of $^{177}$Lu-DOTATATE in vitro. The sensitivity towards VIP116 was correlated with p53 mutational status, with cell lines harbouring mutant p53 displaying a higher $IC_{50}$ value. Treatment with $^{177}$Lu-DOTATATE and/or VIP116 showed growth inhibition of multicellular tumour spheroids, with the combination treatment displaying synergistic effects. Both IMR-32 and Neuro 2a had a specific uptake of $^{177}$Lu-DOTATATE in vivo, with IMR-32 having a higher uptake in the tumour than Neuro 2a. Monotherapy with VIP116 resulted in growth inhibition of IMR-32 tumour xenografts, but not Neuro 2a tumour xenografts. The combination therapy study resulted in a doubled media survival for both monotherapies in comparison to the control (90 and 96.5 days vs. 50 days), with the combination treatment showing a median survival of >120 days. ***Conclusion:*** Both VIP116 and $^{177}$Lu-DOTATATE inhibited neuroblastoma cell growth in vitro and prolonged the median survival in tumour bearing mice. The use of these two therapies, especially in combination, may therefore be a feasible future treatment option for neuroblastoma.

## OP-767

### Substantial Reduction of the Activity Retention in the Kidneys of Radiohybrid-Based Minigastrin Analogues by Modifying the Charge Distribution Within the Linker Section

***N. Holzleitner***[1], *T. Günther*[1], *S. Fischer*[1], *R. Beck*[1], *C. Lapa*[2], *H. Wester*[1];
[1]*Technical University Munich, Munich, GERMANY,*
[2]*University of Augsburg, Augsburg, GERMANY.*

***Aim/Introduction:*** In order to reduce elevated activity retention in the kidneys of previous radiohybrid-based minigastrin analogues, such as [$^{177}$Lu]Lu-DOTA-rhCCK-18 ([$^{177}$Lu]Lu-DOTA-D-Dap(SiFA)-(D-γ-Glu)$_8$-Ala-Tyr-Gly-Trp-Asp-Nle-Phe-NH$_2$), we substituted the negatively charged poly-D-γ-glutamate chain by polyethylene glycol moieties of various length ((PEG)$_{4\text{-}11}$). We further evaluated the influence of a different charge distribution in proximity to the silicon-based fluoride acceptor (SiFA) moiety on CCK-2R affinity, lipophilicity and biodistribution properties by insertion of different SiFA building blocks (SiFA and SiFAlin) as well as a D-γ-glutamate moiety next to the D-Dap(SiFA/SiFAlin) unit. ***Materials and Methods:*** $^{177}$Lu-labelling was performed at 90°C within 15 min (1.0 M NaOAc buffer, pH=5.5, 0.1 M sodium ascorbate). CCK-2R affinity (IC$_{50}$, n=3) was evaluated on AR42J cells. Lipophilicity (expressed as n-octanol/PBS distribution coefficient; logD$_{7.4}$) was determined. Biodistribution studies (n=4) were carried out at 24 h post-injection in AR42J tumour-bearing CB17-SCID mice. ***Results:*** Synthesis via solid-phase peptide synthesis yielded 4-8% RP-HPLC-purified labelling precursor. 177Lu-labelling proceeded in high radiochemical yields and purities of >95% and molar activities of 30-40 GBq/µmol. CCK-2R affinities of most compounds evaluated were found to be in a range of 8-20 nM, which resulted in slightly increased or comparable IC$_{50}$ values to [$^{nat}$Lu]Lu-DOTA-rhCCK-18 and [$^{nat}$Lu]Lu-DOTA-PP-F11N (IC$_{50}$: 4.7±0.6 and 12.8±2.8 nM), respectively. Lipophilicity was noticeably decreased for compounds containing a D-γ-glutamate moiety next to the D-Dap(SiFA) unit as compared to their counterparts lacking the additional negative charge. Combining the highest CCK-2R affinity and lipophilicity of all compounds investigated, [$^{177/nat}$Lu]Lu-DOTA-rhCCK-70 (DOTA-D-Dap(SiFA)-D-γ-Glu-(PEG)$_7$-D-γ-Glu-(PEG)$_3$-Trp-(N-Me)Nle-Asp-1-Nal-NH$_2$; IC$_{50}$: 12.6±2.0 nM; logD$_{7.4}$: −1.67±0.08) and [$^{177/nat}$Lu]Lu-DOTA-rhCCK-91 (DOTA-D-Dap(SiFAlin)-D-γ-Glu-(PEG)$_4$-D-γ-Glu-(PEG)$_3$-Trp-(N-Me)Nle-Asp-1-Nal-NH$_2$; IC$_{50}$: 8.6±0.7 nM; logD$_{7.4}$: −1.66±0.07) were further evaluated in vivo. Biodistribution data at 24 h post-injection for both [$^{177}$Lu]Lu-DOTA-rhCCK-70 and [$^{177}$Lu]Lu-DOTA-rhCCK-91 showed substantially decreased activity levels in the kidneys (8.4±0.8 and 6.6±0.5 %ID/g, respectively), when compared to [$^{177/nat}$Lu]Lu-DOTA-rhCCK-18 (134±18 %ID/g). However, activity levels in the tumour were found to be decreased as well (12.0±0.8 and 7.5±1.0 versus 25.4±4.7 %ID/g, respectively). In comparison to [$^{177}$Lu]Lu-DOTA-PP-F11N (tumour: 1.9±0.8 %ID/g, kidney: 3.0±0.5 %ID/g) activity levels in the tumour at 24 h post-injection were observed to be much higher for both compounds investigated, resulting in favourable tumour to kidney ratios (1.45±0.12 and 1.13±0.12 versus 0.62±0.30). ***Conclusion:*** In this study we could successfully demonstrate a reduction of activity accumulation in the kidneys by a reduction of negative charges in the linker section of radiohybrid-based minigastrin analogues, while maintaining a good tumour uptake, which led to more favourable tumour/kidney ratios in vivo compared to the references [$^{177}$Lu]Lu-DOTA-PP-F11N and [$^{177}$Lu]Lu-DOTA-rhCCK-18.

## OP-768

### Internalising radioimmunoconjugates to target KRAS in pancreatic cancer cells for simultaneous radionuclide therapy and radiosensitisation

***K. Vallis***[1], *J. Lourenco*[1], *N. Sereesongsaeng*[2], *O. Tietz*[3], *T. Rabbitts*[2];
[1]*University of Oxford, Oxford, UNITED KINGDOM,*
[2]*Institute of Cancer Research, London, UNITED KINGDOM,*
[3]*Macquarie University, Sydney, AUSTRALIA.*

***Aim/Introduction:*** Mutant KRAS is a major oncogenic driver of pancreatic ductal adenocarcinoma (PDAC), a cancer of unmet need with 5-year survival of <10%. The goal of this study was to internalise radiolabelled anti-KRAS DARPin and anti-pan-RAS scFv into PDAC cells using a cell-penetrating peptide (CPP), Tri-cTatB, consisting of three copies of cyclised TAT peptide. Internalised KRAS binders were predicted to result in inhibition of downstream signalling, radiosensitisation and cytotoxicity. ***Materials and Methods:*** Recombinant immunomolecules were expressed in E. coli. PDAC cell lines (PSN1 [KRAS$^{G12R}$], PANC-1 [KRAS$^{G12D}$], BxPC3 [KRAS$^{WT}$]) were used. The intracellular uptake of fluorphore-DARPin/scFv, co-delivered with Tri-cTatB, was assessed using live cell immunofluorescence microscopy, and cell viability was assessed using CellTiter-Glo®. As KRAS interacts with the plasma membrane, the effect of farnesylation (DARPin-cFarn, scFv-cFarn) on intracellular distribution was investigated. The chloramine-T method was used to label DARPins/scFvs with 123-Iodine and the intracellular distribution of iodinated constructs was assessed in fractionation assays. Western blot analysis (WBA) was used to evaluate expression of proteins downstream of activated KRAS. Clonogenic assays were done to investigate the effect of internalised anti-KRAS molecules on sensitisation of PANC-1 cells to external beam radiation (EBR; caesium-137 gamma radiation, 0.81 Gy min$^{-1}$). ***Results:*** mCherry-labelled DARPin and scFv were efficiently uptaken by PDAC cells in the presence of Tri-cTatB (1-2 µM). The radiolabelling yield for [$^{123}$I]I-DARPin/scFv was ≥95%. The percentage of internalised [$^{123}$I]I-anti-KRAS DARPin accumulating in the membrane, cytoplasm and nuclei of PANC-1 cells was 29, 9 and 62% respectively. The addition of a farnesylation moiety, [$^{123}$I]I-DARPin-cFarn, resulted in redistribution of the internalised radioactivity with 62, 14 and 24% in the membrane, cytoplasm and nuclei. WBA showed downregulation of pERK in the PANC-1 cell line incubated with anti-KRAS DARPins/scFvs plus Tri-cTatB. DARPin-cFarn and scFv-cFarn (550 nM) plus Tri-cTatB (2 µM) reduced PANC-1 cell viability to <10% by 48 h, but had minimal effect on BxPC3 cells. In clonogenic assays the surviving fraction of PANC-1 cells incubated with or without scFv-cFarn plus Tri-cTatB after exposure to 2 Gy EBR was 37 and 60%, respectively. ***Conclusion:*** Internalising radiolabelled RAS targeting constructs result in KRAS inhibition with simultaneous radiosensitisation, and are cytotoxic and so hold promise as a new approach to radionuclide therapy for cancer.

## OP-769

### Human hematopoietic stem cells show SSTR2 expression and specific binding of radioligands providing a potential explanation for the hematotoxicity of $^{177}$Lu-DOTA-JR11

***S. Kossatz***[1], *Y. Min*[1], *N. T. Nguyen*[1], *J. Rivière*[1], *M. van der Garde*[1], *S. Ghosh*[2], *L. Bartos*[3], *M. Brendel*[3], *F. Bassermann*[1], *K. Götze*[1], *A. Azhdarinia*[4], *W. A. Weber*[1];
[1]*Klinikum rechts der Isar at Technical University Munich, Munich, GERMANY,* [2]*University of Texas Health Science Center at Houston, Houston, VT, UNITED STATES OF AMERICA,* [3]*University Hospital of Munich, LMU Munich, Munich, GERMANY,* [4]*University of Texas Health Science Center at Houston, Munich, GERMANY.*

***Aim/Introduction:*** Peptide Receptor Radionuclide Therapy (PRRT) with the somatostatin receptor subtype 2 (SSTR2) antagonist $^{177}$Lu-DOTA-JR11 has shown promising results for treatment of neuroendocrine tumors (NET). However, hematologic toxicity occurred when patients received a macroscopic bone marrow dose of ≥ 1.44 Gy - <2 Gy, which was considered a well-tolerated dose for the agonist $^{177}$Lu-DOTA-TATE[2]. We hypothesize that $^{177}$Lu-DOTA-JR11 binds to SSTR2-positive subpopulations of hematopoietic stem cells, exerting increased hematotoxicity compared to agonist-PRRT. Here, we synthesized fluorescent analogs with comparable binding characteristics to DOTA-JR11 and DOTA-TOC and investigated their binding to human bone marrow stem cell subpopulations. ***Materials and Methods:*** We synthesized multimodal DOTA-JR11/TOC analogs by replacing DOTA with a multimodality chelator (MMC), and conjugating DBCO-functionalized dyes using copper-free click chemistry. We produced 5 MMC(Dye)-JR11/TOC variants and compared their cellular uptake, $K_D$ and $IC_{50}$ to $^{177}$Lu-DOTA-JR11/TOC. Fluorescence characterization was done using microscopy and flow cytometry. To assess binding to bone marrow stem cell populations, isolated peripheral blood mononuclear cells (PBMCs) were stained for CD34, CD38, CD45RA and CD90, before incubation with MMC(Dye)-JR11/TOC. SSTR1-5 expression of bone marrow stem cell populations was assessed via qRT-PCR. ***Results:*** The Sulfo2Cy5 conjugates MMC(S2Cy5)-JR11/TOC were identified as lead compounds with comparable binding characteristics to $^{177}$Lu-DOTA-JR11/TOC. In flow cytometry, the antagonist MMC(S2Cy5)-JR11 showed up to 10-fold higher binding than the agonists across cell lines, consistent with the binding properties of their radioligand counterparts. Analysis of binding to human bone marrow cells revealed specific, blockable binding to CD34+ PBMCs, but not CD34- PBMCs. Within the CD34+ population, specific binding was further observed to long-term (LT-HSC) and short-term (ST-HSC) multipotent stem cells and progenitors, but not to lineage-committed progenitors. In all cases, the antagonist showed 2-5 fold higher binding than the agonist. LT-HSCs showed the highest binding levels, which were almost comparable (10-20% lower) to the well-known SSTR2-overexpressing cell line AR42J. qRT-PCR to determine SSTR1-5 expression of stem cells and in vitro treatment of stem cells to determine cell viability and proliferation after $^{177}$Lu-DOTA-TOC or -JR11 treatment are currently ongoing. ***Conclusion:*** We have successfully synthesized multimodal variants of clinically used PRRT agents and established protocols to investigate their binding to human bone marrow stem cell subpopulations. Our results indicate SSTR2-mediated binding to multipotent stem cells and progenitors. LT-HSC make up only 0.05-0.1% of the PBMCs, but if ablated, will lead to pancytopenia, as observed after multiple cycles of $^{177}$Lu-DOTA-JR11 despite a tolerable total red marrow dose.

## OP-770

### Reducing the Effective Specific Activity of [$^{225}$Ac]-PSMA-617 to Minimize Salivary Gland and Renal Toxicity

***T. Esposito****, T. Kalidindi, R. Payne, Z. Faudemer, K. Jones, N. Pillarsetty;*
*Memorial Sloan Kettering Cancer Center, New York City, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Peptide-based targeted radioligand therapy (TRT) against prostate-specific membrane antigen (PSMA) is a promising last-line treatment option for patients with metastatic castration-resistant prostate cancer (mCRPC). [$^{177}$Lu]-PSMA-617 (Pluvicto, Novartis) has recently received market authorization and clinical trials are underway with alpha-emitting TRTs, such as [$^{225}$Ac]-PSMA-617. However, dose-limiting xerostomia and renal toxicity limits the potential of PSMA-TRT. We have previously shown with a tracer dose of [$^{177}$Lu]-PSMA-617 (5 uCi, 1.5 pmol) that reducing its effective specific activity (ESA) can minimize salivary gland and kidney uptake without compromising radioligand uptake into PSMA-positive tumors in mice. In this work we explored how this approach works using a therapeutic dose of [$^{225}$Ac]-PSMA-617 in mice bearing xenografts of low- and high-PSMA expression. ***Materials and Methods:*** [$^{225}$Ac]-PSMA-617 was prepared at a clinically-relevant specific activity (~20 mCi/mmol) and injected intravenously into cohorts of mice bearing PC3-PIP (PSMA high) and CWR22RV1 (PSMA low) xenografts. The dose provided (1.58 ± 0.15 µCi, 83.2 ± 6.4 pmol) is equivalent when scaled to the 100 kBq/kg dose commonly used in clinical trials of [225Ac]-PSMA-617. [225Ac]-PSMA-617 was co-injected with between 0-2000 pmol of PSMA-11 to adjust the ESA. Biodistributions were performed at 1.5 h post-injection and tumor growth kinetics were monitored over a 2-month period. ***Results:*** The tumor uptake for the 22RV1 cohort ranged between 2-4 % ID/g. Though there was trend toward lowering of uptake in tumor with reduced ESA, particularly with the 2000 pmol PSMA-11 block, the change was not statistically significant. However, there was a remarkable reduction in the uptake of [$^{225}$Ac]-PSMA-617 in both the kidneys and salivary glands. For example, with the addition of 500 pmol PSMA-11 block, the activity concentration decreased from 12.9 ± 6.9 % ID/g to 2.5 ± 1.8 % ID/g in the kidney and from 0.12 ± 0.04 % ID/g to 0.047 ± 0.02 % ID/g in the salivary glands. For the PC3-PIP xenograft bearing mice, there was no reduction in uptake in the tumors (18-22 % ID/g) but a markedly reduced activity concentration in the kidneys and salivary glands. PC3-PIP xenografts regressed at a similar rate in mice treated with [$^{225}$Ac]-PSMA-617 regardless of the level of PSMA-11 block. ***Conclusion:*** Reducing the ESA of [$^{225}$Ac]-PSMA-617 appears to be an effective way at reducing salivary and kidney uptake without compromising its therapeutic effect. ***References:*** Kalidindi TM et al., Eur J Nucl Med Mol Imaging, PMID: 33495926. ***Funding:*** NIH RO1-1R01CA262675

## OP-771

### Improvement of the pharmacokinetic properties of PSMA-617 by introducing sarcosine moieties

***N. M. Geis***[1,2,3]*, N. Steinacker*[1,2]*, L. Domogalla*[1,2]*, P. T. Meyer*[1,2]*, M. Eder*[1,2]*, A. Eder*[1,2]*;*
*[1]Department of Nuclear Medicine, University Medical Center Freiburg, Freiburg im Breisgau, GERMANY, [2]Division of Radiopharmaceutical Development, German Cancer Consortium, Freiburg im Breisgau, GERMANY, [3]Faculty of Biology, University of Freiburg, Freiburg im Breisgau, GERMANY.*

***Aim/Introduction:*** PSMA-specific radiopharmaceuticals that employ urea containing inhibitors like [$^{177}$Lu]Lu-Glu-urea-Lys-2Nal-ChX-DOTA ([$^{177}$Lu]Lu-PSMA-617) were shown to have significant clinical benefits for targeted radionuclide therapy of metastatic castration-resistant prostate cancer (mCRPC). Recently, the FDA and EMA approved the use of [$^{177}$Lu]Lu-PSMA-617 therapy under the name Pluvicto™. However, the potential efficacy of the treatment with beta- emitting [$^{177}$Lu]Lu-PSMA-617 and with the potentially more effective alpha-emitting [$^{225}$Ac]Ac-PSMA-617 is limited by side-effects like xerostomia. Earlier research showed major effects on biological activity by modifications of the linker region in PSMA-targeting inhibitors. Uncharged linker modifications have been identified as the key method

for developing the best pharmacokinetic profile for PSMA-617. To further improve the pharmacokinetic properties, repeated sarcosine moieties (3-15) were introduced into the linker region of PSMA-617 resulting in a series of modified structures with improved in vitro and in vivo properties. ***Materials and Methods:*** The linker-modified PSMA-targeting inhibitors were synthesized through the introduction of sarcosine moieties adjacent to the chelator of PSMA-617. The inhibitors were radiolabeled with gallium-68 and lutethium-177 to investigate their chemical and stability properties. The biological activity of the compounds was evaluated in competitive cell and internalization assays using PSMA-expressing LNCaP cells. To assess the pharmacokinetic profiles, small-animal PET/MRI imaging studies with $^{68}$Ga-labeled compounds were conducted in BALB/c nu/nu mice bearing LNCaP xenografts. Organ distribution studies were performed at different time points using the $^{177}$Lu-labeled variants with the most promising characteristics. ***Results:*** The novel PSMA-targeting inhibitors exhibited high radiolytic stability. Both reactions of the precursors with either $^{68}$Ga or $^{177}$Lu, respectively, resulted in high yields greater than 95%. The investigated compounds demonstrated a high affinity to PSMA (Ki down to 19.75 ± 9.42 nmol) and PSMA-specific internalization and surface binding in vitro. Small-animal PET imaging revealed high tumor uptake and rapid clearance from kidneys and circulation for the $^{68}$Ga-labeled variants with three or fifteen sarcosine moieties, respectively, resulting in improved tumor-to-kidney ratios as compared to the reference PSMA-617 at 1 h p.i. (PSMA-617 (tumor-to-kidney ratio 0.33), sarcosine-3-moiety (0.96), and sarcosine-15-moiety (0.93)). The organ-distribution studies confirmed these findings of an improved pharmacokinetic profile. ***Conclusion:*** It can be concluded, that the introduction of sarcosine moieties into the linker region of PSMA-617 significantly affects the pharmacokinetic profile with strong improvements of the tumor-to-kidney ratio accompanied by enhanced excretion. Resulting dose reductions in crucial organs indicate potential advantages of the novel variants, highlighting their great potential as an improved treatment option of mCRPC.

## OP-772

### Preclinical toxicity study of [$^{211}$At]PSMA5 in mice and for the FIH clinical trial of targeted alpha therapy against refractory prostate cancer

***T. Watabe***[1], *K. Kaneda-Nakashima*[1], *Y. Kadonaga*[1], *K. Ooe*[1], *T. Sampunta*[1], *X. Yin*[2], *H. Haba*[2], *Y. Kon*[1], *A. Toyoshima*[1], *J. Cardinale*[3], *F. L. Giesel*[3], *K. Fukase*[1], *N. Tomiyama*[1], *Y. Shirakami*[1];
[1]*Osaka University, Suita, JAPAN,* [2]*RIKEN, Wako, JAPAN,*
[3]*University Hospital Duesseldorf, Duesseldorf, GERMANY.*

***Aim/Introduction:*** Astatine ($^{211}$At) is an alpha emitter (half-life=7.2 h) that can be produced by a 30-MeV cyclotron using natural bismuth target. Targeted alpha therapy (TAT) using $^{211}$At-labeled PSMA compound ([$^{211}$At]PSMA5) showed excellent tumor growth suppression using tumor xenograft model. In this study, we performed preclinical toxicity studies for the first-in-human (FIH) clinical trial which is scheduled to start in 2024. ***Materials and Methods:*** [$^{211}$At]PSMA5 solution was injected into the normal ICR mice (male (n = 60), body weight: 28.2 ± 1.4g) and Cynomolgus monkey (n=2, body weight: 2.1 kg). Mice were divided into four groups: 5 MBq/kg (n=15), 12 MBq/kg (n=15), 35 MBq/kg (n=15), and vehicle control (n=15). Mice were followed up for 1 day (main evaluation point for acute toxicity: n=40 (n=10 for each group)) or 14 days (evaluation point for recovery: n=20 (n=5 for each group)) to monitor general condition and body weight change. Monkeys were followed up for 24 hrs post administration of [$^{211}$At]PSMA5 (9MBq/kg). At the end of the observation period, autopsy, blood test, organ weight measurement, and histopathological examination were performed. ***Results:*** In 12 MBq/kg group (day5) and 35MBq/kg group (day10) of mice, significant decrease in body weight was observed compared to control. In the blood test of mice, no significant myelosuppression or renal dysfunction was observed either on the day1 or day14 after administration. In Cynomolgus monkey, mild leukopenia, mainly lymphopenia, was observed 24 hrs after administration. In the organ weight measurement of mice, there was a significant decrease in testis weight in the 12MBq/kg group (organ weight: 0.18 ± 0.02 g) and 35MBq/kg group (organ weight: 0.17 ± 0.003 g) compared to control group (0.24 ± 0.02 g) on day14. Irreversible toxicity was not observed in the histology of risk organs, such as thyroid, salivary gland, and kidneys in mice. ***Conclusion:*** In this toxicity study of [$^{211}$At]PSMA5 which was performed under reliability standard, no severe toxicity was observed. After confirming all pathological results, we will proceed to determine the starting dose in the FIH clinical trial. [$^{211}$At]PSMA5 is expected to be a next-generation TAT against prostate cancer with the domestic production of alpha emitter using cyclotron. ***References:*** Watabe T, Kaneda-Nakashima K, Shirakami Y, et al. ## OP-773

### Using timestamps in fast time-of-flight positron emission tomography detectors to encode the depth of interaction of 511 keV gamma-photons in scintillators

***V. Nadig***[1], *K. Herweg*[1], *K. Weindel*[1], *D. Schug*[1,2], *H. Radermacher*[1], *F. Mueller*[1], *B. Weissler*[1,2], *V. Schulz*[1,2], *S. Gundacker*[1];
[1]*RWTH Aachen University, Aachen, GERMANY,* [2]*Hyperion Hybrid Imaging Systems GmbH, Aachen, GERMANY.*

***Aim/Introduction:*** For positron emission tomography (PET), both precise depth-of-interaction (DOI) encoding, often realized via light-sharing concepts and determined via the energy deposit, and fast time-of-flight (TOF) resolution are key technological features to obtain a tomographic image with a high signal-to-noise ratio (SNR). While a TOF resolution of 100 ps (FWHM) would improve the SNR by a factor of 3.7 compared to a non-TOF scanner, resolving DOI allows to correct for a superposing effect, so-called parallax errors, which further improves the SNR. ***Materials and Methods:*** Since fast TOF-PET electronics require individual timing channels in addition to standard energy channels, resulting in a considerably higher form factor, we propose to omit the energy channel and encode the DOI via the mean time delay between adjacent detector pixels. We employ scalable detector units consisting of two LYSO:Ce,Ca scintillators (Taiwan Applied Crystal, evaluated in [1]) of 3x3x20mm$^3$ size separated by a triangular enhanced specular reflector sheet. These were coupled to two FBK NUV-MT silicon-photomultipliers (SiPMs) using

Cargille Meltmount (n=1.582) and read out by custom ultra-fast high-frequency (HF) electronics, which have been adapted from previous versions to read multiple detector channels [2,3]. ***Results:*** The mean time delay between two adjacent channels clearly increases towards DOIs close to the SiPMs. In contrast to double-sided readout techniques, the time delay measured here does not correspond to the actual optical photon travel time. Still, a mean DOI resolution of about 4 mm to 5 mm (RMSE) is obtained using the information of the timing channel, while a sub-150 ps (FWHM) TOF resolution is achieved. ***Conclusion:*** The DOI resolution obtained would allow to separate the scintillator into at least two DOI bins, which could be fed into reconstruction algorithms to correct for parallax. Together with a high TOF resolution, this would result in an improved SNR in the reconstructed image. ***References:*** This research project "ProtoTOF" is supported by the START-Program of the Faculty of Medicine of the RWTH Aachen University. This work did not involve human subjects or animals in its research. [1] Nadig et al 2023 Phys. Med. Biol. 68 075002. doi: 10.1088/1361-6560/acbde4 [2] Gundacker et al 2019 Phys. Med. Biol. 64 055012 doi: 10.1088/1361-6560/aafd52 [3] Krake et al 2022 NIMA. 1039. 167032. doi: 10.1016/j.nima.2022.167032

## OP-774

### Brain PET Quantitative and Qualitative Interpretation Using Sparse Detector Ring Configuration PET System

***R. Fahmi***[1], *J. Cabello*[1], *G. Platsch*[2], *B. Spottiswoode*[1];
[1]*Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA,* [2]*Siemens Healthineers, Erlangen, GERMANY.*

***Aim/Introduction:*** Brain-PET imaging plays an important role in the diagnosis and prognosis of various neurodegenerative diseases and is being used both as an enrichment tool and an endpoint in various Alzheimer's disease-modifying drug trials. The aim of this work is to assess quantitative and qualitative brain-PET image interpretation using a simulated affordable PET system with a sparse-detector configuration. ***Materials and Methods:*** Using brain PET listmode data (N=7 $^{18}$F-FDG, N=2 $^{18}$F-FDOPA, and N=2 $^{11}$C-PiB) acquired on a Vision scanner, we simulated detectors' decimation by removing 1-out-of-each-X coincidences to achieve decimation levels ranging from 5%-50%. Scanner normalization was kept the same throughout this study. We used commercial Database Comparison, Cortical Analysis, and Striatal Analysis quantification workflows to process reconstructed FDG, PiB, and FDOPA images, respectively. FDG images were also visually read by a clinical expert. ***Results:*** Decimated FDG images were each compared to the same normal database (nDB) and corresponding mean z-scores within 116 Automated-Anatomical-Labelling regions were all in good agreement ($R^2$>0.98) with those from original images compared to the same nDB. Lower agreements were found for 50%-decimation ($R^2$<0.77). About 87% of brain voxels, in both 5%-and-10% decimated images, had z-scores below 10 percent-error relative to z-scores from corresponding original images. Greater percent-errors were found at higher decimation levels. The fraction of z-scores below -2.5 (abnormal-looking) was relatively stable up to 30%-decimation. Visually, 5%-to-20% decimated images and corresponding z-score stereotactic-surface-projections were of acceptable quality for a clinical read. Increased artifacts and noise levels were seen at higher decimation levels rendering visual interpretation more challenging for clinical conditions such-as epilepsy where focal abnormalities may be present. For $^{11}$C-PiB, mean composite SUV-ratio was relatively stable across decimation levels 5%-to-30% compared to original images, with a mean percent-error below 0.8%. For $^{18}$F-FDOPA, striatal-binding-ratios within different striatal regions were all relatively stable up to 30% decimation. However, greater percent-errors were found for 20%-and-25% decimation compared to 30%-decimation level, indicating that the arrangement of removed detectors had greater impact on the quantification results. ***Conclusion:*** We assessed the effect of sparse detector configurations on brain-PET image interpretation. Results comparable to full detector coverage were obtained up to 30%-decimation level. We also observed that the spatial distribution can be more impactful than the number of removed detectors. Other decimation geometries will be evaluated to potentially achieve acceptable results even with fewer detectors. This could offer a cost-effective solution for dedicated brain PET imaging without compromising clinical interpretability.

## OP-775

### PUMA: PET Unification for Multi-Tracer Applications in Multiplexed PET Imaging

***S. Gutschmayer***[1], *B. A. Spencer*[2], *Y. G. Abdelhafez*[2], *R. D. Badawi*[2], *S. R. Cherry*[2], *T. Beyer*[1], *L. Shiyam Sundar*[1];
[1]*Quantitative Imaging and Medical Physics (QIMP) Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Biomedical Engineering and Radiology, University of California-Davis, Davis, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** PET imaging provides functional information on tracer distribution, which can be extracted simultaneously across the entire human body with total-body PET imaging. Dual-tracer protocols have been introduced to complement readouts on diseases that may not be present on either tracer-PET, such as for lesion differentiation with [$^{18}$F]-FDG and [$^{68}$Ga]-DOTATATE or [$^{68}$Ga]-PSMA, as well as for assessing myocardial function using [$^{82}$Rb] and [$^{18}$F]-FDG. However, 2-tracer protocols are complex and not clinically viable. We present an automatic tool called PUMA (PET Unification for Multi-Tracer Applications) as part of the ENHANCE-PET framework for multiplexing different tracer information from the same patient undergoing sequential scans to improve clinical reading value. ***Materials and Methods:*** Eight subjects (4M, 4M) were enrolled in this IRB-approved study and underwent serial whole-body PET/CT imaging using [$^{18}$F]-FDG and [$^{68}$Ga]-DOTATATE (6 subjects, 2M/4F) or [$^{18}$F]-Fluciclovine (2 subjects, 2M). The PET images of each subject were aligned using a co-registration method that utilized both the PET and the structural information of the CT images. First, the CT images were resliced according to the corresponding PET image's dimension and spacing. The [$^{18}$F]-FDG PET/CT image of each patient was used as a reference in a multiscale co-registration procedure. The CT of the patient's other tracer ([$^{68}$Ga]-DOTATATE or [$^{18}$F]-Fluciclovine) PET/CT image was aligned to the CT of the [$^{18}$F]-FDG PET/CT image, and the resulting deformation field was applied to the corresponding PET image. For validation, an automated segmentation tool [1] delineated four target organs: lung, liver, brain and spleen. As with the PET information, extracted deformation fields were also applied to the resulting masks. The dice score was used as a metric to quantify the alignment. The mean intensity distribution within the masks was used to quantify the change in tracer information caused by interpolation after alignment. ***Results:*** After alignment, the dice scores between the first reference and the subsequent multiplexed scans improved on average by 47% (brain), 45% (liver), 64% (spleen) and 46% (lung). The mean intensity change within these reference organs remained below 2.5% on average. ***Conclusion:*** Based on PET/CT data, the proposed tool successfully aligned complementary

PET tracer information of the same patient. As a caveat, care must be taken regarding the PET-CT alignment in each PET/CT study, calling to action standardized imaging protocols and adequate patient positioning and instructions. ***References:*** [1] Sundar LKS, Yu J, Muzik O, et al. ## OP-776

### Comparison of Standardized Uptake Values of [18F]FDG-PET/CT imaging of healthy volunteers: a multi-country PET/CT study

***D. Ferrara***[1], *R. Badawi*[2], *T. Beyer*[1], *Z. Chen*[3], *S. Cherry*[4], *B. Geist*[5], *S. Gutschmayer*[1], *M. Hacker*[5], *S. Kinuya*[3], *L. Shiyam Sundar*[1], *B. Spencer*[4], *S. Takeda*[6], *J. Taki*[6], *H. Wakabayashi*[3];
[1]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Radiology, UC Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [3]*Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, Ishikawa, JAPAN,* [4]*Department of Biomedical Engineering, UC Davis, Davis, CA, UNITED STATES OF AMERICA,* [5]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [6]*PET Center, Kanazawa Advanced Medical Center, Kanazawa, Ishikawa, JAPAN.*

***Aim/Introduction:*** Whole-body [18F]FDG-PET/CT imaging is a clinically-viable means of oncology patient management. Standardized-uptake-values (SUVs) are used to assess disease and treatment response. Lately, the concept of inter-organ mapping of metabolic activities using whole-/total-body PET is gaining traction. To employ PET for studying inter-organ aberrations of metabolic profiles, a SUV normative database is required. This study aimed to investigate potential variations in SUVs among healthy volunteers with distinct geographic backgrounds. ***Materials and Methods:*** 15 Japanese (13M/2F, 71±11 kg), 19 European (10M/9F, 76±17 kg), and 15 American (6M/9F, 82±17 kg) healthy volunteers underwent whole-body [18F]FDG-PET/CT imaging at 60-min post-injection (test). A second scan (retest) was performed for European cohort 90 min after the first scan and for the Japanese cohort 1-y after the initial scan, each using the same protocol. Ten volumes-of-interest (VOI: aorta, brain, pancreas, spleen, thyroid, inferior-vena-cava, lung, skeletal-muscle, subcutaneous-fat, visceral-fat) were segmented automatically from the PET/CT images [1]. Mean SUVs normalized to body weight were extracted for each VOI. To limit confounders from different acquisition/reconstruction protocols, SUVs were normalized for each volunteer to their own liver uptake. The resulting $SUV_{liver}$ across cohorts and test-retest were compared with relative %-differences (%D) and t-tests. To avoid potential sex-related differences, the analysis was subsequently repeated solely on male participants. ***Results:*** Across three cohorts, $SUV_{liver}$ were comparable (%D<=15%) in all VOI, except for thyroid (%D=18%, p=0.01), brain (%D=32%, p<0.01), and visceral-fat (%D=90%, p<0.01). Further, $SUV_{liver}$ was highest and most variable in brain. Japanese subjects had the lowest $SUV_{liver}$, ranging from 0.28 (lungs) to 2.42 (brain). Mean %D in $SUV_{liver}$ were minimal between American and European cohorts, ranging from 1% (lung) to 23% (visceral-fat). Corresponding variations were higher between American and Japanese cohorts, ranging from 4% (skeletal-muscle) to 90% (visceral-fat). Notably, intra-group differences (test-retest) were not significant, with the highest %D of 5% (brain). Similar findings were observed when analysing only male participants for an imbalanced sex-distribution across the 3 cohorts. ***Conclusion:*** The overall differences in $SUV_{liver}$ across American, European, and Japanese cohorts were relatively small, suggesting that it may be possible to establish a normative database across individuals with different geographic upbringings. Limitations of this study, such as differences in PET system calibration, demographics, and small sample size, will be addressed by expanding the sample sizes (ongoing) across the sites. ***References:*** [1] L.K. Shiyam Sundar et al. "Fully-automated, semantic segmentation of whole-body [18F] FDG-PET/CT images based on data-centric artificial-intelligence". In: J Nuc Med (2022).

## OP-777

### Non-rigid anatomical standardization of whole-body PET/CT identifies variation of FDG distribution with age and sex: an AI-assisted study

***K. Hirata***[1,2,3], *S. Watanabe*[1,2], *J. Takenaka*[1,2], *N. Wakabayashi*[1,2], *R. Kimura*[1,4], *T. Nagai*[5], *T. Ogawa*[6], *K. Kudo*[1,3,4];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [3]*Global Center for Biomedical Science and Engineering, Faculty of Medicine, Sapporo, JAPAN,* [4]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN,* [5]*Department of Cardiovascular Medicine, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [6]*Faculty of Information Science and Technology, Hokkaido University, Sapporo, JAPAN.*

***Aim/Introduction:*** Anomaly detection algorithms are expected to play important roles in the development of AI diagnosis for whole-body FDG-PET/CT. While there have been reports on anomaly detection performed using deep learning without anatomical standardization (AS), methods using AS have not been extensively studied. AS for the brain PET has been well established, however, not for the whole-body PET. We aimed to investigate possibility of applying non-rigid transformation to thousands of whole-body FDG-PET/CT scans using a single template and to validate the adequacy of AS by comparing SUV by age and sex. ***Materials and Methods:*** We reviewed all the FDG-PET/CT studies performed at Hokkaido University Hospital from 2015 to 2019, including patients with various diseases. Three different PET/CT scanners were employed. While the field-of-view was either head-to-thigh or head-to-toe, we selected head-to-thigh images taken with arms raised. For this selection, we trained a deep neural network, VGG19, with one-year manually labeled dataset, and used to classify the rest of 4-year images. We then arbitrarily selected one female patient with no abnormal accumulation as a template and overlaid all other patient images using non-rigid deformation implemented with affine transformation. After anatomical standardization, a nuclear medicine physician placed ROIs to evaluate correlations with age and sex differences. ***Results:*** After excluding same-patient studies, 3835 (1723 females) were analyzed. The average image was blurrier compared to an individual image, however, the distribution did not change significantly, indicating the non-rigid deformation was reasonably performed. Regarding correlation analysis with age, no strong correlation was found in any area. However, a weak negative correlation (r=-0.18) was found in the frontal lobe, and weak positive correlations (r=0.20-0.22) were found in the neck subcutaneous tissue and gluteal muscles. Regarding sex differences, the values in parentheses represent the difference in SUV, with a plus indicating that females had higher values. Females had higher SUV in the frontal lobe (1.3), cerebellum (0.9), tongue (0.2), ascending aorta (0.2), liver (0.2), kidney (0.5), lumbar subcutaneous tissue (0.2), and lower part of bladder (1.7), while males had higher SUV in the neck subcutaneous tissue (-0.4),

left ventricular myocardium (-0.3), abdominal wall subcutaneous tissue (-0.2), upper part of bladder (-1.7), and external genitalia (-0.7). ***Conclusion:*** Although the analysis was limited to the particular field-of-view and posture, reasonable results were obtained in terms of correlations with sex and age differences, and this non-rigid transformation was considered applicable for constructing a normal database for anomaly detection.

## OP-778

### Noise and Sharpness estimation in Positron Emission Tomography (PET) images using radiomics and deep learning

***P. Gurunath Bharathi***, *F. Moradi, M. Khalighi;*
*Stanford Medicine, Palo Alto, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Noise and sharpness are important quality metrics in medical imaging. Here we examine if radiomics and deep learning approaches can be used to reliably measure these and compare them. ***Materials and Methods:*** This study utilized FDG PET from 52 patients, (40 patients for training, 6 patients each for testing and validation). The PET scans were reconstructed using Time-Of-Flight Block-Sequential Regularized Expectation Maximization (TOFBSREM) with beta values from 400 to 1200 or ordered subset expectation maximization (OSEM), for time/bed between 60 to 120 seconds. An expert radiologist annotated the liver to calculate the coefficient of variation (CV) as the ground truth noise values. The beta was used as a proxy of sharpness levels. To improve computational efficiency, the input axial scans were cropped into a 64 * 64 matrix to remove excess background. 160 slices above and below the liver position were extracted from each reconstructed volume. Radiomics features such as textural, wavelet, gabor features were extracted from these slices and fed into supervised classifier or regressor for estimating the sharpness and noise levels respectively. Similarly, the extracted slices were also given as input to deep learning model for estimating the sharpness and noise levels. ***Results:*** A total of 10,274 radiomics features were fed into the trained random forest classifier and regressor with 200 trees for sharpness and noise estimation respectively. The accuracy of sharpness and noise estimation through radiomics was 63.1% and coefficient of determination ($r^2$) was 0.583, respectively. On the other hand, deep learning approach showed 77.2% accuracy in sharpness estimation and $r^2 = 0.57$ for noise estimation. Table 1 provides a comprehensive comparison between the two methods. ***Conclusion:*** This study proposed a radiomics and deep learning approach to assess the sharpness and noise levels in PET scans. Our deep learning method achieved good performance in terms of accuracy and $r^2$, and efforts are ongoing to create an integrated approach that combines radiomics and deep learning for improving accuracy. This approach can be used to quantify how changing scan acquisition and reconstruction parameters affects image quality.

## OP-779

### Evaluation of potential dose reduction in O-15 water PET by simulation of low count data and sinogram denoising

***M. Voskamp***[1,2], *F. Büther*[3], *M. Mamach*[4,2], *J. Lücke*[5,6], *S. Salwig*[5], *H. Mousavi*[5], *F. M. Bengel*[1], *T. Lenarz*[2,2], *G. Berding*[1,2];
[1]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY,* [2]*Cluster of Excellence "Hearing4all", Hannover, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital, Münster, GERMANY,* [4]*Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY,* [5]*Department of Medical Physics and Acoustics, Carl von Ossietzky University Oldenburg, Oldenburg, GERMANY,* [6]*Cluster of Excellence "Hearing4all", Oldenburg, GERMANY,* [7]*Department of Otolaryngology, Hannover Medical School, Hannover, GERMANY.*

***Aim/Introduction:*** Positron Emission Tomography (PET) is capable to assess neuronal activity in brain regions using radioactive markers indicating higher regional blood flow. We simulated a reduction in used radioactivity and applied sinogram denoising to examine the feasibility of a lower radiation exposure. ***Materials and Methods:*** O-15 water PET studies of 5 patients with auditory implants in the cochlea (CI, n=1), brainstem (ABI, n=2) or midbrain (AMI, n=2), scanned during quiet and speech stimulation (3-6 per condition) using a Siemens Biography LSO-Duo PET/CT were included [1]. We simulated the application of lower radioactivity doses by randomly reducing the number of coincident events by a factor of 8 (this factor would have left the radiation exposure even below the limit of 1 mSv for the public according to the Euratom directive 2013/59). Those reduced datasets were then denoised by applying the BM4D (Block matching 4D) algorithm to the normalized, attenuation-, random-, and scatter-corrected sinograms. We used statistical parametric mapping (SPM) to compare the number of activated voxels in the auditory cortices ($p<0.001$, uncorrected, Brodmann areas (BA) 21, 22, 41, and 42) in the original, the reduced, and the reduced+denoised datasets. ***Results:*** In comparison to the mean number of activated voxels mapped inside the auditory cortices across patients based on the unreduced data (1130 +- 630 voxel, Zmax 4.96 +- 0.35) we saw significantly ($p<0.01$) less voxels in those areas in the reduced data (383 +- 400 voxel, Zmax 4.36 +- 0.41). When denoised with BM4D (655 +-775 voxel in the auditory cortices, Zmax 4.22 +- 0.45) the difference in comparison to the original data was no longer significant ($p>0.05$). Nevertheless, we did not find a significant difference between reduced and reduced+denoised data ($p>0.1$), and Zmax was significantly lower for both compared to unreduced data ($p<0.05$). ***Conclusion:*** Reducing the applied radioactivity in PET scans of auditory system function may improve the usability for diagnostic measurements by, for example, increasing the number of follow-up studies during auditory rehabilitation after implantation to better detect neuronal plasticity. Our results indicate that even with two-decade-old PET technology, which has lower sensitivity than current scanners, a reduction in the radioactivity by a factor 8 would have been possible if used in combination with advanced denoising algorithms. ***References:***

### Intra-arterial super-selective delivery of Yttrium-90 for the treatment of recurrent Glioblastoma: feasibility and safety results in virtual patients' cohort

***G. Paolani***[1], *S. Strolin*[1], *S. Minosse*[2], *M. Santoro*[1], *N. Pucci*[2], *L. Oddo*[3], *Y. Toumia*[3], *E. Guida*[4], *F. Di Giuliano*[4], *R. Floris*[4], *F. Garaci*[4], *S. Dolci*[4], *G. Paradossi*[3], *F. Domenici*[3], *V. Da Ros*[4], *L. Strigari*[1];
[1]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*UOC Diagnostica per Immagini, University Hospital of Rome "Tor Vergata", Rome, ITALY,* [3]*Department of Chemical Science and Technologies, University of Rome "Tor Vergata", Rome, ITALY,* [4]*Department of Biomedicine and Prevention, University Hospital of Rome "Tor Vergata", Rome, ITALY.*

***Aim/Introduction:*** Glioblastoma (GBM) is the most common malignant neoplasia in the central nervous system. Surgical resection followed by external beam radiation therapy (EBRT) and adjuvant chemotherapy is the standard of care, but median life expectancy remains poor. In this study, the feasibility and safety

of IA injection of Poly(vinyl alcohol) Microbubble ($^{90}$Y-PVA MBs) in GBM recurrent patients are investigated using an ad-hoc tool to calculate the absorbed dose distribution from contrast-enhanced MRI images used as a surrogate of $^{90}$Y-MBs distribution. A comparison between the EBRT approach and the $^{90}$Y absorbed dose per injected activity is reported. ***Materials and Methods:*** Nine GBM patients (7 men and 2 women) were investigated. MRI examinations were performed using a 3T superconductive system to delineate the tumor volumes. CT scans co-registered with MRI images were used to delineate organs at risk, automatically segmented using Deep Learning-based software, and approved by an expert neuroradiologist. Volumetric Modulated Arc Therapy treatment plans with two coplanar arcs were generated using a clinical treatment planning system (TPS). We assumed that the relative intensity at the voxel levels from the MRI post-contrast T1-weighted images was a valid surrogate of $^{90}$Y-MBs distribution post-AI.A specific $^{90}$Y dose voxel kernel (DVK) obtained with a Monte Carlo simulation using DOSExyz was convolved with the MRI images using MATLAB, to obtain the $^{90}$Y-MBs-based dose distribution. The $^{90}$Y-MBs and EBRT-based plans were compared in terms of absorbed dose distribution using a clinical TPS for radioembolization. ***Results:*** The physical dose distribution obtained from the simulation of a total activity of 1GBq of $^{90}$Y-MBs was rescaled to consider the prescribed $^{90}$Y-MBs activities calculated in order to guarantee that the 95% of the prescribed dose is delivered to the 95% or the 99%, (i.e., $A_{95\%}$ and $A_{99\%}$). The calculated activities median [range] were $A_{95\%}$=269.2 MBq[63.6-2334.1] and $A_{99\%}$=370.6 MBq[93.8-3315.2], while the median [range] of mean doses to PTV were 58.21Gy [42.34;61.33] for the VMAT plan, and 133.62Gy[6.02;589.35], 161.33Gy[11.25;856.97] considering $A_{95\%}$ and $A_{99\%}$ respectively. In addition, the brain tissue was spared in the $^{90}$Y simulations compared to the VMAT one with median [range] of mean doses of 13.89Gy [0;61.33] for the VMAT plan, and 6.24Gy [0;589.35] 8.12Gy [0;856.97] considering $A_{95\%}$ and $A_{99\%}$ respectively. ***Conclusion:*** Our results suggest that higher doses to tumor volumes and lower mean doses to the brain might be reached using $^{90}$Y-MBs, compared with EBRT leading to a less toxic and higher treatment.

## OP-781

### Variational autoencoder for detecting coronary artery disease in myocardial perfusion SPECT

***K. Okuda***[1], *K. Nakajima*[2], *T. Hara*[3], *H. Yoneyama*[2], *S. Kinuya*[2];
[1]*Hirosaki University, Hirosaki, JAPAN,* [2]*Kanazawa University, Kanazawa, JAPAN,* [3]*Gifu University, Gifu, JAPAN.*

***Aim/Introduction:*** The variational autoencoder (VAE) (1-2) has been used for unsupervised anomaly detection in medical images. This study evaluated the automatic anomaly detection from myocardial perfusion SPECT (MPS) images using convolutional VAE approach. ***Materials and Methods:*** All patients underwent $^{99m}$Tc-sestamibi or tetrofosmin MPS, and stress polar maps were generated and used as two datasets. A total of 3,432 polar map images (49% male) without known coronary artery disease (CAD) were used as a training dataset, and 111 polar map images (59% male, 43% obstructive CAD) were also used as a validation dataset. By training the convolutional VAE on normal polar map images, we constructed an image generator that could reproduce normal myocardial perfusion distribution from any state of myocardial perfusion. Abnormal myocardial perfusion was automatically detected by performing image operations between the VAE-generated normal polar map images and original images using mean square error (MSE), structural similarity index (SSIM), and peak signal-to-noise ratio (PSNR). A summed stress score (SSS) was also calculated using sex-segregated normal databases. ***Results:*** VAE-based image generator successfully generated all normal polar maps irrespective of difference in male/female and normal/defect patterns. Moreover, MSE, SSIM, and PSNR were calculated automatically by the VAE-based image generator trained from sex-combined polar map images. The area under the receiver-operating characteristic curve for CAD detection was 0.873 (95% confidence interval: 0.792-0.931) for MSE, 0.860 (0.777-0.921) for SSIM, and 0.877 (0.797 to 0.934) for PSNR compared to 0.814 for SSS (p = n.s. for all comparisons). ***Conclusion:*** The convolutional VAE has the potential to improve the detection of CAD in MPS images. Although conventional quantitative analysis is based on sex-segregated normal databases, this new approach using VAE-based analysis does not need to consider the characteristics of myocardial perfusion in males and females. ***References:*** (1) Higaki A, Kawaguchi N, Kurokawa T, Okabe H, Kazatani T, Kido S et al. ### Dual time-point imaging of FAPI-04 in head and neck squamous cell carcinoma

***J. Yaqun***, *L. Chongjiao, H. Yong;*
*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** $^{68}$Ga-FAPI-04 has been most extensively studied clinically as imaging probe and shown favorable imaging properties, especially for HNSCC. However, the optimal acquisition time remains poorly understood. Therefore, we aimed to evaluate the diagnostic value of the dual time-point $^{68}$Ga-FAPI-04 PET/CT in the staging of HNSCC, especially in lymph node metastasis. ***Materials and Methods:*** A total of 43 patients with diagnosed or suspected HNSCC were enrolled for final analysis, including 40 treatment-naïve and 3 relapsing patients. Each patient underwent a whole-body $^{68}$Ga-FAPI-04 PET/CT at 30~60 min and a delayed scan in the head and neck region at 2 h post injection. The tracer uptake of primary and metastatic lesions was semiquantitatively determined using SUVmax and tumor-to-background ratio (TBR). The SUVmean was measured for contralateral normal tissues or organs (palatine tonsils, submandibular glands, sternocleidomastoid muscle, and internal jugular vein). Radiotracer uptake, TBR, retention index (RI), diagnostic performance, and T/N staging was explored. Findings were referred to histopathology or radiographic follow-up. ***Results:*** We evaluated 43 participants (38/43 men; median age, 61 years), including 2 maxillary sinus, 11 oral, 10 oropharyngeal, 13 laryngeal, and 7 hypopharyngeal cancer. As for primary tumors, the mean SUVmax was similar between early (16.91) and delayed scan (16.11, p = 0.315). However, the mean TBR of delayed imaging was significantly

higher than that of early scan (all $p < 0.05$). For the analysis of neck lymph nodes, 30 patients were visually quantified positive and 17 patients underwent neck dissection. Notably, metastatic lymph nodes showed higher mean SUVmax in delayed scan than early imaging (12.13 vs 10.63, $p = 0.000$), while non-metastatic lymph nodes showed the opposite results (delayed 2.53 vs early 3.42, $p = 0.028$). The mean RIs of metastatic and non-metastatic lymph nodes were 15.65% and -19.43%, respectively. N staging had been altered in 3 (3/30) patients based on delayed images. The mean SUVmean of submandibular glands and palatine tonsils was markedly decreased in delayed imaging (both $p = 0.000$). What's more, a second primary tumor which was masked at the early scan appeared on the delayed imaging in the submandibular gland, and the lesion was identified as secretory carcinoma by subsequent surgical pathology. ***Conclusion:*** For $^{68}$Ga-FAPI-04 PET/CT imaging of HNSCC, delayed imaging can effectively acquire high-contrast images, especially adding diagnostic value for the discrimination of metastatic from non-metastatic lymph nodes and detecting hidden lesions near or within the tissues influenced by physiological uptake.

## OP-783

### Effectiveness of HAN-MI-RADS (Head and Neck Molecular Imaging-Reporting and Data System) criterion in head and neck squamous cell carcinoma post concurrent chemoradiotherapy

***M. Gupta***[1], *A. Jajodia*[2], *P. Ahlawat*[3], *M. Gairola*[3], *M. Agarwal*[4], *S. Goyal*[5], *P. Choudhury*[1];
[1]*Department of Nuclear Medicine, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [2]*Department of Radiology, Juravinski Hospital, McMaster University, ON, CANADA,* [3]*Department of Radiotherapy, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [4]*Department of Surgical Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [5]*Department of Medical Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA.*

***Aim/Introduction:*** Post-concurrent chemo-radiotherapy (CRT) response assessment have been challenging in locally advanced head and neck squamous cell carcinoma (LA-HNSCC) due to prevailing post-radiation changes. Molecular response methods have been encouraging, though further clarifications and validations were needed. We tested the effectiveness of a proposed semi-quantitative molecular response criterion in these patients. ***Materials and Methods:*** Two subspecialty-trained physicians evaluated FDG PET/CT of LA-HNSCC patients (n-83) post three months CRT using a five points HAN-MI-RADS (Head and Neck Molecular Imaging-Reporting and Data System) criterion. Where available, histopathology examination with clinical and imaging interpretation was taken as a reference for the disease. A diagnostic accuracy comparison was made with the existing Hopkins score. Further effectiveness was analyzed with disease-free survival (DFI) and overall survival (OS). ***Results:*** Metastasis was developed in 11/83 patients at 3 months of evaluation. Of 72 patients, 39, 2, and 31 patients had a complete response, equivocal response, and partial response as per HAN-MI-RADS. Per patient sensitivity, specificity, PPV, NPV, and accuracy for predicting loco-regional disease up to one year and two years was 93.3%, 92.5%, 90.3%, 94.9%, 92.9% and 84.9%, 91.9%, 90.3%, 87.2%, 88.6% respectively. One year and two years DFI for each HAN-MI-RADS score showed a statistically significant difference while it was not for OS. The ROC curve analysis showed significantly better outcome predictability of HAN-MI-RADS (AUC 0.884) than Hopkins (AUC 0.699). ***Conclusion:*** A five points HAN-MI-RADS criterion was found promising for response assessment with less equivocal results and statistically significant higher AUC than Hopkins for loco-regional recurrence prediction. ***References:*** 1. ## OP-784

### [$^{18}$F]FDG PET/CT in the Therapy Response Evaluation of Head and Neck Carcinoma. How to approach it?

***V. Carrero-Vásquez***[1], *B. Hervas-Sanz*[1], *L. Rodríguez-Bel*[1], *G. Reynes-Llompart*[2], *R. Martin-Vaello*[2], *A. Lozano-Borbalas*[3], *O. Bermejo-Segu*[4], *P. Perlaza-Jiménez*[1], *C. Martínez-Ramos*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine Department, Bellvitge University Hospital, Barcelona, SPAIN,* [2]*Radiophysics Department, Bellvitge University Hospital, Barcelona, SPAIN,* [3]*Radiation Oncology Department, Bellvitge University Hospital, Barcelona, SPAIN,* [4]*Plastic Surgery Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** Despite advances in therapy, recurrence-rates in patients with head and neck squamous cell carcinoma (HNSCC), especially locoregional, are still high. Therefore, its early identification is of utmost importance; hence, it will change clinical management completely. [$^{18}$F]FDG-PET/CT-scan has shown effectiveness in the evaluation of therapeutic response(ETR), although there is no consensus on how to assess and report it using quantitatively with the standardized uptake value (SUVmax) and/or qualitatively with Likert scales like Hopkins(HS) and Deauville(DS) scores. Primary aims: assess the performance method in the evaluation of locoregional control(RC) and whether any technique is superior in predicting RC, progression-free survival(PFS) and overall survival(OS). Secondary aims: determine the relationship between HPV and p16 presence. ***Materials and Methods:*** 149 consecutive patients with HNSCC between 2010 and 2021 were selected; 73: 51 men, mean age 58(42-82) met the inclusion criteria: PET/CT-scan 3-6 months post-radiotherapy (postRT). The studies were scored using a qualitative 5-point-scale: HS and DS, grouped as positives(scores 4 and 5), negatives(scores 1,2,3) for primary tumour, right neck and left neck. The SUVmax was determined for each.All patients were followed until 2023. ***Results:*** 21 patients(p) had recurrence: 15p locoregional, 3p locoregional+metastatic, 3p metastatic. 52p did not show recurrence. The assessment of these positive PET/CT-postRT using the HS was positive in 15p, with a sensitivity, specificity, PPV, NPV, and accuracy of 71%, 100%, 100%, 90% and 91%, respectively, and a significant statistical correlation between HS-positive and recurrence (p=0.0083), HPV and p16-positive (p=0,05 and p=0,09). Using the DS, we observed 36p had positive PET/CT-postRT studies with sensitivity, specificity, PPV, NPV, and accuracy of 100%, 71%. 58%. 100% and 79%, respectively. DS-positive and recurrence also showed a high significance (p=0.028), and a good concordance index between the two scales HS-DS for the ETR was observed. Also, patients with higher SUVmax at the pre-treatment-PET/CT and lower decreased at the post-RT-PET/CT showed a significant

p-value with the recurrence rate (p=0.00972). The PFS (mean 10,3 months, range 2-30) and OS (mean 18,9 months, range 6-44) were lower in patients with HS-positive and DS-positive studies. ***Conclusion:*** Our study found that all assessment methods predicted RC, OS and PFS with high significance and almost equally well, according to the current published data. Regarding the Likert scales, our results showed a good performance in discriminating responders from nonresponders.Also, there was a high significance with the HPV and p16-positive association and a good concordance between the Likert scales.

## OP-785

### C-X-C motif chemokine receptor 4-directed PET/CT in newly diagnosed Head and Neck Squamous Cell Carcinoma - Initial Experience

***S. Serfling***, *R. Werner, S. Andreas, H. Takahiro, A. K. Buck, A. Kosmala, R. Hagen, S. Hackenberg, A. Scherzag, E. Gerhard-Hartmann, Y. Zhi;*
*University Hospital Würzburg, Würzburg, GERMANY.*

***Aim/Introduction:*** In patients affected with head and neck cancer, [$^{18}$F]FDG is used as reference, but its diagnostic accuracy can be hampered by inflammatory processes. We aimed to determine the read-out capabilities of the novel C-X-C motif chemokine receptor 4 (CXCR4)-targeting radiotracer relative to [$^{18}$F]FDG in treatment-naïve individuals. ***Materials and Methods:*** Twelve patients with histologically confirmed head and neck squamous cell carcinoma (HNSCC) were scheduled for dual-tracer imaging without therapy between scans using [$^{18}$F]FDG (FDG) and [$^{68}$Ga]PentixaFor (PEN). We applied target-to-background ratios (TBR) with liver ($TBR_L$) and vena cava superior ($TBR_{VCS}$) serving as reference. 6/12 (50%) were scheduled for LN removal, thereby allowing to compare PEN-PET findings with surgical specimen. ***Results:*** On a visual assessment, [$^{18}$F]FDG identified more sites of disease, with increased detection rates for both the primary (FDG, 12/12 [100%], PEN, 9/12 [75%], P=0.08) and LN (FDG, 10/12 [83%], PEN, 9/12 [75%], P=0.4). Quantification provided slightly higher TBR for FDG relative to PEN for all lesions ($TBR_L$: FDG, 7.54 ± 3.5 vs PEN, 5.61 ± 1.82, P=0.17; $TBR_{VCS}$: FDG, 11.65 ± 8.49 vs PEN, 4.33 ± 1.32, P=0.03), primary ($TBR_L$: FDG, 9.2 ± 4.3 vs PEN, 5.57 ± 2.2, P=0.02; $TBR_{VCS}$: FDG, 13.6 ± 8.7 vs PEN, 4.16 ± 1.58; P<0.01), and LN ($TBR_L$: FDG, 5.43± 4.2 vs PEN, 5.61 ± 1.92; $TBR_{VCS}$: FDG, 9.3 ± 10.64 vs PEN, 4.4 ± 1.6; P≥0.24). Of note, in patients with available LN derived from surgical removal, PEN was true positive in 4/18 (22.2%) and false positive in 14/18 (77.8%), with the latter classified as reactive LNs by histological work-up. Respective sensitivity and specificity for FDG was 100% and 96%, which was higher relative to PEN (80% and 90.7%, respectively). ***Conclusion:*** In treatment-naïve HNSCC, FDG was superior for assessing the primary when compared to PEN. For LN, PEN achieved lower rates of sensitivity and specificity, with false-positive findings in reactive/inflammatory conditions probably due to the physiological expression of CXCR4 in germinal centers.

## OP-786

### Targeted imaging of αvβ6-integrin in patients of Head and Neck Squamous Cell Carcinoma and Pancreatic Ductal Adenocarcinoma with $^{68}$Ga-Trivehexin PET/CT scan and correlation with immunohistochemistry- a pilot study

***S. Das***, *I. B. Sen, D. Malik, P. Thakral;*
*Fortis Memorial Research Institute, Gurugram, INDIA.*

***Aim/Introduction:*** αvβ6-integrin is exclusively expressed in epithelial cells and is upregulated in many carcinomas, such as Pancreatic Ductal Adenocarcinoma (PDAC) and head and neck squamous cell carcinoma (H&N-SCC). Expression of αvβ6 integrin is almost always tumour specific. αvβ6 modulates invasion and inhibit apoptosis. Trivehexin is a trimerized αvβ6-integrin selective nanopeptide which can be used as a diagnostic agent after labelling with a positron emitter like $^{68}$Gallium. This is a pilot study to assess the correlation between $^{68}$Ga-Trivehexin positron emission tomography/computed tomography (PET/CT) tumour uptake and αvβ6-integrin expression by the tumour tissue on immunohistochemistry (IHC). ***Materials and Methods:*** 33 patients (19-76 years; 24 males) with suspected H&N-SCC (n=20), or PDAC (n=13) underwent 68Ga-Trivehexin PET/CT scans and 18F-FDG PET/CT scans on two-separate days. 29 patients underwent tissue biopsy from the suspected primary/ metastatic tumor site. An experienced pathologist categorized αvβ6-integrin expression on IHC using the immune-reactive score (IRS) and modified 4-point IRS classification. ***Results:*** $^{68}$Ga-Trivehexin PET/CT images demonstrated good tracer uptake in 24/29 patients. 18F-FDG PET/CT images demonstrated good tracer uptake in 27/29 patients. Subsequent biopsy results from 29 lesions revealed 09 PDACs, 01 pancreatic neuroendocrine tumour, 01 adenocarcinoma colon, 15 H&N-SCCs, while benign inflammatory changes was observed in two patient and in one patient biopsy was inconclusive. All the 24 patients with PDACs and H&N-SCC showed good tracer uptake in the primary as well as the metastatic lesions on $^{68}$Ga-Trivehexin PET/CT scan (mean SUVmax 6.04 ± 3.8) with a better tumor to background ratio in comparison to 18F-FDG PET/CT scan. The SUVmax of biopsied lesions calculated on $^{68}$Ga-Trivehexin PET/CT scan demonstrates a strong correlation with the IRS scores with significant p-value (r=0.61; P=0.002), while there was no such correlation observed on the FDG PET/CT scan (r= 0.38; P=0.066). The αvβ6-integrins expression was higher along the tumor margins, than in the center, which was consistent with the pattern of $^{68}$Ga-Trivehexin uptake. ***Conclusion:*** To our knowledge, this is the first in human study evaluating αvβ6 expression in various carcinomas by both in-vivo and in-vitro methods. Our study shows $^{68}$Ga-Trivehexin as a promising molecular imaging agent for tumors expressing αvβ6 integrins with a good correlation with αvβ6 expression seen on IHC.

## OP-787

### Role of pet biomarkers (suvmax, tlg and mtv) in the response to treatment in patients with nasopharyngeal carcinoma and its evolution.

***S. Lopez Puche***, *F. Gómez-Caminero López, P. García-Talavera San Miguel, L. Diaz Gonzalez, E. Casillas Sagrado, J. Badell Martinez, S. Rama Alonso, E. Campaña Diaz, P. Tamayo Alonso;*
*Hospital Universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** To evaluate by means of PET biomarkers the response to QT/RT treatment in patients with nasopharyngeal carcinoma. ***Materials and Methods:*** Retrospective study including patients diagnosed with nasopharyngeal carcinoma between 2014-2022 treated with concomitant QT+RT (70Gy in main lesion [PTV1] and 56-63Gy in nodes [PTV2]). All underwent staging/planning PET/CT with [18F]-fluorodeoxyglucose (FDG) and response assessment PET/CT at 3 months post-treatment. Some patients received neoadjuvant QT (QTNA-scheme TPF with docetaxel, cisplatin and fluorouracil), with an early PET/CT study performed 3 weeks post-treatment. Pre/post-treatment biomarkers were measured by quantitative analysis (Syngovia® software). They were divided into two groups according to response to treatment and evolution: relapsed/non-relapsed. Statistical analysis by subgroups was performed with Jamovi® to evaluate the difference in the percentage

of pre/post-treatment biomarker decline in both groups and between those who received each treatment regimen. ***Results:*** 52 patients, excluding 8 as baseline PET was not available; final sample size: 44 patients (33 males and 11 females; mean age 56 years +/- 11.4 years). 13 with squamous cell carcinoma, 24 undifferentiated, 6 lymphoepithelioma and 1 low-grade papillary adenocarcinoma. Non recurrent (36): stage I (4), II (8), III (15) and IV (10). 24 received QT/RT; 13 QTNA+QT/RT. Pre/post-treatment decline was observed in PTV1 SUVmax 79% MTV 56% and TLG: 90% and in PTV2 SUVmax 88%; MTV 67% and TLG 96%. Currently, all remain under follow-up. Relapsed (8): stage III (3), IV (4). 5 received QT-RT and 2 QTNA+QT/RT, the decrease in PTV1 was (SUVmax 74%; MTV 54% and TLG: 86%) and in PTV2 (SUVmax 83%; MTV 74% and TLG 93%). Of these, 4 have died (57%). Mean values of all biomarkers in PTV1 and PTV2 were higher in patients who progressed, with a mean decrease in patients who did not relapse of (SUVmax 11.9%; MTV 35.9% and TLG 24.1) in PTV1 and of (SUVmax 16.8%; MTV 40.6% and TLG 53.1) in PTV2. Student's t-test showed statistical significance in the decrease of SUVmax PTV1 pre/post-treatment (p=0.032) and in TLG PTV2 (p=0.04) with no significance in the rest of parameters (p>0.05). ***Conclusion:*** PET/CT biomarkers were able to determine the metabolic response in most cases. Furthermore, the results obtained showed a statistically significant percentage decrease of SUVmax values in PTV1 and TLG in PTV2 pre- and post-treatment, as well as higher mean values of all biomarkers in patients who progressed, so they could be useful as prognostic markers of patient outcome.

## OP-788

### Evaluation of relationship between Total Tumor Metabolic Volume and tumour tissue modified viral Human papilloma virus DNA levels at initial staging in HPV driven oropharyngeal squamous cell carcinoma.

***R. Kulkarni***, *M. Posner, S. Roof, N. Ghesani;*
*Mount Sinai Hospital, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The biology of Human papilloma virus (HPV) driven oropharyngeal squamous cell carcinoma (OPSCC) varies from non-HPV driven OPSCC. The NCCN guidelines therefore advise a separate management strategy for HPV driven OPSCC. Total metabolic tumor volume (TMTV) a volumetric parameter, derived from 18F-FDG PET/CT, is proven to be a more complete representation of disease burden than conventional response assessment criteria such as two-dimensional measurements and highest standardised uptake value (SUVmax) and recently has been validated in numerous malignancies. Tumor Tissue Modified Viral (TTMV) HPV DNA is a recently introduced highly sensitive serum marker for HPV driven OPSCC. TTMV-HPV DNA is produced during the break-down of integrated and/or episomal HPV DNA of malignant epithelial cells during the degradation of tumours. In this retrospective review, we studied correlation between TTMV-HPV DNA value and TMTV from 18F-FDG PET/CT scan at initial staging in patients with HPV driven OPSCC to understand tumor biology and disease burden and to explore complementary role between the two tests. ***Materials and Methods:*** TTMV from 18F-FDG PET/CT scans performed for initial staging in patients with biopsy proven HPV genotype positive OPSCC were obtained using a proprietary software. Voxels of interest (VOIs) were manually drawn around the lesions and the software analysed these VOIs to derive a TTMV. The TTMV-HPV DNA values were obtained from patient charts. Pearson's correlation co-efficient was used to derive the correlation between TTV at initial staging and TTMV-HPV DNA. The statistical significance of this correlation was assessed. Statistical significance was considered when the p value was <0.05. ***Results:*** 30 patients, 24 males and 6 females, average age of 64.4 were examined. The primary sites of malignancies were base of the tongue in 9/30 patients, palatine tonsils in 16/30, tonsils/base of tongue combined in 2/30, and pyriform sinus, nasal cavity, and watershed area of the nasopharynx/tonsil in remaining 3. 27/30 patients had biopsy proven nodal metastases and one with distal metastasis. 18F-FDG PET CT had 75% specificity and 100% sensitivity in detecting nodal metastases. The mean tumor volume was 43.9 mL and mean TTMV-HPV DNA value was 2354.2 fragment/mL. The Pearson's correlation co-efficient between TTMV-HPV DNA values and the TTV was 0.41 with a p value of 0.03 (p <0.05). ***Conclusion:*** TTV is well established as an imaging parameter of disease burden and on preliminary investigation, has a significant correlation with TTMV-HPV DNA values. This likely denotes a complementary relationship between the two parameters.

## OP-789

### A prospective Comparison of $^{68}$Ga-FAPI and $^{18}$F-FDG PET/MR in the Diagnosis of Residual Tumor Tissue for Head and Neck Squamous Cell Carcinoma Patients after Neoadjuvant Treatment

***X. Zhong***[1], *Y. Luo*[2], *M. Su*[3], *X. Peng*[2], *W. Zhang*[4];
[1]*Nuclear Medicine Department and Biomedical Big Data Center, West China Hospital of Sichuan University, Chengdu, CHINA,* [2]*Cancer Center, West China Hospital of Sichuan University, Chengdu, CHINA,* [3]*Nuclear Medicine Department, West China Hospital of Sichuan University, Chengdu, CHINA,* [4]*Biomedical Big Data Center, West China Hospital of Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** To perform a head-to-head comparison of $^{68}$Ga-FAPI and $^{18}$F-FDG PET/MR of their diagnostic capabilities for detecting residual tumor tissue in patients with head and neck squamous cell carcinoma (HNSCC) following neoadjuvant therapy. ***Materials and Methods:*** Our study included patients with HNSCC who underwent $^{68}$Ga-FAPI and $^{18}$F-FDG PET/MR examinations before and after neoadjuvant treatment starting from June 2022. Patients with primary malignant tumors other than HNSCC were excluded. Tracer uptake of primary tumor were compared by SUVmax and visual evaluation. A diagnosis of positive residual tumor tissue was made if a lesion or lymph node showed a higher uptake of $^{68}$Ga-FAPI and $^{18}$F-FDG than the surrounding normal soft tissues. Differences in SUVmax between groups were determined by paired t test. The diagnostic abilities of $^{68}$Ga-FAPI and $^{18}$F-FDG PET/MR were compared by chi-square test. Two-tailed p values of less than 0.05 were considered statistically significant. ***Results:*** Currently, a total of 8 patients with primary tumors located in the oropharynx (n=1), hypopharynx (n=6), and tonsil (n=1) were included. All included patients underwent radical surgery after treatment. The comparison of SUVmax of $^{68}$Ga-FAPI versus $^{18}$F-FDG PET/MR showed no significant difference before neoadjuvant therapy with values of 16.77±5.01 vs. 16.40±3.91 (P=0.803) but significantly different after therapy with values of 9.00±3.28 vs. 5.62±3.18 (P=0.011). ΔSUVmax before and after neoadjuvant therapy of the two imaging methods were significantly different with values of 7.77±4.62 vs. 10.78±5.69 (P=0.016). In total, 32 cervical lymph node regions were dissected. The sensitivity, specificity and accuracy of $^{68}$Ga-FAPI vs. $^{18}$F-FDG PET/MR for diagnosing residual malignant lymph node regions were 57.14% vs. 57.14% (P>0.05), 60.00% vs. 88.00% (P<0.05), and 59.38% vs. 81.25% (P<0.05), respectively. Postoperative pathology revealed

that one patient had no residual malignant tumor in the primary tumor area after neoadjuvant therapy. Although the diagnosis of $^{18}$F-FDG PET/MR was negative, $^{68}$Ga-FAPI PET/MR was positive for this patient. For the other seven patients, pathological results showed different quantities of residual malignant tumor tissues in the primary tumor area, of which 4 cases were diagnosed correctly by $^{18}$F-FDG PET/MR, while all cases were correctly diagnosed by $^{68}$Ga-FAPI PET/MR. ***Conclusion:*** $^{68}$Ga-FAPI PET/MR is superior to $^{18}$F-FDG PET/MR in the diagnosis of residual malignant tumor of HNSCC patients in the primary focus.

## OP-790

### Preclinical and clinical evaluation of$^{68}$Ga-FAPI-LM3 for PET imaging in nasopharyngeal carcinoma

***L. Zhao***, *H. Chen, Q. Lin;*
*the First Affiliated Hospital of Xiamen University, Xiamen, CHINA.*

***Aim/Introduction:*** Radiolabeled fibroblast activation protein inhibitors (FAPIs) and LM3 peptides have been extensively widely explored for imaging of FAP- and SSTR2 positive tumors. A FAPI-LM3 heterodimer that was radiolabeled with $^{68}$Ga and evaluated in tumor xenografts and NPC patients with cancer. ***Materials and Methods:*** FAPI-LM3 was synthesized based on FAPI-46 and LM3, and then radiolabeling with $^{68}$Ga to creat$^{68}$Ga-FAPI-LM3. Its dual-receptor-binding affinity was evaluated in vitro and in vivo. Preclinical studies, including micro-PET and biodistribution studies, were performed using HT-1080-FAP+ HT-1080-SSTR2 xenografts. The effective dosimetry of $^{68}$Ga-FAPI-LM3 was evaluated in three healthy volunteers. The clinical feasibility of $^{68}$Ga-FAPI-LM3 PET/CT was evaluated in 6 NPC patients (5 for primary staging and 1 for restaging). ***Results:*** $^{68}$Ga-FAPI-LM3 was stable in phosphate buffered saline and fetal bovine serum for 2 h. $^{68}$Ga-FAPI-LM3 yielded FAP- and SSTR2-binding affinities comparable to those of monomeric FAPI ($IC_{50}$, 4.4nM vs. 11.7nM) and DOTA-LM3 ($IC_{50}$, 13.2nM vs. 1.3nM), respectively. The tumor uptake of $^{68}$Ga-FAPI-LM3 was significantly higher than that of $^{68}$Ga-FAPI-46 (14.78 ± 0.76 %ID/g vs. 8.08 ± 1.51 %ID/g at 1h, P<0.001; 17.68 ± 2.46 %ID/g vs. 7.11 ± 0.99 %ID/g at 4h, P<0.001) and $^{68}$Ga-DOTA-LM3 (14.78 ± 0.76 %ID/g vs. 7.88 ± 1.10 %ID/g at 1h, P<0.001; 17.68 ± 2.46 %ID/g vs. 5.46 ± 0.41 %ID/g at 4h, P<0.001) in HT-1080-FAP+ HT-1080-SSTR2 double-target-positive xenografts, while the normal organs showed low tracer uptake. The tumor uptake of $^{68}$Ga-FAPI-LM3 at 1 h p.i. (14.78 ± 0.76 %ID/g) was mostly suppressed by FAPI46+DOTA-LM3 (0.86% ± 0.06%, 94% blockade), partially inhibited by FAPI46 (6.51 ± 0.89 %ID/g, 56% blockade) and DOTA-LM3 (6.34 ± 0.77 %ID/g, 57% blockade) in HT-1080-FAP+ HT-1080-SSTR2 double-target-positive xenografts. $^{68}$Ga-FAPI-LM3 was tolerated well, with no adverse events in any of the healthy volunteers or patients. The effective dose from $^{68}$Ga-FAPI-LM3 PET/CT was $1.96 \times 10^{-2}$ mSv/MBq. In clinical investigations with NPC, the radiotracer uptake of primary and metastatic lesions in $^{68}$Ga-FAPI-LM3 PET/CT was significantly higher than those in $^{18}$F-FDG PET/CT (median SUVmax: primary tumors, 13.8 vs. 9.0, P=0.043; regional lymph nodes, 10.7 vs. 9.2, P=0.039; distant metastases, 12.9 vs. 5.2, P<0.001). Moreover, 3 bone metastases and 1 liver metastasis were found to be negative in 18F-FDG PET/CT but positive in 68Ga-FAPI-LM3 PET/CT. ***Conclusion:*** $^{68}$Ga-FAPI-LM3 exhibited promising FAP and SSTR2 dual-receptor-targeting properties, leading to favorable tumor imaging in NPC patients. This study demonstrated the safety and clinical feasibility of $^{68}$Ga-FAPI-LM3 PET/CT for imaging of NPC patients.

### Potentially incremental role of $^{18}$F-DPA714 PET to conventional MRI in the detection and therapeutic monitoring of autoimmune encephalomyelitis

***M. Zhang***[1], *H. Meng*[2], *S. Chen*[2], *B. Li*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,*
[2]*Department of Neurology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Our previous case reports have shown the potential value of translocator protein (TSPO) radioligand 18F-DPA714 positron emission tomography (PET) in the detection of autoimmune encephalomyelitis (AE) [1]. Therefore, we aim to further assess the role of 18F-DPA714 PET in the detection and therapeutic monitoring of AE compared to conventional MRI in our clinical trial (Trial registration number ClinicalTrials.gov: NCT05293405). ***Materials and Methods:*** Forty-one patients with a definite diagnosis of AE underwent hybrid 18F-DPA714 PET and conventional MRI sequences, modified Rankin scale (mRS) scores assessment and antibody titer testing at baseline. The intensity and extent of 18F-DPA714 uptake in involved brain regions were evaluated. Ten healthy volunteers (HVs) were recruited in the study as normal controls on 18F-DPA714 PET. Fourteen of 41 patients further underwent follow-up PET/MRI at an average of 7 months after receiving immunosuppressive therapy. ***Results:*** Higher physiological uptake of 18F-DPA714 in the thalamus and brainstem than that in other brain cortical regions was observed in HVs ($P < 0.05$). The overall detection positive rate of AE on 18F-DPA714 PET was significantly higher than that on conventional MRI (53.66% vs. 36.58%, $P = 0.027$). For sixteen seronegative AE patients, abnormal 18F-DPA714 uptakes were observed in four patients whereas only one patient had positive MRI findings. For the patents with positive findings on 18F-DPA714 PET, the extent and intensity of 18F-DPA714 uptake at baseline showed no significant correlation with mRS score or antibody titer. However, significant decrease in the uptake extent and intensity of 18F-DPA714 in involved brain regions after receiving immunosuppressive therapy was clearly observed. ***Conclusion:*** 18F-DPA714 PET might have potentially incremental role to conventional MRI for detection and therapeutic monitoring of AE. ***References:*** 1. Shen R, Shen D, Zhou Q, Zhang M, Chen S. Antibody-mediated autoimmune encephalitis evaluated by (18) F-DPA714 PET/MRI. Brain Behav Immun Health 2022;26:100535. doi: 10.1016/j.bbih.2022.100535

## OP-792

### Activated Microglia Detected by TSPO PET in Anti-N-Methyl-D-Aspartate Receptor (NMDAR) Encephalitis: Distinct Pattern of Disease

***J. Ge***, *J. Wang, P. Wu, Y. Guan, C. Zuo;*
*Huashan Hospital, Shanghai, CHINA.*

***Aim/Introduction:*** Autoimmune encephalitis (AIE) constitutes a group of inflammatory brain disorders that are characterized by prominent neuropsychiatric symptoms and are associated

with antibodies against neuronal cell-surface proteins, ion channels, or receptors. The disorders most frequently recognized on clinical grounds are anti-N-methyl-D-aspartate receptor (NMDAR) encephalitis and autoimmune limbic encephalitis (ALE) such as anti-leucine-rich glioma-inactivated 1 (LGI1) protein encephalitis and anti-γ-aminobutyric acid receptor-B (GABAB) encephalitis. We have previously reported that patients with ALE exhibited abnormal microglial activation, primarily in the bilateral hippocampus, as detected by 18-kDa translocator-protein (TSPO) PET imaging [1]. While brain MRI in anti-NMDAR encephalitis is often normal, this study aimed to investigate the activated microglia pattern of anti-NMDAR encephalitis and to evaluate its correlation with clinical phenotype. ***Materials and Methods:*** Twenty patients with anti-NMDAR encephalitis from the AIE cohort in Huashan hospital and ten controls with ALE or non-inflammatory diseases were included in the current study. All patients with anti-NMDAR encephalitis were diagnosed based on clinical manifestations and positive anti-NMDAR antibodies both in serum and in CSF samples. Cerebral TSPO PET imaging with 18F-DPA714 was performed in individual subjects. The abnormal microglial activation of anti-NMDAR encephalitis was evaluated by comparing TSPO PET images between individual patients with anti-NMDAR AIE and those of the ten controls using visual reading, voxel-wise statistical parametric mapping analysis, and semi-quantitative analysis with standardized uptake value ratios normalized to the cerebellum (SUVRc), respectively. ***Results:*** Remarkable and extensive microglial activation in the frontal-parieto-temporal lobes was demonstrated in anti-NMDAR AIE. Notably, the changes of abnormally activated microglia in individual patients commonly involved unilateral cerebral hemisphere or exhibited an apparently asymmetric pattern of two hemispheres. The semi-quantification of the affected frontal-parieto-temporal regions showed significant difference between anti-NMDAR AIE and controls with ALE or non-inflammatory diseases ($P<0.05$). Longitudinal analysis of two cases showed normalization of the pattern of cerebral microglial activation with recovery. ***Conclusion:*** This study revealed that anti-NMDAR encephalitis has a distinctive pattern presented by TSPO PET imaging, which indicated underlying mechanisms of microglia in pathogenesis and clinical phenotype. We propose that this pattern may offer valuable information for the diagnosis, treatment decision and prognosis prediction of this elusive but treatable disease. ***References:*** 1Wang J, Ge J, Jin L, et al: Characterization of neuroinflammation pattern in anti-LGI1 encephalitis based on TSPO PET and symptom clustering analysis. ## OP-793

### Safety, biodistribution, and dosimetry of [18F]OP-801, a novel neuroinflammation PET biomarker, in healthy individuals

***F. Moradi***[1], *M. Jovin*[1], *N. Malik*[1], *J. H. Park*[1], *V. Ferri*[1], *M. L. James*[1], *J. L. Cleland*[2], *S. Maricich*[2];
[1]*Stanford University, Stanford, CA, UNITED STATES OF AMERICA,* [2]*Ashvattha Therapeutics, Redwood City, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** [18F]OP-801, a fluorine labeled hydroxyl dendrimer, is a novel PET radiopharmaceutical for neuroinflammation. Pre-clinical studies showed that [18F]OP-801 crossed blood-brain barrier in areas of neuroinflammation and was selectively taken up by activated microglia and macrophages, predominantly via fluid phase endocytosis[1]. The degree of uptake correlated linearly with severity of neuroinflammation, and in contrast to TSPO PET which is complicated by TSPO expression across many cell types, nonspecific uptake was minimal. We are now conducting a first in human, phase 1/2 clinical trial in healthy controls and patients with amyotrophic lateral sclerosis (NCT05395624), and hereby reporting the results of the first cohort (healthy volunteers). ***Materials and Methods:*** Healthy individuals without personal or family history of neurodegenerative disorders were recruited for the study. Exclusion criteria include recent acute illness or use of anti-inflammatory medications. [18F] OP-801 ($RCY_{EOS\text{-}dc}$ 10%; Radiochemical purity ~100%; SA>55 GBq/mg) was produced using automated radiosynthesis[2]. Following intravenous administration of 400 MBq [18F]OP-801, PET/MR images of vertex to lower legs were acquired using a 3 Tesla GE SIGNA scanner at 0, 1, 2, and 3 hours post injection. Blood and urine samples were collected and measured for activity up to 6 hours. Clinical, laboratory and ECG data were acquired at baseline and after administration, and participants were followed up for 15 days. Image-based dosimetry was performed using MIRDCalc version 1.1 (MIRDsoft.org). ***Results:*** Three male and two female healthy volunteers completed the study without experiencing any adverse events related to the radiopharmaceutical. PET images demonstrated blood pool activity followed by renal excretion. No significant uptake was observed in the brain, spine, or any other organs. A very small amount of biliary excretion was present in the gallbladder after first hour, with visualization of low-level activity in small bowel in subsequent time points. The overall biodistribution and dosimetry were similar to the mouse model in preclinical studies, with kidney and bladder wall receiving the highest dose. ***Conclusion:*** As expected from pre-clinical studies, [18F]OP-801 is safe and has favorable biodistribution with no or little background uptake in normal central nervous system, and non-uptaken circulating radiopharmaceutical is eliminated via urinary excretion, resulting in low effective radiation dose. ***References:*** 1. Clinical Radiosynthesis and Translation of [18F] OP-801: A Novel Radiotracer for Imaging Reactive Microglia and Macrophages. Submitted

## OP-794

### Dopaminergic Damage Pattern Predicts Phenoconversion Time in Isolated Rapid Eye Movement Sleep Behaviour Disorder

***J. Ge***, *Q. Xu, H. Lin, Y. Guan, C. Zuo, P. Wu, H. Yu; Huashan Hospital, Shanghai, CHINA.*

***Aim/Introduction:*** The exact phenoconversion time from isolated rapid eye movement sleep behaviour disorder (iRBD) to synucleinopathies remains unpredictable. This study investigated whole-brain dopaminergic damage pattern (DDP) with disease progression and predicted phenoconversion time in individual patients. ***Materials and Methods:*** Age-matched 33 iRBD patients and 20 healthy controls with $^{11}$C-CFT-PET scans were enrolled. The patients were followed up 2-10 (6.7 ± 2.0) years. The phenoconversion year was defined as the base year, and every two years before conversion was defined as a stage. Support vector machine with leave-one-out cross-validation strategy was used to perform prediction. ***Results:*** We found dopaminergic degeneration of iRBD occurred about 6 years before conversion and then abnormal brain regions gradually expanded. Using DDP, area under curve (AUC) was 0.879 (90% sensitivity and 88.3% specificity) for predicting conversion in 0-2 years, 0.807 (72.7% sensitivity and 83.3% specificity) in 2-4 years, 0.940 (100%

sensitivity and 84.6% specificity) in 4-6 years and 0.879 (100% sensitivity and 80.7% specificity) over 6 years. In individual patients, predicted stage correlated with whole-brain dopaminergic level (r = -0.740, p < 0.001). ***Conclusion:*** Our findings suggest that DDP could accurately predict phenoconversion time of individual iRBD patients, which may help to screen patients for early intervention.

## OP-795

### [18F]F-SynVesT-1 and [18F]F-FDG PET imaging in the pre-surgical evaluation of MRI-negative children with focal cortical dysplasia

***L. Xiao***, *Y. Tang, J. Yang, S. Hu;*
*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA.*

***Aim/Introduction:*** Focal cortical dysplasia (FCD) is the most common cause of drug-resistant epilepsy in children undergoing epilepsy surgery. In children with epilepsy caused by FCD, MRI-negative focal epilepsy is one of the most challenging cases in surgical epilepsy treatment, which represent approximately one-third of the total cohort. It is difficult to identify the epileptogenic zone (EZ) in MRI-negative cases, and these cases have poor surgical outcomes, with postoperative seizure-free rates as low as 50%. Our study aims at utilizing quantitative positron emission tomography (QPET) analysis to complement [18F]F-SynVesT-1 and [18F]F-FDG positron emission tomography (PET) imaging to facilitate the identification of EZ in MRI-negative children with FCD. ***Materials and Methods:*** We prospectively enrolled 17 MRI-negative patients with FCD who underwent [18F]F-SynVesT-1 and [18F]F-FDG PET before undergoing surgical resection. QPET was analyzed using statistical parametric mapping (SPM) with comparison to age- and gender-matched normal controls. The sensitivity, specificity, and area under the curve (AUC) of [18F]SynVesT-1 PET, [18F]FDG PET, [18F]SynVesT-1 QPET, and [18F]FDG PET QPET in EZ localization were assessed. Additionally, logistic regression analyses were performed based on electroencephalography (EEG), [18F]F-SynVesT-1 and [18F]F-FDG PET. ***Results:*** The AUC values of EEG, [18F]F-FDG PET, and [18F]F-SynVesT-1 PET were 0.849 (sensitivity = 100.0%, specificity = 69.7%), 0.924 (sensitivity = 94.1%, specificity = 90.8%), and 0.908 (sensitivity = 82.4%, specificity = 99.2%), respectively. [18F]F-FDG QPET showed reduced sensitivity (64.7%) but increased specificity (95.8%) when compared to visual assessment, whereas [18F]F-SynVesT-1 QPET exhibited increased sensitivity (94.1%) but reduced specificity (97.5%). Notably, the hybrid model that relied on EEG, [18F]F-FDG PET, and [18F]F-SynVesT-1 PET demonstrated the highest AUC value (AUC = 0.996, sensitivity = 100.0%, specificity = 96.6%) among all models. ***Conclusion:*** The study outcomes exhibit a favorable utilization of a multivariate prediction model that incorporates EEG, [18F]SynVesT-1 PET, and [18F]FDG PET as a tool for enhancing the precision of diagnostic tests designed to identify the location of EZ. Also, the research indicates that QPET analysis holds great potential for refining the precision of diagnostic tests utilized for EZ localization, specifically in situations where only [18F]FDG PET or [18F]SynVesT-1 PET data are attainable. These research results suggest that QPET analysis could potentially lead to better surgical outcomes for MRI-negative children with FCD.

## OP-796

### Mapping Sudden sensorineural hearing loss-related brain activation: a preliminary study by Using [18 F] SynVesT-1 and PET Imaging.

***J. Zhong***[1], *S. Hu*[1], *E. Zhou*[2];
[1]*Department of Nuclear Medicine, XiangYa Hospital, Central South University, Changsha, CHINA,* [2]*2Department of Otolaryngology Head and Neck Surgery, Hunan Provincial People's Hospital (First Affiliated Hospital of Hunan Normal University), Changsha, CHINA.*

***Aim/Introduction:*** Sudden sensorineural hearing loss (SSNHL) is commonly encountered in audiologic and otolaryngologic practice. SSNHL is most commonly defined as sensorineural hearing loss of 30 dB or greater over at least three contiguous audiometric frequencies occurring within a 72-hr period. Although the differential for SSNHL is vast, for the majority of patients an etiologic factor is not identified. In recent years, some studies suggested that the essence of SSNHL is hearing loss caused by nerve injury.As an consequence, the neurologic cause arise our interest. Synaptic vesicle protein 2A(SV2A) can reflect neuronal abnormality. The abnormalities of synaptic density in SSNHL has not yet been tested directly by SV2A. In this positron emission tomography (PET) study with the new tracer 18F-SynVesT-1, we evaluated SV2A abnormalities in patients with SSNHL. ***Materials and Methods:*** Twenty patients with SSNHL and twenty-five healthy controls were recruited. All SSNHL patients and healthy controls underwent magnetic resonance imaging (MRI) and static PET imaging with 18F-SynVesT-1.Visual assessment of PET images and ROI analysis by whole brain analyses were undertaken. Standardized uptake value (SUV) of 18F-SynVesT-1 and ratio (SUVr) were computed between regions of interest. ***Results:*** Lesions in the brain of tinnitus patients had increased 18F-SynVesT-1 uptake compared with controls. The patients revealed increased metabolism of the unilateral hemisphere, including 11 brain areas prior to the bilateral Accumbens Area , bilateral Caudate,Putamen and posterior cingulate,left angular gyrus ,right frontal pole ,right lingual gyrus.18F-SynVesT-1 PET indicated high lesion uptake in 17 cases (85%). Further SPM assessment indicated that the degree and frequency of SSNHL are related to high 18F-SynVesT-1 uptake (P<0.05). ***Conclusion:*** SV2A PET with 18F-SynVesT-1 is the first in vivo evidence linking higher synaptic density to network alterations and confirming to the hypothesis of increased neuronal activity in SSNHL. Our findings provide further incentive to evaluate interventions that restore synaptic connections to treat SSNHL.

## OP-797

### Lower synaptic density and its association with cognitive dysfunction in patients with obsessive-compulsive disorder

***J. Hou***, *Q. Xiao, L. Xiao, S. Hu;*
*Xiangya Hospital, Central South University, Changsha, CHINA.*

***Aim/Introduction:*** The exploration of synaptic alteration of obsessive-compulsive disorder (OCD) is helpful for detecting pathological mechanism, but there is still a lack of in vivo research. The aim of this study is to investigate the synaptic density indicators of OCD, and to explore the relationship between cognitive dysfunction of OCD and synaptic density changes. ***Materials and Methods:*** This research enrolled 28 drug-naïve adults with OCD aged 18-40 years and 16 healthy controls (HCs). A 3D-T1 weighted structural Magnetic resonance imaging (MRI) and 18F-SynVesT-1 Positron Emission Computed Tomography

(PET) was collected. In this study, the Wisconsin cart sorting test (WCST) was used to test cognitive function in patients with OCD and HCs. Correlative analysis of synaptic density reduction with cognitive dysfunction was also calculated. ***Results:*** Compared with HCs, patients with OCD showed reduced synaptic density in regions of the cortico-striato-thalamo-cortical (CSTC) circuit such as bilateral putamen, left caudate, left parahippocampal gyrus, left insula, and left parahippocampal gyrus as well as in the left middle occipital lobe (voxel P <0.001, with cluster level above 50 contiguous voxels). The Percent Conceptual Level Responses of WCST were positively associated with the synaptic density reduction in the left middle occipital gyrus ($R^2$=0.1690, P=0.0298), the left parahippocampal gyrus ($R^2$=0.1464, P=0.0445), and left putamen ($R^2$=0.1967, P=0.0181) in OCD patients. ***Conclusion:*** There was lower 18F-SynVesT-1 uptake in adults with OCD relative to HCs, potentially reflecting lower synaptic density. This study is the first attempt to explore the synaptic density of vivo OCD patients, and is helpful to find biological targets for cognitive dysfunction in OCD. ***References:*** 1. ### A1 adenosine receptor availability and perfusion in the human brain during acute normobaric hypoxia measured with [F-18]CPFPX PET/MRI

***H. Weis***[1,2], *M. Michno*[3], *J. Schmitz*[4], *A. Foerges*[3], *S. Beer*[3], *B. Neumaier*[5], *A. Drzezga*[1], *D. Aeschbach*[4], *A. Bauer*[3], *J. Tank*[4], *E. Elmenhorst*[6], *D. Elmenhorst*[3];
[1]*Department of Nuclear Medicine, University Cologne, Germany, Cologne, GERMANY,* [2]*Institute of Aerospace Medicine, German Aerospace Center, Cologne, Germany, GERMANY,* [3]*Institute of Neuroscience and Medicine (INM-2), Forschungszentrum Jülich, Jülich, GERMANY,* [4]*Institute of Aerospace Medicine, German Aerospace Center, Cologne, GERMANY,* [5]*Institute of Neuroscience and Medicine (INM-5), Forschungszentrum Jülich, Jülich, GERMANY,* [6]*Institute of Aerospace Medicine, German Aerospace Center, Cologne, Cologne, GERMANY.*

***Aim/Introduction:*** Hypoxia alters cerebral metabolism, perfusion, and electric activity. The neuromodulator adenosine is produced/and or released into the interstitial space during hypoxia and may mediate some of these effects. A1 adenosine receptor ($A_1$AR) antagonism or knock-out attenuates this neuronal inhibition in mice. Here we tested the hypothesis that exposure to short term hypoxia compared to normoxia reduces the availability of A1AR in the human brain, providing evidence for a hypoxia-induced increase in endogenous adenosine. As exploratory objectives, we tested the hypotheses that psychomotor vigilance is affected during hypoxia and that perfusion is altered. ***Materials and Methods:*** Ten healthy volunteers (32 ± 13 years, 3f) completed a 110-min bolus plus constant infusion [F-18]CPFPX PET-MRI hybrid experiment: Subjects spent 60 minutes in normoxia followed by 30 minutes of normobaric hypoxia with peripheral oxygen saturation of 70 - 75 %, followed by 20 minutes of normoxia. Blood samples were used to calculate metabolite-corrected steady-state distribution volumes ($V_T$) of A1AR (i. e., 40 - 100 min after start of [F-18]CPFPX administration). Brain perfusion was measured using arterial spin labeling. A 3-minute psychomotor vigilance test (PVT) was conducted every 10 minutes. Heart rate and peripheral blood oxygen saturation were measured continuously. ***Results:*** Compared to normoxia, acute hypoxia reduces $A_1$AR availability in the cerebral cortex by 11 % ($p = 0.033$). Cortical gray matter brain perfusion on the other hand increased by 25 % ($p < 0.001$). Heart rate increased by 22 % ($p < 0.001$). PVT mean reaction time was longer by 7 ms ($p = 0.027$). ***Conclusion:*** Acute normobaric hypoxia reduces cerebral $A_1$AR availability, indicating increased adenosine concentration and receptor occupancy. Simultaneously cognitive performance is impaired and brain perfusion increases.

## OP-799

### mGluR5 and glutamate involvement in Autism spectrum disorder (ASD) adult patients : a multimodal imaging study

***A. Dupont***[1,2], *N. Arlicot*[1,2,3], *L. Barantin*[4], *J. Vercouillie*[4], *C. Tauber*[5], *V. Gissot*[6], *F. Bonnet-Brilhault*[7,2], *M. Santiago-Ribeiro*[8,2,3];
[1]*Radiopharmacie, CHRU Tours, Tours, FRANCE,* [2]*Inserm U 1253, Tours, FRANCE,* [3]*Inserm CIC 1415, Tours, FRANCE,* [4]*Inserm U 1253, Tours, FRANCE,* [5]*Inserm U1253, Tours, FRANCE,* [6]*CIC1415, Chru Tours, Tours, FRANCE,* [7]*Centre Universitaire de Pédopsychiatrie, Chru Tours, Tours, FRANCE,* [8]*Médecine nucléaire, Chru Tours, Tours, FRANCE.*

***Aim/Introduction:*** Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder whose pathophysiological mechanisms are still unclear. Hypotheses suggest a role for glutamate dysfunctions in ASD development and more precisely the mGlu5 receptor. To further understand the role of the glutamatergic transmission and the mGluR5 in the pathophysiology of ASD, we conducted a multimodal clinical study combining proton magnetic resonance spectroscopy ($^1$H-MRS) and Positron Emission Tomography (PET) to explore the cerebral glutamate levels along with the brain mGluR5 density in adults with ASD and controls. ***Materials and Methods:*** Two groups consisting in 12 adult males with ASD and 14 healthy adult males were recruited and matched on age. Before PET scan, each subject underwent a MRI study for brain anatomical imaging to define Regions Of Interest. Glutamate (Glu) and glutamine (Gln) levels were assessed from $^1$H-MRS data collected from the anterior-cingulate cortex (ACC). After a CT acquisition for attenuation correction, healthy volunteers were intravenously injected with [$^{18}$F]FPEB as a bolus, and underwent a 90 min brain dynamic acquisition. To shorten the acquisition duration for the ASD group, PET data were collected between 30 and 50 minutes post [18F]FPEB injection. Thus, the same time window of 20-minute images from 30 to 50 minutes post [$^{18}$F]FPEB injection was used for comparison between the two groups. ***Results:*** No modifications in cingulate Glu levels were observed between individuals with ASD and control subjects. Our imaging results showed an overall increased density in mGluR5 in adults with ASD. The z-score maps comparing the SUVr obtained in ASD individuals and controls revealed significant differences in binding in almost all the studied brain areas at the exception of the pallidum and hippocampus. In the cortex, higher values in SUVr were detected in the frontal, parietal, temporal, occipital and insular lobes. Lower values in SUVr in the ASD group vs controls were only observed in parts of the medial precentral and inferior

temporal cortices. ***Conclusion:*** No modifications in Glu levels were observed supporting the difficulty to evaluate modifications in excitatory transmission using spectroscopy in this population, and the complexity of its glutamate-related changes. Only two other studies suggested higher densities in adult subjects with ASD in the cerebellum and postcentral gyrus using PET but were either post-mortem or limited by a small number of participants. We showed that adult individuals with ASD exhibit higher mGluR5 densities in almost all the cortex and subcortical areas.

### OP-800

**The Risk of Malignancy of Thyroid PET-Avidomas on $^{18}$F-FDG PET/CT using the Bethesda System for Reporting Thyroid Cytopathology**

***H. Coerts***[1], *F. J. van Kemenade*[1], *F. A. Verburg*[1], *B. de Keizer*[2], *J. L. F. Raithel*[1], *T. M. van Ginhoven*[1];
[1]*Erasmus Medical Center, Rotterdam, NETHERLANDS,*
[2]*University Medical Center Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Incidental PET-positive thyroid lesions are detected on PET scans performed for non-thyroid indications. This study aims to investigate the risk of malignancy, as classified according to the Bethesda System for Reporting Thyroid Cytopathology, in patients with PET-avidomas and non-PET patients. ***Materials and Methods:*** The national pathology database (PALGA) was used to identify all patients who underwent fine needle biopsy of one or more thyroid nodules between 2012 and 2022 in the Netherlands. Bethesda classifications and indications for performing fine needle aspiration cytology were extracted from the record. ***Results:*** A total of 50,782 PALGA reports were evaluated, and the incidence of Bethesda classes in the Netherlands was as follows: 27.0% Bethesda 1 (n=13703), 55.0% Bethesda 2 (n=27951), 7.4% Bethesda 3 (n=3771), 5.1% Bethesda 4 (n=2588), 2.8% Bethesda 5 (n=1440) and 2.6% Bethesda 6 (n=1329). Among patients with a PET-avidoma who underwent surgery, the risk of malignancy by Bethesda classification was as follows: 30.3% (44/145) for Bethesda 1, 31.4% (22/70) for Bethesda 2, 29.4% (37/126) for Bethesda 3, 35.8% (100/279) for Bethesda 4, 86.1% (155/180) for Bethesda 5 and 99.4% (172/173) for Bethesda 6. Among patients who did not undergo PET and had surgery, the risk of malignancy by Bethesda classification was as follows: 14.8% (362/2446) for Bethesda 1, 9.8% (366/3740) for Bethesda 2, 26.4% (424/1607) for Bethesda 3, 39.8% (790/1983) for Bethesda 4, 83.0% (901/1086) for Bethesda 5 and 98.6% (872/884) for Bethesda 6. ***Conclusion:*** In conclusion, our findings suggest that thyroid PET-avidomas have a higher a priori risk of malignancy compared to non-PET patients.

### OP-801

**Iodine-123 diagnostic imaging in the early follow-up of differentiated thyroid cancer patients: wich is the best acquisition timing ?**

***A. Campenni'***[1], *R. Ruggeri*[1], *M. Siracusa*[1], *A. Rappazzo*[1], *V. Davì*[1], *A. Nicocia*[1], *D. Cardile*[1], *S. Baldari*[1], *L. Giovanella*[2];
[1]*Ospedale Gaetano Martino, Messina, ITALY,* [2]*Ente Ospedaliero Cantonale, 6500, Bellinzona, SWITZERLAND.*

***Aim/Introduction:*** In differentiated thyroid cancer (DTC) patients, the response to initial treatments is evaluated 6-12 months after radioiodine therapy (RIT) according to 2015 American Thyroid Association (2015 ATA) criteria. In selected patients, diagnostic $^{131/123}$I whole body scintigraphy (Dx-WBS) is recommended. $^{123}$Iodine offers physical advantages compared to iodine-131 but up to date no data have been reported on the best timing to perform imaging study. We evaluated the diagnostic-performance of $^{123}$I-Dx-WBS-SPECT/CT ($^{123}$I-Dx-imaging) in the early follow-up of DTC patients and compared early (+3 hours) and late (+20 hours) imaging results for identifying the best acquisition timing. ***Materials and Methods:*** We reviewed the records of 61 (F=43, M=18; female-to-male ratio=2.38:1; mean age=45.4±13.8, median=45, range=18-78) low (n=21) or intermediate-risk DTC patients [pT1-T3,Nx(0,1),Mx]. Papillary thyroid cancer was carried out in 58/61 (95.1%) patients while 3 had a follicular thyroid carcinoma. All patients had undergone (near)-total thyroidectomy followed by RIT, using low (1.1 GBq) or moderate (2.2 GBq) radioiodine activities. A post-therapy whole body scintigraphy coupled with SPECT-CT (pT-imaging) was obtained 2-5 days after RIT. The response to initial treatments was evaluated 8-12 months after RIT using basal and rhTSH-stimulated Tg measurements, neck-ultrasound (nUS) and $^{123}$I-Dx-imaging. The latter was obtained 3 and 20 hours after tracer administration. Then patients were classified according to 2015 ATA. ***Results:*** According to 2015 ATA criteria, 31, 13 and, 17 DTC patients were classified to have excellent response (ER), indeterminate (n=9) or incomplete bio-chemical response (BIndR/BIR) or structural incomplete response (SIR), respectively. In all patients with SIR, metastatic disease was detected by $^{123}$I-Dx-imaging while nUS was positive in 4 (16%) patients only (regional lymph-node metastases, n=3; local lymph-node metastasis, n=1). $^{123}$I-Dx-imaging was positive at early, late or both acquisition in 2, 5, 10 patients, respectively. Acconrdingly, late $^{123}$I-Dx-imaging was able to detect structural disease in 15/17 (88.2%) patients. Early, late or both planar imaging was positive in 1, 1, 4 patients, respectively. Accordingly, planar imaging was able to detect structural disease in 6/17(35.3%) patients only. ***Conclusion:*** Our data confirms the role of $^{123}$I-Dx-imaging in assessing the response to initial treatments in DTC patients being able to change response assessment (from biochemical to SIR) in 13/31 (41.9%) patients with persistent disease after initial treatments. SPECT/CT imaging sensitivity is significantly superior than planar imaging. According to our preliminary results, late acquisition should be considered as the best timing for $^{123}$I-Dx-imaging being able to increase diagnostic performance and reduce patients' discomfort.

## OP-802

### Prospective comparison of F-18-TFB and I-124 PET/CT in metastatic thyroid cancer

***P. Backhaus***[1,2], *K. Pentlow*[2], *A. L. Ho*[2,3], *A. Mauguen*[2], *J. A. Fagin*[2], *N. V. K. Pillarsetty*[2], *S. K. Lyashchenko*[2], *E. Burnazi*[3], *R. A. Ghossein*[2], *S. Chhabra*[2], *M. Abusamra*[2], *S. M. Larson*[2], *H. Schöder*[2], *J. O'Donoghue*[2], *W. Weber*[4], *R. K. Grewal*[2];
[1]*University Hospital Münster, Münster, GERMANY,* [2]*Memorial Sloan Kettering Cancer Center, New York City, NY, UNITED STATES OF AMERICA,* [3]*Weill Cornell Medical College, New York City, NY, UNITED STATES OF AMERICA,* [4]*Technical University Munich, München, GERMANY.*

***Aim/Introduction:*** Fluorine 18 labelled tetrafluoroborate (F-18-TFB) is a substrate for the sodium/iodide symporter. In thyroid cancer, F-18-TFB-PET/CT may be an alternative to iodine imaging to evaluate the extent of disease and eligibility to radioiodine treatment. We report the results of the pilot study "Study of PET Imaging With 18-F-TFB in Patients With Thyroid Cancer" (NCT03196518) to determine tumor uptake of F-18-TFB and to compare properties to I-124 PET/CT in thyroid cancer. ***Materials and Methods:*** 5 patients were included in a prospective study. Following application of 0.9 mg thyrotropin alfa (Thyrogen, Sanofi Genzyme, Paris, France) on two consecutive days, patients received PET/CT 1 h after injection of 356 ± 12 MBq F-18-TFB. On the same day, patients were given 230 ± 9 MBq I-124 orally followed by PET/CT after 48 h. PET/CTs were analyzed by two board certified specialists. Detection rates and Spearman correlation for F-18-TFB and I-124 was calculated. ***Results:*** Two patients had metastatic papillary and three patients had poorly differentiated thyroid cancer. Patients with poorly differentiated cancer were treated on a redifferentiation trial preceding near-simultaneous I-124 and F-18-TFB PET/CT and had additional I-124 PET/CT at baseline. Overall 81 metastatic lesions were detected. Of these 19 (23 %) were F-18-TFB positive, whereas 78 lesions (96 %) were I-124 positive. Lesions' F-18-TFB and near-simultaneous I-124 $SUV_{max}$ did not show a good correlation (R = 0.06, P = 0.61). In patients undergoing redifferentiation therapy, 48 lesions were newly seen in I-124-PET/CT compared to baseline with $SUV_{max}$ up to 285. All these lesions were F-18-TFB negative. ***Conclusion:*** F-18-TFB can strongly underestimate radioactive iodine uptake. Future studies may resolve whether such relevant underestimation is a unique feature of certain redifferentiation therapies in poorly differentiated thyroid cancer or can appear also in redifferentiation naïve differentiated thyroid cancer.

## OP-803

### Diagnostic value of [99mTc] Tc-HYNIC-TOC scintigraphy in the management of differentiated thyroid cancer with elevated thyroglobulin and negative radioiodine whole-body scan

***A. Aghaee***, *E. Askari, S. Shafiei, K. Aryana;*
*Nuclear Medicine Research Center,Mashhad University Of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Negative radioiodine (131I) whole-body scan with elevated serum thyroglobulin (Tg) level are found in 20% of patients with differentiated thyroid cancer (DTC), which can be a diagnostic challenge. We evaluated the efficacy of Technetium-99m-Hydrazinonicotinyl-Tyr3-Octreotide ([99mTc] Tc-HYNIC-TOC) somatostatin receptor scintigraphy (SRS) for detection of non-iodine-avid metastases and its impact on staging and management of these patients. ***Materials and Methods:*** The study population consisted of 35 DTC patients (25 females; PTC = 88.2%, FTC = 11.8%) who had elevated serum Tg levels despite negative post-ablation radioiodine whole-body scan. All patients underwent whole body SRS 3-4 hours after intravenous injection of 20mCi (740 MBq) of [99mTc]Tc-HYNIC-TOC. Sites of suspected radiotracer accumulation were confirmed with anatomic imaging. Ultimately, corresponding changes in the staging and management were recorded. ***Results:*** SRS was positive in 27 (77.1%) cases. Patients with positive scan had significantly higher Tg levels at the time of scan, compared to those with negative scans (154.5±188.6 vs. 28.2±32.7 ng/mL, p-value = 0.005). Interestingly, previous history of neck external beam radiation therapy (EBRT) was significantly correlated with [99mTc] Tc-HYNIC-TOC avidity (Likelihood ratio = 11.2, p = 0.005). Addition of SSTR scintigraphy changed overall staging and management in 11% and 32.4% of the patients, respectively. ***Conclusion:*** SRS can be a useful diagnostic adjunct in DTC patients with highly elevated Tg and negative radioiodine whole-body scan. The likelihood of positive findings on [99mTc]TcHYNICTOC was higher in cases with previous history of EBRT or high Tg levels (i.e. suppressed-Tg >80 ng/mL) at the time of scan.

## OP-804

### Dual time $^{18}$F-Fluorocholine PET/CT in patients with primary hyperparathyroidism

***L. Vija***[1], *A. Latgé*[1], *M. Sinigaglia*[1], *C. Renaud*[2], *S. Grunenwald*[2], *P. Pascal*[1], *S. Kanoun*[1], *S. Zerdoud*[1], *S. Brillouet*[1], *M. Terroir Cassou-Mounat*[1], *T. Cassou Mounat*[1], *L. O. Dierickx*[1], *F. Courbon*[1];
[1]*Institut Claudius Regaud-Oncopole, Toulouse Cedex 9, FRANCE,* [2]*CHU Toulouse, Toulouse Cedex 9, FRANCE.*

***Aim/Introduction:*** $^{18}$F-Fluorocholine ($^{18}$F-FCH) PET/CT is becoming the reference imaging method to locate hyperfunctioning parathyroid glands in patients with primary hyperparathyroidism (pHPT), due to its increasing availability and better performances compared to $^{99m}$Tc- MIBI scan and neck ultrasound. Despite a growing body of evidence, the acquisition protocol still remains unstandardized and can vary significantly (single vs dual time, early vs late acquisition). With this study, we aimed to assess the value of dual-time acquisition and discuss possible ways for optimization. ***Materials and Methods:*** Patients who were referred to our center from March 2016 to April 2022 for 18F-FCH PET/CT in the context of pHPT were included in the analysis. History of neck surgery, biology and genetic results were considered. Dual time PET/CT was performed at 10 minutes (early phase) and 60 minutes (late phase) after 18F-FCH injection. For patients who benefited from neck surgery after PET/CT exploration, histology analysis of parathyroids was used as gold standard. Both phases were evaluated by two nuclear medicine physicians (consensual reading). Presence, location, SUVmax, SUVpeak and parathyroid-to-thyroid ratio of presumed hyperfunctioning glands were reported. ***Results:*** 145 patients and 165 glands were evaluated. Mean corrected calcemia was 2.58 ± 0.48 mmol/l ; mean PTH was 89.92 ± 42.88 pg/ml. Mean SUVmax of hyperfunctioning lesions was superior at 60 min p.i compared to 10 min p.i (5.77 ± 3.33 vs 5.16 ± 2.97, p < 0.01), with no significant variation of SUVpeak (2.83 ± 1.64 vs 2.92 ± 1.73, p = 0.10). Parathyroid-to-thyroid ratio was higher at 60 min p.i compared to 10 min p.i (1.78 ± 0.98 vs 1.46 ± 0.77, p < 0.01). 99 patients benefited from neck surgery after PET/CT and 119 glands were removed: 91 adenomas, 18 hyperplasias, 9 unspecified or normal glands. Lesion-based performances of PET/CT versus surgery were 87.88% for sensitivity and 86.14% for predictive positive value. We observed higher SUVmax for operated hyperplasia compared to adenoma at 10 min p.i (6.47 ± 1.98 vs 4.94 ± 2.96 ; p = 0.03) no difference at 60 min p.i. All

hyperfunctioning glands were seen on both acquisition times; only 27/119 (23%) operated glands (78% adenomas) presented higher uptake on early FCH PET. ***Conclusion:*** All hyperfunctioning glands were detected on both acquisition times, with higher SUVmax and lesion/background ratio on $^{18}$F-FCH PET-CT late acquisition. Compared to pathology results, in our cohort, SUVmax was more intense for hyperplastic glands on early PET acquisition.

## OP-805

### $^{18}$F-fluorocholine (FCH) PET/CT performance to detect hyperfunctioning parathyroid glands in patients with no definite kidney disease and whose PTH serum level and/or calcemia are within the normal range. 786 PET/CTs in one centre.

***J. Talbot***[1], *C. Aveline*[2], *J. Zhang-Ying*[2], *O. Belissant-Benesty*[2], *J. Ohnona*[2], *S. Périé*[3], *S. Gaujoux*[4], *I. Wagner*[2], *M. Bennis*[5], *F. Ménégaux*[4], *S. Christin-Maître*[5], *J. Haymann*[1], *B. Baujat*[6], *S. Balogova*[7], *F. Montravers*[2];

***Aim/Introduction:*** In the current EANM Guidelines for parathyroid imaging, primary hyperparathyroidism (pHPT) is characterised by high serum PTH levels due to the presence of enlarged hyperfunctioning parathyroid gland(s) (PT); calcemia in some cases may be normal; rarely, PTH levels are normal with concomitant hypercalcemia. We aimed to check the performance of FCH PET/CT to detect abnormal PTs according to whether those two serum markers were in the normal range or not. ***Materials and Methods:*** From our database, we gathered 786 FCH-PET/CTs performed in patients with pHPT, excluding secondary HPT, in particular CKD grade>3 or hemodialysis or renal graft, or genetically-proven familial HPT. Four groups were considered: G0 (n=389): hypercalcemia with high PTH level, the reference for indication of HPT imaging, G1 (n=245): high PTH level but normocalcemia (<=2.6 mmol/L), G2 (n=84): hypercalcemia (>2.6 mmol/L) with inappropriate PTH level but still within the normal range, G3 (n=68) normocalcemia and normal PTH level. We determined in each group the FCH-PET/CT positivity rate, and in operated (PTX) patients, patient-based sensitivity (Se), multiglandular disease (MGD) detection, gland based sensitivity and specificity, with histology of the removed PTs as standard of truth. FCH foci interpreted as equivocal were considered negative. G0 results were compared with those of the other groups with the chi-2 test, * notes significant difference p<0.05 if the 4x2 overall test is significant ***Results:*** FCH positivity rate. G0: 330/389=85%, G1: 147/245=60%*, G2: 65/84=77%, G3: 36/68=33%* No follow-up was obtained in 98 patients whose data were excluded from further analysis. PTX rate. G0: 272/353=77%, G1: 123/207=59%*, G2: 54/74=73%, G3: 31/54=57%* FCH Se patient-based. G0: 230/256=90%, G1: 88/115=77%*, G2: 46/50=92%, G3: 22/27=81% MGD at PTX. G0: 31/272=11%, G1: 24/123=20%*, G2: 6/52=12%, G3: 8/27= 33%* FCH MGD detection. G0: 14/31=45%, G1: 8/24=33%, G2: 3/6=50%, G3: 2/8=25% FCH Se gland-based. G0: 238/283=84%, G1: 90/158=57%*, G2: 49/58=84%, G3: 26/40=65%* Adenomas / abnormal PTs. G0: 228/283=81%, G1: 71/158=45%*, G2: 39/58=67%*, G3: 17/40=43%* FCH gland-based specificity. G0: 27/36=75%, G1: 12/14=86%, G2+G3: 2/2(=100%) ***Conclusion:*** In case of pHPT, high serum levels of both PTH and calcium are not mandatory for a successful detection of hyperfunctioning PTs with FCH PET/CT. Group G2 shared several patterns with the reference group G0. The results in groups G1 and G3 with normal calcemia were rather different, with a higher frequency of MGD and a minority of adenomas vs. hyperplastic PTs, with a trend to a lower FCH sensitivity compared with hypercalcemic pHPT.

## OP-806

### First-line FCH PET/CT versus MIBI SPECT/CT in the surgical management of primary hyperparathyroidism: the multicentre APACH2 phase III trial

***E. Quak***[1], *A. Lasne-Cardon*[1], *M. Cavarec*[2], *B. Lireux*[1], *V. Bastit*[1], *N. Roudaut*[2], *P. Salaun*[2], *N. Keromnes*[2], *G. Potard*[2], *P. Vaduva*[3], *A. Esvant*[3], *F. Clarisse*[1];
[1]*Francois Baclesse Cancer Centre, Caen, FRANCE,* [2]*University Hospital of Brest, Brest, FRANCE,* [3]*University Hospital of Rennes, Rennes, FRANCE,* [4]*Eugene Marquis Cancer Institute, Rennes, FRANCE.*

***Aim/Introduction:*** Whether F18-choline PET/CT (FCH PET/CT) should replace Tc99m-sestaMIBI SPECT/CT (MIBI SPECT/CT) as a first-line imaging technique for preoperative localisation of parathyroid adenomas in primary hyperparathyroidism (pHPT) is unclear. ***Materials and Methods:*** We conducted a multicentre randomized open diagnostic intervention phase III trial in adults with primary hyperparathyroidism and indication for surgical treatment (NCT04040946). Patients were assigned in a 1:1 ratio to receive first-line FCH PET/CT (FCH1) or MIBI SPECT/CT (MIBI1). In case of negative or inconclusive first-line imaging, patients received second-line FCH PET/CT (FCH2) after MIBI1 or MIBI SPECT/CT (MIBI2) after FCH1. The main aim of the trial was to compare the proportions of patients in whom the first-line imaging method resulted in successful mini-invasive parathyroidectomy (MIP) and cure, defined as the normalisation of serum calcium and parathyroid hormone levels at 1 month. We hypothesized a 30% superiority of FCH1 over MIBI1 for sample size determination (Quak_2021). ***Results:*** From 11/2019 to 05/2022, 58 patients were assigned to receive FCH1 (n=30) or MIBI1 (n=28). Baseline patient characteristics were similar between groups. FCH1 was positive in 23/29 patients and led to successful MIP and cure in 22/23 patients. MIBI1 was positive in 18/28 and led to MIP in 16/17 operated patients, and video-assisted thoracoscopy (VATS) in 1/17 patient. Cure was obtained in 15/17 patients. The proportion of patients in whom the first-line imaging exam led to successful MIP and cure was 22 (76%) for FCH1 and 13 (50%) for MIBI1 (p=0.047). Diagnostic performances were superior for FCH1 than for MIBI1: sensitivity (92% vs 68%), specificity (100% vs 75%), positive predictive value (100% vs 94%), negative predictive value (67% vs 30%), and area under the ROC curve (96% vs 71%, p=0.022), respectively. Ten patients received FCH2 and 6 patients received MIBI2. FCH2 was positive in 8/10 patients, leading to 7/9 MIP and 2/9 bilateral cervical explorations (surgery recused in 1 patient), and cure in 9/9 patients. MIBI2 was positive in 2/6 patients, leading to 1 MIP and 1 VATS; all 6 patients were cured. No adverse events related to imaging and 4 adverse events related to surgery were reported. ***Conclusion:*** The proportion of patients who underwent correct imaging-guided MIP leading to cure was higher for FCH1 than for MIBI1, 76% vs 50% respectively. Diagnostic performances were better for FCH1 than for MIBI1. Cost-benefit analyses should elucidate whether first-line FCH PET/CT in pHPT management is justified. ***References:*** Quak et al, PMID: 33413316

## OP-807

### PET/CT with [11C]-methionine in the diagnosis of tertiary hyperparathyroidism

***M. Kolodziej***[1], *M. Saracyn*[1], *A. Lubas*[2], *M. Dziuk*[3], *A. Mazurek*[3], *J. Smoszna*[2], *O. Kaminska*[3], *S. Niemczyk*[2], *G. Kaminski*[1];
[1]*Department of Endocrinology and Isotope Therapy, Military Institute of Medicine - National Research Institute, Warszawa, POLAND,* [2]*Department of Internal Medicine, Nephrology and Dialysis, Military Institute of Medicine - National Research Institute, Warszawa, POLAND,* [3]*Department of Nuclear Medicine, Military Institute of Medicine - National Research Institute, Warszawa, POLAND.*

***Aim/Introduction:*** Tertiary hyperparathyroidism (tHP) may develop in patients treated with hemodialysis or peritoneal dialysis. Parathyroidectomy may be a chance for a significant reduction in the severity of symptoms. For the effective surgical treatment of hyperparathyroidism proper localization of the parathyroid glands prior to surgery is essential. The sensitivity of scintigraphy in the diagnosis of tHP is lower than in the diagnosis of primary hyperparathyroidism. In recent years, positron emission tomography (PET/CT) has been gaining importance, usually as a complementary technique. The aim of the study was to determine the usefulness of PET/CT with [11C]MET in the preoperative localization diagnosis of patients with tertiary hyperparathyroidism caused by chronic kidney disease, in whom first-line diagnostic methods did not allow the localization of pathologically parathyroid glands. ***Materials and Methods:*** The study was conducted in a group of 19 adult patients with severe tHP, resistant or intolerant for non-invasive treatment with negative results of scintigraphy and ultrasound of the neck. The study protocol included measurement the concentration of calcium, phosphorus and PTH in the blood serum and performing PET/CT with [11C]MET. ***Results:*** A positive result of PET/CT was obtained in 89.5% of patients (17/19). Among patients with positive PET/CT with [11C]MET results, parathyroidectomy was performed in 52.9% of them (9/17) with full consistency of the histopathological examinations with a positive results of PET/CT with [11C]MET. On this basis, the sensitivity of PET/CT with [11C]MET in the preoperative localization diagnosis of patients with tHP was assessed at 100%. Multiple lesions were visualized in 57.9% of patients (11/19). Ectopic lesions were visualized in 21.1% of patients (4/19). ***Conclusion:*** PET/CT with [11C]MET is a sensitive technique of the second-line pre-operative imaging of parathyroid glands in patients with tertiary hyperparathyroidism, in whom first-line examinations such as ultrasound and scintigraphy failed.

## OP-808

### Performance of multiphase iodine contrast enhanced CZT SPECT-CT in the detection of parathyroid adenomas

***M. Ochoa Figueroa***, *F. Askling, T. Lööw, P. Norberg, M. Ressner, J. Dahl, V. Sanchez-Rodriguez;
Universitetssjukhuset i Linköping, Linköping, SWEDEN.*

***Aim/Introduction:*** The aim of this study was to evaluate the performance of a CZT SPECT-CT camera using 99mTc-MIBI, imaging in three different time-points and using a three phase contrast-enhanced CT protocol for preoperative localization of parathyroid adenomas. ***Materials and Methods:*** Thirty patients with suspected parathyroid adenoma (22 females and 8 males, mean age 65 y.o.) were prospectively evaluated with a CZT SPECT-CT camera using a three time-point SPECT protocol (10, 90 and 160 minutes after the intravenous administration of 500 MBq of 99mTc-MIBI), nonenhanced CT and contrast enhanced CT in the arterial and venous phase from December 2020 to October 2022. In 11 patients, the imaging results could be correlated with histopathology after surgery. The rest of the patients have a follow-up time of at least 5 months. All focal 99mTc-MIBI uptake suspicious of adenoma was quantified using a VOI sphere. ***Results:*** The overall results of the multimodality study was a sensitivity of 96%, specificity of 80%, positive predictive value of 96%, negative predictive value of 80% and an accuracy of 93%. The median maximum concentration for the adenoma suspicious uptake at 10 minutes was 27,6 kBq/ml, at 90 minutes 18,1 kBq/ml and at 160 minutes 12,1 kBq/ml. The combination of a focal 99mTc-MIBI lesion at 90 minutes in CZT SPECT and a pathological contrast enhanced soft tissue lesion in CT provided the most useful imaging information to reach diagnosis. ***Conclusion:*** Our CZT SPECT-CT iodine contrast enhanced CT protocol has provided satisfactory performance for parathyroid adenoma detection, allowing quantification of the suspicious adenoma uptake providing better characterization of the lesion and could be of help to avoid potential pitfalls like thyroid tissue, cysts and lymph nodes. Further research is required to confirm our results.

### Estimation of absorbed tumour doses in patients treated with Yttrium-90 radioembolization in the prospective TRACE trial

***B. Lambert***[1], *Y. D'Asseler*[2], *E. Dhondt*[2], *L. Hermie*[2], *L. Huyck*[2], *H. Van Vlierberghe*[3], *L. Defreyne*[3];
[1]*AZ Maria Middelares en AZ Jan Palfijn Gent, Gent, BELGIUM,* [2]*Ghent University Hospital, Gent, BELGIUM,* [3]*Ghent University, Gent, BELGIUM.*

***Aim/Introduction:*** In the prospective TRACE-trial Yttrium-90 radioembolization compared favorable to chemo-embolization in unresectable HCC. The trial was designed with activity prescription according to the TheraSphere package insert at that time. It was planned to deliver ≥120Gy in the perfused liver volume, unless risk factors such as high exposed volumes, liver dysfunction or low tumour-to-background ratio favored a reduction to 80-100Gy. In this subanalysis we estimate the absorbed tumour dose and confront the absorbed doses with outcome. ***Materials and Methods:*** We retrospectively calculated the absorbed tumour dose in the subset of patients treated with TheraSphere in the TRACE-trial[1]. Tumour dose was estimated with Simplicity® based on Tc99mMAA-SPECT/CT and the actual net 90-Yttrium activity given. We compared the absorbed tumour dose of the target lesions with the mRECIST response at 6months. We dichotomized the group in patients with a minimum tumour dose of 205Gy. ***Results:*** We investigated 27 patients. The median perfused volume was 694ml (min82-max2200). The median net administered activity 90Y was 1,28GBq (min0,22-max3,94). Based on monocompartimental dosimetry we obtained a median perfused liver dose of 87Gy (min67-max159) whereas median tumour doses were estimated 259Gy (min64-max1100). Sixteen patients had tumour doses ≥205Gy: 15 showed a good response at 6months; 1 patient suffered from new lesions outside the treated area. 11 patients had an estimated tumour dose <205Gy: 3 without response vs 8

with reponse. ***Conclusion:*** We retrospectively assessed absorbed tumour doses in 27 HCC-patients treated with TheraSphere in the prospective TRACE trial. The median absorbed tumour dose was 259Gy. 23/27 patients in this dosimetric subanalysis showed complete or partial response in the whole liver at 6 months on imaging, of whom respectively 8 and 15 presented with a tumour dose <205Gy and ≥205 Gy. 1/16 patients with a tumour dose ≥205Gy did not achieve a response. ***References:*** 1.Dhondt E, 90Y Radioembolization versus Drug-eluting Bead Chemoembolization for Unresectable Hepatocellular Carcinoma: Results from the TRACE Phase II Randomized Controlled Trial. ### A Dosimetric Study of Liver and Tumors for Patients Undergoing HO-166 Microspheres Radioembolization

***L. Miseo***[1], *G. Iaccarino*[1], *M. D'Andrea*[1], *S. Ungania*[1], *A. Soriani*[1], *F. Murtas*[1], *M. Pacilio*[2], *D. Maccora*[3], *R. Sciuto*[3], *G. E. Vallati*[4], *B. Cassano*[1];
[1]*Laboratory of Medical Physics and Expert Systems, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [2]*Medical Physics Division, Azienda Ospedaliera-Universitaria Policlinico Umberto I, Rome, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [4]*Interventional Radiology Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.*

***Aim/Introduction:*** Holmium-166 labeled microspheres (Ho-166-ms) have been successfully introduced, in the last few years, in transarterial radioembolization treatments. Ho-166-ms have two main advantages, compared to Y-90 microspheres: the former is an 81 keV photopeak, that permits the acquisition of SPECT/CT quantitative images, and the latter is that can be used in both Pre-Treatment administrations (PTa) and In-Treatment ones (ITa). The reporting of the therapeutic administered activities was the goal of this study, aiming to not exceed a mean absorbed dose (mAD) to the whole liver of 60 Gy, and to study the PTa predictive power on the ITa. ***Materials and Methods:*** A cohort of fifteen patients was enrolled, diagnosed with a cumulative count of 25 hepatic metastases. Every patient underwent the PTa (that ranged into 180-250 MBq of Ho-166-ms) and, after two weeks, the ITa. Contours of liver and metastases were delineated on the PTa SPECT/CT scan, and transferred, with a rigid registration (based on liver contour), to the images acquired after the treatment. The co-registration quality was assessed with the Pearson Corelation Coefficient. For both PTa and ITa a Local Deposition Method-based dosimetric evaluation was performed: the former had the aim to determine the therapeutic activity to keep the liver mAD under or equal to 60 Gy, and the latter to calculate the in-treatment mAD of the liver and the metastases. In order to study the reproducibility of the dose spatial distribution, a local gamma function analysis was performed, with 10% dose difference and 10 mm Distance to Agreement (DTA). ***Results:*** The ITa activities varied in a (median[min;max]) 6.9[4.6;11.2] GBq range, with a tumor mAD of 115[60;315] Gy. A simulation of a 1 GBq administration was performed, resulting in a linear correlation of the liver mAD in PTa and ITa, with an $R^2$ equal to 0.95 (their respective differences ranged between -0.76[-2.54;0.23] Gy). The local gamma function analysis gave a minimum pass rate of 80%. None of the patients had reported toxicity symptoms within the first month. ***Conclusion:*** Considering the limit of maintaining the liver mAD within 60 Gy, the Ho-166-ms treatment is a safe choice, even with activity administration that are greater than 10 GBq. The advantage of using the same radionuclide in both of the administrations leads to having liver mAD differences that confirm a high predictive power.

## EPS-233

### Quantification accuracy evaluation of Yttrium-90 PET for post-therapeutic voxelised dosimetry on three generations PET/CT scanners: a phantom study

***G. Croes****, J. van Sluis, A. Willemsen, W. Noordzij, O. Ivashchenko; UMCG, Groningen, NETHERLANDS.*

***Aim/Introduction:*** Post-therapeutic dosimetry plays an important role in predicting response in patients undergoing liver radioembolization with $^{90}$Y-microspheres. Although accurate quantification of $^{90}$Y distribution is challenging regardless of the imaging modality, multiple studies have shown that PET/CT imaging of low incidence positrons emitted by $^{90}$Y (0.003% branching) has better accuracy compared to Bremsstrahlung SPECT/CT. Nevertheless, associated effects on dosimetric accuracy have not yet been investigated. We evaluate the quantification accuracy of post-therapeutic dosimetry calculation using voxelised local energy deposition models (LDM) of $^{90}$Y for three generation PET/CT systems: analogue, digital and long axial field of view (LAFOV) using phantom scans. ***Materials and Methods:*** PET/CT systems used were analogue, digital and digital-LAFOV scanners. To evaluate quantitative accuracy, two types of phantoms were utilized: uniform (6.2 L) and a NEMA-IQ phantom. Each was filled with 0.24 and 0.22/2.92 MBq/ml (13.3 sphere-to-background ratio) of $^{90}YCl_3$, respectively. Citric acid solution (0.05M) was used to prevent material interaction. Next, a 30-minute list mode acquisition was performed for each phantom-scanner combination. They were reconstructed using 15- and 30-minute frames with 4 iterations and 5 subsets (digital, digital-LAFOV) and 3 iterations 21 subsets (analogue), 3D-OSEM with PSF modelling, to mimic clinical protocols. Effects of all-pass, 7- and 9-mm Gaussian filtering were evaluated. Quantitative accuracy was assessed by means of Coefficient of Variation (COV) in the uniform and mean Recovery Coefficient (RC-mean) in the NEMA-IQ phantom. Theoretical LDM dosimetry within NEMA-IQ spheres was compared to CE-marked software calculations, with and without partial volume effect (PVE) correction. ***Results:*** In the uniform phantom, COV, activity concentration and total activity accuracies were [127%/9.7%/12%; 36%/1.7%/11%; 28%/6.8%/-6%] (analogue), [58%/-3%/11.1%; 20%/-2.5%/11.2%; 13%/-0.1%/3.5%] (digital) and [76%/-0.3%/-0.3%; 24%/-2.0%/3.0%; 17%/-0.2%/3.2%] (digital-LAFOV), for all-pass, 7- and 9-mm filtered reconstruction, respectively. The RC-mean for 22-mm sphere (clinically relevant tumour size) was [1.37/0.92/0.79] (analogue), [1.16/0.84/0.74] (digital) and [1.04/0.74/0.67] (digital-LAFOV), for all-pass, 7- and 9-mm filtered reconstruction. Absorbed dose error varied from 13%-75% for NEMA-IQ spheres, without differences in the mean, yet significant uncertainty variations between the scanners. On average, PVE correction resulted in dosimetry error reduction from 27% to 13% (sphere of 22 mm). ***Conclusion:*** Despite variations in noise levels for $^{90}$Y scans between tested PET/CT scanners, the average activity concentration remained comparable. Our results suggest that to exploit the full potential of digital-LAFOV PET/CT for $^{90}$Y, improved scatter correction techniques are needed. Additionally, accurate quantification of $^{90}$Y PET/CT dosimetry with clinically relevant tumour size range requires PVE-correction.

## EPS-234

### Overestimation in 90Y-PET/CT based mean lung doses following 90Y-radioembolization

***S. Kappadath****, B. P. Lopez, E. C. Henry, B. M. Kelley, A. Mahvash; UT MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Accurate and practical clinical estimates of delivered lung doses after $^{90}$Y-radioembolization are sparsely reported in publications but are essential to address radiation dose concerns as $^{90}$Y-activity prescriptions are increased in pursuit of curative radioembolization treatments. We investigate the effects of image noise and respiratory motion in post-treatment $^{90}$Y-PET/CT for lung dose estimation. ***Materials and Methods:*** Thirty-four $^{90}$Y-microsphere radioembolization patients underwent pre-therapy $^{99m}$Tc-MAA planar (Siemens SymbiaT16) and post-therapy $^{90}$Y-PET/CT (GE DMI 5-Ring, 25-minute single bed) imaging as part of a prospective clinical trial (NCT03896646). Left and right lung dose-volume histograms (DVH) were calculated using local deposition dosimetry with patient-specific CT-based lung densities (g/mL) and PET-based $^{90}$Y-activity concentrations (Bq/mL). For each patient, we defined left lung median dose (D50L) as the reference dose and report the right lung median dose (D50R), the left and right lung average (DavgL, DavgR), and the predicted lung dose using pre-therapy $^{99m}$Tc-MAA planar lung and liver ROI counts, 1 kg mass, and administered $^{90}$Y activity (Dplanar). Respiratory motion mismatch in PET was assessed visually. To assess impact of image noise, the $^{90}$Y-PET images were denoised by removing "hot" lung voxels with activity concentrations exceeding the median value by >10x the interquartile range (IQR). ***Results:*** PET and CT data required manual registration in 21/34 (62%) patients to minimize breathing motion misalignment. The median ($25^{th}$-$75^{th}$) reference $^{90}$Y-PET left lung doses D50L of 0.6 (0.4-1.1) Gy were substantially lower than Dplanar values of 3.5 (2.1-8.0) Gy. While PET right lung doses D50R were modestly higher (factor of 2) than reference doses, the median absolute difference was <1 Gy. In contrast, the PET lung average doses (DavgL & DavgR) were respectively 8 to 10 times higher than the reference doses (i.e., 4 to 8 Gy median differences). The denoising algorithm removed a median 2.9% (2.1%-3.8% IQR) of the hottest lung voxels. D50L and D50R estimates were minimally affected by de-noising (<1 Gy change) while DavgL and DavgR values decreased by about 50%, corresponding to 2 to 4 Gy changes. Mean DVH values approximated median DVH values after de-noising. ***Conclusion:*** Post-treatment $^{90}$Y-PET/CT mean lung doses can be considerably over-estimated by the presence of a small number of hot noisy voxels in the reconstructed images. This dose bias can be easily mitigated by extracting median, instead of mean, dose values from $^{90}$Y-PET lung contour data or by applying simple data-driven thresholds to remove unrealistic hot voxels.

## EPS-235

### A Model to Describe the DNA Damage Response in Blood Cells During Radioiodine Therapy

***S. Schumann***[1], *H. Scherthan*[2], *S. Schoof*[2], *P. Hartrampf*[1], *A. K. Buck*[1], *M. Port*[2], *M. Lassmann*[1], *U. Eberlein*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.*

***Aim/Introduction:*** The aim of the study was to develop a model describing patient-specifically the absorbed-dose-dependent DNA damage response in blood cells during radionuclide therapy. For this purpose we used data sets collected as part of the MEDIRAD project which analysed blood samples from patients with differentiated thyroid carcinoma. ***Materials and Methods:*** Blood samples of 18 patients receiving their first radioiodine therapy were collected at up to nine different time points up to 168 h after therapy start and analysed for radiation-induced gamma-H2AX+53BP1 foci (RIF) as markers of DNA double-strand breaks (DSBs) in peripheral blood mononuclear cells (PBMCs). Blood-based dosimetry was performed as described by Eberlein et al. [1]. To describe the time course of the number of RIF, a linear two-compartment model was developed, which assumes that the change in RIF is proportional to the dose rate. The induction is described by a proportionality constant c and the repair by a time-constant rate k. Since potentially not all DSB damage repair is described by a single constant repair rate, time-dependent induction and repair are characterized by a fast ($k_1$) and a slow ($k_2$) repair rate. Fits were performed for all patients separately taking into account patient-specific blood dosimetry data. ***Results:*** 4 of 18 patients had to be excluded due to insufficient data points (< 8) or large errors of the fit parameters. In all other patients, the data were described well by the model ($r^2 > 0.83$). Fit parameters differed substantially between patients. The median value of c is 0.026 $mGy^{-1}$ (min: 0.012; max: 0.109) and, in average, 96% of the damage is repaired with $k_1$ varying between 0.19 $h^{-1}$ and 3.03 $h^{-1}$ while $k_2$ ranged from 0 to 0.04 $h^{-1}$. Our analysis revealed that patients can be divided into two groups based on their $k_1$-values: Patients with faster repair rates (n=6, $k_1 > 1.1$ $h^{-1}$) and patients with slower repair rates (n=8, $k_1 < 0.6$ $h^{-1}$). ***Conclusion:*** Our model is well suited to describe patient-specific DNA damage induction and repair in PBMCs in vivo during radioiodine therapy. It indicates that repair rates vary strongly between individual patients and that different patient groups need to be considered separately. In a next step, correlations with clinical parameters will be tested. ***References:*** [1] Eberlein et al., JNM 2016 (10.2967/jnumed.115.164814)

## EPS-236

### Validation of a Monte Carlo Simulation Model for Quantification of DNA Double-Strand Breaks in Lymphocyte Nuclei by Ex Vivo Internal Irradiation with Radionuclides

***M. Salas Ramirez***[1], *L. Maigne*[2], *G. Fois*[2], *H. Scherthan*[3], *M. Lassmann*[1], *U. Eberlein*[1];
[1]*University Hospital Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY,* [2]*Physics Laboratory of Clermont, University of Clermont Auvergne, Clermont, FRANCE,* [3]*Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.*

***Aim/Introduction:*** The aim of this study was to validate a radiation transport model that quantifies the number of DNA double-strand breaks (DSBs) produced in lymphocyte nuclei by internal ex vivo irradiation of whole blood with radionuclides at low absorbed doses (<100 mGy). The Monte Carlo simulation was performed using the GATE/Geant4 code at the macroscopic level and the Geant4-DNA code at the cellular level. ***Materials and Methods:*** The simulation in GATE reproduced an 8 ml cylindrical water-equivalent medium contained in a vial mimicking the geometry of ex vivo blood irradiation. Lymphocytes were simulated as randomly distributed spheres with a radius of 3.75 µm and a concentration of 125 spheres/ml. At the cellular level, the clustering example based on a density-based spatial clustering of applications with a noise algorithm was used for each of the simulated radionuclides ($^{90}$Y, $^{99m}$Tc, $^{123}$I, $^{131}$I, $^{177}$Lu, $^{223}$Ra, and $^{225}$Ac). The absorbed dose coefficients for lymphocyte nuclei ($d_{Lymph}$) were calculated and compared with reference absorbed dose coefficients for whole blood ($d_{Blood}$) [1]. For gamma/beta-emitting radionuclides, the number of DSBs·$cell^{-1}$·$mGy^{-1}$ was quantified by modeling and compared with the number of radiation-induced foci per cell and absorbed doses (RIF·$cell^{-1}$·$mGy^{-1}$) obtained from experimental data [2]. For alpha emitters, the number of αtracks·$cell^{-1}$·$mGy^{-1}$, DSBs·$µm^{-1}$ and the number of DSBs·$cell^{-1}$·$Gy^{-1}$ were calculated using thresholds

derived from experiments for the αtrack lengths and DBSs·track$^{-1}$ values. The results were compared with an ex vivo study with $^{223}$Ra [3, 4]. ***Results:*** The $d_{Lymph}$ values differed from the $d_{Blood}$ values by -1.0% ($^{90}$Y), -5.2% ($^{99m}$Tc), -22.3% ($^{123}$I), 0.35% ($^{131}$I), 2.4% ($^{177}$Lu), -5.6% ($^{223}$Ra) and -6.1% ($^{225}$Ac). The number of DSB·cell$^{-1}$·mGy$^{-1}$ for each beta/gamma emitting radionuclide was 0.015 DSB·cell$^{-1}$·mGy$^{-1}$ ($^{90}$Y), 0.012 DSB·cell$^{-1}$·mGy$^{-1}$ ($^{99m}$Tc), 0.014 DSB·cell$^{-1}$·mGy$^{-1}$ ($^{123}$I), 0.012 DSB·cell$^{-1}$·mGy$^{-1}$ ($^{131}$I), and 0.016 DSB·cell$^{-1}$·mGy$^{-1}$ ($^{177}$Lu). For $^{223}$Ra and $^{225}$Ac, the number of α-tracks·cells$^{-1}$·mGy$^{-1}$, the linear density of DSBs·µm$^{-1}$ of α-track length, and the number of DSBs cell$^{-1}$·Gy$^{-1}$ were 0.00144 αtracks·cell$^{1}$·mGy$^{1}$ and 0.00151 α-tracks·cell$^{-1}$·mGy$^{-1}$, 11.13 DSBs·µm$^{-1}$ and 10.86 DSBs·µm$^{-1}$, and 67.9 DSBs·cell$^{-1}$·Gy$^{-1}$ and 69.1 DSBs·cell$^{-1}$·Gy$^{-1}$, respectively. These results are in agreement with experimental data [2, 3, 4]. ***Conclusion:*** In conclusion, this study presents and validates a radiation transport model that simulates the α-tracks and DNA damage in lymphocyte nuclei induced by internal ex vivo irradiation with alpha emitters radionuclides. ***References:*** [1] Salas-Ramirez, M. et al. ZMedPhys. 2023 [2] Eberlein, U. et al. PLoSOne. 2015 [3] Göring, L. et al. EJNMMI. 2022 [4] Scherthan, H. et al. Cancers. 2019

## EPS-237

### Dose-dependent relative biological effectiveness of $^{225}$Ac compared to $^{177}$Lu during [$^{225}$Ac]Ac-PSMA and [$^{177}$Lu]Lu-PSMA radionuclide therapy

***M. Rumiantcev***[1], *W. Li*[2], *S. Lindner*[1], *G. Liubchenko*[1], *S. Resch*[1], *P. Bartenstein*[1], *S. Ziegler*[1], *G. Böning*[1], *A. Delker*[1];
*[1]Department of Nuclear Medicine, LMU Hospital, Munich, GERMANY, [2]Federal Office for Radiation Protection, Oberschleißheim, GERMANY.*

***Aim/Introduction:*** [$^{225}$Ac]Ac-PSMA radionuclide therapy, which utilizes α-emitting $^{225}$Ac, has evolved as a promising treatment option for patients with advanced metastatic castration-resistant prostate cancer (mCRPC) who became resistant to [$^{177}$Lu]Lu-PSMA therapy. For α-particle emitter treatments, improved knowledge on the relative biological effectiveness (RBE) is required. Therefore, this simulation study aimed to determine the RBE of $^{225}$Ac compared to $^{177}$Lu during [$^{225}$Ac]Ac-PSMA and [$^{177}$Lu]Lu-PSMA in a wide range of absorbed doses to the cell nucleus . ***Materials and Methods:*** This study employed the TOol for PArtcile Simulation (TOPAS) [1,2] based on the Geant4 simulation toolkit. Simulation of the nuclear DNA and the damage scoring were performed using the TOPAS-nBio [3] extension of TOPAS. DNA repair was modeled utilizing the Python-based program MEDRAS [4,5]. The number of double-strand breaks was considered as the biological endpoint. Five different cell geometries of equal volume and two radionuclide internalization assumptions, as well as two cell arrangement scenarios (2D and 3D) were considered. The radionuclide activity (number of source points) was adopted on the basis of SPECT images of patients undergoing [$^{177}$Lu]Lu-PSMA-617 or [$^{177}$Lu]Lu-PSMA-I&T therapy. ***Results:*** $^{225}$Ac emitting high-LET α-particles revealed a linear dose-effect relationship, whereas $^{177}$Lu showed a linear-quadratic dose-effect relationship. Based on the simulated dose-effect curves, the RBE of $^{225}$Ac compared to $^{177}$Lu as a function of $^{225}$Ac nucleus absorbed dose was derived in a wide range of doses. ***Conclusion:*** Considering DNA damage repair, a dependence of the RBE of $^{225}$Ac on the nucleus absorbed dose was observed. The dose-dependent RBE values can improve clinical dosimetry for radionuclide therapy with $^{225}$Ac. ***References:*** [1]. Perl J et al. ### PET Quantification Performance of the Oversize-Volume-of-Interest Approach in the Context of Tumour Dosimetry in Radionuclide Therapy Planning

***N. Hammersen***, *W. Jentzen, F. Stawitzki, K. Herrmann, D. Kersting, P. Fragoso Costa, A. Moraitis;
Department of Nuclear Medicine at University Hospital Essen, Essen, GERMANY.*

***Aim/Introduction:*** In PET imaging, the partial-volume effect (PVE) is an important factor impairing quantification of tumour uptake - a key quantity for predicting tumour absorbed dose in radionuclide therapy planning. Applying an effective and easy PVE correction in clinical routine is of great interest. Aims of this study were to provide a procedure for the application of the oversize-volume-of-interest (VOI) approach and to compare its performance to the commonly used contour-VOI approach that utilizes phantom-based recovery coefficients. ***Materials and Methods:*** A mathematical sphere model was applied to determine the oversize volume (in units of the PET spatial resolution) that contained 98% of the total activity. Experimental investigations involving phantom and clinical data were conducted to study the performance of the applied PVE correction approaches. All phantom measurements were performed in a novel PET/CT scanner using 12 spherical tumour-inserts (diameters of 3.7 to 37.4 mm) containing solution with $^{18}$F. Both PVE correction approaches were compared for various imaged signal-to-background ratios (20 to 3). Performance was evaluated based on percentage deviation between the PVE-corrected and the actual activity concentrations. In clinical application, both approaches were applied to images acquired with $^{18}$F-PSMA in patients with prostate cancer. ***Results:*** To reduce the contribution of background correction while containing at least 98 % of the total activity, we used an oversize-VOI diameter of two PET spatial resolutions larger than the physical sphere diameter. In comparison, the oversize-VOI approach showed a favorable performance for tumours below 10 mm in diameter, whereas the contour-VOI approach is more suitable for sizes above 10 mm. Both approaches were robust against varying phantom and clinical imaging conditions. ***Conclusion:*** The oversize-VOI approach is an accurate and easy to implement PVE correction approach, especially for small tumours, that may be used for pre-therapeutic tumour dosimetry. A systematic analysis of the influence of PET quantification approaches on tumour dose predictions is further warranted.

## EPS-239

### Investigating various parameters on the labeling efficiency of $^{67}$Ga-phytate and its absorbed dose estimation in humans based on mouse data

***z. bayat***[1], *N. Vahidfar*[2], *E. Saeedzadeh*[1], *M. Sadeghi*[3], *S. Farzanefar*[2];
*[1]Radiation Medical Engineering, Science and Research branch, Islamic Azad University, Tehran, Iran, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, Vali-Asr Hospital, Tehran University of Medical Sciences, Tehran, Iran, ISLAMIC REPUBLIC OF, [3]Medical Physics Department, School of Medicine, Iran University of Medical Sciences, Tehran, Iran, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** lymphoscintigraphy is one of the most considerable and common methods for early detection of breast cancer in the world.Among the routine radiopharmaceuticals for this purpose, [$^{99m}$Tc]Tc-phytate have been demonstrated remarkable results in pre-surgery detection of metastatic axillary

lymph nodes in clinical trials. According the longer half-life of $^{67}$Ga compared to $^{99m}$Tc (78.25 h versus 6 h), introducing and development of an appropriate alternative radiopharmaceutical including $^{67}$Ga for lymphoscintigraphy in order to extension of evaluation and surgery procedure time will be an important deal in the clinic.In this study radiolabeling of phytic acid with $^{67}$Ga was accomplished. Based on radioactive thin layer chromatography (RTLC), radiochemical purity (RCP) was estimated >99%.The final product represented satisfactory stability in human serum circumstances which was calculated >89% during 3 days of study. Pre-clinical studies confirmed urinary system as the main excretion way for the radiopharmaceutical.Finally human estimation dosimetry study based on preclinical data was reported. ***Materials and Methods:*** The radiochemical purity of the labeled compound was investigated at 100 degrees Celsius and at times of 1, 5, 10, 15, 20 and 30 minutes.All the experiments were done in a laboratory scale and repeated three times (n=3).Since the pH of the final product was acidic, NaHCO3 (0.1 M) was used to adjust pH=6-7. The radiochemical purity of the final compound was determined using thin layer radiochromatography (RTLC). ***Results:*** The results of the stability study of the labeled compound showed that this compound will still have a radiochemical purity higher than 89% even after 48 hours at room temperature and in human blood serum.(100 °C, 30 min, 10 mg phytic acid).The absorbed dose of different human organs after the injection of $^{67}$Ga-phytate labeled compound was estimated using the RADAR formulation based on the rat biodistribution data.The results of the dose evaluation show that most of the organs did not receive a relatively high dose, and the equivalent and effective dose in humans after the injection of the labeled compound $^{67}$Ga-phytate was estimated as 1.949 mGy/MBq and 0.015 mSv/MBq, respectively. ***Conclusion:*** In this study, after producing the labeled compound $^{67}$Ga-phytate with a radiochemical purity of more than 99% under optimal conditions, the biodistribution of the compound was investigated in healthy mice. The results showed that the marked compound has high accumulation in lymph nodes and kidneys.

## EPS-240

### Head-to-head comparison of $^{177}$Lu-DOTATATE dosimetry between high-speed 360° CZT-SPECT/CT and conventional SPECT/CT systems

***L. Imbert***, *C. Boursier, V. Roch, E. Chevalier, P. Marie;*
*CHU Nancy Hopital Brabois Adultes,*
*Vandoeuvre Les Nancy, FRANCE.*

***Aim/Introduction:*** $^{177}$Lu-DOTATATE is an efficient therapy for neuroendocrine tumors expressing somatostatin receptors. A drawback is a possible deleterious effect due to excessive absorbed dose (AD) by several critical organs, especially kidneys and bone marrow. These ADs may be determined through serial conventional SPECT (Conv-SPECT) recorded after $^{177}$Lu-DOTATATE injection, however recording times are too long for clinical routine. The aim of this study was to determine whether the ADs determined by a high-speed whole-body 360° CZT-SPECT camera are equivalent to those provided by Conv-SPECT in the same patients. ***Materials and Methods:*** Thirteen patients referred for $^{177}$Lu-DOTATATE treatment were enrolled and underwent, during a single treatment cycle and at 3 time-points (i.e., 24 hours, 96 hours and 7 days after $^{177}$Lu-DOTATATE injection), (i) a thoraco-abdominopelvic Conv-SPECT recording of 32 min, immediately followed by (ii) a whole-body CZT-SPECT recording of 18 minutes (1). Right and left kidneys, bone marrow and spleen were automatically segmented by an artificial intelligence-based tool on the CT acquisitions from each system recorded at 24 hours. Time-integrated activity curves, convolved by the voxel S value kernel, were computed with a well-validated dosimetry software to determine the AD from kidneys, bone marrow and spleen. Partial volume effect was corrected by fitting recovery coefficients with the volume's spheres from an IEC body phantom and with a 10/1 tumor-to-background ratio. The ADs from Conv-SPECT and CZT-SPECT were compared using paired Student's t-tests. ***Results:*** Mean ADs, determined in the 13 patients (6 women, 63±12 years-old, 25±4 kg.m$^{-2}$ body mass index) and expressed per MBq of injected $^{177}$Lu-DOTATATE, were not significantly different between Conv-SPECT and CZT-SPECT for kidneys (0.42±0.13 vs. 0.44±0.15 mGy/MBq, p=0.11), bone marrow (0.05±0.04 vs. 0.06±0.04 mGy/MBq, p=0.09), and spleen (0.53±0.29 vs. 0.55±0.28 mGy/MBq, p=0.57). ***Conclusion:*** This head-to-head comparison shows that the ADs determined after $^{177}$Lu-DOTATATE injection for kidneys, bone marrow and spleen with this 360° whole-body CZT-SPECT/CT system, are concordant with those obtained with a conventional SPECT/CT, but with the advantages of much shorter recording times and the added ability to determine AD on a whole-body scale. ***References:*** (1) Chevalier E, Boursier C, Claudin M, Marie PY, Imbert L. Feasibility of $^{177}$Lu Therapy Monitoring Using Fast Whole-Body SPECT Recordings Provided by a High-Speed 360° CZT Camera. Clin Nucl Med. 2020 Nov;45(11):e493-e494.

## EPS-241

### Validation of Lu-177 PSMA dosimetry from 113keV energy peak using digital 3D SPECT/CT imaging system

***H. Gröhn***, *M. Hakulinen, K. T. Tapani, T. M. Laitinen;*
*Kuopio University Hospital, Kuopio, FINLAND.*

***Aim/Introduction:*** Our clinical dosimetry protocol consists of two imaging sessions, 4h and 24h post Lu-PSMA treatment, and is based on Lu-177 208keV energy peak with analog SPECT/CT. Current imaging sessions are challenging for patients due to long acquisition time. Our new digital 3D SPECT/CT system allows markedly shorter (<50%) imaging time for the same anatomical coverage. However, the 3D SPECT/CT system utilizes 113keV energy peak instead of 208keV peak for Lu-177 imaging. The aim of this study was to validate the use of lower energy peak of Lu-177 for our clinical PSMA dosimetry protocol. ***Materials and Methods:*** Ten patients were scanned using both analog SPECT/CT utilizing 208keV energy peak and 3D digital SPECT/CT utilizing 113keV peak, 4h and 24h after Lu-PSMA treatment. Absorbed doses were calculated for kidneys and salivary glands based on MIRD dosimetry. Four raters drew VOIs based on experience from current protocol for both data sets. Then criteria for drawing VOIs were optimized for new dataset and VOIs were redrawn. Interrater variability was estimated using intraclass correlation coefficient (ICC) with two-way random effects, absolute agreement, multiple raters. Difference between means was evaluated using paired t-test. ***Results:*** Preliminary results from the first five patients are presented here. After optimizing VOI drawing criteria, interrater reliability increased both for kidneys (from ICC=0.96 [ 0.83-1.00, 95% confident interval] to ICC=0.99 [0.97-1.00]) and salivary glands (from ICC=0.84 [ 0.43-0.98] to ICC=0.99 [0.96-1.00]). At group level, there was no difference in absorbed doses between approaches utilizing different energy peaks (p=0.39 and p=0.66, kidneys and salivary glands, respectively). However, in some of the individual patients there were marked differences in absorbed doses up to 26% and 27% for kidney and salivary glands, respectively. ***Conclusion:*** Lu-PSMA dosimetry from 113keV energy peak gave promising results after optimizing VOI drawing criteria.

There was no significant difference between absorbed doses calculated from different peaks, nor trend towards consistently higher values with one of the approaches. The relatively large differences between approaches in some patients could be due to lack of experience in evaluating images from the new system with different reconstruction parameters and resolution. To validate in more detail the difference between approaches, we are currently measuring IQ phantom and analyzing already scanned patients. We are confident that after optimization and validation is completed, dosimetry with 3D digital SPECT/CT utilizing 113keV peak will become preferred method for clinical workflow saving scan time and increasing patient comfort.

## EPS-242

### Semiautomatic Segmentation for Tumour Dosimetry in PSMA Radiopharmaceutical Therapy using a Novel Digital Twins Framework

***R. Fedrigo***[1,2], *L. Polson*[1,2], *C. Li*[1,2], *S. Harsini*[1], *I. Bloise*[1], *J. Brosch-Lenz*[1], *B. Saboury*[3], *F. Bénard*[1,2,4], *A. Rahmim*[1,2,4], *C. Uribe*[1,2,4];

[2]*University of British Columbia, Vancouver, BC, CANADA,*
[3]*National Institutes of Health (NIH), Bethesda, MD, UNITED STATES OF AMERICA,* [4]*BC Cancer, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Prostate-specific membrane antigen radiopharmaceutical therapy (PSMA-RPT) has shown promising results for treating metastatic prostate cancer (mPCa). Conventionally, PET images are obtained for initial diagnosis and staging, while SPECT is used to quantify radiopharmaceutical uptake and monitor the effects of treatment in real-time. To gain understanding of dose-response relationships, a method that can aid in tumor segmentation is required. The aim of this study was to test qPSMA [1], a semiautomatic liver-based thresholding method for lesion segmentation, that is based on $^{68}$Ga-PSMA scans, and to determine new thresholds that can extend it to $^{18}$F-DCFPyL PET and $^{177}$Lu-PSMA-617 SPECT. ***Materials and Methods:*** Sixteen digital twins (i.e., very realistic digital versions of a patient) were created for two imaging paradigms: (i) $^{18}$F-DCFPyL, and (ii) $^{177}$Lu-PSMA-617, with 64 metastases positioned in the pelvis and abdomen. Data was simulated for a GE Discovery RX PET/CT with Ashrafinia 2017 code and Siemens Symbia SPECT/CT using Simind Monte Carlo. Images were processed using clinical parameters (8subsets,4iterations) and compared to 20-40 iterative updates. Lesions were segmented with qPSMA using population-based liver parameter; $SUV_{pop}$=4.3. We determined new $SUV_{pop}$=6.2 and 1.18 by analyzing images of 10 patients imaged with $^{18}$F-DCFPyL and $^{177}$Lu-PSMA-617, respectively. Lesion detection sensitivity was measured for each $SUV_{pop}$. We used Fisher's exact test to determine if differences observed with each $SUV_{pop}$ were statistically significant. We performed 8 noise realizations for each phantom and verified recovery coefficients (RCs) for total tumour activity. ***Results:*** Lesion detection sensitivity was 87.5% for the $^{18}$F-DCFPyL scans, which did not significantly differ for the modified threshold (p=0.80). In $^{177}$Lu-PSMA-617, detection sensitivity significantly increased from 12.5% to 65.6% (p<0.0001). Lesion quantification was most accurate for $^{18}$F-DCFPyL using clinical reconstruction parameters, with RCs of 16.3%, 56.9%, 84.9%, 79.6%, for the 4,8,12,16mm spheres, respectively. For $^{177}$Lu-PSMA-617 with the adjusted population threshold, RCs were 23.4%, 43.8%, 52.1%, 53.1% using 4 iterations, which increased to 8.3%, 57.8%, 89.2%, 87.5% using 20 iterations, for the 4,8,12,16mm spheres, respectively. ***Conclusion:*** The qPSMA method showed that adequate detection sensitivity and quantification can be obtained in 2-16mm PCa metastases. Performing additional iterative updates (20-40) in combination with an updated liver threshold, can greatly improve tumour quantification accuracy in $^{177}$Lu-SPECT. Overall, our results suggest that qPSMA tumour detection for dosimetry can be reliably performed with $^{18}$F-PET and $^{177}$Lu-SPECT imaging. This tool can help in closing the knowledge gap between absorbed dose and tumor response in RPTs. ***References:*** 1. Gafita, JNM, 60(9):1277-1283, 2019.

## EPS-243

### Does urinary excretion rate change over the courses of 177Lu-PSMA therapies ?

***L. Ferrer***[1,2], *M. CHABIRON*[3], *C. Rousseau*[1,2], *N. Varmenot*[1,2];
[1]*ICO René Gauducheau, St Herblain cedex, FRANCE,*
[2]*Nantes Université, Univ Angers, INSERM, CNRS, CRCI2NA, Nantes, FRANCE,* [3]*Nantes Université, Nantes, FRANCE.*

***Aim/Introduction:*** Patients with refractory metastatic prostate cancer (mCRPC) are referred to 177Lu-PSMA therapies. Some studies [1,2] have shown that patient's renal excreted mean activities can be as high as 80% of the initial injected activity in the first hours of this treatment. This study aims at assessing a patient's urine activity as a renal excreted activity surrogate and at evaluating its changes according to the therapy cycles'number. ***Materials and Methods:*** Patients with mCRPC were treated with one to six injections of 7.4 GBq 177Lu-PSMA between March-2022 and April-2023. The patient's normal renal function was assessed prior to any given treatment. Their urines were collected in 2L containers until they performed their first SPECT/CT examination 3 to 5 hours later. Each container was weighted without and with the urines on a scale (±5g) and 20ml samples were withdrawn and measured with a 177Lu-calibrated well counter. Urine's activity per unit of injected activity (%I.A) as well as its concentration per minute (rate_%I.A) were derived at the injection time. Statistical tests were conducted with Scipy's statistics module (v1.10.1). ***Results:*** Twenty-one patients benefited from 79 treatments (N = [21, 20, 15, 12, 7, 4] treated with 1 to 6 cycles). All urines were collected between the injection and the first imaging time with a delay of 280.6 min [±34.5 min]. The urine volume was 461.5 ml [±320 ml]. Two patients urinated more than 1000 ml (2 times). Neither the median %I.A [nor rate_%I.A] for all patients were different among the cycles: 18%, 21%, 20%, 17%, 25%, and 28% [0.09, 0.13, 0.11, 0.12, 0.13, 0.15 %/(L.min) resp.] for the cycle 1 to 6 respectively (Kruskal-Wallis p-value: 0.4 [0.49 resp.]). But some patients' treatment exhibited extreme values as low as 4% or as up to 43%. ***Conclusion:*** This study's findings are not completely in line with previously published data suggesting an incomplete vesical voiding. Nonetheless, we showed that the urine excretion did not change much from cycle to cycle regardless of tumor response to treatment. Further investigations are undergoing to extract urine activity from SPECT images and look after correlations with renal function indices. ***References:*** [1]: Kurth, J., Krause, B.J., Schwarzenböck, S.M. et al. External radiation exposure, excretion, and effective half-life in 177Lu-PSMA-targeted therapies. EJNMMI Res 8, 32 (2018). [2]: Demir M, Abuqbeitah M, Uslu-Beşli L, et al. Evaluation of radiation safety in (177)Lu-PSMA therapy and development of outpatient treatment protocol. J Radiol Prot. 2016 Jun;36(2):269-78

## EPS-244

### Outcome-Driven Assessment of Single-Time-Point Dosimetry for PSMA-Directed Radiopharmaceutical Therapy

***J. Hu***, *S. Xue, C. Vinicius Gomes Ferreira, L. Mercolli, A. Afshar-Oromieh, A. Rominger, K. Shi;*
*University of Bern, Department of Nuclear Medicine, 3008 Bern, SWITZERLAND.*

***Aim/Introduction:*** Single time point (STP) dosimetry is preferred in the practice of monitoring radiation dosimetry in radiopharmaceutical therapy. However, the current development of STP methodology is often guided by the assumed ground-truth of multiple-time-point (MTP) dosimetry. Unfortunately, MTP dosimetry is typically based on limited measurements and modeling, with no established common sense and limited accuracy. Considering the ultimate goal of dosimetry monitoring, we propose an alternative perspective to assess and develop STP dosimetry methodologies using treatment outcomes. ***Materials and Methods:*** 20 mCRPC patients with multiple $^{177}$Lu-PSMA-617 treatment cycles with SPECT/CT dosimetry measurements (2-4 h, and at least 2 time-point (TPs) of 24 h/48 h/72 h/4-9 days p.i.) were retrospectively included. STP dose-map generated with the measurements at different time points were generated using voxel dosimetry module (Version 1.1) from Hermes Medical Solution. Mean absorbed doses were estimated for organs at risk (OARs) and whole-body tumor, and corresponding individual cumulated dose (MTP/STPDose) for each therapy cycle were calculated. Therapy outcomes were evaluated by overall survival (OS), PSA response rate and toxicity assessment. The predictive accuracy of MTP/STPDoses for treatment outcomes and toxicity were analyzed. ***Results:*** Patients with greater OS than 18 months (9/20) had significantly higher tumor MTPDose ($p<0.05$), higher STPDose of 24h ($p<0.05$) and 4-9D ($p<0.02$). Patients with PSA reduction of ≥ 50% (17/20) had a significantly higher tumor MTPDose ($p<0.05$) and STPDose of 4-9D ($p<0.05$). For patients with hematotoxicity ≥ grade 3 (3/20), only bone marrow STPDose of 24h (Spearman's $r=.22$, $p<0.05$) was identified as independent indicators. ***Conclusion:*** Our study provides an alternative perspective for the investigation of STP dosimetry and our preliminary results suggested that late scan (>72h) is preferred for STP dosimetry while early scan (24h) is preferred for STP dosimetry for toxicity assessment. The current study was limited by the number of patients, which shall be improved in the follow-up study.

## EPS-245

### Comparison of the Images Taken at the 1st and 4th Hours After $^{99m}$TC-MAA Injection in $^{90}$Y TARE Treatment Planning

***B. Kovan***[1], *E. Işık*[1], *Y. Şanlı*[1], *S. Kuyumcu*[1], *B. Demir*[2];
[1]*Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE,* [2]*Istanbul University, Faculty of Science, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** In the treatment of $^{90}$Y Radioembolization, $^{99m}$Tc-MAA imaging is an important step in treatment planning and dose calculation. There may be changes in the activity distribution depending on time due to reasons such as the physical shape of MAA, its fragility, and due to free pertechnetate released from $^{99m}$Tc-MAA. In this study, the distribution of MAA in early and late imaging after $^{99m}$Tc-MAA application were evaluated. ***Materials and Methods:*** A total of 51 patients (22 F, 29 M, (60.86 years ±12.65)) diagnosed with HCC (n:22), mCRC (n:11), and liver metastases secondary to other malignancies (n:18) who were applied $^{99m}$Tc-MAA simulation application before $^{90}$Y microsphere treatment are included to the study. SPECT/CT imaging of the whole body and liver were performed within 1 hour after $^{99m}$Tc-MAA application. Whole body and SPECT imaging of the patients were repeated 3 hours after the first imaging. SPECT/CT images were analysed using a software. Perfused volume (PV) was detected in both images using the threshold values of 5% and 10%. In addition, lung shunt ratios (LSF) were determined from SPECT/CT images. Obtained values were compared with Student's T test. ***Results:*** Averages of LSF in the whole patient group were 4.59 (±4.19) and 6.00 (±4.67) in early and late imaging, respectively ($p:<0.01$). By using 10% threshold values, the mean PV was calculated as 559 cm$^3$ (±412) and 565 cm$^3$ (±421) in early and late imaging. Mean PV values by using 5% threshold values were calculated as 825 cm$^3$ (± 573) and 836 cm$^3$ (± 573) in early and late imaging ($p:<0.01$). ***Conclusion:*** In our study, it was determined that there were changes in the activity distribution in case of late imaging after $^{99m}$Tc-MAA application. When a comparison are made between In the early and late images, LSF values showed an average increase of 30.71%, and the highest increase was found to be 162% in late imaging. PV values by using 10% threshold increased by an average of 1% in late imaging, maximum increase was 40.77% and the maximum decrease was 16.66%. PV values increased by an average of 1.4% with a threshold of 5%, maximum increase was 33.02% and the maximum decrease was 14.42% in the late image. Since the differences in the late imaging of LSF and PV values change the dose calculations to be applied to the patient, imaging within the 1st hour after $^{99m}$Tc-MAA application provides a more accurate dose calculation.

## EPS-246

### Evaluation of a portable high-resolution gamma camera for personalized dosimetry during radioiodine treatment ofthyroid diseases

***T. Bossis***[1,2], *M. Verdier*[1,2], *L. Pinot*[1], *F. Bouvet*[1], *T. Beaumont*[3], *D. Broggio*[3], *S. Lamart*[3], *O. Caselles*[4], *S. Zerdoud*[4], *L. Ménard*[1,2];
[1]*IJCLab - CNRS/IN2P3, Université Paris-Saclay, Orsay, FRANCE,* [2]*IJCLab - CNRS/IN2P3, Université Paris Cité, Orsay, FRANCE,* [3]*Internal Dose Assessment Laboratory, IRSN, Fontenay-aux-Roses, FRANCE,* [4]*Institut Claudius Regaud, IUCTO, Toulouse, FRANCE.*

***Aim/Introduction:*** In the recent years, molecular radiotherapy has been in great expansion thanks to new radiopharmaceuticals for more targeted therapies or theranostic approaches. As for external radiotherapy, a patient specific planning and post-treatment control are strongly recommended. However, in clinical practice, personalized dosimetry is the exception rather than the rule. This is mainly due to a lack of dedicated imaging devices and standardized dosimetry protocols. In that context, we propose to develop a portable gamma-camera dedicated to reinforce dosimetry during radioiodine treatment of thyroid diseases. ***Materials and Methods:*** The performance of the gamma-camera was optimized for quantitative imaging with $^{131}$I. Its field of view is 10x10cm$^2$ and the detection of gamma-rays is done by a monolithic $CeBr_3$ scintillator coupled to a 16x16 SiPMs array. This detection module reaches an intrinsic energy resolution of 8% at 356keV and an intrinsic spatial resolution of 1.15mm, thanks to a convolutional neural network. Two high-energy parallel-holes tungsten collimators made with 3D printing were developed for treatment planning (high-sensitivity, HS) and post-treatment control (high-resolution, HR). The camera is shielded from background radiations to optimize signal-to-noise ratio for early imaging after treatment administration. The counting capability reaches 160kcps with negligible deadtime.

The camera is mounted on a mobile structure to adjust its position to the patient neck. An accurate sensitivity calibration was performed with cylindrical $^{131}$I sources of varying radius depending on the source distance and the attenuation media. The quantification performance was assessed with various 3D thyroid phantoms (from 3 to 30ml) by implementing different quantification protocols, optimized correction (scattering and attenuation) and delineation methods. ***Results:*** The sensitivity of the camera at a 5cm distance is 45 and 268cps/MBq and its spatial resolution is 5.2 and 10mm for the HR and HS collimator, respectively. The recovery coefficient measured with the thyroid phantoms ranges between 100 and 101% and between 98% and 104% with the HR and HS collimator, respectively. Optimal quantification was achieved when using an anterior view to measure the activity biodistribution combined with a lateral view for estimation of anatomical dimensions. ***Conclusion:*** We developed a high-resolution portable gamma-camera dedicated to thyroid quantitative imaging with $^{131}$I. Its optimized imaging features enable near 100% activity recovery coefficients to be achieved, even for small sources. The quantification performance on heterogeneous thyroid phantoms, mimicking toxic nodules or tumor remnants, will be also presented at the conference. ***References:*** Trigila et al. Phys. Med. Biol. 67 (2022) 035011

## EPS-247

### 3D Whole-Body SPECT images for dosimetry of $^{177}$Lu-PSMA treatment using a 360° CZT gamma camera

***L. Vergnaud***[1], *A. Giraudet*[2], *E. Paquet*[2], *T. Baudier*[1], *J. Badel*[1], *D. Sarrut*[1];
[1]*Centre Léon Bérard / CREATIS, Lyon, FRANCE,*
[2]*Centre Léon Bérard, Lyon, FRANCE.*

***Aim/Introduction:*** Monitoring and dosimetry of patients treated with $^{177}$Lu-PSMA require wide field of view SPECT/CT acquisitions (4-5 beds instead of 2) and therefore, a longer total acquisition time. This time can be reduced with 360° CZT gamma cameras which are more sensitive than conventional cameras. However, some detectors have a SPECT energy range of less than 200 keV while the 208 keV photopeak is recommended. For this type of detector, we tested the feasibility of dosimetry for patients treated with $^{177}$Lu-PSMA based on 3D whole-body SPECT images. ***Materials and Methods:*** Thirteen patients with castration-resistant metastatic prostate cancer were treated with $^{177}$Lu-PSMA at the Léon Bérard centre. They received between 1 and 6 injections of 6601±437 MBq of $^{177}$Lu at six week intervals. Three 3D whole-body SPECT/CT acquisitions were performed with a 360° CZT gamma camera after the first treatment at 4h, 24h and between 96h and 144h and then a single acquisition after each other treatment at 24h. Attenuation and scatter corrections were applied during the reconstruction process which includes 12 iterations and 8 subsets. For each time-point, a dose-rate map was calculated using low-statistic Monte Carlo simulations and CT-based contours of the organs at risk (kidneys, liver and spleen) were made to compute mean organ dose-rates. A tri-exponential function was used to model the time dose-rate curve and to estimate the absorbed doses by time integration. For cases with a single acquisition, the procedure used was described in article [1]. ***Results:*** Absorbed doses by left and right kidneys, liver and spleen for all cycles and all patients were 0.56 ± 0.19 Gy/GBq (mean ± std), 0.61 ± 0.18 Gy/GBq, 0.12 ± 0.10 Gy/GBq and 0.11 ± 0.07 Gy/GBq. The acquisition time is about 25 minutes for a 3D whole-body SPECT acquisition, three times less than with a conventional gamma camera (4-5 beds of 15 minutes). ***Conclusion:*** Dosimetry of patients treated with $^{177}$Lu-PSMA is feasible using 3D whole-body SPECT acquisition and gives results comparable to those in the literature although the acquisition time is reduced compared to conventional gamma cameras. ***References:*** [1] Vergnaud et al. ### Comparison of Model Implementations in SAAM II and MATLAB/SimBiology: a PBPK model for PRRT with [$^{177}$Lu]Lu-DOTATATE

***V. Vasic***[1,2], *J. Gustafsson*[3], *E. Yousefzadeh-Nowshahr*[1,2], *A. Beer*[1], *K. Sjögreen Gleisner*[3], *G. Glatting*[1,2];
[1]*Department of Nuclear Medicine, Ulm University Medical Centre, Ulm, GERMANY,* [2]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, Germany, Ulm, GERMANY,* [3]*Medical Radiation Physics, Lund University, Lund, Sweden, Lund, SWEDEN.*

***Aim/Introduction:*** Physiologically-based pharmacokinetic (PBPK) models allow simulation and prediction of the biodistribution of radiopharmaceuticals and have the potential to accomplish individualised treatment planning in molecular radiotherapy. In this work, the same model for peptide receptor radionuclide therapy (PRRT) with [$^{177}$Lu]Lu-DOTATATE is implemented and analysed in SAAM II (version 2.3, The Epsilon Group, Charlottesville, Virginia 22901, USA) and Simbiology (MATLAB version 2021a, The MathWorks Inc., Natick, Massachusetts 01760, USA). The concordance of the results is investigated to establish the performance of the model implemented in MATLAB. ***Materials and Methods:*** A PBPK model for a combined evaluation of [$^{68}$Ga]Ga-DOTATATE and [$^{177}$Lu]Lu-DOTATATE was developed and implemented in SAAM II and SimBiology. The data from 12 patients (8 males, 4 females, aged (65±12 years)) with low-grade metastatic neuroendocrine tumours were analysed retrospectively (1). Patients received (1.7 ± 0.4) pmol and (197 ± 48) MBq [$^{68}$Ga]Ga-DOTATATE and (10.26 ± 0.09) nmol and (7.46 ± 0.07) GBq [$^{177}$Lu]Lu-DOTATATE. Accurate dosimetry has been done previously (2), and the biokinetic data were used to fit the model parameters. Time-activity curves were calculated using both software and compared for (a) identical pharmacokinetic parameter values and (b) fitted parameter values. The absorbed dose (AD) for kidney, spleen, liver and lesions were calculated according to the MIRD guidelines (3). ***Results:*** Simulations with the same parameters gave maximum differences in ADs for kidneys, spleen, liver, and tumours of -14 mGy (0.25%), 23 mGy (0.17%), 5 mGy (0.12%), and 74 mGy (0.17%), respectively. The fitted parameters in both software were equal within the 95% confidence level. The Akaike Information Criterion (AIC) of the Simbiology/MATLAB fit was lower than that of the SAAM II fit. After fitting, the maximum differences in AD in kidneys, spleen, liver, and tumours were -0.17 Gy (3.4%), -0.29 Gy (4.0%), -0.07 Gy (1.9%), -1.84 Gy (17%), respectively. ***Conclusion:*** A model implemented in Simbiology/MATLAB is now available, which has been tested against SAAMII. The Simbiology/MATLAB model provides easy access to the calculation system and is, therefore, more flexible to changes in the primary functions and for future improvements. The differences reported after the fit is due to the different minimisation algorithms. Based on the AIC, the fit with the sbiofit function of MATLAB is better than the Rosenbrock fit of SAAM II. ***References:*** 1) Sundlöv et. al, Eur J Nucl Med Mol Imag. 2022;49:3830-3840 2) Stenvall et. al, EJNMMI Res 2022;12:75 3) Bolch et.al, J Nucl Med. 2009;50:477-84

### Current Practice in Reporting Internal Dosimetry for [177Lu]Lu-DOTA-TATE Therapy: Literature Review

***O. Ivashchenko***[1], *J. O'Doherty*[2], *T. Perez*[3], *J. Tran-Gia*[4], *E. Hippeläinen*[5], *M. Sandström*[6], *C. Stokke*[7], *G. Glatting*[8], *M. Cremonesi*[9];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*Siemens Medical Solutions, Malvern, PA, UNITED STATES OF AMERICA,* [3]*University Hospital of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, SPAIN,* [4]*University Hospital Würzburg, Würzburg, GERMANY,* [5]*University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND,* [6]*Uppsala University, Uppsala, SWEDEN,* [7]*Oslo University Hospital, Oslo, NORWAY,* [8]*Ulm University Hospital, Ulm, GERMANY,* [9]*European Institute of Oncology IRCCS, Milan, ITALY.*

***Aim/Introduction:*** Radionuclide therapy (RNT) has experienced rapid growth in recent years. Given the wide variety of mathematical techniques that can be used to calculate image-derived radiation absorbed dose, initiatives have been taken to standardise the reporting of dosimetry results, such as the EANM Dosimetry Committee guidance 2010. Clear guidelines are given about the minimum detail necessary to guarantee the reproducibility of published work and to make research comparable. EFOMP's SIGFRID workgroup on time-activity data fitting decided to review a selection of published papers on [177Lu]Lu-DOTA-TATE therapy (as showcase example) to evaluate the quality of reported parameters according to EANM guidance and to note whether sufficient data are provided to reproduce the methodologies presented. ***Materials and Methods:*** A retrospective meta-analysis was conducted. Articles in PubMed published up to December 17, 2022 focused on [177Lu]Lu-DOTA-TATE RNT, including tumour, renal dosimetry, used SPECT imaging, were searched. Subsequently, the results were screened for duplicates and refined using the following criteria: a clinical study with >=5 patients (no case reports) and the presence of dosimetric results. Each article meeting these criteria was reviewed and compared to the EANM Dosimetry Reporting Guidance. ***Results:*** A total of 110 articles were extracted, 46 of which met the search criteria. Of these, 93% fully complied with reporting guidelines for imaging equipment used, 85% image acquisition, 89% image processing, 85% corrections applied, 56% phantom and calibration measurements, 100% sequential imaging scheme, 82% time-activity fit type, 74% fit integration and extrapolation procedure, 63% reference dosimetry phantom used, 70% reported S-values used, 87% described tumour dosimetry calculation, 76% mentioned dosimetry software name, 100% reported absorbed doses, and 14% provided statistical error calculations. Only 21% of papers fully complied with the EANM guidance. ***Conclusion:*** Although EANM guidelines for clinical dosimetry reporting have been in place for more than 13 years, these recommendations are insufficiently implemented in articles on RNT dosimetry. While data collection information is well documented, details on actual dosimetric calculations are scarce. To establish reproducible and comparable RNT dosimetry studies, quality criteria for RNT dosimetry reporting must be adopted and enforced by major nuclear medicine and medical physics journals, as has been done, for example, in radiomics, AI, and radiochemical nomenclature.

### Clinical dosimetry in [177Lu]Lu-PSMA therapy: kidney mean absorbed dose difference between subsequent cycles

***E. Owers***, *E. Rijkhorst, M. Dotinga, L. J. de Wit-van der Veen, D. M. V. de Vries - Huizing;*
*Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Peptide radioligand therapy (PRLT) is an established treatment for stage IV metastatic castration resistant prostate cancer (mCRPC). Most studies to date have implemented a standard therapeutic activity of 7.4 GBq [177Lu]Lu-PSMA per cycle without any personalised dosimetric considerations. By introducing dosimetry, the maximum dose to normal tissue can be determined, thereby allowing a personalised approach. However, post-therapy scans required for individual dosimetry are resource consuming and taxing on the patient. Therefore, an optimal clinical regimen must be determined to overcome these aspects. This study aims to determine differences in the kidney mean absorbed dose (MAD) between the first and second therapy cycle in patients with mCRPC. ***Materials and Methods:*** In this retrospective analysis, a total of 37 patients with mCRPC were included. All patients had progressive disease with an indication for PRLT and were treated with 7.4 GBq [177Lu]Lu-PSMA-I&T under our standard protocol with 2 administrations injected 2 weeks apart. Post-treatment SPECT/CT imaging was performed after 24 hours and 5-7 days. Segmentation of the kidney cortex on low-dose CT and calculation of the dose-rate (convolution kernel) was performed in PLANET Onco and Dose (DOSIsoft), after which a mono-exponential fit was used to determine the MAD. The MAD averaged over both kidneys was used for analysis to exclude intra-patient bias. The difference ΔMAD in Gy/GBq between the subsequent treatment cycles was evaluated using Bland-Altman analysis and the reliability using the intraclass correlation coefficient (ICC, two-way random effects, absolute agreement). ***Results:*** The median kidney MAD was 0.44 Gy/GBq [interquartile range (IQR) 0.35-0.68] and 0.46 Gy/GBq [IQR 0.38-0.63] for cycle 1 and cycle 2, respectively. The median of the ΔMAD between cycles was -0.03 Gy/GBq [IQR -0.10-0.08]. With respect to the dose in Gy/GBq, the bias was -0.009 ± 0.097 Gy/GBq [95% limits of agreement -0.200-0.181] with an ICC of 0.856 [95% CI 0.738-0.923]. ***Conclusion:*** The difference in kidney MAD between the first two cycles was limited and showed a good reliability. This suggests that the kidney MAD of the first treatment cycle can be used as an estimate of the kidney MAD of the second cycle. This could allow the omission of post-therapy imaging after the second therapy cycle in this patient population and treatment protocol. However, in case of any clinical changes that could lead to differences in kidney kinetics and uptake, post-therapy imaging should be repeated after the second therapy cycle.

## EPS-251

### Implementation of an 18F PET / 177Lu SPECT Phantom Study for Personalized Theranostics in PSMA Radiopharmaceutical Therapies

***R. Fedrigo***[1,2], *J. Tran-Gia*[3], *J. Brosch-Lenz*[1], *P. Petric*[4], *L. Fougner*[1], *K. Sabo*[4], *R. Ralea*[5], *S. Harsini*[1], *I. Bloise*[1], *J. Beauregard*[6], *F. Bénard*[1,2,4], *A. Rahmim*[1,2,4], *C. Uribe*[1,2,4];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA,* [3]*University of Würzburg, Würzburg, GERMANY,* [4]*BC Cancer, Vancouver, BC, CANADA,* [5]*Vancouver General Hospital, Vancouver, BC, CANADA,* [6]*Laval University, Laval, QC, CANADA.*

***Aim/Introduction:*** The development of prostate-specific membrane antigen (PSMA)-targeting radiopharmaceuticals has shown the promising capabilities of theranostics in diagnosing and treating metastatic prostate cancer (mPCa). PET imaging is used to verify that the target is present (diagnosis), while SPECT is used to monitor radiopharmaceutical uptake and perform dosimetry calculations during therapy. The aim of this work was to develop a first-of-its-kind theranostics phantom for $^{18}$F-PET and $^{177}$Lu-SPECT imaging, such that the information from the higher quality PET images can be used towards improving image-based dosimetry with SPECT. ***Materials and Methods:*** Our $^{18}$F/$^{177}$Lu theranostics phantom consisted of re-purposed shells from the Probe-IQ [1] and Q3P [2] phantoms to model the thorax and head, respectively. A fillable liver and two-compartment kidney were 3D-printed based on ICRP templates (Tran-Gia 2021). To ensure reproducible comparison between $^{18}$F-PET and $^{177}$Lu-SPECT, a negative-cast modeling technique was used to create small target regions (24 metastases, 4 salivary glands) that were simultaneously prepared with $^{18}$F and $^{177}$Lu. Due to the short half-life of $^{18}$F relative to $^{177}$Lu, the $^{18}$F activity was imaged with a GE Discovery MI PET/CT (2.5min/bed), followed by $^{177}$Lu acquisitions with a Siemens Symbia SPECT/CT (15s/projection). Images were reconstructed using OSEM (8subsets, 1-12iterations, 6.4mm) with attenuation and scatter correction. Regions-of-interest were segmented using 20-60% of $SUV_{max}$ fixed thresholding and recovery coefficients (RCs) were computed for total activity. Recovery factors will be determined for converting RCs between $^{18}$F-PET and $^{177}$Lu-SPECT acquisitions, and to improve detection of low-contrast lesions for $^{177}$Lu-SPECT. ***Results:*** We report initial results for our $^{18}$F-PET images, though analysis and comparison of $^{177}$Lu-SPECT scans will be released shortly. Applying our diagnostic $^{18}$F-PSMA PET/CT protocol, we found that accurate kidney and liver quantification can be achieved using 5% and 15% fixed thresholds, with RCs 96.1±0.2% and 99.4±0.6%, respectively. Threshold-based activity quantification was reasonably accurate for salivary glands (73.0±0.1% to 122.4±0.7%) and mid-sized tumours (107.1±0.9% and 98.5±3.5% for 14,16mm), but consistently overestimated metastases <10mm. ***Conclusion:*** Our initial results show that threshold-based activity measurements may be used for $^{18}$F-PET quantification of larger organs (i.e., kidneys, liver), although more robust segmentation methods may be needed for smaller glands and metastases. Our next steps include correlating recovery factors between $^{18}$F-PET and $^{177}$Lu-SPECT for better mass estimation needed for dosimetry, and incorporating lesions that can be detected by PET but missed in SPECT scans for improved dosimetry calculations. ***References:*** 1. **An Update on Normal Tissue Absorbed Doses for Patients Treated with [$^{177}$Lu]Lu-lilotomab satetraxetan; Results From Two Studies**
***J. Blakkisrud***[1,2], *A. Løndalen*[1], *R. Midthun*[1], *C. Stokke*[1,3];
[1]*Oslo University Hospital, Oslo, NORWAY,* [2]*University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,* [3]*University of Oslo, Oslo, NORWAY.*

***Aim/Introduction:*** [$^{177}$Lu]Lu-lilotomab satetraxetan is an anti-CD37 antibody radionuclide conjugate developed to treat B-cell non-Hodgkin lymphoma. Liver, spleen, kidney and red bone marrow (RM) are known source organs for this treatment, and RM is the primary organ at risk. Previously we have reported absorbed dose for patients in the LYMRIT 37-01 phase I/IIa-trial [1]. The current work presents absorbed dose to normal tissues in the two studies LYMRIT 37-01 phase IIb, and the activity escalation trial LYMRIT 37-07. The latter included [$^{177}$Lu]Lu-lilotomab satetraxetan in combination with rituximab. ***Materials and Methods:*** Ten patients from the LYMRIT 37-01 phase IIb (n = 4) and the LYMRIT 37-07 (n = 6) were included for dosimetry. In both trials pre-dosing with unlabelled lilotomab was given. In the LYMRIT 37-01 phase IIb trial patients were randomized into receiving either 100 mg/m$^2$ body surface area of lilotomab and 20 MBq/kg body mass of [$^{177}$Lu]Lu-lilotomab satetraxetan or a fixed amount of 40 mg lilotomab and 15 MBq/kg body mass of [$^{177}$Lu]Lu-lilotomab satetraxetan. In LYMRIT 37-07, patients were either given 10, 15 or 20 MBq/kg body mass of [$^{177}$Lu]Lu-lilotomab satetraxetan. Organ level absorbed dose calculations were performed based on four SPECT/CT-scans nominally conducted 4, 24, 96 and 168 hours post administration. Absorbed dose to RM was calculated using the lumbar vertebrae L2-L4. Two patients, one in each trial, were excluded from RM-dosimetry due to previous external beam radiation therapy to the lumbar area. ***Results:*** Median absorbed doses for liver, spleen and kidneys in the two arms of the LYMRIT 37-01 IIb trial were 0.97, 1.40 and 0.58 mGy/MBq (100 mg/m$^2$ lilotomab), and 0.72, 2.67 and 0.47 (40 mg lilotomab). Median absorbed doses per administered activity for liver, spleen and kidneys in the LYMRIT 37-07 trial were 1.01, 2.38 and 0.58 mGy/MBq, respectively. Across both studies, liver, spleen, and kidneys received absorbed doses below 2.0, 3.7 and 1.2 Gy, respectively. In the LYMRIT 37-01 phase IIb trial, the median absorbed doses to RM were 0.73 mGy/MBq (100 mg/m$^2$ lilotomab) and 0.91 mGy/MBq (40 mg lilotomab). For RM, absorbed dose per administered activity was 0.84 mGy/MBq in the LYMRIT 37-07 trial. ***Conclusion:*** The absorbed doses to normal tissues for LYMRIT 37-01 phase IIb patients treated with [$^{177}$Lu]Lu-lilotomab satetraxetan were in agreement with phase I/IIa results. The addition of rituximab in the LYMRIT 37-07 study did not significantly change the biodistribution. ***References:*** 1) Stokke et. al EJNMMI 2018(45)

## OP-832

### Absorbed Doses to Kidneys and Tumours for Alpha-Emitter Peptide Receptor Radionuclide Therapies Estimated with [$^{177}$Lu]Lu-DOTATATE SPECT Images and Biokinetic Models

***M. Kvassheim***[1,2], *J. Blakkisrud*[1,3], *M. E. Revheim*[4,2,5], *A. J. Tulipan*[4,6], *C. Stokke*[1,7];
[1]*Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [2]*Faculty of Medicine, University of Oslo, Oslo, NORWAY,* [3]*University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA,* [4]*Department of Nuclear Medicine, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [5]*The Intervention Centre, Oslo University Hospital, Oslo, NORWAY,* [6]*Nuclear Medicine/PET center, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY,* [7]*Department of Physics, University of Oslo, Oslo, NORWAY.*

***Aim/Introduction:*** Alpha-emitter therapies are proposed for patients with tumours requiring higher and more localised absorbed doses than practical and feasible with beta-emitters. Insight into expected absorbed doses to organs at risk and tumours from different alpha-emitters for a carrier might guide the choice of radionuclide. To estimate absorbed doses to kidneys and tumours for potential alpha-emitter somatostatin receptor therapies, we utilised [$^{177}$Lu]Lu-DOTATATE as a surrogate for alpha-emitters $^{212}$Pb, $^{212}$Bi, $^{213}$Bi, $^{211}$At, $^{225}$Ac, $^{227}$Th, and $^{149}$Tb, and modelled redistribution of released radioactive daughters. ***Materials and Methods:*** Post-therapy SPECT/CT (day 0, 1, 4, and 7) images from six patients receiving their first fraction of [$^{177}$Lu]Lu-DOTATATE were analysed to estimate time-activity-curves for kidneys, livers, spleens, and tumours. The corresponding kinetics were simulated for alpha emitters assuming biological behaviour was unaffected by the radionuclide substitution. Redistribution of daughters was modelled with IDACAlpha (ABX-CRO) using patient specific uptake data, allowing dose estimations for a range of daughter retention values. The uptake values of the specified organs were subtracted from whole body retention constructed from probe measurements. This remaining activity was assumed to reside in the 'other' compartment in the biokinetic model, with instant uptake and two retention coefficients. To estimate the ratio of daughters to parents at injection, a parent half-life was assumed to pass from production to injection. Absorbed doses from alpha and beta radiations were calculated, with the CT-defined mass and assuming local energy deposition (1). ***Results:*** Setting z as the fraction of daughters released from the carrier and leaving the tumour before decaying, and y as the fraction released from the carrier in normal tissues, the tumour-to-kidney absorbed dose ratio is: tumour-to-kindey absorbed dose ratio = (A+(1-z)×B) / [(C+(1-y)×D)+y×E+z×F], with A and B as the parent and daughter contributions to dose in the tumours, respectively, and C and D as the parent and daughter contributions to dose in the kidneys, respectively. E and F are the modelled dose contributions from free daughters, from normal tissues and tumours respectively, to the kidney. F was mostly negligible (<7% of E). ***Conclusion:*** The physical half-life of the radionuclide and redistributing daughters released from their carriers are the main factors influencing the tumour-to-kidney absorbed dose ratio. For some alpha-emitters, daughters may contribute strongly to the kidney dose, while for others it will have a smaller effect. ***References:*** (1) ICRP. Nuclear Decay Data for Dosimetric Calculations. ICRP Publication 107 Annals of the ICRP. 2008; 38 (3).

## OP-833

### Comparison of Commercial Software Solutions for $^{177}$Lu Labelled Radiopharmaceutical Therapies

***S. Beykan****, M. Lassmann, S. Schlögl;*
*University Hospital Würzburg, Würzburg, GERMANY.*

***Aim/Introduction:*** Dosimetry is an important tool for determining safety and efficacy of radiopharmaceutical therapies and requires robust and reliable software solutions. The main aim of this project was to create a measured phantom data set for testing the dosimetry calculation process and suggesting improvements or additional features. ***Materials and Methods:*** A NEMA phantom with 6 spheres ($^{177}$Lu activity concentration per sphere: 2.14 MBq/ml) was used for analysis of three commercial software solutions. SPECT/CT scans were acquired at 1,8,12 and 19 d post-injection with two Siemens SPECT/CTs with different crystal thicknesses. The phantom positioning was identical except at 8 d post-injection for one camera (test 1) (phantom rotation: 180°). To simulate kidney time-activity curves of a patient, the phantom was scanned five times at day 1 post-injection by using different acquisition durations (test 2). Test 1 aimed to check the ability of the software to convert count-based images to activity-based images with variable scan-dependent image calibration factors (ICFs) (use case: different cameras are used for same patient). Test 2 tested the user-freedom to manipulate e.g. acquisition times and the ability to integrate time-activity values that increase and decrease. All scans were reconstructed with FLASH-3D and xSPECTquant with attenuation and scatter correction without post-filtering. The alignment, segmentation and fitting were checked for both reconstructed data sets. The resulting activities, fitting parameters, time-integrated activity coefficients (TIACs) and absorbed doses (ADs) were compared to the reference. ***Results:*** All programs were able to work with count-based images and apply variable ICFs. For high differences in positioning, either manual scan or manual segment alignment was required instead of automatic alignment. Editing the drawn segment for each SPECT and CT scan individually and using 2 different segments for the same organ to quantify the activity and the volume was possible for all programs. 2/3 programs allowed manipulation of acquisition times for test 2. For test 1 and all programs, the relative differences in the activities, TIACs and ADs were <±4.7%, similar to the activity calculations for test 2. Nevertheless, a large heterogeneity in the fitting process was observed in test 2. Relative differences in TIACs of 10% and <120% were obtained for 2/3 programs. ***Conclusion:*** Independent of the dosimetry-software, imaging protocols, segmentation, alignment and fitting impact the dosimetry results considerably. Performing similar workflows result in differences in the same order of magnitude. Improvements especially with respect to fitting would be desirable for all software solutions.

## OP-834

### Determination of the treatment coverage of theragnostic $^{124}$I-8H9 antibody to treat diffuse pontine glioma by convective enhance delivery

***A. França Velo***[1], *A. Giantini Larsen*[2,3], *J. Humm*[1], *P. Zanzonico*[1], *M. Souweidane*[3], *N. Pandit-Taskar*[4];
[1]*Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Department of Neurosurgery, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [3]*Department of Neurological Surgery, Weill Medical College of Cornell University, New York, NY, UNITED STATES OF AMERICA,* [4]*Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** The aim of this study was to evaluate intra-lesional distribution and dosimetry of an $^{124}$I-labeled antibody administered by convection-enhanced delivery (CED) in diffuse intrinsic pontine glioma following treatment. ***Materials and Methods:*** Patients from a phase 1-2 trial underwent MRI scans and serial PET-CT scans at multiple times; on average 3 (immediately after, 24 and 48 hr) following infusion by CED. In this study, $^{124}$I was used both as the diagnostic PET isotope and the therapeutic isotope. The brain stem lesions were delineated on the MRI scans using MIM Sureplan MRT by a neurosurgeon and nuclear medicine physician and saved as RT structures. Similarly, the distribution volume of the injected radiotracer from the PET scan was segmented using a 42% threshold. The volumetric intersection between the PET and MRI delineations were calculated and represent the percentage coverage of the target volume. Worth to mention that all calculations are based on a single injection using a single catheter. Using a MIM workflow, the PET/CT images were co-registered and used to generate voxelwise absorbed dose distributions. Dose volume histograms were calculated from the activity distribution to the target volume. ***Results:*** The dosimetry was performed for 38 patients with diffuse intrinsic pontine glioma. The range of administered activity was from 8.8 to 369 MBq. The overlap of the MRI target volume by the PET volume ranged from 22 to 95% with a median of 83%. The median and maximum absorbed doses to the overlap volume ranged from 5.06 to 55.6 Gy and 15.2 to 165 Gy respectively, depending upon the treatment activity and therefore the infuscate volume and the target volume. In 21 of 38 patients, the coverage volume was greater than 80%. ***Conclusion:*** Our study showed that CED allows for distribution and radiation delivery to large parts of the tumor of a therapeutic absorbed doses objective. These are the first data to quantitively assess the accuracy of coverage of intra-lesional CED of a targeted radioimmunotherapy. ***References:*** Souweidane MM, Kramer K, Pandit-Taskar N, Zhou Z, Haque S, Zanzonico P, Carrasquillo JA, Lyashchenko SK, Thakur SB, Donzelli M, Turner RS, Lewis JS, Cheung NV, Larson SM, Dunkel IJ. ## OP-835

### Accuracy of single-time-point dosimetry using a population-based model selection and Bayesian fitting method

***B. Patrianesha***[1], *A. Jundi*[1], *M. Naqiyyun*[2], *D. Hardiansyah*[1]; *[1]Medical Physics and Biophysics Research Group, Physics Department, Faculty of Mathematics and Natura, Depok, INDONESIA, [2]Nuclear Medicine Department, MRCCC Siloam Hospital, Jakarta, INDONESIA.*

***Aim/Introduction:*** Population-based model selection with shared parameters (SP-PBMS) performed better in calculating the time-integrated activity (TIAs) compared to the individual model selection (IBMS) [1]. The aim of this study was to investigate the accuracy of single-time-point (STP) dosimetry using SP-PBMS and Bayesian fitting (BF) method. ***Materials and Methods:*** Biokinetic data of $^{177}$Lu-DOTATATE in kidneys were obtained from the literature [2]. In brief, the biokinetics in the kidneys were collected using SPECT/CT after injection of (6.9±1.1) GBq of $^{177}$Lu-DOTATATE at either two (N=4) or four (N=8) time points. The sum of exponentials (SOE) function $A_1/\{((1-\alpha)/(\lambda1+\lambda phys))-(\alpha/(\lambda2+\lambda phys))-((1-2\alpha)/(\lambda bc+\lambda phys))\}$ $e^{-\lambda phys(t)}$ $\{(1-\alpha)e^{-\lambda1(t)}-\alpha e^{-\lambda2(t)}-(1-2\alpha)e^{-\lambda bc(t)}\}$ which was selected as the best model for the kidney data of $^{111}$In-DOTATATE in the literature [3] was used as the basic structure of the mathematical model in our study. The function parameters were fitted to all-time-point data with different combinations of parameter settings, i.e. as shared-fitting, individual-fitting and fixed parameter as reported in the literature [3]. The best combination of parameter settings was selected using the SP-PBMS method based on the Goodness-of-fit, i.e. visual inspection of the fitted curves and the coefficient of variations of the fitted curves <0.5, and the Akaike weight. The SOE function with the best parameter setting from SP-PBMS (SOE-SP-PBMS) was used to derive reference time-integrated activities (rTIAs). The STP with BF Method and the SOE-SP-PBMS was done with Jackknife at time point that has been shown as the best time point for STP dosimetry, i.e. (99.8 ± 1.5) p.i. [2], to determine the predicted time-integrated activity (pTIAs). The accuracy of STP dosimetry was assessed by calculating the relative deviation (RD) and root-mean-square error (RMSE) between rTIAs and pTIAs. ***Results:*** Parameter setting with shared-fitting of λ2, individual-fitting of A1 and λ1, and fixed value of α to the literature value for $^{111}$In-DOTATATE was selected as the SOE-SP-PBMS. The RD and RMSE of the SOE-SP-PBMS at (99.8 ± 1.5) p.i. between pTIAs and rTIAs was (1.4±16.9) % and 16.9%, respectively. ***Conclusion:*** In this study, we showed the accuracy of STP dosimetry in PRRT using the SP-PBMS and BF methods. This approach could be a beneficial recommendation for clinicians to improve patient care while lowering costs and improving overall treatment efficiency. ***References:*** [1]D. Hardiansyah, et al., Z. Med. Phys., pp. 1-9, 2023, doi: 10.1016/j.zemedi.2023.01.007.[2]T. P. Devasia, et al., J. Nucl. Med., vol. 62, no. 8, pp. 1118-1125, 2021, doi: 10.2967/jnumed.120.256255.[3]D. ## OP-836

### AI-Generated Synthetic Intermediate Projections could enable SPECT-based bone marrow dosimetry with reduced acquisition time

***K. Smits***[1], *F. Westerbergh*[1], *J. Hemmingsson*[1], *J. Svensson*[2], *T. Rydén*[3], *P. Bernhardt*[1,3]; *[1]Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN, [2]Department of Oncology, Institution of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN, [3]Department of Medical Physics and Biomedical Engineering (MFT), Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

***Aim/Introduction:*** Over the last few years, the number of patients treated with [$^{177}$Lu]Lu-DOTATATE has rapidly increased. However, clinical resources are limited, making shorter acquisition times desirable. Short acquisitions are problematic in vertebral bone marrow dosimetry, as the low signal results in significant degradation from noise. The aim of this study was to determine if synthetic intermediate projections (SIPs) could be used to compensate for the loss of image quality caused by a decreased acquisition time, by examining different clinically realistic noise levels. ***Materials and Methods:*** A Jaszczak phantom with spherical inserts was filled with a sphere-to-background activity concentration ratio of 5:1 (0.937:0.191 MBq/mL of 177Lu). The phantom was imaged with a GE Discovery NM/CT 670 Pro system (120 projections, 66 s per projection). The four largest spheres (2-16 mL) were analysed based on their size being roughly the same as the volumes-of-interest used for vertebral delineation. Poisson-distributed noise was added to the SPECT

projection data (10%, 5%, 1%, 0.5%, and 0.1% relative to the true acquisition time) to mimic noise levels observed in the vertebral (T8-L5) bone marrow in 177Lu-DOTATATE patients examined 24 h p.i. (n = 16). Thus, five noise levels were obtained, ranging from the maximum concentration observed in patients to 60% of the minimum. Thirty realizations were generated for each noise level. The images were reconstructed using a Monte Carlo-based OSEM algorithm (6i10s), with either 120 projections, 30 projections, or 30 projections + 90 SIPs. Recovery coefficient (RCs) and uncertainties (coefficient of variation) of the RCs were determined for each reconstruction method. ***Results:*** The uncertainties for SIPs, 120 projections and 30 projections for the 2 mL-sphere were 50%, 98%, and 267%, respectively. The corresponding values for the 16 mL-sphere were 26%, 22%, and 53%, respectively. When including SIPs, RCs tended to decrease with increasing noise, indicating a greater loss of resolution at high noise levels. ***Conclusion:*** When using conventional projections and small spheres, high variations were observed between realizations, risking large quantitative errors when calculating the absorbed dose. With larger spheres, the uncertainties decreased substantially, indicating that the smallest bone marrow cavities are less appropriate for bone marrow dosimetry. The loss of resolution obtained at higher noise levels might decrease the quantitative accuracy for SIPs reconstructions. Nevertheless, for larger volumes, uncertainties were similar for SIPs and 120 projections, highlighting SIPs potential to improve bone marrow dosimetry for SPECT protocols with sparsely acquired projections.

### RPT-TEC assessment of normal organ toxicity avoidance thresholds for alpha-emitter radiopharmaceutical therapy - an appeal for data.

***J. Hesterman***[1], *R. Hobbs*[2], *G. Sgouros*[2], *Radiopharmaceutical Therapy Normal Tissue Effectsin the Clinic (RPT-TEC);*
*[1]Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA, [2]Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** To determine the normal organ toxicity avoidance (NOTA) dose thresholds for alpha-emitter radiopharmaceutical therapy (αRPT). ***Materials and Methods:*** The inaugural Radiopharmaceutical Therapy Normal Tissue Effects in the Clinic (RPT-TEC) meeting was held in September 2022 to establish NOTA dose thresholds in approved radiopharmaceutical therapy (RPT), consistent with previous projects for external beam NOTA thresholds, QUANTEC and HyTEC. A committee, consisting of physicists and clinicians from industry and academia, was formed to pursue the determination of thresholds specifically for αRPT. A three-phase approach was identified. First, characterization of available clinical data to increase understanding of the relationships between administered activity (AA), absorbed dose (AD), and toxicity. Second, application of robust, existing methods to compute consistent whole organ dosimetry values, particularly for cases with observed toxicity. These data are used to determine an interim set of NOTA dose thresholds, based on whole organ EQD2 and BED. Third, extending existing dosimetry methodology specific to the concerns of αRPT, including RBE, daughter radionuclides, and small-scale modeling with standardized apportionment factors. ***Results:*** An assessment of existing clinical αRPT evidence revealed a lack of data. While studies assessing long-term safety and/or administered activity escalation of $^{223}$Ra-dichloride exist[1-3], inter- and intra-patient data spanning AA, AD estimates, and toxicity are unavailable. These limitations extend to other αRPTs. Only 11 publications were identified that include dosimetry values estimated directly from administered alpha therapy in people. Generally, minimal toxicity is reported. Related biomarkers, important to extending understanding of individual radio-sensitivity, are lacking. New clinical trials should bring new data. A clinicaltrials.gov search of the "Hopeful Eight" αRPT radionuclides[4] identified 176 alpha therapy trials, of which 45 have a "Start Date" within the last three years and only 26 with results reported. Additionally, 115 trials are funded by industry with 19 unique industry sponsors represented. Early phase trials must include dosimetry, making them essential to generating AA, AD, and toxicity data capable of supporting NOTA dosimetry. A reporting template has been developed and disseminated to industry and academic groups to facilitate the collection of these data. ***Conclusion:*** There is an urgent need to improve collection and standardization of intra- and inter-patient administered activity, absorbed dose, and toxicity data in αTRT. Clinical workflows and early phase clinical trials must acquire and report these data consistently to improve our understanding of αRPT dose-response relationships, thus enabling a NOTA dose threshold paradigm. ***References:*** 1. 10.1016/j.eururo.2017.06.021, 2. 10.1056/NEJMoa1213755, 3. 10.3389/fmed.2022.1070392, 4. 10.3390/pharmaceutics13060906

## OP-838

### Impact Of Small Patient Motion During SPECT/CT Scans Onto Activity Quantification Of $^{177}$Lu-PSMA Based on A Phantom Simulation

***S. Resch***[1], *X. Shen*[1], *M. Reymann*[2], *F. Basi Massanes*[3], *P. Bartenstein*[1], *G. Platsch*[2], *A. Vija*[3], *G. Böning*[1], *A. Delker*[1];
*[1]LMU Klinikum Großhadern, München, GERMANY, [2]Siemens Healthcare GmbH, Molecular Imaging, Forchheim, GERMANY, [3]Siemens Medical Solutions UNITED STATES OF AMERICA Inc., Molecular Imaging, Hoffman Estates, IL, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** $^{177}$Lu-PSMA patients commonly suffer from progressing bone metastases causing severe pain. Thus, lying still during long SPECT scans (>20min.) can be difficult and uncomfortable. To alleviate pain, they may perform sudden movements, which distort the activity distribution, the quantification and ultimately the dosimetry. The aim of this preliminary study was to investigate the impact of this sudden motion onto the recovery coefficients (RCs) of a simulated NEMA body phantom. ***Materials and Methods:*** The NEMA body phantom (sphere-to-background ratio 8:1, 781MBq $^{177}$Lu-solution) was used as input for the SIMIND Monte Carlo program (128 projections, 5 and 15s acquisition times, 256x256 pixels, Symbia Intevo T16 (Siemens Healthineers) SPECT/CT, MELP collimator, emission peak at 208keV, width 15% plus lower and upper scatter windows). In addition to a baseline tomography (BL), different positions of the phantom were simulated (shifted 5, 10, 20mm in lateral and anterior direction). These simulations were stacked together randomly, creating different motion-affected tomographic data sets. It is assumed that the phantom moves instantaneously to a shifted position, remains there for a motion duration (MD) of either 5 or 15s, and moves back instantaneously. The mean motion frequency (MMF) was randomly sampled from a normal distribution with a mean of 1/60 or 1/120s$^{-1}$ ($\sigma$ = 10%), allowing for a motion at any time during the scan. Motion magnitudes and directions were randomly chosen from the simulated parameter sets. Ten different scans per parameter combination were generated leading to 240 reconstructions in total. The RCs of the three largest spheres (37, 28, 22 mm diameter) and their

deviation from the BL data were calculated. ***Results:*** The RCs of the BL are 0.84, 0.80, 0.69 and 1.00, 0.88, 0.64 for decreasing sphere size and 5 and 15s acquisition times, respectively. Assuming a MMF of 1/60s$^{-1}$ and a MD of 15s, the RCs deviated from the BL by -4, -18, -27% and -9, -11, -9% for acquisition times of 5 and 15s, respectively. The latter changed to -4, -6, -3% for half the MMF (1/120s$^{-1}$). Reducing the MD to a third (5s) with a MMF of 1/60s$^{-1}$ and an acquisition time of 15s resulted in deviations of -5, -7, -6%. ***Conclusion:*** This preliminary study shows that small, even visually non-detectable motions, can lead to strong distortions of the activity quantification during $^{177}$Lu-PSMA SPECT/CT scans. These results motivate further simulations, evaluations of the motion parameters and their impact on quantification and dosimetry.

## OP-839

### Comparison of transmission-dependent and energy-window based scatter correction methods for quantitative SPECT imaging for $^{225}$Ac

***G. Liubchenko***, *M. Rumiantcev, S. Resch, M. Zacherl, F. Gildehaus, P. Bartenstein, S. Ziegler, G. Böning, A. Delker; LMU Klinikum Munich, Munich, GERMANY.*

***Aim/Introduction:*** In single photon emission computed tomography (SPECT), photon scatter leads to a reduction of image quality and impairs image quantification. The aim of this study was to compare a transmission-dependent (TD[1]) and an energy-window-based scatter corrections embedded in a MAP-EM algorithm for $^{225}$Ac SPECT imaging. ***Materials and Methods:*** Quantitative SPECT reconstructions for both, the 440keV and 218keV peak, were carried out via in-house MAP-EM, including attenuation correction, resolution modelling and TD or energy-window-based scatter correction. To generate the scatter kernels for TD method, SIMIND[2] Monte Carlo program was used to simulate line profiles behind water slabs of varying thicknesses (2-20 cm). For all slab thicknesses, the tails of the scatter signal were fitted using mono-exponential function, and scatter-to-primary fractions were obtained from SIMIND. The scatter kernels were convolved with the current image estimate to generate a scatter image. For every iteration and projection angle, the scatter image was forwardprojected and added to the current projection estimate. To compare the scatter correction methods, a self-made phantom (3 volumes-of-interest (VOIs) with 20, 45, 200ml) filled with $^{225}$Ac (64 projections; 128x128 matrix; foreground-to-background ratio of 6; three measurements with 2s and 6s (imitating the patient cases), and 60s (high count case) per projection) was imaged. In addition, 24h post injection (p.i.) SPECT/CT scans of three patients treated with 8 MBq [$^{225}$Ac]Ac-PSMA-I&T were evaluated using both scatter correction methods. ***Results:*** For the self-made $^{225}$Ac phantom study, comparable recovery coefficients were observed for energy-window-based and TD methods for both 440 and 218keV peaks (440kev, TD: 15.02%-47.7%; DEW: 15.92%-47.51%; 218kev, TD: 17.29%-35.98%, TEW: 18.13%-36.72%). TD method, however, resulted in higher SNRs (12-34%) for all VOIs and step times, for both, the 440 and 218keV peak. For the patient cases and the 440keV peak, the absorbed dose and the SUV at 24h p.i. in the kidneys were found to be 3-7% and 5-9% higher for the TD method, respectively. The lesion evaluation showed comparable absorbed doses and SUV at 24h p.i. For the 218keV peak, the absorbed dose and the SUV at 24h p.i. in the kidneys were found to be 14-36% and 21-36% higher for the TD method, respectively. The lesion absorbed dose and the lesion SUV at 24h p.i. were found to be 6-21% and 20-38% higher for the TD method, respectively. ***Conclusion:*** TD method showed improved SNR for the phantom and higher recovered activities for the patient studies. ***References:*** 1. https://doi.org/10.1007/s12149-008-0170-z. 2. https://doi.org/10.1201/b13073-8.

### Prediction of bone turnover in chronic kidney disease with hemodialysis patients using $K_i$-Patlak dynamic $^{18}$F-NaF PET/CT imaging

***K. Khamwan***[1], *V. Sanoesan*[1], *J. Phannajit*[1], *T. Sawatnatee*[2], *B. Phromphao*[2], *C. Sukprakhun*[1], *P. Susantitaphong*[1], *K. Kingpetch*[1]; [1]*Chulalongkorn University, Bangkok, THAILAND,* [2]*King Chulalongkorn Memorial Hospital, Bangkok, THAILAND.*

***Aim/Introduction:*** The diagnosis of renal osteodystrophy (ROD) is based on the bone turnover, mineralization, and volume (TMV system), which can be assessed through bone histomorphometry from bone biopsy. While bone biopsy is considered the gold standard for ROD classification, it is an invasive and painful procedure that is limited to a single bone site and requires considerable expertise to interpret specimens. This study aimed to evaluate the use of $^{18}$F-NaF PET/CT kinetic parameters of bone metabolic flux in chronic kidney disease (CKD) patients on hemodialysis to predict bone turnover rate as a non-invasive biomarker. ***Materials and Methods:*** Thirty-five CKD patients (16 males and 19 females) with an average age of 55.6 ± 9.6 years and biochemical abnormalities indicative of mineral and bone disorder were enrolled in the study. Following injection with 111-185 MBq of 18F-NaF, dynamic PET/CT scans were acquired for 60 minutes covering the T12 to anterior iliac crest to determine the Patlak-derived influx rate constant (Ki). The images were reconstructed into 37 frames of 12 × 5 s, 6 × 10 s, 8 × 30 s, and 11 × 300 s. 3D volumes of interest (VOIs) were drawn at L1-L4 and both anterior iliac crests to generate time-activity curves (TACs) for kinetic modeling using PMOD software. Kinetic parameters for the Ki Patlak model were derived using an image-derived input function (IDIF) drawn at the abdominal aorta. The Ki-Patlak values calculated from dynamic $^{18}$F-NaF were compared with biochemical markers to evaluate bone turnover rate. ***Results:*** We found a strong correlation of $K_i$-Patlak between the average influx rate of L1-L4 and each lumbar region, as well as between the average L1-L4 and both iliac crests. Using a cut-off value of 0.040 mL/min/mL in the lumbar region or at the anterior iliac crest, low bone turnover was detected in 7 patients (20%) while high bone turnover was detected in 28 patients (80%) based on the biochemical markers. ***Conclusion:*** This study indicated a potential of dynamic $^{18}$F-NaF PET/CT scans as a noninvasive diagnostic tool for determining bone turnover rate in CKD hemodialysis patients.

### Automated and reproducible processing and kinetic modelling of whole-body [15O]H2O PET/CT data

***S. Palonen***[1], *J. Tuisku*[2], *H. Kärpijoki*[2], *S. Nesterov*[2], *V. Oikonen*[2], *R. Klén*[2], *L. Nummenmaa*[2], *J. Knuuti*[1];
[1]*Turku PET centre, Turku University, Turku, FINLAND,*
[2]*Turku PET centre, Turku, FINLAND.*

***Aim/Introduction:*** Manual pre-processing of PET-data is time-consuming and less reproducible than automated methods, particularly when multiple target tissues need to be analysed. Several tools exist for automated brain-PET data processing, but similar pipelines are not yet widely available for whole-body PET data. Here we present a novel method for automated and reproducible processing and kinetic modelling for whole-body PET dynamic [$^{15}$O]$H_2O$ data. ***Materials and Methods:*** Automated analysis was developed and tested using whole-body [$^{15}$O]$H_2O$ PET/CT data from 36 subjects with suspected coronary artery disease. In the proposed approach, CT-based segmentation (TotalSegmentator1) is used for extracting the regional PET tissue time-activity curves for all major organs (including brain, myocardium, lungs, liver, kidney, pancreas, spleen, gut, gluteal muscle). Manually defined image-based input (abdominal aorta) is corrected for radiotracer delay separately for each organ before 1-tissue compartment model fitting process, providing blood flow estimates for each organ. Voxel-level parametric maps are calculated for each organ separately by using the delay-corrected input curves, after which they are combined in parametric 3D flow-maps. As a separate analysis branch, the brain is extracted from the PET images, followed by motion correction, template-based normalization, automated ROI-delineation, and regional and voxel-level kinetic modelling by using an in-house magia-toolbox[2] for brain PET data processing. ***Results:*** Based on visual inspection, the 1-tissue compartment model fits had good quality, and the automated process produced consistent regional and voxel level blood flow estimates with minimal user input. ***Conclusion:*** The present study describes an example framework for the automated processing of whole-body [$^{15}$O]$H_2O$ PET data from multiple organs with minimal manual labour. This framework will provide means to study characteristics of the inter-organ blood flow such as brain-body interactions. A detailed comparison against the results of manual workflow is warranted. ***References:*** 1. J. ## OP-843

### Shortening Dynamic [$^{11}$C]PK11195 PET Protocol for Parametric Imaging Using Supervised Clustering to Improve Clinical Feasibility

***D. B. A. Mantovani***[1], *M. S. Pitombeira*[1], *P. N. Schuck*[2], *C. Buchpiguel*[1], *D. de Paula Faria*[1], *A. Marques da Silva*[1];
[1]*University of Sao Paulo, Sao Paulo, BRAZIL,* [2]*Weill Cornell Medical College, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Positron emission tomography (PET) quantification using parametric imaging is superior to semi-quantitative parameters extracted from static images. However, there are many obstacles to incorporating parametric imaging into clinical practice, such as the time-consuming of dynamic PET acquisitions. While input functions from reference regions provide a good approach for PET quantification, some tracers, such as the 18kDa Translocator Protein (TSPO) ligand [$^{11}$C]PK11195, are spread in the central nervous system, with no reference region available. In this case, pseudo-reference regions are identified by a supervised clustering algorithm (SVCA). This work investigates the shortening of the dynamic [$^{11}$C]PK11195 PET acquisition protocol while obtaining reliable distribution volume ratio (DVR). ***Materials and Methods:*** Pseudo-reference regions were extracted using the SVCA approach (1) with a full-time scan (60 min) and a reduced-time scan (40 min) from dynamic [$^{11}$C]PK11195 PET-MR images of 24 relapsing-remitting multiple sclerosis (RRMS) patients and 16 healthy volunteers (HV). Gray matter, white matter, and blood pool classes were extracted from the HV group, while the specific-binding class was extracted from the patients' thalamus (2). Using the reference-tissue-based Logan analysis, DVR values were determined in the gray matter, white matter, caudate nucleus, putamen, pallidum, thalamus, brainstem, and nucleus accumbens. In addition, the DVR correlation between the full-time (SVCA60) and reduced-time (SVCA40) were tested. ***Results:*** Pseudo-reference regions extraction was not affected significantly by shortened scan, showing that the SVCA approach applies to reduced [$^{11}$C]PK11195 PET acquisitions. The reduced-time PET scan produced DVR values comparable to the full-time scan, with a Pearson correlation coefficient in all brain regions between 0.77-0.95 ($p<0.0001$) for HV group and 0.61-0.95 (<0.0001) for RRMS group. SVCA40 showed good correlations with SVCA60 ($r2 = 0.9118$ for HV and $r2 = 0.8986$ for RRMS) and the arterial input function approach ($r2 = 0.9170$ for HV and $r2 = 0.8998$ for RRMS). ***Conclusion:*** A 40-minute [$^{11}$C]PK11195 PET acquisition produces reliable SVCA pseudo-reference regions and DVR values. This may improve the clinical feasibility of kinetic modeling and dynamic PET imaging for MS patients. ***References:*** (1)-Yaqub M, van Berckel BN, Schuitemaker A, Hinz R, Turkheimer FE, Tomasi G, et al. ## OP-844

### Feasibility of Dynamic Total-Body Pre-therapy PET for Predicting Radiopharmaceutical Therapy (RPT) Dosimetry: a simulation study

***J. Hong***[1], *M. Kassar*[2], *A. Rominger*[1], *K. Shi*[1];
[1]*University of Bern/Inselspital, Bern, SWITZERLAND,*
[2]*Technical University Munich, Munich, GERMANY.*

***Aim/Introduction:*** The dosimetry of radiopharmaceutical therapy (RPT) is determined by whole-body pharmacokinetics. The dynamic total-body PET enables us to characterize the multi-organ pharmacokinetics of radiopharmaceuticals. This study aimed to predict the dosimetry of RPT from pre-therapy imaging in voxel level using deep learning method. For proof-of-concept, the realistic computational simulation PET images were utilized for this work. ***Materials and Methods:*** We aimed to predict $^{177}$Lu-PSMA-617 dosimetry from dynamic $^{68}$Ga-PSMA-11 total-body PET in voxel-level using seq2seq model. We simulated 200 pairs of dynamic $^{68}$Ga-PSMA-11 pre-therapeutic PET images and $^{177}$Lu-PSMA-617 dosimetry images using 4D XCAT phantom, of which we divided 150 and 50 for training and test, respectively. 2 ellipsoidal tumor lesions were placed in the regions frequently reported: liver, lung, bone, or lymph node. We then

performed physiologically based pharmacokinetic (PBPK) model to simulate the dynamic time-activity curve (TAC) of each organ in the phantom for each $^{177}$Lu-PSMA-617 and $^{68}$Ga-PSMA-11. The kinetic parameters were taken from literatures and noise was added to generate more individual variations. The parameters such as kidney volume, kidney receptor density, and flow rate to the kidney, as well as those of tumor, were randomly sampled from Gaussian distribution; Height and weight were sampled from multivariate Gaussian distribution. For dynamic $^{68}$Ga-PSMA-11 total-body PET, the time frames were set as [1(min)*2; 3(min)*1; 5(min)*1; 20(min)*3; 30(min)*1]. The dynamic pre-therapeutic images were then reconstructed by ordered subset expectation maximization (OSEM) algorithm. Similarly, the paired dosimetry images were simulated by applying the dose voxel kernel (DVK) to the integral of TAC over 20 days that is generated by PBPK model for $^{177}$Lu-PSMA-617. The reduction of lesion volume was considered in simulation by using the linear-quadratic model and exponential tumor growth. The seq2seq model was established to predict the dosimetry images from the dynamic pre-therapeutic images. ***Results:*** The dynamic $^{68}$Ga-PSMA-11 total-body PET simulation agreed well with the previous literatures except for lung and liver. The activity of lung was overestimated and that of liver was underestimated across full frame. On average, the prediction underestimated 0.016 Gy/GBq in tumor, and the bias and variance were 0.888 and 0.145. However, MAE, variance and bias showed a positive relationship with the ground truth absorbed dose in organs($p<0.05$); the higher the absorbed dose was, the prediction error was higher in organs. ***Conclusion:*** Dosimetry of RPT may be predicted by dynamic pre-therapy PET scans using deep learning model.

## OP-845

### Voxel-wise parametric imaging of 4D PET data :evaluation of new software solution for [$^{18}$F]-FDG PET kinetic modeling at the whole FOV level.

***F. Besson***[1,2], *E. Marchal*[1], *S. Faure*[3];
[1]*CEA / Inserm / CNRS / Université Paris Saclay, BioMaps, Orsay, FRANCE,* [2]*Department of Nuclear Medicine-Molecular Imaging, Hôpitaux Universitaires Paris Saclay, AP-HP, Le Kremlin-Bicêtre, FRANCE,* [3]*Laboratoire de Mathématique d'Orsay, CNRS, Université Paris Saclay, Orsay, FRANCE.*

***Aim/Introduction:*** voxel-wise PET kinetic modeling constitutes a high computational challenge at the whole FOV level. Here we assessed the performance of a new dedicated software solution we developed to perform parametric imaging from 4D PET data in a very fast and efficient way. ***Materials and Methods:*** the one-hour dynamic thoracic PET data from 12 patients with NSCLC who had prospectively undergone [$^{18}$F]-FDG PET/MR for oncology purpose were processed with our software solution to generate, at the whole FOV level (5 million voxels, whole blood image-derived input function defined in the aorta), the parametric maps of the net influx constant Ki, both using Patlak ($Ki_{Patlak}$) and the irreversible 2 tissue compartment model ($Ki_{2TCM}$). We compared the computation times, robustness and Ki values with those estimated by PMOD kinetic tool (PKIN, PMOD Technologies LLC 1996-2022, Zurich, Switzerland) within 3 small volumes of interest (VOI < 300 voxels) - tumor, tissue and bone targets respectively - due to the inability of PMOD to compute whole FOV parametric images. Quantitative data are expressed as median [interquartile ranges]. ***Results:*** per patient, our solution took around 1 minute to read, compute and write the whole FOV parametric maps ($Ki_{Patlak}$ and $Ki_{2TCM}$, 5 millions voxels) from the 4D PET data, whereas PKIN took 10 seconds to compute $Ki_{Patlak}$ and 7 minutes [4.2; 10.6] to compute $Ki_{2TCM}$ within the VOIs (< 300 voxels). The voxel fitting failure rate (i.e. 0 or negative values) per target was for $Ki_{Patlak}$: 0% [0; 0], 0% [0; 0], 0% [0; 0] with our soft and 44% [35; 68], 76.1% [73.7; 78.6], and 70.4% [64.5; 77.4] with PKIN. And for $Ki_{2TCM}$: 11% [6; 16.8], 10.3% [3.8; 16.7], 0% [0; 0.9] with our soft and 13.1% [9.2; 14.7], 14.6% [11.9; 15.9], 12.4% [0; 15.3] with PKIN. On average, the differences between our soft and PKIN were 33% [28; 65], 131% [86; 164], 109% [47; 200] for $Ki_{Patlak}$ and -6% [-13; 8], 9% [0; 18], 13% [7; 20] for $Ki_{2TCM}$. ***Conclusion:*** our solution overpassed PKIN for $Ki_{Patlak}$ and provided less than 20% median differences for $Ki_{2TCM}$ within the VOIs. Our soft appears promising for fast and robust IDIF-based voxel-wise PET kinetic modeling at the whole FOV level.

## OP-846

### Incorporating prior knowledge with physics-informed neural networks to predict arterial input functions from dynamic PET images

***M. Ferrante***[1], *M. Inglese*[1], *L. Brusaferri*[2], *A. C. Whitehead*[3], *M. L. Loggia*[4], *N. Toschi*[1];
[1]*University of Rome Tor Vergata, Roma, ITALY,* [2]*Department of Radiology, Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA,* [3]*Institute of Nuclear Medicine, University College London, (UNITED KINGDOM), London, UNITED KINGDOM,* [4]*2)Department of Radiology, Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Translocator protein 18kDa (TSPO) is a critical target for [$^{11}$C]PBR28 PET-based in-vivo imaging of neuroinflammation [1,2,5] as it is upregulated by activated microglia and macrophages. Quantitative PET imaging requires sampling of the arterial input function (AIF) through invasive arterial cannulation, which poses several challenges, including higher clinical staff demands and additional patient burden. In this study, we aimed to estimate the AIF from a dynamic PET acquisition while employing a parameter-efficient, physics-informed convolutional neural network (PINN) [3,4] that combines the advantages of model-based and data-driven methods. ***Materials and Methods:*** We performed [$^{11}$C]PBR28 PET/MRI brain scans on 50 individuals and collected arterial blood samples for each subject. Our architecture consisted of six depthwise separable 3D strided convolution layers, which repeatedly downsampled the dynamic 4D PET image by a factor of two. The interaction between channels was split through the implementation of depthwise and pointwise convolutions, resulting in both a considerable reduction of parameter count and computation of spatiotemporal features. The multilayer perceptron of depth 3 with hyperbolic tangent activation functions mapped the features onto the ten parameters of the Parker's model. ***Results:*** After training, the estimated AIF in the test set was used to model [$^{11}$C]PBR28 kinetics with the 2TCM-1k, leading to an estimation of the distribution volume VT. No statistical difference in VT values was found when comparing estimates from the estimated and real AIF in various regions of interest, including the hippocampus, thalamus, and frontal cortex. Furthermore, the intraclass correlation coefficient (ICC) indicated strong agreement between the estimated and real AIF-derived VT values. The PINN model demonstrated robustness across different brain regions and maintained high accuracy in the presence of varying noise levels, providing more confidence in the use of the estimated AIF for quantitative PET. ***Conclusion:*** Our results demonstrate the potential of incorporating prior knowledge into neural networks and employing depthwise

separable convolutions to handle high-dimensional time series data, achieving comparable performance to real-world measured plasma components even with limited data availability. This work has the potential to reduce the invasiveness of quantitative PET and promote the use of this technique, which has greater diagnostic and prognostic power than static PET imaging. Further advancements in this field could lead to practical applications in clinical settings, enabling quantitative PET without the need for invasive measurements. ***References:*** 1. ## OP-847

### Impact of AI-based Image Denoising on Quantitative Kinetic Analysis in Dynamic PET imaging

***B. Liu***[1], *G. Hu*[2], *X. Wang*[2], *L. Huo*[2], *H. Ding*[1], *H. Zhang*[1]; [1]*Tsinghua University, Beijing, CHINA,* [2]*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** AI$^{18}$F-PSMA-617 has excellent detectability of tumors and favorable pharmacokinetic profiles, while dynamic PET imaging provides valuable parameters for quantitative description of the physiological state. This study aims to investigate whether AI-based denoising process affects the quantitative accuracy in kinetic analysis of AI$^{18}$F-PSMA-617 PET imaging compared to the traditional method. ***Materials and Methods:*** 12 PCa patients recruited in this study underwent a 60-min dynamic AI$^{18}$F-PSMA-617 PET scan. The list mode data were reconstructed with and without Gauss filtering, images without Gauss filter processing were sent to the AI-based denoising algorithm named a novel segmentation guided style based generative adversarial network (SGSGAN). Physicians' perceptions of image quality were determined by scoring image preference and anatomical clarity on a 5-point Likert scale, while objective evaluation was conducted by calculating signal-to-noise (SNR). The reversible two-tissue compartment model was used and validated based on $R^2$ values. Statistical analysis was performed with P values, AUCs, and ICCs. ***Results:*** The two physicians showed good consistency in ratings with coefficients of agreement (COA) > 60%, agreed that AI denoising improved image quality compared to traditional method, which was also revealed by significantly increased SNR. $R^2$ was 0.838±0.132 and 0.805±0.085 for lesions and normal tissues in the Gauss group, while in the AI group there was a significant improvement to 0.940±0.056 and 0.885±0.062. Kinetic parameter Ki were 0.103±0.095 and 0.030±0.013 / 0.111±0.106 and 0.027±0.013 for lesions and normal tissues in Gauss / AI group, Vd were 9.361±7.004 and 1.166±0.347 / 8.677±6.715 and 1.234±0.396, all exhibited significant differences (P<0.0005) between tumors and normal tissues. Ki AUCs in the Gauss and AI group were 0.927 (P=0.0004) and 0.948 (P=0.0002), Vd AUCs were both 1 (P<0.0001) in two groups, indicating that diagnostic efficiency was improved after AI noise reduction for Ki, while Vd had even higher differentiation ability that was barely affected by noise reduction. ICC values for Ki were 0.989 (P<0.0001) and 0.973 (P<0.0001) for lesions and normal tissues, and for Vd were 0.962 (P<0.0001) and 0.951 (P<0.0001), revealing excellent consistency between two groups. ***Conclusion:*** AI-based denoising techniques are effective in enhancing image quality without compromising the quantitative accuracy and diagnostic efficiency of kinetic analysis for dynamic PET imaging. Future research should explore other factors affecting kinetic analysis stability to enhance clinical parameter utilization.

## OP-848

### Myocardial Dynamic Positron Emission Tomography Later Time Frames Prediction Using Deep Learning

***M. Mokri***[1], *M. Safari*[2], *L. Archambault*[2], *S. Kaviani*[1], *D. Juneau*[3], *C. Cohalan*[3], *J. Carrier*[1,3]; [1]*Université de Montréal, Montreal, QC, CANADA,* [2]*Université Laval, Quebec City, QC, CANADA,* [3]*Centre hospitalier de l'Université de Montréal, Montreal, QC, CANADA.*

***Aim/Introduction:*** Dynamic Myocardial Positron Emission Tomography (PET) imaging is a technique for assessing myocardial uptake. The long acquisition time of dynamic PET might hinder its applications due to the patient's discomfort and movement. Deep learning (DL) techniques have been utilized for medical image synthesis. Our goal is to utilize deep learning techniques to predict the late time frames of myocardial PET images using the initial time frames, which will reduce the acquisition time. ***Materials and Methods:*** This study used dataset of 350 patients to train two DL models. The patients underwent $^{13}$N-ammonia myocardial PET/CT scans constituting 21 time frames. We introduced a temporal normalization in the preprocessing step to keep the correlation between different time points. The networks were Unet and Attention Unet with self-attention layers that capture dependencies between feature maps, which focus on more relevant regions of the image. We used L1 regressor to train the networks. The networks were used for two independent prediction scenarios: to predict the last 10 and 14 late time frames, respectively, using the initial 11 and 7 time frames. ***Results:*** For both models, the predicted frames showed a close resemblance in appearance and texture compared to the reference frames. Qualitative examinations illustrate a comparable pattern of radiotracer uptake biodistribution in predicted images and reference images. Quantitative metrics including Peak Signal-to-Noise Ratio (PSNR), Mean squared Error (MSE) and (Structural Similarity Index Measure) SSIM, were used to assess performance in terms of image distortion and structural similarity. For the prediction of 10 time frames, Attention Unet outperformed Unet with average PSNR of 39.14, and MSE of 0.003 compared to Unet's PSNR of 35.56, and MSE of 0.0051. Attention Unet demonstrated higher average SSIM value of 0.96 compared to Unet with SSIM value 0.91. For the prediction of the last 14 time frames, Attention Unet performed Unet with average PSNR of 38.88, SSIM of 0.95, and MSE of 0.0035 compared to Unet's PSNR of 31.35, SSIM of 0.89, and MSE of 0.0056. Attention-Unet outperformed Unet in terms of PSNR and SSIM, as determined by a pairwise t-test (p-value < 0.05). ***Conclusion:*** We developed and evaluated deep learning models to predict the late time frames of dynamic myocardial images from initial data points. The quantitative metrics indicate that Attention Unet outperformed Unet for two different prediction scenarios. The results demonstrate the potential of deep learning models for predicting late frames for dynamic PET.

## Clinical Oncology Track - TROP Session: Localised Treatments

### OP-849

**Is there any factor that influences the quality of the I125 placement in non palpable breast lesions?**

***O. Ajuria Illarramendi***, *A. Martinez Lorca, U. Vera Schmulling, P. Azpeitia Hernandez, M. Gutierrez Guerrero, P. Paredes Rodriguez, T. Navarro Martinez, M. Orduña Diez;*
*Hospital universitario ramon y cajal, Madrid, SPAIN.*

***Aim/Introduction:*** Radioguided Seed Localization(RSL) has become the elected technique to perform the surgery of non palpable breast lesion at our institution. The success of the technique is related to the correct placement of the seed in the lesion. The aim of this study is to find out if the histology of the lesion, the size of the lesion or the imaging technique used to deploy the seed influence the result of the placement. ***Materials and Methods:*** We review 533 consecutive patients who underwent RSL technique at our institution. The histology (invasive ductal carcinoma(CDI), invasive lobulilllar carcinoma(CLI), in situ(IS) or non tumoral(NT)); the size and the imaging technique (US, stereotactic or MRI) used to deploy the seed were recorded. Correct placement was considered when the seed was deployed inside or within 5mm the lesion, marginal placement was considered when the seed was released above 5mm the lesion and failure of the placement was considered when another marking technique was necessary to accomplish the excision of the lesion. All the sizes of the lesions were recorded in cm. ***Results:*** In 456/533 the seed was released guided by US: 435/456(95,4%) had correct placement, 17/456(3,7%) marginal and 4/456(0,9%) failed. 76/533 were guided by stereotactic: 55/76 (72,4%) had correct placement, 13/76 (17,1%) marginal and 8/76(10, 5%) failed. 1/533 was deployed guided by MRI and failed. Statistical significance was achieved with p<0,001. According to the histology: 91,8% CDI, 97,5% CLI, 87,5% IS and 93,2% NT had correct placement, while 5,8% CDI, 2,5% CLI, 8,9% IS and 3,4% NT had marginal placement and in 2,4% CDI, 0% CLI, 3,6% IS and 3,4% NT the placement failed. There was no statistical significance with p:0,665. When the influence of the size was analyzed there was no statistical significance neither (p:0,266). ***Conclusion:*** The success on the seed placement is related to the imaging technique that is used to guide the deployment, earning better results when using the US. On the other hand, there is no relation between the histology or the size of lesion with the result of the seed placement.

### OP-850

**Investigation on Dose-Toxicity and Dose-Response Relationship in Neuroendocrine Liver Metastases treated with Holmium-166 Radioembolization**

***K. Ramdhani***, *J. J. Verduin, S. C. Ebbers, M. L. J. Smits, R. C. G. Bruijnen, M. G. E. H. Lam, A. J. A. T. Braat;*
*University Medical Center Utrecht, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Aim of this study was to investigate a lesion-based dose-response relationship and patient-based dose-toxicity relationship in neuroendocrine liver metastases (NELM) treated with holmium-166-radioembolization. ***Materials and Methods:*** Single center, retrospective study including patients with NELM that received holmium-166-radioembolization with post-treatment SPECT/CT and evaluation imaging. SPECT was scaled based on total net administered activity to calculate tumor and whole liver healthy tissue (Dh) absorbed dose. Clinical and laboratory toxicity was graded by Common Terminology Criteria for Adverse Events (CTCAE), version 5 at baseline and three months follow-up. Response was determined according to RECIST 1.1. ***Results:*** Twenty-seven treatments in 25 patients were included, with a total of 114 tumors. Sixteen patients had grade 1-2 clinical toxicity and only one patient with grade 3. No new grade 4-5 toxicity was encountered. No clear dose-toxicity relationship was found. None of the treatments with Dh <30 Gy experienced any clinical toxicity. There was minimal change in laboratory parameters (57%, grade 1-2). Of the treatments with Dh >30 Gy, 66% experienced clinical toxicities (max grade 2) and 71% laboratory toxicities (max grade 3). Six tumors had CR, 36 tumors had PR, 69 tumors had SD and only three tumors had PD, resulting in a disease control rate of 97% of target lesions. The mean dose in non-responders (PD+SD) was 68 Gy versus 118 Gy in responders (CR+PR), p=0.01. On patient level, there was no significant difference between responders and non responders with a mean tumor absorbed dose of 76 Gy in the non responders and 81 Gy in the responders group, p=0.7 ***Conclusion:*** This study confirms the safety of holmium-166-radioembolization in NELM in a real-world setting, with a clear dose-response relationship, high disease control rates (97%) and limited toxicities.

### OP-851

**Radioembolization of HCC Patients for Curative Intent with Personalized Yttrium-90 Dosimetry (RAPY90D)**

***S. Kappadath***, *E. C. Henry, B. P. Lopez, A. Mahvash;*
*UT MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** To report on a single-arm single-institution prospective clinical trial (NCT03896646) on $^{90}$Y-glass radioembolization for hepatocellular carcinoma (HCC) patients (n=40) using patient-specific voxel-dosimetry treatment planning. The primary endpoint was localized mRECIST objective response rate (ORR) at 6-month follow-up. Secondary analysis evaluated concordance between planned and delivered absorbed doses based on pre- and post-therapy quantitative SPECT/CT and PET/CT. ***Materials and Methods:*** Eligibility criteria included all adult HCC patients eligible for $^{90}$Y-glass radioembolization with non-infiltrative tumors of maximum single dimension ≥3 cm (index tumors). All patients underwent hepatic angiography with fan-beam CT (AngioCT), received $^{99m}$Tc-MAA injections at all planned treatment sites, and imaged with SPECT/CT. AngioCT and $^{99m}$Tc-MAA SPECT/CT were used to determine the volume of perfused territories and to calculate the $^{90}$Y-microsphere activities needed to achieve tumor mean dose ($D_{mean}$) ≥200 Gy and normal liver $D_{mean}$ ≤100 Gy with voxel dosimetry. Localized mRECIST tumor responses and overall toxicities (CTCAE v5.0) were determined at 6-month follow-up. Post-treatment imaging for dose verification was performed within 24 hours using both $^{90}$Y-SPECT/CT and $^{90}$Y-PET/CT. Inter-modality concordance of $D_{mean}$ for tumors and normal livers were assessed. The delivered $D_{mean}$ was defined as the average of bias-corrected $^{90}$Y-SPECT and $^{90}$Y-PET estimates. ***Results:*** Forty patients received $^{90}$Y-radioembolization, and 37 patients (58 tumors and 48 index tumors) completed 6-month follow-up. The median (range) index lesion effective-diameter

was 4.7 (2.8-13.0) cm. Bland-Altman analyses between $^{90}$Y-PET and $^{90}$Y-SPECT yielded, on average (95% limits-of-agreement), higher $^{90}$Y-PET tumor $D_{mean}$ by 16% (±28%) and lower $^{90}$Y-PET normal liver $D_{mean}$ by 11% (±27%). The median (range) planned and delivered tumor $D_{mean}$ were 350 (224-574) Gy and 357 (206-981) Gy, respectively. Pre- and post-therapy doses were strongly correlated ($R^2$=0.92) and clinically comparable (within ±20%) in 83% of cases. Similarly, post-therapy bias-corrected $^{90}$Y-SPECT and $^{90}$Y-PET doses were strongly correlated ($R^2$=0.95) and clinically comparable (within ±20%) in 85% of cases. The ORR at 6-month follow-up was 97% (56/58), with CR=72% (42/58), PR=24% (14/58), and SD=3% (2/58). Two patients experienced one nontreatment-related grade 3 toxicity, and one patient developed duodenal ulcer with grade 5 toxicity. ***Conclusion:*** RAPY90D trial has demonstrated the feasibility and clinical benefits of prospective, $^{99m}$Tc-MAA-SPECT-based, patient-specific voxel dosimetry treatment planning for $^{90}$Y-radioembolization of HCC patients. A 97% tumor response rate was achieved by targeting high tumor doses (≥200 Gy) while minimizing normal liver doses. Excellent concordance between planned and delivered doses were achieved through careful image-guided treatment planning, delivery, and verification.

## OP-852

### 166Holmium-SIRT after PRRT (HEPAR PLuS) versus PRRT-only in Patients with Metastatic Neuroendocrine Tumors: a Propensity-score Matched Analysis

***A. Braat***[1], *T. Walter*[2], *D. de Vries-Huizing*[3], *J. Theysohn*[4], *S. Barton*[5], *E. Ekkelenkamp*[6], *B. Lachachi*[2], *R. de Jong*[6], *L. van Golen*[3], *H. Lanzafame*[4], *L. Milot*[2], *H. Lahner*[4], *W. Veldhuis*[1], *M. Tesselaar*[3], *M. Lam*[1];
[1]*University Medical Center Utrecht, Utrecht, NETHERLANDS,* [2]*Hospices Civils de Lyon, Lyon, FRANCE,* [3]*NKI-AVL, Amsterdam, NETHERLANDS,* [4]*University Hospital Essen, Essen, GERMANY,* [5]*Barton Biostatistics Ltd, London, UNITED KINGDOM,* [6]*Medical Affairs Interventional Oncology Terumo Europe NV, Leuven, BELGIUM.*

***Aim/Introduction:*** Patients with bulky neuroendocrine liver metastases undergoing peptide receptor radionuclide therapy (PRRT) with [$^{177}$Lu]Lu-DOTATATE have a worse survival than patients with limited liver metastases.[1] Previously, safety and efficacy of additional selective internal radiotherapy (SIRT), using $^{166}$Holmium microspheres, directly following PRRT in patients with liver metastatic neuroendocrine tumors (mNET) was confirmed in the prospective HEPAR PLuS study.[2] Aim of the current study is to provide insight into efficacy and progression-free survival (PFS) benefit of $^{166}$Ho SIRT+PRRT over PRRT-only by means of a propensity score matched historical cohort ***Materials and Methods:*** A multicenter retrospective data collection of patients treated with PRRT-only was initiated to match with prospectively collected HEPAR PLuS study patients. Demographic, clinical, laboratory and imaging data were collected. All imaging data was centrally re-assessed: RECIST 1.1 response and liver tumor load segmentation. Matching criteria included liver tumor burden, RECIST 1.1 response after PRRT, primary tumor location and resection, Ki-67 score, days from liver metastases diagnosis to PRRT initiation, previous treatments, extrahepatic disease, albumin, gender and age. Primary endpoint is proportion of patients with PFS (defined as surviving, not requiring subsequent treatment and radiological PFS) at 2 years after start of PRRT. Secondary endpoints include proportion of patients with 2-years hepatic PFS (hPFS), general PFS and hPFS, objective response rates (ORR), and overall survival. ***Results:*** 24 SIRT+PRRT-treated patients and 24 PRRT-only patients were included in the analysis set. All key matching criteria were balanced between cohorts. The proportion of patients with PFS and hPFS at 2 years was 68% and 82% with SIRT+PRRT versus 55% and 50% with PRRT-only. Time to median PFS (i.e. 50% probability of PFS) was comparable (31 versus 30 months). However, notable in mNET patients with primary intestinal tumors (i.e. small intestine+colon+rectal) a delay in PFS was observed in SIRT+PRRT patients (75% probability of PFS at 26 versus 20 months). A delay in hPFS was also observed in SIRT+PRRT mNET patients (75% probability of PFS 27 versus 22 months) and most notably in intestinal tumors (75% probability of PFS at 26 versus 15 months). Best ORR was 71% with SIRT+PRRT versus 25% with PRRT-only. ***Conclusion:*** SIRT+PRRT results in a higher PFS-rate at 2 years and best objective response compared to PRRT-only. A delay in hPFS was observed in the patients treated with PRRT+SIRT compared to PRRT-only. ***References:*** [1]Strosberg J et al EJNMMI 2020;47(10). [2]Braat AJAT et al. Lancet Oncology 2020;21(4):561-570.

## OP-853

### Intratumoral Holmium-166 Microsphere Brachytherapy in Patients with Pancreatic Ductal Adenocarcinoma: The Sloth Project

***C. Y. Willink***, *S. F. M. Jenniskens, M. W. J. Stommel, M. J. R. Janssen, J. J. Fütterer, K. J. H. M. van Laarhoven, J. F. W. Nijsen; Radboudumc, Nijmegen, NETHERLANDS.*

***Aim/Introduction:*** To evaluate the safety and feasibility of intratumoral holmium-166 microsphere brachytherapy in patients suffering from pancreatic ductal adenocarcinoma (PDAC). ***Materials and Methods:*** The multi-disciplinary research project comprises a pre-clinical study (SLOTH ex-vivo) and clinical pilot studies (SLOTH-1 and SLOTH-2). In the SLOTH ex vivo: phantoms and ex vivo PDAC tumors are used to establish basic injection parameters. With both MRI and CT for holmium-165 (stable isotope) visualization and quantification, microsphere distribution within the target-area and off-target tracking are evaluated. The SLOTH-1 study is the first pilot study in which 3 patients, in whom PDAC resection is not possible during explorative surgery, are directly treated with ultrasound guided intratumoral holmium-166 microsphere brachytherapy. Safety (CTCAE v4.0) and feasibility (SPECT) are primary outcomes after a follow-up of 12 weeks. SLOTH-2 is a second pilot study in which 6 patients with terminal PDAC will receive CT-guided percutaneous holmium-166 microsphere brachytherapy. Primary outcomes are safety (CTCAE v5.0) and feasibility (SPECT) with a follow-up of 16 weeks and Quality of Life as exploratory outcome. ***Results:*** Feasibility of intratumoral injection of holmium microspheres was established in ex vivo PDAC with sufficient control of needle placement and injections. Basic injection and imaging parameters were established and applied in the SLOTH-1 clinical trial. In the SLOTH-1 trail, two patients are currently treated, one was identified with metastasis and the other with irresectable disease. Preliminary dosimetry by SPECT showed a mean tumor dose of 8.9 Gy and 71.5 Gy with off-target irradiation up to 0.3 Gy in the lungs, liver and colon. Treatment was well tolerated with two procedure-related AEs grade 1-2 and non-related 23 grade 1-2, five grade 3 and zero grade 4-5 AEs. Screening and inclusion for the SLOTH-2 trial will commence in Q2 2023. Approval by the Medical Research Ethics Committee and Radiation Safety has already been granted. ***Conclusion:*** Intratumoral holmium-166 microsphere brachytherapy is a potential treatment option for patients suffering from pancreatic ductal adenocarcinoma. Preliminary feasibility is demonstrated and short toxicity seems acceptable. Additional research will be conducted during the SLOTH-project.

## OP-854

### A phase II trial to evaluate the accuracy of an intra-operative radio-guided approach with a beta probe for 68Ga-DOTATOC in patients affected by GEP-NET of the ileum.

***F. Mattana***[1], *E. Bertani*[2], *F. Collamati*[3], *R. Mirabelli*[3], *A. M. Bonomi*[2], *A. Barone*[1], *L. L. Travaini*[1], *M. Ferrari*[4], *E. Pisa*[5], *N. Fusco*[5], *U. Fumagalli Romario*[2], *F. Ceci*[1,6];
[1]*IEO European Institute of Oncology, Nuclear Medicine, Milano, ITALY,* [2]*IEO European Institute of Oncology, Division of Digestive Surgery, Milano, ITALY,* [3]*INFN National Institute of Nuclear Physics, Nuclear Physics, Rome, ITALY,* [4]*IEO European Institute of Oncology, Medical Physics, Milano, ITALY,* [5]*IEO European Institute of Oncology, Pathology, Milano, ITALY,* [6]*Department of Oncology and Hemato-Oncology, University of Milan, ITALY.*

***Aim/Introduction:*** The primary aim was to evaluate the diagnostic accuracy of intra-operative positron detector (beta-Probe) to detect Gastro-Entero-Pancreatic-Neuroendocrine-Tumor (GEP-NET) lesions, using histopathology of the surgical specimens as reference standard. The secondary aim was to evaluate feasibility and safety of the intra-operative beta-probe RGS approach. ***Materials and Methods:*** This is a prospective, single-arm, single-center, non-interventional, phase II trial (NCT05448157) performed at our institution between May2022 and April2023. Inclusion criteria were:1)proven ileum GEP-NET;2)baseline 68Ga-DOTATOC-PET/CT(SSR-PET) performed within 4weeks from surgery;3)SSR-PET performed for initial staging or disease recurrence;4)age≥18 years-old;5)willing to sign informed consent form. Exclusion criteria were:1)patients not fit for surgery;2)negative SSR-PET. 1.1 MBq/Kg of 68Ga-DOTATOC was intravenously administered in the surgery theatre 10 minutes before surgery. The in-vivo measurements were performed by the surgeon using hand-held (open-surgery procedures) or DROP-IN (laparotomic procedures) systems. The tumor-to-background-ratio(TBR) was evaluated using real-time counts per second(CPS). Data derived from the SSR-PET, beta-Probe and histopathological analysis were compared. The primary endpoint was explored with a per-lesion analysis. ROC curve analysis was used to calculate the CPS cut-off with the highest accuracy. The absorbed dose for the surgery staff was measured using an electronic personal dosimeter (EPD). The sample size calculation consisted in 20 patients. ***Results:*** The intra-operative RGS approach was feasible in all cases, without significant changes in surgery timing and no side effects. A total of 132 specimens (26 ileum specimens, 31 lymph nodes, 75 omental or mesenteric fat specimens; mean of 6.6 specimens per-patient) have been surgically removed and considered for primary end-point analysis. The per-lesion specificity, sensibility, PPV and NPN were 86%, 89%, 89%, 86% respectively. The CPS cut-off with the higher performance was 1.3. The mean absorbed dose from the surgery staff was 30μSv (range 12-41μSv). ***Conclusion:*** These first ever published data derived from a live-surgery-experience using a beta-probe, showed optimal accuracy in detecting lesions of GEP-NET of the ileum. A favorable TBR has been observed also in the latest phases of the surgical procedures suggesting the possibility to use a lower activity while maintaining good performance. The procedure was safe, feasible, easily reproducible in the daily clinical practice with a limited absorbed dose from the surgeon. ***References:*** El Lakis M, Gianakou A, Nockel P, Wiseman D, Tirosh A, Quezado MA, Patel D, Nilubol N, Pacak K, Sadowski SM, Kebebew E. ## OP-855

### Prediction of acute radiation-induced lung toxicity after SBRT using dose-volume parameters from functional mapping on Gallium-68 lung perfusion PET/CT

***P. Le Roux***, *D. Bourhis, F. Pinot, M. Hamya, G. Goasduff, F. Blanc, S. Hennebicq, M. Mauguen, K. Kerleguer, U. Schick, M. Consigny, O. Pradier, G. Le Gal, P. Salaun, V. Bourbonne, F. Lucia;
Brest University Hospital, Brest, FRANCE.*

***Aim/Introduction:*** Stereotactic body radiotherapy (SBRT) has an increasing role in the treatment of both primary and secondary lung tumors. However, while local tumor control rate is higher than 90%, lung SBRT remains associated with significant radiation-induced lung toxicity (RILT). The aim of this study was to evaluate the performance of anatomical and functional dosimetric parameters based on Gallium-68 lung perfusion PET/CT imaging to predict the risk of symptomatic acute RILT in patients with lung tumors treated with SBRT. ***Materials and Methods:*** 59 patients were prospectively included and underwent, before lung SBRT, lung perfusion PET/CT after administration of [68Ga] Ga-MacroAggregatted Albumin (MAA). Mean lung dose (MLD) and volumes receiving xGy (VxGy, 5 to 30 Gy) were calculated in five lung volumes: the conventional anatomical volume (AV) delineated on CT images, three lung functional volumes defined on lung perfusion PET imaging (FV50%, FV70%, FV90%, i.e. the minimal volume containing 50%, 70% and 90% of the total activity within the AV), and a low functional volume (LFV = AV-FV90%).The primary endpoint of this analysis was grade ≥2 acute RILT at 3 months as assessed with NCI CTCAE v.5. Dose volume parameters in patients with and without acute RILT were compared. ROC curved to assess the ability of dose-volume parameters to discriminate between patients with and without acute RILT were generated and area under the curves (AUC) were calculated. ***Results:*** Out of the 59 patients, 10 (17%) had grade ≥2 acute RILT. The MLD and the VxGy (5 to 30 Gy) in the AV and LFV were not statistically different in patients with and without acute RILT. In contrast, all dose volume parameters were significantly higher in the FV50%, FV70% and FV90% volumes in patients with acute RILT ($p<0.05$). AUCs of MLD FV70% and FV90% were significantly higher than AUC of MLD AV ($p<0.05$). AUCs of V20 FV50%, FV70% and FV90% were significantly higher than AUC of V20 AV ($p<0.05$). ***Conclusion:*** In our study, the predictive value of PET perfusion-based functional parameters outperformed the standard CT-based dose-volume parameters for the risk of grade ≥2 acute RILT in patients treated with lung SBRT. Functional parameters could be useful to guide radiotherapy planning to reduce the risk of acute RILT.

## OP-856

### Intra-arterial Administration of PRRT in Patients with Advanced Meningioma

***A. Amerein***[1], *A. Rinscheid*[2], *A. Gäble*[1], *A. Krebold*[1], *O. Viering*[1], *A. Berlis*[3], *C. Maurer*[3], *C. Lapa*[1], *C. Pfob*[1], *R. Bundschuh*[1];
[1]*Nuclear Medicine, faculty of medicine, University of Augsburg, Augsburg, GERMANY,* [2]*Medical Physics, University Hospital Augsburg, Augsburg, GERMANY,* [3]*Neuroradiology, faculty of medicine, University of Augsburg, Augsburg, GERMANY.*

***Aim/Introduction:*** Peptide Receptor Radionuclide Therapy (PRRT) is a treatment option in advanced WHO CNS grade 1 and 2 meningioma. Recently, intra-arterial application of the radiolabelled somatostatin receptor agonist has been introduced as an alternative to standard intravenous procedures. In this study, we evaluated the safety, achievable tumor doses as well as efficacy of intra-arterial PRRT in patients with progressive

meningioma. ***Materials and Methods:*** Eight patients (5 female, mean age, 70±13 years) with advanced progressive meningioma underwent intra-arterial PRRT (median, 3 cycles; range, 1-4) using [$^{177}$Lu]Lu-DOTA-TATE (mean activity per cycle, 7436±77 MBq). Safety of PRRT was assessed according to Common Terminology Criteria for Adverse Events (CTCAE) v5.0. During the first treatment cycle, dosimetry including whole-body scans (0.5, 4, 24, 46-48 and 90-120 h p.i.) and single photon emission computed tomography/computed tomography (SPECT/CT; 4 and 46-48 h p.i.) was performed to estimate achieved tumor doses. Four to twelve weeks after the second treatment cycle, early treatment response was evaluated using somatostatin receptor-directed positron emission tomography/CT and magnetic resonance imaging. ***Results:*** Treatment was well tolerated by all individuals with no acute adverse events. One patient died of treatment-unrelated complications four weeks after the first treatment cycle before follow-up imaging. In the remaining seven patients, no grade 3 or higher toxicity according to CTCAE v5.0 was observed. Mean achievable meningioma doses were 2.05 (range, 0.25-12.6) Gy/GBq administered activity, resulting in a maximum per cycle tumor dose of 91.2 Gy. At first follow-up, all subjects presented with disease stabilization. ***Conclusion:*** Intra-arterial PRRT of meningioma is feasible and safe. It might result in favorable tumor doses as compared to standard intravenous therapy. Further research to corroborate these initial findings as well as to investigate long-term treatment outcome is highly warranted.

## OP-857

### Preliminary Clinical data in the Phase 1/2a Dose Escalation Trial of 186RNL (Rhenium-186 nanoliposome) (186Re) Obisbemeda in Leptomeningeal Metastases (LM): the ReSPECT-LM Trial

***W. Phillips***[1], *A. Bao*[2], *N. LaFrance*[3], *M. Hedrick*[3], *M. Moore*[3], *T. Patel*[4], *J. Floyd*[1], *M. Youssef*[4], *J. Michalek*[1], *A. Brenner*[1];
[1]*The University of Texas Health Science Center at San Antonio, San Antonio, TX, UNITED STATES OF AMERICA,* [2]*Case Western Reserve University, San Antonio, TX, UNITED STATES OF AMERICA,* [3]*Plus Therapeutics, Inc, Austin, TX, UNITED STATES OF AMERICA,* [4]*UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Leptomeningeal metastases (LM) are a devastating clinical complication where the primary cancer spreads to the leptomeninges. Treatment options for LM are limited, and survival is dismal. Rhenium ($^{186}$Re) obisbemeda ($^{186}$RNL) is a BMEDA-chelated $^{186}$Re encapsulated in nanoliposomes β-emitter with a ~2 mm path length, allowing directly targeted radiation therapy delivery with limited exposure to surrounding tissue. We present preliminary clinical data for the first 9 patients from our ReSPECT-LM trial (NCT05034497). ***Materials and Methods:*** ReSPECT-LM is a multi-center, sequential cohort, open-label, dose-escalation, phase 1/2a clinical trial evaluating the safety, tolerability, and activity of a single dose of $^{186}$RNL given by a direct CNS intraventricular [Ommaya Reservoir] route in LM adult patients. Primary objectives are: maximum tolerated dose/maximum feasible dose in up to 21 LM patients in 7 cohorts using a modified 3x3 Fibonacci design, 3 cohorts have been enrolled beginning at 6.6 mCi with administered dose doubling at each successive cohort to 26.4mCi administered in 5 mL through a Ommaya reservoir. Whole body planar and SPECT/CT imaging were obtained up to 7 days following treatment for dosimetry, distribution and CSF tumor cells/ml using microfluidic chamber assay were assessed up to 56 days. Patients were followed for safety, progression, and survival. ***Results:*** A total of 9 LM patients [3 each in Cohorts 1-3} have been treated. Patients had primary diagnoses of small cell carcinoma, metastatic breast cancer (both triple negative), and lung adenocarcinoma. $^{186}$RNL showed prompt, complete distribution throughout the CSF with durable retention in the subarachnoid space and leptomeninges through protocol defined observation on Day 7 and achieved absorbed doses ranging from 18.7 to ~200 Gray (Gy) to the ventricles and cranial subarachnoid spaces. All patients experienced a decreased CSF cell count ranging from 46% to 92%. Patient treatment started in March of 2022, eight patients remain alive [1 patient has died due to primary tumor progression. No patients had treatment related adverse events (AEs) greater than Grade 1, and the most common AE was headache. ***Conclusion:*** Preliminary, interim results of this ongoing phase 1 trial showed that a single treatment with $^{186}$RNL delivered by an intraventricular catheter (Ommaya reservoir) in 9 adult patients is well tolerated, without dose limiting toxicity and with decreased CSF tumor cell counts durable through at least 30 days. Enrollment and dose escalation is continuing, and repeated dosing will be explored.:

***Aim/Introduction:*** The diagnosis of transthyretin cardiac amyloidosis (ATTR-CM) requires a good collaboration between physicians to confirm the diagnosis. This study aimed to assess current practices of nuclear medicine (NM) physicians for cardiac scintigraphy with bone radiotracers and to evaluate access to cardiac bone scintigraphy in the healthcare circuit for the diagnosis of ATTR-CM. ***Materials and Methods:*** A nationwide electronic survey was sent to 13 830 French physicians including 775 nuclear medicine (NM) physicians to assess their knowledge of 1. clinical signs of amyloidosis and 2. the recommended diagnostic algorithm to identify TTR cardiac amyloidosis. In addition, accessibility, appointment delays and results interpretation difficulties for each of the explorations required to confirm the diagnosis of ATTR-CM were evaluated among different medical specialists. A part of the questionnaire was exclusively dedicated to NM to understand their current practice regarding acquisitions protocols and reporting of cardiac bone scans. ***Results:*** 1264 physicians including 148 NM physicians (19 % of all NM physicians contacted) completed the survey. NM physicians who answered to the survey worked in academic hospitals (35 %), general hospitals (31 %), or private practices (26 %). Cardiac bone scans using early acquisitions were performed by 20 % of NM and SPECT acquisitions by 72 %. Grading of cardiac uptake of bone tracers using the Perugini score was carried out by 93 % of the NM but only 31% and 5% of NM systematically performed heart/whole body or heart/mediastinum signal quantification, respectively. Median (Q1; Q3) delay to obtain results for a cardiac bone scan was estimated at 2 (2; 4) weeks compared to 4 (3; 8) weeks for cardiac MRI, and 2 (2; 4) weeks for a biopsy. Among physicians, 68% rarely or never faced difficulties for cardiac scintigraphy. The main difficulties encountered were: appointment delay (60%), geographical distance (17%), interpretation (12%). ***Conclusion:*** In this large French national survey, access to cardiac bone scintigraphy for patients with a suspicion of ATTR cardiac amyloidosis and quality of reports appear excellent thanks to good adherence of NM physicians to the recommended acquisition protocols for cardiac bone scans and the widespread use of the Perugini grading scale in reports. However, quantitative measurements of cardiac uptake of bone tracers were performed only in one third of bone scans underscoring room for improvement in the next procedural guidelines for cardiac bone scans.

## OP-859

### SPECT/CT SUV based metrics: a promising diagnostic tool in patients with suspected transthyretin cardiac amyloidosis.

***S. Koukouraki***[1,2], *N. Kapsoritakis*[1,2], *O. Bourogianni*[1,2], *M. Stathaki*[1,2], *I. Zaganas*[3,4], *A. Patrianakos*[3,5], *A. Plevritaki*[1,5], *D. Corela*[6], *M. Marketou*[7], *E. Foukarakis*[6];
[1]*Medical School, University of Crete, Heraklion-Crete, GREECE,* [2]*Nuclear Medicine department, Medical School, University of Crete, Heraklion, crete, GREECE,* [3]*Medical School, University of Crete, HERAKLION, CRETE, GREECE,* [4]*Neurology Department, Medical School, University of Crete, Heraklion, crete, GREECE,* [5]*Cardiology Department , Medical School University of Crete, Heraklion, crete, GREECE,* [6]*Cardiology Department Venizeleion Hospital, Heraklion-Crete, GREECE,* [7]*Cardiology Department, Medical School, University of Crete, Heraklion-Crete, GREECE.*

***Aim/Introduction:*** The purpose of this study was to investigate the additional contribution of SPECT/CT SUV-based metrics to diagnostic confidence in patients suspected of ATTR-CA. ***Materials and Methods:*** One hundred four pts suspected of ATTR-CA underwent planar scintigraphy (PS), and a subset of 48 pts received additional SPECT/CT. Pts were classified according to the Perugini grading scale, the H/CL, H/Bone and H/Bkg ratios. SPECT/CT SUV measurements of the heart, myocardium, lungs, liver, soft tissues and bone, together with the ratios SUVmaxmyo, SUVmax,lungs, SUVmaxliver, SUVmaxbone and SUVmaxst, were evaluated in order to investigate potential critical metrics that would differentiate pts with different Perugini grades. ***Results:*** 33.7% of pts were considered grade 0, 34.6% grade 1 and 31.7% grade 2 or 3. The most reliable marker for differentiating grade 0 or 1 versus grades 2 or 3 was the H/CL ratio. A combination of H/CL>1.33 and H/Bone>0.85 showed sensitivity 100%. SUV-based metrics clearly differentiated grade 0 or 1 versus grades 2 or 3 with statistical significance, whereas no significant difference was found between grades 0 and 1, or between grades 1 and 2.The combined cut-off values H/CL 1.33 and SUVmaxmyo 2.88 yielded 100% sensitivity and 84.6% specificity in differentiating ATTR-CA positives versus negatives. The metric SUVmaxmyo/SUVmaxliver was able to differentiate pts with grade 1 as negative (grade 0) or positive (grade 2 or 3). ***Conclusion:*** Among SPECT/CT SUV metrics, the ratio SUVmaxmyo/SUVmaxliver was the only parameter able to classify pts with grade 1 as negative (grade 0) or positive (grade 2 or 3) for ATTR-CA

## OP-860

### 99mTc-hydroxydiphosphonate Uptake in Soft Tissue Reflects Amyloid Load in Subcutaneous Abdominal Fat Tissue and Harbors Prognostic Value in Wild Type Transthyretin Amyloidosis Patients

***H. Tingen***[1], *D. Groothof*[1], *A. Tubben*[1], *E. J. Houwerzijl*[1], *F. L. H. Muntinghe*[1], *P. van der Meer*[1], *B. P. C. Hazenberg*[1], *H. L. A. Nienhuis*[1], *R. H. J. A. Slart*[1,2];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*University Twente, Enschede, NETHERLANDS.*

***Aim/Introduction:*** Wild type transthyretin (ATTRwt) amyloidosis is a progressive protein misfolding disease mainly characterized by cardiomyopathy. Cardiac tracer uptake on bone scintigraphy is the cornerstone of non-invasive diagnosis of ATTRwt amyloidosis. Extracardiac tracer uptake on bone scintigraphy might reflect amyloid deposition and its presence has been associated with worse prognosis in patients with cardiac tracer uptake. We investigated whether intensity of soft tissue tracer uptake reflects amyloid load in subcutaneous abdominal fat tissue and whether it has added prognostic value compared to current staging systems. ***Materials and Methods:*** In this retrospective study, 89 ATTRwt amyloidosis patients who underwent whole-body 99mTc-hydroxydiphosphonate scintigraphy at the University Medical Center Groningen in The Netherlands between 2012 and 2021 were included. Twenty-six amyloid-negative heart failure patients were included as controls. Regions of interest were drawn in the skull, shoulders, heart, sixth left rib, elbows, wrists, abdominal soft tissue and thigh soft tissue on anterior planar images. Region-to-rib ratios were calculated. Differences between ATTRwt amyloidosis patients and controls were assessed with a Mann-Whitney U test. A trend between soft-tissue-to-rib (ST/rib) ratio and amyloid load as measured by Congo Red score in abdominal fat tissue aspirates was assessed with a Jonckheere-Terpstra test. Cox proportional hazards regression was used to evaluate whether ST/rib ratio was prognostically relevant. Bonferroni correction for multiple testing was applied. ***Results:*** Differences in ST/rib ratio, heart/rib ratio and skull/rib ratio were found between ATTRwt amyloidosis patients and controls (respectively 0.30 [0.24-0.38] vs 0.26 [0.22-0.29], p=.004; 1.92 [1.60-2.34] vs 0.86 [0.71-0.96], p<.001; 0.33 [0.27-0.40]

vs 0.67 [0.47-0.89], p<.001; median [interquartile range]). The Jonckheere-Terpstra test showed a statistically significant trend of higher median ST/rib ratio's with higher Congo Red scores in ATTRwt amyloidosis patients ($T_{JT}$ = 1669.0, z=3.022, p=.003). Cox regression revealed that ST/rib ratio has prognostic value on top of currently used staging systems when corrected for age, with a hazard ratio of 1.476 (1.025-2.127) (p=.036) for the Grogan staging system and 1.570 (1.017-2.424) (p=.042) for the Gillmore staging system and an improvement in -2 Log Likelihood from 161.921 to 157.836 (p=.043) and 165.316 to 161.160 (p=.041) respectively. ***Conclusion:*** ST/rib ratio on bone scintigraphy reflects amyloid load in subcutaneous abdominal fat tissue in ATTRwt amyloidosis patients and harbors prognostic value on top of currently used staging systems. As bone scintigraphy is performed in nearly every ATTRwt amyloidosis patient, measurement of soft tissue uptake could easily be applied in clinical practice.

## OP-861

### Agreement of 68Ga-DOTANOC PET/CT with 18F-FDG PET/CT and Cardiac MR in sarcoid patients with suspected cardiac involvement: A tertiary care center experience

***R. Solanki***, *A. Sood, S. Kumar, B. R. Mittal;*
*Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, INDIA.*

***Aim/Introduction:*** Sarcoidosis is an inflammatory disease, characterized by non-caseous granulomas predominantly involving the lung and lymph nodes. Cardiac sarcoidosis (CS) is a rare presentation with poor prognosis. Imaging modalities like cardiac magnetic resonance imaging (CMR), positron emission tomography (PET) and radionuclide scans are helpful in early diagnosis and treatment of CS. $^{18}$F-FDG PET/CT in CS provides inflammatory disease activity information and helps in early detection and therapy monitoring, but requires prior preparation in order to suppress the variable physiological uptake. $^{68}$Ga-DOTANOC has high affinity for somatostatin receptors (SSTR) 2, 3 and 5 expressed in inflammatory cells in sarcoid granulomas without physiological uptake. Therefore $^{68}$Ga-DOTANOC can be an alternative to $^{18}$F-FDG without the need for suppression of physiological FDG uptake. ***Materials and Methods:*** Twenty-three patients recruited from the pulmonary out- patient department (OPD) with biopsy proven pulmonary sarcoidosis with suspected cardiac involvement and patients from cardiology OPD with a primary cardiac abnormality, in whom systemic sarcoidosis was diagnosed on the basis of clinical/histopathological features were prospectively included in this study. Patients underwent cardiac specific imaging like CMR, $^{13}$N-$NH_3$ PET/CT for myocardial perfusion, $^{18}$F-FDG PET/CT for glucose metabolism and $^{68}$Ga-DOTANOC PET/CT for abnormal SSTR expression in the myocardium. Intermodality agreement between CMR, $^{18}$F-FDG PET/CT and $^{68}$Ga-DOTANOC PET/CT was evaluated. ***Results:*** CMR could be done in only 19 out of 23 patients. CMR and $^{18}$F-FDG PET/CT were concordant in 17/19 (89.4%) patients and discordant in 2/19 (10.5%) with a substantial intermodality agreement with Cohen's kappa=0.774 and p value of 0.001 (statistically significant). CMR and $^{68}$Ga-DOTANOC PET/CT were concordant in 16/19 (84.2%) patients and discordant in 3/19 (15.7%) with substantial intermodality agreement with Cohen's kappa=0.671 with p value of 0.003 (statistically significant) and $^{18}$F-FDG and $^{68}$GaDOTANOC were concordant in 18/23 (78.2%) patients and discordant in 5/23 (21.7%) with moderate intermodality agreement with Cohen's kappa =0.563 and p value of 0.007 (statistically significant). ***Conclusion:*** The physiological cardiac suppression with $^{18}$F-FDG PET/CT is a tedious process and may not be achieved in many patients, whereas SSTR imaging with $^{68}$GaDOTANOC PET/CT has this advantage. In our study, although both $^{18}$F-FDG and $^{68}$GaDOTANOC PET/CT had strong inter-modality agreement with CMR, the role of these imaging techniques is more complementary. Though there is paucity of data to validate its role, but with more sample size and evidence, SSTR imaging has the potential to replace $^{18}$F-FDG PET/CT in the diagnosis, prognostication and response assessment in the upcoming future.

## OP-862

### Cardiac Viability Imaging With 15O-H2O/18F-FDG Positron Emission Tomography Does Not Predict Left Ventricular Ejection Fraction Improvement After Revascularization in Patients With Chronic Ischemic Heart Failure

***M. Gram Kjærulff***[1], *K. Pryds*[2], *R. Nielsen*[2], *S. Madsen*[1], *T. V. Luong*[1], *L. P. Tolbod*[1], *L. C. Gormsen*[1];
[1]*Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK,* [2]*Department of Cardiology, Aarhus University Hospital, Aarhus, DENMARK.*

***Aim/Introduction:*** Different imaging methods can assess cardiac viability, including positron emission tomography (PET) which differentiates hibernating myocardium from scar tissue by assessing myocardial perfusion and metabolism simultaneously. Previous observational studies have demonstrated that imaging-guided revascularization improved patient outcomes. However, the usefulness of viability imaging in revascularization decision-making is debated due to newer randomized studies showing the opposite. To our knowledge, there have been no PET studies conducted on this issue using $^{15}$O-$H_2O$ combined with $^{18}$F-FDG. The aim of this study was therefore to assess the predictive value of $^{15}$O-$H_2O$/$^{18}$F-FDG PET metrics on improving left ventricular ejection fraction (LVEF) following revascularization in patients with chronic ischemic heart failure (iHF). ***Materials and Methods:*** In this prospective study, 78 chronic iHF patients with reduced LVEF (mean baseline LVEF 33.7±10.7) underwent viability imaging using $^{15}$O-$H_2O$ and $^{18}$F-FDG prior to potential revascularization. The primary outcome measure was an absolute increase of at least 5% in LVEF from baseline to follow-up, as assessed by echocardiography. The significance of PET metrics in predicting LVEF improvement was assessed by receiver operating curves (ROC) and their respective area under curve (AUC) values analysing PET metrics, including scar percent, hibernation score, and myocardial flow reserve (MFR). ***Results:*** Of the 78 patients undergoing viability imaging by PET, 32 (41%) underwent revascularization. The proportion of patients with an LVEF improvement of ≥5% was not significantly different between revascularized and non-revascularized patients (47% vs. 53%; p = 0.36). In revascularized patients, the ROC analysis of the predictive value of PET metrics resulted in AUC values of 0.46 for scar (95% confidence interval (CI): 0.25-0.67), 0.45 for hibernation (95% CI: 0.24-0.65), and 0.58 for MFR (95% CI: 0.34-0.83). The predictive value of PET metrics was equally poor in the non-revascularized group. ***Conclusion:*** No significant difference in LVEF improvement between revascularized and non-revascularized patients with chronic ischemic herat failure was observed. No PET metrics obtained from $^{15}$O-$H_2O$/$^{18}$F-FDG PET viability imaging could predict LVEF improvement following revascularization. The clinical use of viability PET imaging should therefore be questioned.

## OP-863

### Epicardial adipose tissue is differently associated with myocardial remodeling and perfusion in heart failure with reduced and preserved ejection fraction

***Y. Cui***, *C. Zheng, S. Gu, J. Lu;*
*Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** Epicardial adipose tissue (EAT) has been investigated in patients with heart failure (HF) and suggested to play a pathogenic role[1]. However, different association of EAT with cardiac haemodynamic and metabolic profile has been presented in HF patients with reduced (HFrEF) and preserved (HFpEF) ejection fraction [2]. We aimed to evaluate the relationship of EAT with myocardial remodeling and perfusion by using integrated PET/MR in patients with HFrEF and HFpEF. ***Materials and Methods:*** Fifty-two consecutive HF patients (HFrEF n=24, HFpEF n=28) who underwent resting cardiac $^{13}$N-$NH_3$ PET/MR were retrospectively included. EAT volume, left ventricular volume and function parameters, myocardial native T1 value, and scar volume were analyzed from cardiac MR images, and global absolute myocardial blood flow (MBF) was calculated from dynamic PET data. The difference of EAT volume between HFrEF and HFpEF was assessed with the independent sample t-test. Pearson correlation coefficient and multiple linear regression analysis was used to estimate the relationship between PET/MR parameters and EAT. ***Results:*** Patients with HFrEF and HFpEF showed similar EAT volume (83.89 ± 35.54 mL vs. 80.90 ± 23.00 mL, P = 0.716). For all HF patients, EAT volume was positively correlated with age (r = 0.28, P = 0.043) and MBF (r = 0.37, P = 0.023), and negatively correlated with myocardial native T1 value (r = 0.30, P = 0.033). Increased EAT volume was associated with higher left ventricular ejection fraction (r = 0.42, P = 0.041), and lower end-systolic volume (r=0.44, P=0.032) and myocardial native T1 value (r = 0.51, P = 0.013) in patients with HFrEF. However, EAT volume was not significantly associated with other PET/MR parameters in patients with HFpEF. Multiple linear regression analysis showed native T1 value was independently associated with EAT in patients with HFrEF (P = 0.013). ***Conclusion:*** Increased EAT volume is associated better myocardial remodeling and perfusion in HFrEF, but not in HFpEF, indicating different roles of EAT in the two HF phenotypes. ***References:*** 1. ## OP-864

### Relationship between left ventricular mechanical dyssynchrony with cardiac resynchronization therapy response in chronic heart failure patients with CRT-D

***T. Atabekov***, *A. Mishkina, R. Batalov, S. Sazonova, S. Krivolapov, V. Saushkin, M. Khlynin, Y. Varlamova, K. Zavadovsky, S. Popov;*
*Cardiology Research Institute, branch of the Federal State Budgetary Scientific Institution "Tomsk National Research Medical Center of the Russian Academy of Sciences", Tomsk, RUSSIAN FEDERATION.*

***Aim/Introduction:*** Cardiac resynchronization therapy (CRT) improves outcomes in only two-thirds of patients (pts) with chronic heart failure (CHF) and implanted CRT devices with cardioverter-defibrillator function (CRT-D). These pts qualified as responders to CRT. Unfortunately, in the remaining one-third of pts, there is no improvement of the left ventricular (LV) contraction and clinical status. We aimed to investigate the relationship between LV mechanical dyssynchrony with CRT response in CHF pts with CRT-D. ***Materials and Methods:*** Forty nine pts (male - 34 [69.4%], average age 58.3 ± 11.4 years) with sinus rhythm, permanent left bundle branch block (LBBB) with QRS duration ≥ 150 ms and New York Heart Association (NYHA) II-III functional class (FC) of CHF were included to the study. In addition to full examination, myocardial perfusion scintigraphy (MPS) and gated blood pool single-photon emission computed tomography (gBPS) were performed before and 6 month after CRT-D implantation. Pts were considered as responders to CRT if they fulfilled after 6 month follow-up the following combined criteria: NYHA FC improvement ≥ 1 class + LV end systolic volume (LVESV) decrease > 15% or NYHA FC improvement ≥ 1 class + LV ejection fraction (LVEF) improvement > 5%. ***Results:*** The 1$^{st}$ and 2$^{nd}$ groups included 35 (71.4%) and 14 (28.6%) pts with and without the response to CRT respectively. Groups were comparable in terms of pre CRT-D implantation clinical and instrumental parameters, with the exception of MPS and gBPS parameters. The multivariate logistic regression with the inclusion factors such as baseline QRS duration, ΔQRS, female gender, non-ischemic CHF, LV lead lateral position, quadripolar LV lead, biventricular pacing percentage, MPS and gBPS indicators had shown that only ΔSkewness (adjusted odds ratio [OR] 0.1293; 95% confidence interval [CI] 0.0226-0.7396; p=0.02), LV septal phase standard deviation (PSD) (OR 1.0669; 95% CI 1.0118-1.1251; p=0.01) and interventricular dyssynchrony (IVD) (OR 1.0625; 95% CI 1.0202-1.1067; p=0.003) were the independent predictors to CRT response. The univariate ROC-analysis showed that ΔSkewness decrease ≤ -0.06 (AUC=0.809; p<0.0001), LV septal PSD increase > 23° (AUC=0.708; p=0.01) and IVD increase > 67.2 ms (AUC=0.851; p<0.0001) were predictors to CRT response. ***Conclusion:*** The mechanical dyssynchrony assessed by MPS and gBPS may be useful in identifying responders to CRT. ΔSkewness decrease ≤ -0.06, LV septal PSD increase > 23° and IVD increase > 67.2 ms are predictors to CRT response. Further investigations of their predictive significance are warranted.

## OP-865

### The prognostic value of mechanical and electrical dyssynchrony and hibernating myocardium in patients with ischemic heart failure: a comparative study of medical and revascularization therapy

***L. Shan***[1], *X. Zhang*[2];
[1]*Department of Cardiology, Beijing Anzhen Hospital, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Molecular Imaging Lab, Beijing Anzhen Hospital, Beijing, CHINA.*

***Aim/Introduction:*** We aimed to assess the prognostic value of QRS duration, LV mechanical dyssynchronization (LVMD) and hibernating myocardium (HM) in patients with ischemic heart failure (IHF), and to guide for therapeutic strategy decision-making. ***Materials and Methods:*** Two hundred and forty-seven (age, 59 (31, 82) y, 213 men) consecutive IHF patients with gated SPECT-LVEF≤35%, who underwent gated $^{99m}$Tc-sestamibi SPECT myocardial perfusion imaging (MPI) and gated $^{18}$F-FDG PET imaging, were followed-up for a median of 3.4 y (range, 0.1-5.7 y). LVMD was defined as standard deviation (SD)> 30 or histogram bandwidth (BW)>120 by gated MPI and ROC analysis. HM+ was defined as >10% LV of HM (perfusion defect mismatche score of 1.0 or greater). Electrical dyssynchrony was defined as QRS duration ≥130 ms. Patients were classified into 4 subgroups according to LVMD, combined with QRS or HM. All-cause death

served as the only endpoint. The estimated survival curve was analyzed and compared with the log-rank test. Cox proportional hazards regression analysis identified the independent predictors for all-cause death. ***Results:*** A total of 59 patients (23.8%) suffered all-cause death. The correlation between the QRS duration and BW (r = 0.223; p = 0.001) or SD (r = 0.213; p = 0.002) was weak, even in subgroup of patients with QRS<130ms. Among 4 subgroups, the cardiac survival in patients with QRS<130ms and LVMD- (BW≤120 or SD≤30) was the highest, which was significantly higher than that in patients with QRS<130ms and LVMD+ (BW>120, P = 0.016; SD>30, P = 0.008, respectively). Additionally, in subgroup of patients with QRS<130ms, the lowest survival was observed in patients with HM+ and LVMD+ (BW>120, P = 0.048; SD>30, P = 0.024, respectively). Revascularization could significantly improve the survival in comparison with medical therapy in these patients (HM+ and BW>120: $\chi$ 2 = 10.439, P = 0.001; HM+ and SD>30: $\chi$ 2 = 13.528, P < 0.001). Multivariate Cox analysis identified that age, QRS duration ≥ 130 ms, gated PET LVEF>25%, and BW >120 were independent predictors of all-cause death in patients with IHF (all P<0.05). By combining the four independent determinants, the prognostic power significantly (P < 0.0001) increased maximally to 28.86. ***Conclusion:*** Mechanical dyssynchrony by gated MPI provided an incremental prognostic value in patients with electrical dyssynchrony. Compared with medical therapy, coronary revascularization was significantly associated with improved long-term survival in patients with HM accompanied with mechanical dyssynchrony.

## OP-866

### C-X-C Motif Chemokine Receptor 4-directed Molecular Imaging of the Cardiac Lymphatic System after Acute Myocardial Infarction - Initial Results from the Phase II LOMI Trial

***A. Kosmala***[1], *A. Dörrler*[1], *N. Hasenauer*[1], *N. Kraus*[2], *S. E. Serfling*[1], *P. E. Hartrampf*[1], *A. K. Buck*[1,3], *T. Higuchi*[1,3,4], *T. Reiter*[2], *R. A. Werner*[1,3,5]; [1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Department of Internal Medicine I, Cardiology, University Hospital Würzburg, Würzburg, GERMANY,* [3]*Comprehensive Heart Failure Center, University Hospital Würzburg, Würzburg, GERMANY,* [4]*Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN,* [5]*The Russell H Morgan Department of Radiology and Radiological Sciences, Johns Hopkins School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** After acute myocardial infarction (MI), the cardiac lymphatic system mediates resolution of the local inflammatory response in the infarct territory by immune cell trafficking to heart-draining mediastinal lymph nodes (MLN). Image biomarkers providing a quantitative read-out of the lymphatic-immune cell axis may identify subjects at increased risk for cardiac functional decline. ***Materials and Methods:*** We report on initial results of a Phase II Trial (NCT05519735), which enrolls patients with acute ST-elevation MI followed by reperfusion and imaged with C-X-C motif chemokine receptor 4 (CXCR4)-directed PET/CT using [$^{68}$Ga]Ga-PentixaFor. At baseline, patients are scheduled for molecular imaging and cardiac magnetic resonance (CMR). To determine functional decline, CMR will be repeated six months after the acute event. [$^{68}$Ga]Ga-PentixaFor uptake ($SUV_{peak}$) in the myocardium and MLN is determined, providing infarct/remote myocardial (IRR) and MLN/Remote LN Ratios (LNR). Association of uptake with adverse outcome is also tested. ***Results:*** At day of abstract submission, 20 patients were imaged median 4.5 days after STEMI (available follow-up after 6 months, 14/20 [70.0%]). $SUV_{peak}$ from infarcted myocardium (3.35±0.55) and LN (4.00±0.67) were elevated when compared to blood-pool (2.30±0.32, P≤0.05). Respective IRR (2.23±0.59) and LNR (2.25±0.70) were consistently >1, with variance among patients (IRR, 1.34-2.99; LNR, 1.16-3.45). Upon first follow-up, CMR-derived left ventricular ejection fraction (LVEF) was improved when compared to baseline (48.4±7.88 vs 53.6±4.99, P<0.05), while late gadolinium enhancement (LGE, in g) declined (32.55±17.18 vs 18.06±13.99, P<0.05). Derived changes of cardiac outcome parameters correlated with LNR (%LVEF, R=0.59; LGE, R=0.62; P<0.05, each), but not with IRR (%LVEF, R=0.01; LGE, R=-0.06, P≥0.85). Comparing cohorts with declining vs. improved LVEF, LNR was increased in subjects with deteriorating LVEF (2.87±0.60 vs. improved LVEF, 1.99±0.48, P<0.05). In regression analysis, increased LNR was associated with declining LVEF (Odds Ratio, 20.04, P<0.05), while conventional parameters were not significantly associated with LVEF changes (including baseline-LGE/-LVEF, IRR, high sensitivity-Troponin T, B-type natriuretic peptide, creatine kinase, C-reactive protein, white blood cell count, P≥0.08). ***Conclusion:*** CXCR4-directed imaging of inflammatory leukocytes provides information on the extent of local and systemic tissue inflammation in patients after first acute MI. Chemokine receptor imaging of MLN involved in the adaptive immune response also identifies subjects at risk for cardiac functional decline. This novel image biomarker may guide reparative interventions for selective stimulation of cardiac lymphangiogenesis, which may prevent inflammatory-driven on-set of heart failure in coronary artery disease. ***Funding***: German Research Foundation (453989101, 507803309).

### Predictors for Disease Free and Progression Free Survival in Metabolic Responders and Non-responders on follow-up FDG PET/CT after Chemoradiation in Nasopharyngeal Cancers

***M. Zaman***[1], *N. Fatima*[2], *R. Tahseen*[3], *A. Ahmed*[1], *A. Zaman*[4], *S. Zaman*[5], *U. Zaman*[6];
[1]*Dept of Radiology, Aga Khan University Hospital, Karachi, PAKISTAN,* [2]*Dept of Radiology, Aga Khan University Hospital, KARACHI, PAKISTAN,* [3]*Dept of Radiation Oncology, Aga Khan University Hospital, Karachi, PAKISTAN,* [4]*Dept of Medicine, Sunny Downstate Medical Centre, NY, New York, NY, UNITED STATES OF AMERICA,* [5]*Dept of Medicine, Dr Ruth Pfau Hospital, Karachi, PAKISTAN,* [6]*Dept ogf Hem Oncology, Oklahoma University, Okla, Oklahoma, OK, UNITED STATES OF AMERICA.*

***Aim/Introduction: Aim/Introduction:*** To determine disease free survival (DFS) and progression free survival (PFS) in patients with nasopharyngeal cancer (NPC) having achieved complete (CMR) and partial metabolic response (PMR) on post-chemoradiation (CRT) FDG PET/CT. ***Materials and Methods:*** Retro-prospective study conducted at PET/CT Section of JCIA accredited healthcare facility of Pakistan. Total 68 patients of NPC patients who had baseline and post-CRT FDG PET/CT were included and prospectively followed till predefined study end points of recurrence or disease progression or death from April-2016 till October 2022. Based on CMR on post-CRT FDG PET/CT, 40 patients labelled as responders and 18 as non-responder based on PMR respectively. By using ROC analysis, the predictors of PMR and recurrence were analyzed. Kaplan Meier's survival plots were analyzed to measure DFS in responders and PFS in non-responders respectively. ***Results:*** On follow-up, mean DFS in responders was 49.6 ± 6.3 month, 78% survival and recurrence was found in 09 (22%) patients. Baseline SUVmax >8.3 of primary tumor, stage IV, body mass index >24.609 and male gender were found significant predictors of recurrence in responder group using ROC ($p < 0.05$). In non-responders group, the mean PFS was 6.8 ± 1.8 months. Higher SUVmax >9.5 and more stage IV disease on baseline FDG PET/CT were found significant predictors of shorter PFS in non-responders on ROC ($p < 0.05$). ***Conclusion:*** Male gender, higher BMI and primary tumor SUVmax (>8.3) on baseline FDG PET/CT predict shorter DFS in patients who achieved complete metabolic response after CRT. In patients with partial metabolic response on post-CRT, higher primary tumor SUVmax >9.5 and stage IV disease on baseline FDG PET/CT were found significant predictors of shorter PFS.

## EPS-253

### Performance of hybrid [$^{18}$F]FDG PET-MRI for staging of head and neck cancer

***E. Droogers***, *I. J. Pruis, A. W. A. van der Eerden, A. A. Harteveld, R. Valkema, S. E. M. Veldhuijzen van Zanten;*
*Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** This is the first retrospective study in the Netherlands to evaluate the diagnostic yield of hybrid 2-[18F] fluoro-2-deoxy-d-glucose ([18F]FDG) PET-MRI for staging of head and neck squamous cell carcinoma (HNSCC). ***Materials and Methods:*** Patients suspected of HNSCC underwent hybrid [18F] FDG PET-MRI following dedicated head and neck and whole-body protocol, either at time of initial diagnosis or suspected tumor recurrence. Images were analyzed in the setting of regular clinical care by both a nuclear medicine physician as well as a dedicated neuro/H&N radiologist. Data on the interpretation of multiple variables related to the primary tumor (T), lymph nodes (N), distant metastases (M) and second primary tumors (SPT) were extracted from the radiology reports retrospectively. Based on the combined interpretation of both PET and MRI, all lesions (T/N/M/SPT) were denominated as malignant, suspicious or not malignant/ absent and compared to reference values, including pathology and/or follow-up (clinical and/or imaging), to enable lesion-wise and patient-wise analyses on the diagnostic accuracy. ***Results:*** Ninety-five patients (68.4% male, mean age of 64.7) with histologically proven HNSCC were included. The true positive rate for T was 97.5% (79/81 correct diagnosis), the true negative rate was 100% (14/14). The latter group included nine patients with carcinoma of unknown primary (CUP) and five patients with unmeasurable T due to previous treatment. A true positive and true negative rate of 100% was shown for lymph nodes denominated as malignant (both in lesion-wise and patient-wise analyses) or benign (only patient-wise analysis possible). The lesion-wise analysis of suspicious lymph nodes demonstrated a true positive rate of 22.1% (15/68), i.e., a correct diagnosis in 1/5 patients, and overcall in 4/5 patients. Ten suspicious sites for M and sixteen suspicious sites for SPT were detected in eight and thirteen patients, respectively. ***Conclusion:*** Hybrid [18F]FDG PET-MRI in patients with HNSCC has a high diagnostic yield with particular high true positive/negative rates for primary tumors and pronounced malignant or benign lymph nodes. Further research is needed, however, to develop and validate optimal criteria for reading [18F]FDG PET-MRI, particularly for accurate interpretation of suspicious lymph nodes, and to compare its performance with [18F]FDG PET-CT. Additionally, novel radiotracers beyond [18F] FDG for diagnosis of head and neck cancer may be promising and must therefore be further analyzed.

## EPS-254

### The Validity of F-18-FDG PET/CT in the Management of the Patients with Laryngeal Carcinoma After Therapy

***J. Petrovic***, *J. Milovanovic, A. Jotic, D. Sobic Saranovic;*
*Center for Nuclear Medicine, University Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.*

***Aim/Introduction:*** The aim of this investigation is to estimate the diagnostic performance of positron emission tomography/computed tomography using fluorine-18 fluoro-deoxyglucose (FDG PET/CT) in the follow up of the post-treatment laryngeal squamocellular squamous cell cancer carcinoma (SCC), as well as survival rate. ***Materials and Methods:*** Total of 68 patients (57 males and 11 females), mean age (69.1±6.8), with post-treatment laryngeal SCC were investigated. Indications for FDG PET/CT

were: staging after surgery, restaging after therapy with positive/uncertain CT, follow-up, suspected recurrence on CT. FDG PET/CT findings were compared to clinical follow-up of up to 12 years after imaging. Degree of metabolic activity was analyzed visually and semi-quantitatively using maximal standardized uptake value (SUVmax). ***Results:*** High accumulation of radiopharmaceutical was found in 48 (70.6%) patients (42 males and 6 females) who were considered true positive, physiological in 17 patients (25%) (13 males and 4 females) and only 3 (3.5%) (2 males and one female) were false positive. Overall sensitivity of FDG PET/CT was 100%, specificity 85.0%, positive predictive value 94.0%, negative predictive value 100% and accuracy 95.6%. In 25 cases (36.8%) PET/CT findings significantly influenced further management of the patients. Progression free survival (PFS) in the FDG positive group was 41.8 ± 12.9 months, median 40, range 21-70, while in FDG negative group it was 47.6 ± 19.7 months, median 44, range 17-97, without significant differences between the groups (p= 0.30). Statistically significant correlation between SUVmax and PFS was not observed (p>0.05). ***Conclusion:*** FDG PET/CT is a valuable tool for follow-up of laryngeal SCC due to its high sensitivity, specificity, PPV, NPV and accuracy. It can influence the patients' management in significant number of cases. Patients with negative FDG PET/CT findings had longer PFS than those with positive ones, but without statistical significance. SUVmax was not proven to be a strong predictor of the disease-free survival of the patients.

## EPS-255

### PET/CT-guided GTV delineation during radiotherapy planning and prognosis evaluation in recurrent oral cavity squamous cell carcinoma

***Y. Tian***, *Y. Zhang, C. Li, Y. He;*
*Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** To evaluate the usefulness of PET/CT in gross tumor volume (GTV) delineation during radiotherapy planning and the prognostic value in recurrent oral cavity squamous cell carcinoma (OSCC). ***Materials and Methods:*** 20 patients with recurrent OSCC underwent PET/CT and MRI. The GTV for primary tumor and lymph nodes (nGTV) were defined on CT (GTV-CT) and compared to GTVs obtained from PET (GTV-PET) and MRI (GTV-MRI) images. Two methods of GTV determination were used: visual interpretation of CT, PET (GTV-PETvis) and MRI images and quantitative automatic method based on a chosen threshold value (20%, 30%, 40%, 50% 60%) of standardized uptake values (SUVmax) from PET examination (GTV-PET20%, GTV-PET30%, etc.). Statistical analysis of differences in GTV values obtained from CT, PET and MRI studies was performed. GTV-CT was used as a reference. SUVmax, whole-body metabolic tumor volume (WBMTV), and whole-body total lesion glycolysis (WBTLG) derived from PET/CT were measured. Using receiver operator characteristic (ROC) curves, Kaplan-Meier analysis, and log-rank tests, we identified the optimal cutoff values for SUVmax, WBMTV, and WBTLG to determine independent predictors of survival. ***Results:*** In all, 70% of GTV-MRI and 40% of GTV-PETvis were larger than GTV-CT. GTV-PET 30% were the most closely related volumes to GTV-CT from all threshold methods in 50% of patients. GTV-PETvis generated the most similar volumes to GTV-CT from all PET measurements. Compared to nGTV-CT, 70% of nGTV-MRI and 20% of nGTV-PETvis were larger. The remaining nGTV-MRI and nGTV-PETvis measurements were smaller than nGTV-CT. nGTV-PET20% were the most closely related volumes to nGTV-CT in 40% of the cases. GTV-PET20%, nGTV-PETvis, and nGTV-PET50% ($p < 0.05$) diverge significantly from nGTV-CT results. ROC's optimal cutoff values of the primary focus SUVmax, WBMTV, and WBTLG, were 10.36, 9.52$cm^3$and 52.12, respectively. Patients with WBMTV < 9.52 $cm^3$ had significantly better 3-year overall survival (OS) ($P = 0.003$) and disease-free survival (DFS) ($P < 0.001$) than patients with a WBMTV ≥ 9.52 $cm^3$. Patients with WBTLG < 52.12 had significantly better 3-year OS (90.9% vs. 76.9%, $P = 0.002$) and DFS (90.0% vs. 66.3%, $P < 0.001$) than patients with a WBTLG ≥ 52.12. Multivariate Cox regression modeling showed WBMTV (HR, 0.425) and WBTLG (HR, 0.317) could be predictive of OS and DFS. ***Conclusion:*** PET/CT provides more information during target tumor mass delineation in radiotherapy planning in recurrent OSCC. PET/CT measurements of WBMTV and WBTLG could predict survival.

## EPS-256

### Detection of Perineural Tumour Spread in Head and Neck Cancers by 18F-FDG PET/CT

***A. Ormanci***, *M. Tuncel;*
*Hacettepe University Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Perineural spread(PNS) refers to tumour growth along large nerves. It most commonly occurs in head and neck cancers(HNC). Accurate detection of PNS is crucial since it changes treatment plans and prognosis. However accuracy of PET/CT in detection of PNS is not extensively studied. Therefore, our study aimed to retrospectively analyse the PNS detection rate of 18F-FDG-PET/CT in patients with HNC. ***Materials and Methods:*** We have retrospectively analysed the 18F-FDG-PET/CT images of 478 patients with HNC.Among these patients,26 were diagnosed as having PNS by MRI and/or clinical findings. These patients had whole-body PET/CT scans within one-month of MRI.Seven of the 26 patients also had dedicated head and neck PET images. PET/CT images were re-evaluated by two nuclear medicine physicians(rePET). SUVmax and SUVmean values of the primary tumour region and PNS were measured. PNS pattern (focal/linear/focal+lineer),agreement with the MRI findings and original PET/CT reports were evaluated. ***Results:*** Our retrospective study enrolled 26 patients (F/M:7/19, median age:56 range:11-81) with FDG-avid HNC. Of these patients, 19/26(73%) had SCC,6/26(23%) had adenoid cystic carcinoma and 1/26(4%) had salivary ductus carcinoma. The primary tumor localisation was nasopharynx in 13/26(50%), oral cavity in 9/26(34%),nasal cavity in 1/26(4%),sphenoid sinus in 1/26(4%),maxillary sinus in 1/26(4%) and parotid gland in 1/26(4%) patients. While 14/26(54%) patients were newly diagnosed,12/26(46%) were evaluated after surgery and/or chemoradiotherapy. In 20/26(77%) patients, primary tumour was detected in PET/CT images, whereas in 6/26(23%) patients primary tumour was not detected because of previous treatments.The number of patients in which rePET and MRI were fully compatible was 19/26(73%).In 5/26(19%) patients MRI showed more extensive disease than rePET, and in 2/26(8%)patients MRI showed PNS, whereas rePET was negative. The median PET SUVmax values of the primary tumours were 12(range:3,27-41) and PNS was 8,6(range:2-41). Out of 24 patients that rePET detected PNS; 15/24(63%)had focal, 1/24(4%)had linear and 8/24(33%) had both focal & linear PNS.V2 nerve involvement was observed in 7/24(29%),V3 in 12/24(50%) and both V2 & V3 nerve involvement was observed in 5/24(21%) of patients. In 10/26(38%) of patients, rePET and original PET/CT reports described PNS consistently. However, in 16/26(62%) of patients, rePET detected PNS which was not reported at the original PET/CT report. ***Conclusion:*** 18F-FDG-PET/CT had lower sensitivity in the detection of PNS when compared to MRI. However, careful and dedicated interpretation of PET/CT images could detect more lesions compatible with PNS and can assist MRI findings.

## EPS-257

### 18F-FDG PET CT andTumour Tissue Modified Viral (TTMV) -Human papilloma virus DNA : Role in Recurrent HPV driven oropharyngeal squamous cell carcinoma.

***R. Kulkarni***, *M. Posner, S. Roof, M. Ghesani, N. Ghesani;*
*Mount SInai Hospital, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Human papilloma virus (HPV) driven oropharyngeal squamous cell carcinoma (OPSCC) has better outcomes than HPV negative ones. While around 1/5 of the patients develop locoregional failure, treatment with curative intent is still an option. Surveillance is therefore important for early detection of recurrence. Image-guided surveillance with $^{18}$F Fluorodeoxyglucose (FDG)-positron emission tomography/computerized tomography (PET/CT) has demonstrated excellent survival rates and quality of life benefits. Liquid biomarkers such as Tumour Tissue Modified Viral (TTMV) -HPV DNA offer potential for early detection of recurrence. In this presumably first study of its kind, retrospective study, we present the preliminary data comparing the TTMV HPV DNA levels and tumour burden, represented by tumour lesion glycolysis (TLG). This is a volumetric parameter, more representative of disease burden than traditional criteria such as highest standardised uptake value (SUVmax), derived from $^{18}$F-FDG PET CT studies. The utility of this parameter has been validated in large volume diseases. We are attempting to understand the role in oligometastases and locoregional recurrence. We are also studying the relationship between tumor burden and the TTMV HPV DNA to understand tumor biology and a possible complementary role between imaging and liquid biopsies. ***Materials and Methods:*** Patients with OPSCC positive for HPV 16 genotype at initial diagnosis and recurrence were included. Surveillance $^{18}$F-FDG PET/CTs at recurrence, and for restaging prior to definitive treatment of recurrence were studied. Voxels of interest were drawn around the lesions and a proprietary software derived the TLG, SUVmax and SUVmean. Correlation between the TLG and the TTMV HPV DNA levels for each disease site was assessed using Pearson's correlation coefficient. ***Results:*** 25 patients, 22 males and 3 females, mean age 69.1 years, with biopsy proven, recurrent HPV positive OPSCC were included. Primary tumor sites were base of tongue cancer in 9/25 pts, palatine tonsil in 13/25, left nasal cavity, pyriform sinus SCC and unknown in rest. 5/25 had local, 8/25 had regional nodal, 5/25 had loco-regional recurrences and 7/25 had distant metastases. At recurrence, 25/25 patients had positive PET CT studies and 17/25 patients had a positive TTMV HPV DNA. Comparing the average site-specific tumour burden and the TTMV HPV DNA values when considering (Table 1), we see a strong positive correlation with a Pearson's correlation co-efficient of 0.99. ***Conclusion:*** In small volume disease, site-specific tumour burden correlates to the average TTMV HPV DNA. More sophisticated methods are needed to study overall tumor volumes and burden.

## EPS-258

### Convolutional Neural Network for Prediction of Early Disease Progression in Patients with Advanced Epidermal Growth Factor Receptor-Mutated Lung Adenocarcinoma Receiving Tyrosine Kinase Inhibitor Therapy Based on 18F-FDG PET Images

***K. Lue***[1], *Y. Chen*[2,3], *L. Yong*[1], *X. Wong*[1], *S. Liu*[1,2], *H. Lin*[4,5];
[1]*Tzu Chi University of Science and Technology, Hualien, TAIWAN,* [2]*Hualien Tzu Chi Hospital, Hualien, TAIWAN,* [3]*Tzu Chi University, Hualien, TAIWAN,* [4]*Chang Gung University, Taoyuan, TAIWAN,* [5]*Keelung Chang Gung Memorial Hospital, Keelung, TAIWAN.*

***Aim/Introduction:*** Patients with advanced epidermal growth factor receptor (EGFR)-mutated lung adenocarcinoma are known to respond to first-line tyrosine kinase inhibitor (TKI) treatment. However, approximately half of the patients who initially respond to TKI experience drug resistance within 12 months. In this study, we used a convolutional neural network (CNN) based on $^{18}$F-FDG PET images to predict disease progression in patients with advanced EGFR-mutated lung adenocarcinoma treated with TKI. ***Materials and Methods:*** In total, 112 patients diagnosed with EGFR-mutated lung adenocarcinoma were retrospectively enrolled. $^{18}$F-FDG PET images were acquired before the TKI treatment. A standardised uptake value threshold > 2.5 was used for primary tumour segmentation. The segmented images were augmented via the intersection of the three-dimensional domain with triples of orthogonal planes, which were used as input images for the CNN model. The augmented images were randomly divided into training (80%), validation (10%), and testing (10%) datasets. The ResNet-50 architecture was adopted to construct a deep-learning CNN and predict the disease progression within 12 months. Random rotation, reflection, and scaling were applied to the images during the training to avoid overfitting. Predictive power was assessed using the area under the receiver operating characteristic curve (AUC). A confusion matrix was generated to estimate the performance, including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy. An occlusion sensitivity map was used to visualise the important areas of a PET image for prediction. MATLAB with the Deep Learning Toolbox Release 2022a (MathWorks, Natick, USA) was used in this study. ***Results:*** In the study population, 19 and 93 patients were diagnosed with stage IIIB and IV disease, respectively. Fifty-one patients experienced disease progression within 12 months of receiving TKI treatment. The CNN ResNet-50 model was trained, fine-tuned, and utilised to predict early disease progression in the testing dataset. The AUC estimation was 0.93, accuracy was 93.3%, sensitivity and specificity were 88.4% and 97.4%, respectively, and PPV and NPV were 96.5% and 91.0%, respectively. The occlusion method for trained model interpretability highlighted important areas in regional parts of the primary lung tumour. ***Conclusion:*** The CNN ResNet-50 model based on $^{18}$F-FDG PET images can predict disease progression within 12 months in patients with advanced EGFR-mutated lung adenocarcinoma treated with TKI. This model may be clinically helpful for facilitating the management of patients with advanced EGFR-mutated lung adenocarcinomas.

## EPS-259

### Role Of Novel Geometric Variables Derived From 18F-FDG PET/CT As Predictive Factors In Patients With Non-Small Cell Lung Cancer

***G. Jimenez Londoño***[1], *A. M. Garcia Vicente*[2], *J. J. Bosque*[3], *J. Perez-Beteta*[3], *M. Amo-Salas*[4], *A. F. Honguero-Martinez*[5], *E. Noriega Alvarez*[1], *C. Lucas Lucas*[1], *V. M. Perez-Garcia*[3], *A. M. Soriano Castrejon*[2];
[1]*Department of Nuclear Medicine, Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Department of Nuclear Medicine, Complejo Hospitalario Universitario de Toledo, Toledo, SPAIN,* [3]*Department of Mathematics, Mathematical Oncology Laboratory (MOLAB), Universidad de Castilla-La Mancha, Ciudad Real, SPAIN,* [4]*Department of Mathematics, Universidad de Castilla-La Mancha, Ciudad Real, SPAIN,* [5]*Department of Surgery, Hospital General Universitario de Albacete, Albacete, SPAIN.*

***Aim/Introduction:*** This retrospective study aimed to compare the prognostic significance of traditional and novel geometric parameters obtained from pretreatment 18F-FDG PET/CT scans in patients diagnosed with non-small cell lung cancer (NSCLC). ***Materials and Methods:*** The study included NSCLC patients who had a baseline 18F-FDG PET/CT scan. Inclusion criteria required

stage I-III, complete surgical resection, absence of neoadjuvant treatment, lung lesions with significant 18FDG avidity, diameter ≥10 mm and clinical/radiological follow-up ≥24 months. Clinical variables such as age, Charlson Comorbidity Index, Haemoglobin, tumour location, TNM stage, histology, differentiation degree, lymph nodal infiltration and lymphovascular and pleural invasion were recorded. Lung lesions were segmented in 3D using a semi-automatic algorithm, and parameters were obtained including SUV and volume-based metrics, global texture, sphericity, and two novel metrics, SUVpeak to centroid distance (SCD) and SUVmax to perimeter distance (SPD). SCD measured the distance between the SUVpeak voxel centre and tumor centre on PET images, while SPD represented the shortest distance from the SUVmax voxel to the tumor border in the same axial slice. Size dependence was eliminated by normalizing these metrics with the mean spherical radius of tumour, resulting in nSCD and nSPD. In the statistical analysis, early recurrence (ER) and short-term mortality (STM) were the outcome variables, defined as disease-free survival under 12 months and overall survival under 36 months, respectively. Univariate and multivariate logistic regression analyses were conducted for ER and STM. ***Results:*** A total of 173 patients were included in the study. After semi-automatic segmentation, 15 cases needed manual adjustment. Forty-nine of 104 patients developed ER and 100 patients died, 53 of whom had STM. Age, pathological lymphovascular invasion, lymph nodal infiltration, TNM stage, nSCD, and nSPD were all linked to ER. However, only age (OR=1.06, p=0.002), pathological lymphovascular invasion (OR=3.40, p=0.022), and nSPD (OR=0.02, p=0.018) were significant independent predictors of ER in multivariate analysis. Age, lymph nodal infiltration, TNM stage, nSCD, and nSPD were predictors of STM. Nonetheless, age (OR=1.05, p=0.006), lymph nodal infiltration (OR=2.72, p=0.005), and nSPD (OR=0.03, p=0.022) were significantly associated with STM in multivariate analysis. SUV and volumetric metabolic variables, as well as coefficient of variation (COV) and SUVmean/SUVmax ratio, were not significant predictors of ER or STM. ***Conclusion:*** The novel geometric variables nSCD and nSPD are reliable biomarkers for predicting unfavourable outcomes in NSCLC patients when compared to traditional PET variables. The use of these novel parameters could assist in treatment planning and patient management.

## EPS-260

### Correlation between 18F-FDG-PET parameters and outcome od Durvalumab treatment in unresectable locally advanced Non Small Cell Lung Cancer (NSCLC, stage IIIa-b-c)

***K. Beshiri***[1], *F. G. Dall'Olio*[1], *M. Aldea*[1], *C. Genova*[2], *F. Barlesi*[1], *A. Botticella*[1], *A. Levy*[1], *C. Le Pechoux*[1], *P. Lavaud*[1], *M. Frelaut*[1], *P. Abdayem*[1], *J. Remon Masip*[1], *D. Planchard*[1], *B. Besse*[1], *S. Ponce-Aix*[1], *F. Selhane*[1], *D. Deandreis*[1], *M. Bauckneht*[2], *C. Garcia*[1];
[1]*Institute Gustave Roussy, Villejuif, FRANCE,* [2]*IRCCS Ospedale Policlinico San Martino, Genova, ITALY.*

***Aim/Introduction:*** Unresectable locally advanced NSCLC is commonly treated with curative-intent chemo-radiotherapy followed by Durvalumab consolidation. However, around 70% of patients progress at 5 years despite PDL-1 expression, highlighting the need for new prognostic biomarkers. The potential role of 18F-FDG-PET-derived parameters as biomarkers in patients receiving immune checkpoint inhibitors (ICIs) has been investigated, especially in advanced NSCLC. This study aims to evaluate whether 18F-FDG-PET-derived parameters could serve as prognostic biomarkers for unresectable locally advanced NSCLC and predictive biomarkers for those undergoing consolidation immunotherapy with Durvalumab. ***Materials and Methods:*** This is a retrospective study enrolling patients with unresectable locally advanced NSCLC. Patients were divided into two arms one receiving, after chemo-radiotherapy, consolidation treatment with Durvalumab (arm A) and the other without consolidation (arm B). 18F-FDG-PET images were obtained 40 days before treatment initiation. SULmax, SULpeak were recorded for primary lesions and for the whole examination, Total Lesion Glycolysis (TLG), and Metabolic Tumoral Volume (MTV) was calculated for all lesion >1cm3, using for segmentation 42% SULmax thresholding in a dedicated commercial software (PETVcar; GE-Healthcare). Per patient, Total body (TB)MTV and TBTLG was obtained by summing all segmented lesion's. Cox models had been used for the statistical analysis in order to correlate the variables to PFS/OS calculated from C1D1. ***Results:*** 112 patients were included, 66% were male, median age was 64 years, 65% were smokers, and 93% had an ECOG PS of 0-1. Concomitant chemo-radiotherapy was performed in 75% and 67.3% of patients of arm A and B, respectively. The ORR were 67% and 52%. The median PFS was not reached in arm A and 24 months in arm B. The survival at 50 months was 48% in Durvaluamb arm vs 27% in no-Durvalumab arm. ORR was respectively 67% vs 52%. Patients' PFS in the Durvalumab arm was not significantly predicted by TBTLG and TBMTV (p≥0.6, 0.7). In this cohort a positive correlation with PFS was observed between SULmax, SULpeak and Durvalumab cohort (HR 0.3, 0.37; p 0.035), which was not confirmed by multivariate analysis. No 18F-FDG-PET parameters correlation was found for OS in both arms. ***Conclusion:*** Our restrospective study showed in a univariate analysis a predictive role of SULmax and SULpeak in unresectable locally advanced stage III NSCLC receiving curative chemo-radiotherapy and Durvalumab consolidation. This result was not confirmed in a multivariate analysis. Further studies with a larger cohort and eventually a prospective trial design are needed to confirm the results.

## EPS-262

### Usefulness of imaging parameters by FDG-PET/CT and conventional CT in early T-stage lung adenocarcinoma patients who underwent surgery

***S. Tsukamoto****, S. Koyasu, M. Hamaji, H. Date, Y. Nakamoto; Kyoto University, Kyoto, JAPAN.*

***Aim/Introduction:*** Recently, evidence for the effectiveness of wedge resection in early-stage lung cancer has been accumulated [1]. Prior stratification by imaging is desired to improve outcomes, but its usefulness is not well established. The aim of this study was to evaluate the relationship between preoperative imaging parameters and histopathological findings or gene mutation status in surgically resected early T-stage lung cancer patients. ***Materials and Methods:*** We retrospectively enrolled pTis or pT1 lung adenocarcinoma which underwent preoperative FDG-PET/CT and conventional CT examination and surgically resected during 2020. The following imaging parameters were obtained using three-dimensional semiautomatic segmentation system: tumor volume of the entire lesion (TV) and percentage of the solid component (SC) by conventional CT, maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) by FDG-PET/CT delineated with a threshold of SUV value 1.0 [2]. The relationship between these radiological parameters and histopathological high-risk findings such as international association for the study of lung cancer (IASLC) grade and spread through air space (STAS) as well as gene mutation status (EGFR, KRAS) was evaluated.

***Results:*** A total of 72 lesions was included and the TNM classification was: pStage 0, I, II, III = 6, 62, 3, 1, respectively. The part solid (n=39), solid (n=20) and pure GGO type (n=13) were classified by conventional CT. In the tumors with IASLC grade 3 (n=8), SC, SUVmax, MTV and TLG were significantly higher (p=0.0007, 0.0008, 0.0329, and 0.0013, respectively) than those in tumors with IASLC grade 1-2 (n=57). In terms of STAS, SC, SUVmax and TLG of the STAS-positive tumors (n=14) were significantly higher (p= less than 0.0001, 0.0002, and 0.0002, respectively) than that of negative tumors (n=53), which was not observed in MTV (p=0.0625). TV with EGFR mutation (n=32) was significantly higher (p=0.0377) than that without EGFR mutation (n=34), and SC with KRAS mutation (n=10) was significantly higher (p=0.0175) than that without KRAS mutation (n=51). The significant differences of FDG-PET/CT parameters were not observed depending on the status of these gene mutations. ***Conclusion:*** In early T-stage lung cancer, the parameters obtained by FDG-PET/CT were significantly higher in tumors with STAS or higher IASLC grade. FDG-PET/CT parameters may be useful to stratify early T-stage lung adenocarcinoma with higher histopathological risk factors. ***References:*** [1] Aokage et al. Lancet Respir Med. 2023 (ahead of print) [2] Iwano et al. Clin Nucl Med. 44:560 2019.

## EPS-263

### Prognostic Value of Total Body Metabolic Tumour Volume in Patients with Advanced SCLC Treated by Chemotherapy and Immunotherapy.

***A. CABARET***[1], *C. GARCIA*[1], *F. DALL-OLIO*[1], *E. AUCLIN*[2], *B. BESSE*[1], *P. LAVAUD*[1];
[1]*Institut Gustave Roussy, Villejuif, FRANCE,*
[2]*Hopital George Pompidou, Paris, FRANCE.*

***Aim/Introduction:*** ICI in association with a platine-based chemotherapy are the first agents in the last decades to determine a statistical improvement in OS and PFS in patients with advanced SCLC. Only a small fraction of patients experiences a long-term benefit. Reliable predictive and prognostic markers are lacking to identify these patients. We aim to investigate the prognostic and predictive values of different baseline metabolic parameters, from $^{18F}$FDG PET-CT imaging in patients receiving first line treatment for a metastatic SCLC. ***Materials and Methods:*** In this retrospective monocentric cohort study, we selected all patients between October 2013 and December 2021 with advanced SCLC who underwent baseline $^{18F}$FDG PET-CT within 4 weeks before treatment initiation : chemotherapy (CT-group) or chemotherapy + immunotherapy (CT-IO group). Metabolically active tumour regions were segmented on pretreatment PET using a commercial software with a 42% SULmax threshold. Total body Metabolic tumor volume (TBMTV, defined as the addition of the tumor volume segmented with ≥ 42% of the SULmax for all lesions >1cm$^3$), Total body Total Lesions Glycolysis (TBTLG, defined as the addition of MTV x SULmean), SULmax and SULPeak of the biggest lesion, were calculated in both groups. Association between these parameters and OS or PFS was evaluated. ***Results:*** 67 patients were enrolled, 29 treated with CT-IO and 38 treated with CT. Median follow up was 48,3 months for the CT group and 18,4 months for the CT-IO group. A high TBMTV and a high TBTLG were significantly associated with a poorer OS in the CT group.Median OS was 6,3 months in patients with high TBTLG versus 15,4 months in patients with low TBTLG (p=0.001). In the CT-IO group, the same trend was found but not statistically significant, probably due to the small number of patients in this cohort (p=0.3). In patients with high tumour volume (high TBTLG or TBMTV) there was a statistically significant difference between patients treated with CT alone and patients treated with CT-IO in terms of overall survival (p=0.04). SULmax and SULpeak of the biggest lesion were both associated with OS (HR 3.657 (p=0.009) and HR 1.104 (p=0.019) respectively). ***Conclusion:*** Our results indicate that TBMTV and TBTLG as well SULmax and SULpeak of the predominant lesion, are strong prognostics factors for OS in patients with metastatic SCLC and suggest that the addition of immunotherapy to chemotherapy appears to provide a greater benefit for patients with a high tumour volume.

## EPS-264

### Lymph Node Ultrasound Prior to Sentinel Lymph Node Biopsy in 414 Patients with Melanoma: Usefulness in the Era of Adjuvant Systemic Therapy

***G. Horvatic Herceg***[1], *S. Kusacic-Kuna*[2], *M. Ciglar-Hlasc*[2], *D. Herceg*[3], *L. Simetic*[3], *D. Mijatovic*[4];
[1]*University Hospital Zagreb, Zagreb, CROATIA,* [2]*Department of nuclear medicine and radiation protection, University Hospital Zagreb, Zagreb, CROATIA,* [3]*Clinic of oncology, University Hospital Zagreb, Zagreb, CROATIA,* [4]*Clinic of surgery, University Hospital Zagreb, Zagreb, CROATIA.*

***Aim/Introduction:*** Sentinel lymph node biopsy (SLNB) in melanoma has still been the subject of discussions. Namely, it is a staging procedure for melanoma which is thicker than 0.8mm or thinner in the presence of ulceration. Following with the complete lymph node dissection (CLND), in case of positive sentinel node, it provides better locoregional disease control, however it does not prevent distant metastases. Furthermore, SLNB provides crucial information for both prognostic and treatment purposes. The aim of this study is to evaluate contribution of preoperative ultrasound (US), power Doppler, and US-guided FNAC in the diagnosing non-palpable, metastatic lymph nodes in melanoma patients. ***Materials and Methods:*** We performed a prospective study of 414 patients (194 females and 220 males; mean age 54 years, range: 19-82 years) with clinical stage I-II primary melanoma who underwent locoregional lymph node ultrasound prior to SLNB between 2010 and 2022. Median tumor depth was 2.38 mm (range 0.5- 15.0). The rate of ulceration was 39,13%. All patients were examined by US before preoperative lymphoscintigraphy and FNAC was performed in suspicious lymph nodes (round shaped, eccentric cortical hypertrophy and the presence of peripheral vascularization). In cases of malignant results, patients were submitted to CLND. The US-guided FNAC was considered positive, if US and FNAC were positive. If US was suspicious of malignancy, but FNAC was negative, the US-guided FNAC was considered negative. The findings were correlated with histopathology results after CLND. ***Results:*** US and US-guided FNAC were true positive in 59 cases, with no false positive results. All FNAC findings were confirmed by histopathology. There were 37 false negative results out of 355 patients with negative echographic findings. In those patients histopathology revealed metastases in form of tumor cells' foci, which were less than 1 mm in 16 patients, 1-5 mm in 4 patients and individual tumor cells were found in 17 patients. The sensitivity, specificity, positive predictive value, and negative predictive value of US combined with FNAC were 61.46%, 100%, 100% and 89.58%. ***Conclusion:*** Unnecessary surgical sentinel node staging can be avoided by ultrasound detection of regional melanoma metastases, combined with power Doppler and FNAC. In case of a negative US examination of the lymph nodes SLNB is required for adequate staging, furthermore it is of crucial importance for therapy planning. Due to the vast growing usage of novel adjuvant systemic treatment strategies for stage III melanoma, SLNB has been established as even more important.

## EPS-265

### Could lymphadenectomy be avoided in a selection of patients diagnosed with cutaneous melanoma with metastatic sentinel lymph node biopsy?

***B. Hervás-Sanz***[1], *M. T. Bajén-Lázaro*[1], *J. G. Reyes-Junca*[1], *A. M. Benítez-Segura*[1], *I. E. Sánchez-Rodríguez*[1], *S. Maymó-Garrido*[2], *J. L. Díaz-Moreno*[1], *M. A. Crespí-Busquets*[2], *M. Pudis*[1], *S. Bondia-Bescós*[1], *R. M. Penín-Mosquera*[3], *J. Marcoval-Caus*[4], *J. O. Bermejo-Segú*[5], *J. J. Martín-Liberal*[6], *I. Linares-Galiana*[7], *M. Cortés-Romera*[1]; [1]*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Radiopharmaceutical Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [3]*Anatomical Pathology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [4]*Dermatology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [5]*Plastic Surgery Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [6]*Medical Oncology Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN,* [7]*Radiation Oncology Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN.*

***Aim/Introduction:*** Current protocols for cutaneous melanoma recommend primary tumor excision with safety margins and sentinel lymph node biopsy (SLNB) depending on Breslow thickness after confirmation by anatomopathological study. When metastasis is identified in the sentinel lymph node (SLN), the standard procedure to date has been full lymph node dissection (LND) in the region of the SLN metastasis. The aim of this study is to determine whether lymphadenectomy can be avoided in a group of patients (p), depending on Breslow's depth and SLNB metastases size. ***Materials and Methods:*** We retrospectively studied 393p diagnosed with cutaneous melanoma between January 2011 and December 2020. 10p were excluded from the study: 3 for non-detection of the SLN and 7 for loss to follow-up. The remaining 383p underwent SLNB and in all these patients, a lymphoscintigraphy was performed the day before the surgery, after the perilesional injection of 185 MBq of 99mTc-nanocolloid. In those patients with metastatic SLNB, a LND of the corresponding lymphatic station was performed. The following parameters were analyzed: Breslow's depth, number of lymphatic stations with metastatic SLNB, metastases size (<1mm or >1mm), number of LND and number of LND with additional lymph nodes (LN) metastasis. ***Results:*** Among the 383p analyzed, we found 106 lymphatic stations with metastatic SLNB. LND was performed in 100 out of the 106 (it did not take place in three cases because of patient's rejection, in two cases because of pulmonary metastasis diagnosis and in one case because of patient's exitus). Patients were classified as follows:<1mm Breslow's depth: 68p → 4 lymphatic stations with metastatic SLNB: 2 >1mm and 2 <1mm → 0/4 LND with additional LN metastasis (0%).1-2 mm Breslow's depth: 130p → 14 lymphatic stations with metastatic SLNB: 8 >1mm, 6 <1mm → 0/12 LND with additional LN metastasis (0%).2,01-4 mm Breslow's depth: 95p → 36 lymphatic stations with metastatic SLNB: 26 >1mm, 10 <1mm → 8 (all with SLNB metastases >1mm) out of 35 LND with additional LN metastasis (22,9%).>4 mm Breslow's depth: 90p → 52 lymphatic stations with metastatic SLNB: 42 >1mm, 10 <1mm → 13 (12 with SLNB >1mm and 1 <1mm) out of 49 LND with additional LN metastasis (26,5%). ***Conclusion:*** According to our results, LND could be avoided in patients with Breslow equal or lower than 2 mm and in patients with Breslow between 2,01-4 mm with SLNB metastases <1mm. However, more prospective studies should be performed.

## EPS-266

### Can physiologic colonic [18F]FDG uptake in PET/CT imaging predict response to immunotherapy in metastatic melanoma?

***C. Sachpekidis***[1], *C. K. Stein-Thoeringer*[2], *A. Kopp-Schneider*[1], *V. Weru*[1], *A. Dimitrakopoulou-Strauss*[1], *J. C. Hassel*[3]; [1]*German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [2]*Laboratory of Translational Microbiome Science, Internal Medicine I, University Clinic Tuebingen, Tuebingen, GERMANY,* [3]*Department of Dermatology and National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, GERMANY.*

***Aim/Introduction:*** To investigate if physiologic colonic [$^{18}$F]FDG uptake in PET/CT before start of immune checkpoint inhibitors (ICIs) correlates with clinical outcome of metastatic melanoma patients. The relation between [$^{18}$F]FDG uptake in lymphoid cell-rich organs and long-term patient outcome is also assessed. ***Materials and Methods:*** 119 patients scheduled for immunotherapy with ipilimumab underwent baseline [$^{18}$F]FDG PET/CT. PET/CT data analysis consisted of standardised uptake value (SUV), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) calculations in the colon as well as measurements of the colon-to-liver SUV ratios ($CLR_{mean}$, $CLR_{max}$). Visual grading of colon uptake based on a four-point scale was also performed. Moreover, the spleen-to-liver SUV ratios ($SLR_{mean}$, $SLR_{max}$) and the bone marrow-to-liver SUV ratios ($BLR_{mean}$, $BLR_{max}$) were calculated. We also measured serum lipopolysaccharide (LPS) levels as a marker for bacterial translocation and surrogate for mucosal defense homeostasis. The results were correlated with patients' best clinical response, progression-free survival (PFS), and overall survival (OS) as well as clinical signs of colitis. ***Results:*** Median follow-up [95%CI] from the beginning of immunotherapy was 64.6 months [61.0 - 68.6 months]. Best response to treatment was progressive disease (PD) for 60 patients, stable disease (SD) for 37 patients, partial response (PR) for 18 patients and complete response (CR) for 4 patients. Kaplan-Meier curves demonstrated a trend for longer PFS and OS in patients with lower colonic SUV and CLR values, however no statistical significance was demonstrated. On the other hand, patients showing disease control as best response to treatment (SD, PR, CR) had significantly lower colonic MTV and TLG than those showing PD. Moreover, in multivariate analysis, colonic MTV and TLG correlated significantly with patient survival, with higher values of these parameters having an adverse effect on PFS. With regard to lymphoid cell-rich organs, significantly lower baseline $SLR_{max}$ and $BLR_{max}$ were observed in patients responding with disease control than progression to treatment, Furthermore, patients with lower $SLR_{max}$ and $BLR_{max}$ values had a significantly longer OS when dichotomized at their median. ***Conclusion:*** Physiologic colonic [$^{18}$F]FDG uptake, as assessed by means of SUV, before start of ipilimumab does not seem to independently predict patient survival of metastatic melanoma . On the other hand, colonic volumetric PET parameters, such as MTV and TLG, may identify patients showing disease control to immunotherapy, and significantly correlate with PFS. Finally, the investigation of glucose metabolism in the spleen and the bone marrow, may offer prognostic information.

## EPS-267

### The role of 18F-FDG PET/CT in changing the therapeutic plan in cutaneous melanoma patients at different clinical stages and time points of the disease.

***Z. Dancheva***, *T. Stoeva, M. Dyankova, S. Chausheva, T. Yordanova, B. Chaushev, A. Klisarova;*
*Medical University, "Prf. Dr. Paraskev Stoyanov", Varna, BULGARIA.*

***Aim/Introduction:*** A definite survival benefit has been found in patients with cutaneous melanoma (CM) after radical metastasectomy, with 2-year survival as high as 50%. Therefore, it is important to identify the group of metastatic patients who would have a chance for radical surgery. In most cases 18F-FDG PET/CT upstages the patient, which leads to the redirection to targeted and immunotherapy that could improve significantly the one-year survival rates from 25% to over 70%. Our aim was to investigate the role of 18F-FDG PET/CT in changing the therapeutic plan in CM patients at different clinical stages and time points. ***Materials and Methods:*** We retrospectively analyzed 347 patients, 117 (33.7%) females and 230 (66.3%) males, aged between 10 and 87 years (mean 59.6 years). We divided the patients, according to the initial stage and by the clinical indication (staging, suspicion recurrence, restaging after first and second recurrence, and systemic therapy assessment). We investigated the relationship between the increase in stage and current clinical setting and the change in the therapeutic plan determined by 18F-FDG PET/CT. ***Results:*** 18F-FDG-PET/CT lead to change in treatment plan in 302 (87.8%) patients. The results demonstrated that the change correlates with the advanced initial stage of the patient. Notably, in patients with stage IIC and higher, 18F-FDG PET/CT significantly influenced the therapeutic decisions in over 83.0 % (p=0.035). We had data on the type of treatment changed in 280 of the patients. Stage II diagnosis was predominated by an earlier finding of operable lesions (56.09%- 65.3%). In patients diagnosed in stage III, 18F-FDG PET/CT was associated with a more frequent conversion to systemic treatment (59.3%.-85.7%). At staging a substantial amount of patients required additional surgical treatment (43.3%) or systemic treatment- 23.3%. In patients referred for suspected progression, we identified a similar number of cases suitable for surgery (36.4%) and systemic treatment in 40.3%. Among the patients after the first and second relapse, those suitable for systemic treatment or for changing the latter significantly were respectively 53.4% and 66.7%. ***Conclusion:*** 18F-FDG PET/CT is a whole body scanning and very sensitive procedure for CM because of their high glucose metabolism, which permit visualization the whole body, including the limbs, and allow the detection of small subclinical metastases. This study elicits the substantial role of 18F-FDG PET/CT in CM therapy management and precise redirection of patients to the most appropriate therapy for extending of their life expectancy.

## EPS-268

### Prognostic Value of Restaging FDG-PET/CT for Detecting Recurrence in Patients with Malignant Cutaneous Melanoma

***Aim/Introduction:*** To analyse the diagnostic capacity of FDG-PET/CT for the detection of tumoral recurrence in patients with malignant cutaneous melanoma (MM). ***Materials and Methods:*** Retrospective observational study of consecutive patients with confirmed MM referred for restaging FDG-PET/CT due to suspected recurrence between 2011 and 2022. Final diagnosis of recurrence was established by histopathological analysis or clinical follow-up of at least 6 months. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy values were calculated. Statistical analysis was performed with SPSS v25 program ($p<0.05$ was considered significant). Univariant correlations between qualitative (sex, recurrence, localization of recurrence) and quantitative variables (age, initial MM stage) were measured with Chi-Square, Kendall's Tau_b and Pearson correlation indexes. Cox multivariate regression analysis between qualitative-quantitative variables was performed, including overall survival (OS) and progression-free survival (PFS). PFS and OS were assessed using Kaplan-Meier curves. ***Results:*** We evaluated 234 patients (101 women) with a mean age of 59.5 years (range: 22-88 years). Tumoral recurrence was detected in a total of 117 patients with pathologic FDG-PET/CT results in 111. Remaining 117 patients showed no recurrence, with negative FDG-PET/CT in 113. FDG-PET/CT sensitivity, specificity, PPV, NPV and accuracy values were 94.9%, 96.6%, 96.5%, 95% and 95.7%, respectively ($\chi^2$:195.8; $p<0.01$). In univariate analysis with Pearson and Kendall's Tau_b correlation indexes, FDG-PET/CT results showed significant correlation with recurrence, location and initial stage of MM ($p<0.01$), and sex of the patients ($p<0.05$). Cox regression analysis showed that cutaneous lesions had greater risk of death, and increased risk of recurrence/death in bone lesions ($p<0.01$ and $p=0.001$). Tumour stage II showed higher risk of recurrence ($p=0.009$), while tumour stages II-IV showed higher risk of death ($p=0.02$). Male patients also had greater risk of recurrence ($p=0.03$) or death ($p=0.04$). Analyzing Kaplan-Meier curves, both OS and PFS were significantly higher in patients with negative restaging FDG-PET/CT scans than positive ones, showing a mean OS of 329.1 months (95%CI: 312.5-345.8) vs. 72.8 months (95%CI: 65.8-82.8), and mean PFS of 315.9 months (95%CI: 300.6-331.3) vs. 38.6 months (95%CI: 32.2-44.9), respectively. Comparing OS by sex in FDG-PET/CT positive patients, a shorter survival was found in men, with median OS of 119 (95%CI: 96.2-141.8) vs. 172.9 months (95%CI: 132.5- 209.3) in women. ***Conclusion:*** In concordance with the existing literature, we verified that restaging FDG-PET/CT has excellent diagnostic performance for detection of recurrences in patients with malignant cutaneous melanoma, and also seems to have prognostic value.

## EPS-269

### Survival and risk factors analysis for locoregional and distant metastases in patients with sentinel lymph node-negative cutaneous melanoma

***A. Leiva Montejo***, *A. Blesa Jimenez, A. De Agrela Serrao, C. Ruiz Corbalán, D. Cáceres Silva, J. Contreras Gutierrez, J. Navarro Fernández, A. Hernandez Martinez, T. Rodriguez Lorcano, L. Frutos Esteban, L. Mohamed Salem, M. Castellon Sánchez;*
*Hospital Virgen de la Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** Sentinel lymph node biopsy(SLNB) is a staging surgical procedure for patients with melanoma who are at risk of having occult nodal metastases which are the most important prognostic factor in early-stage melanoma. However, the rate of metastasic melanoma following negative SLNB long-term is from 6 to 24%. The aim of this study was to analyze the overall

survival and risk factors for regional and systemic metastases in patients with SLNB-negative melanoma during the clinical follow-up. ***Materials and Methods:*** Designed as a retrospective study, a multivariate analysis was done using the SPSS version 28 program. Data from 294 patients with negative and positive SLNB were collected since 2013 until 2023. A total of 211 SLNB-negative patients were analyzed. Variables studied were sex, age, tumor characteristics (melanoma subtype, tumor thickness, ulceration), location (head and neck, trunk and extremities), positive, negative and false negative SLNB. Metastases were classified as regional lymph node/locoregional cutaneous metastases and distant metastases. p<0.05 was considered statistically significant. Overall survival(OS) and Progression Free Survival(PFS) was calculated since the diagnosis date until death date and until progression date, respectively. Both were studied with Kaplan-Meier. ***Results:*** 294 patients were included, SLNB were positive in 83(28.24%) and negative in 211(71.76%). A total of 24(11.37%) SLNB-negative developed metastases, including 10(41.66%) distant and 14(58.33%) locoregional. SLNB-negative patients who progressed were older[(68.17+/-2.82years)(p<0.044)]. SLNB-negative patients that didn't progress had mostly the superficial spreading melanoma(SSM) subtype[155(82.9%)(p<0.05)]. Tumor ulceration was present in 9(37.5%)SLNB-negative patients with metastases and in 23(12.29%)SLNB-negative patients without metastases. (p<0.05). SLNB-false negative patients were 10(4.73%) and they were compared to SLNB-positive patients. SLNB-false negative patients were mostly men[6(60%)(p=0.04)], with the SSM subtype[7(70%)(p=0.033)]. A higher tumor thickness[(3.33cm+/-0.29)(p<0.001)] was related to a SLNB-positive.Mean follow-up was 61 months. SLNB-negative patients: 20(9.47%) died from melanoma and 180(85.30%) remained alive and stable. Median OS for SLNB-negative patients was 125.18 months (IC95% 120.33-130.03) and for SLNB-positive patients was 86.86 months (IC95% 76.56-97,16)(p=0.00). Mean PFS for SLNB-negative was 122.50 months (IC95% 117-127.9) ***Conclusion:*** Our patients who underwent SLNB in early stages were mostly negative. Only 24 SLNB-negative patients progressed during the clinical follow-up. Age and tumor ulceration are significant risk factors for developing melanoma metastases in this kind of patients. OS and PFS were almost the same in SLNB-negative patients.

## EPS-270

### A steerable modality for simultaneous radio- and fluorescence-guidance during robotic surgery

***M. van Oosterom***[1,2], *L. J. Slof*[1], *S. I. van Leeuwen*[1], *S. Azargoshasb*[1], *A. Berrens*[2], *K. Houwing*[1], *H. G. van der Poel*[2], *F. W. B. van Leeuwen*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*NETHERLANDS Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Intraoperative image guidance is needed to facilitate surgeons in the quest to resect diseased tissues with a high precision. Hybrid tracers have demonstrated to be more than the sum of their parts by fully integrating the complementary image-guidance provided via radioactive emissions (in-depth target localization) and fluorescent emissions (high resolution superficial target delineation) [1]. In parallel the engineering of steerable DROP-IN gamma probes has helped open up the way for robotic radioguided surgery [2]. Building on these findings, and new concepts such as the Click-On gamma probe [3] and handheld Optonuclear probe [4], we generated a miniaturized hybrid Click-On detector and evaluated it on clinical specimens. ***Materials and Methods:*** The hybrid Click-On detector was designed for a ProGrasp robotic forceps, and to facilitate both radio-tracing ($^{99m}$Tc) and near-infrared fluorescence detection (indocyanine green; ICG). Following the mechanical engineering, the system was produced using 3D printing and multi-axis precision milling. The technical aspects of the prototype modality were characterized and its compatibility with the robotic platform was evaluated on freshly excised tissue specimens of seven prostate cancer patients that underwent a sentinel lymph node procedure guided by the hybrid tracer ICG-$^{99m}$Tc-nanoscan [5]. A computer-vision algorithm was built to register the probe movements during the evaluations [3], and to visualize the recorded counts with respect to the anatomic areas visible in the endoscopic view. ***Results:*** When 'clicked on' the daVinci ProGrasp instrument, the Click-On Optonuclear provided the surgeon with autonomous and fully 6 degrees of freedom maneuverable molecular detection at the tips of the laparoscopic instrument. The modalities sensitivity for $^{99m}$Tc was found to be $>10^{-4}$ MBq and sensitivity for ICG $>10^{-6}$ mg/mL. During the analysis of 17 specimens, the system was able to correctly identify both tracer signatures. The tracking algorithm, allowed us to augment the endoscopic view with a heat-map based display of the radioactive and fluorescent count rates. ***Conclusion:*** With the steerable hybrid Click-On modality, a first step towards 'fingertip' radio- and fluorescence-sensing by surgical instruments has been realized. At the same time the sensing capabilities help support robotic molecular imaging. A potentially new approach to image guided surgery. ***References:*** 1. ### Feasibility of [99mTc] Tc-FAPI-SPECT Imaging for Detection of Primary Tumors, Lymph Node, and Distant Metastasis in Various Cancers

***S. Rezaei****, E. Gharepapagh, S. Dabiri Oskue;*
*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Cancer-associated fibroblasts (CAFs) express high levels of fibroblast activation protein (FAP). A variety of cancers with desmoplastic reactions, such as breast cancer, can be imaged with SPECT imaging with FAP inhibitors (FAPIs) since FAP is almost absent from healthy tissue. This study evaluated $^{99m}$Tc-labeled FAP inhibitor radioligand ([$^{99m}$Tc] Tc-FAPI) for tumor stroma imaging in patients with various cancers and analyzed results from the perspective of stromal heterogeneity. ***Materials and Methods:*** Twenty patients with confirmed breast, lung, and colorectal cancers were included in this study. The patients had previously undergone other scans to evaluate the disease. SPECT imaging was performed one hour after [$^{99m}$Tc] Tc-FAPI injection. Lesions were categorized into three types: primary tumors, lymph node metastases, and distant metastases (Dm). Tumor-to-background ratios (T/B) were used to calculate semi-quantitative lesion uptake analysis. In all cases, histopathology corroborated the oncological diagnosis. ***Results:*** [$^{99m}$Tc] Tc-FAPI detected primary tumors, with 100% and 94% sensitivity and specificity, respectively. Moreover, Tc-FAPI demonstrated lymph nodes and distant metastases with high accuracy due to lower background activity and higher uptake in sub-centimetric lesions. Compared to lymph nodes and distant metastases, [$^{99m}$Tc] Tc-FAPI uptake was greater in primary tumors in the T/B data. Interestingly, [$^{99m}$Tc] Tc-FAPI was well absorbed in

peritoneal carcinomatosis lesions in recurrent colorectal cancer. ***Conclusion:*** [$^{99m}$Tc] Tc-FAPI SPECT imaging can provid valuable information about the microenvironment surrounding tumors and is considered a promising tool in the prognostic assessment of tumors, particularly breast cancer and recurrent colorectal cancers.

Gemelli, IRCCS, Rome, ITALY.*

***Aim/Introduction:*** We aimed to investigated whether metabolic parameters by [$^{18}$F]FDG PET/CT were associated with histology and their potential prognostic role in patients with resected thymic lesions. ***Materials and Methods:*** A total of 84 patients (36 male, 48 female; mean age 56.9 y) who underwent thymectomy and preoperative [$^{18}$F]FDG PET/CT from 2012 to 2022 were retrospectively analyzed. Associations between histology and metabolic parameters (i.e. SUVmax, SUVmean, SUVpeak, TLG, and MTV), as well as the tumor-to-mediastinum (T/M) and SUVmax/Tcm ratios were examined. Progression-free-survival (PFS) was determined and compared using the Kaplan-Meier and the log-rank test. The median follow-up was 46 months (range 3-121 months). ***Results:*** The anterior mediastinal masses included 22 thymic hyperplasia, 32 low-risk thymomas (LRT, types A, AB, B1), and 30 high-risk thymomas (HRT, types B2, B3, and carcinoma). We observed a statistically significant difference between LRT and HRT among metabolic parameters, expressed by SUVmax (mean 3.89 ± 2.56 vs 6.10 ± 3.37, p=0.001), SUVmean (mean 2.36 ± 1.43 vs 3.10 ± 1.99, p=0.003), SUVpeak (mean 3.28 ± 2.20 vs 5.12 ± 2.70, p=0.001), TLG (mean 398 ± 1290 vs 258 ± 387, p=0.021), and T/M (mean 2.22 ± 1.47 vs 3.70 ± 2.75, p=0.001). Moreover, patients with median SUVmax lower than 4.3, as well as those with median SUVmean and median SUVpeak lower than 2.87 and 4.03, respectively, showed a longer PFS (p = 0.009, p= 0.05, and p=0.05), whereas volumetric parameters (i.e. MTV, and TLG) and metabolic ratios (i.e. T/M, and SUVmax/Tcm) were not associated with PFS. ***Conclusion:*** In our study metabolic parameters, derived from preoperative [$^{18}$F]FDG PET/CT, seem to provide useful information to differentiate thymic histotypes. Furthermore, SUVs-based parameters appear promising prognostic factors in terms of recurrence. ***References:*** Chiappetta M, Mendogni P, Cattaneo M, et al. **FAPi imaging identified occurrence of fibrosis may indicate rapid progression of liver failure induced by immune checkpoint inhibitor**

***X. Jia**[1], R. Tao[1], Y. Yang[1], Y. Wang[1], X. Li[1], B. Jia[2], R. Gao[1];*
*[1]The first hospital of Xi'an jiaotong university, Xi'an, CHINA, [2]Medical Isotopes Research Center and Department of Radiation Medicine, School of Basic Medical Sciences, Peking University, Beijing, CHINA.*

***Aim/Introduction:*** The emergence of immune checkpoint inhibitors (ICIs) offers hope for the treatment of malignant tumors; however, they may lead to immune-related adverse reactions (irAE). ICI-related liver injury is a poorly understood irAE with varied clinical presentations and histopathological correlates, and there is still lack of non-invasive predictor to differentiate patients who will soon escalate to acute liver failure (ALF). ***Materials and Methods:*** A 34-year-old male patient with extensive-stage small cell lung cancer was treated with durvalumab (an anti-PD-L 1 antibody) and developed Grade 1 liver irAE during the eighth treatment. Slightly elevated liver enzyme was observed and abdomen US and CT revealed fatty liver. With exclusion of other potential liver disease, including liver metastasis, alcoholic hepatitis, and viral hepatitis, a diagnose of liver irAE was made. The ICIs induced liver injury slowly progressed to Grade 2 though prednisone (80mg/d for 1 week) was applied. In the mean time, Fapi imaging was prescribed to evaluate the tumor burden. ***Results:*** Except for tumor uptake in left lung, strong and diffuse fibroblast activation protein expression in hepatic tissue was imaged by radiolabled FAP inhibitor . The patient presented with abdominal distention and nausea, and abrupt rise of liver enzymes and bilirubin in the following week after FAPI imaging. Despite prompt administration of high dose intravenous methylprednisolone (240 mg/d) and plasmapheresis (2000 mL/d), the patient's liver enzymes rise rapidly. Hepatic encephalopathy, characterized by confusion and disturbed conscious occurred and the patient died within the following 24 hrs. Liver tissue from patients with ALF showed hepatic stellate cells (HSCs) activation and collagen deposition, which is thought to serve as a scaffolding that maintains hepatic integrity in the rapid progression of liver failure. The HSCs activation caused short-term occurrence of fibrosis, which identified by FAPI imaging in this ICIs induced ALF, is reported to be an important step in this process. The other 9 cases with mild ICIs-induced liver injury underwent FAPI imaging provided further support: except for focal concentration in liver metastasis, no diffuse uptake of the FAPI was revealed in their hepatic tissue. All 9 patients responded well to routine therapy and their liver dysfunction was promptly improved. ***Conclusion:*** Our data suggest that FAPI imaging has the potential to serve as a new diagnostic basis for early ICI-induced ALF.

## OP-879

**Is This a Real [68Ga]Ga-FAPI Scan? The Strange Case of [68Ga]Ga-FAPI-avid Liver**

***E. Fortunati**[1], G. Cuzzani[1], S. Telo[2], C. Nanni[3], P. Castellucci[3], A. Farolfi[3], L. Zanoni[3], T. Galasso[4], M. Ferrari[4], F. Natali[4], G. Bandelli[4], P. Candoli[4], S. Fanti[1,3];*
*[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, AUSL Romagna, Cesena, ITALY, [3]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Interventional Pulmunology Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** A 68y.o. patient with history of smoking, heavy-drinking, hepatic cirrhosis(Child-Pugh Score:B7)with ascites, severe portal hypertension and previous HBV-infection, underwent both[18F]F-FDG-PET/CT and [68Ga]Ga-FAPI-PET/CT to stage lung neoplasia in the right lower lobe. As it is well known,[68Ga]Ga-FAPI presents low uptake and high Tumour-to-Background-Ratio(TBR) in healthy liver parenchyma, thus offering the opportunity to better study liver metastases. Fibroblast activation protein(FAP) expression is associated with the activation of hepatic stellate cells in fibrotic conditions involving the liver leading to cirrhosis and derived from different chronic causes. ***Materials and Methods:*** The patient was enrolled to perform a staging [18F]F-FDG-PET/CT for lung cancer within a prospective interventional study conducted in our Nuclear Medicine Department. He later underwent[68Ga]Ga-FAPI-46-PET/CT and images were acquired both at 10'and at60'. The two PET/CTs were performed 13days apart. ***Results:*** Blood tests have confirmed the presence of cirrhosis by showing altered bilirubin values, both total(2.76mg/dL) and fractionated (direct 0.8mg/dL;indirect 1.96mg/dL), elevated transaminases(AST:52U/L) and gamma glutamyl transferase values(215U/L). Both [18F]F-FDG and [68Ga]Ga-FAPI-PET/CT showed radiotracer uptake of the known pulmonary lesion and of a focality at the 10th left rib, described as a metastasis. Early(10') and late(60') [68Ga]Ga-FAPI-scans confirmed the uptake in correspondence of the primary lesion and of the bone localization. Intense and diffuse uptake was detected in the liver parenchyma (SUVmax10'=9.9;SUVmax60'=7.2;SUVmean10'=7.1;SUVmean60'=4.7). In a sample of 10 patients who underwent [68Ga]Ga-FAPI-PET/CT without any liver disease or liver parenchyma alterations at conventional imaging, the average SUVmax of liver parenchyma is1.3[median:1.3;range:0.8-1.9] at10'scan and 1.2[median:1.2;range:0.9-1.4] at 60'scan. The average SUVmean of liver parenchyma is 0.8[median:0.8;range:0.5-1] at10'scan and 0.6[median:0.6;range:0.4-0.7] at60'scan. ***Conclusion:*** This case-report is an extremely brilliant example of what already reported in literature[1-3] on how the presence of cirrhosis leads to an increased [68Ga]Ga-FAPI uptake in liver parenchyma. This is a relevant finding because it leads to a reduced TBR with a consecutive lower detection of possible liver metastasis. The collection of an accurate anamnesis before PET/CT is also of primary importance, in order to avoid mistakes in interpretation of similar findings. This case pointed out how [68Ga]Ga-FAPI-PET/CT could be an important tool to precociously recognize fibrosis in non-oncological disease, also before the execution of conventional imaging.

## OP-880

### Role of 68Ga FAPI-04 PET/CT in detecting cardiac sarcoidosis in a patient mimicking malignancy and its comparison with 18F-FDG PET/CT

***S. Patel***, *P. Sundaram, P. Sundaram, F. Saju;*
*Amrita Institute of Medical Sciences & Research Center, Kochi, INDIA.*

***Aim/Introduction:*** 1. To characterize specific imaging findings of cardiac sarcoidosis using $^{68}$Ga FAPI-04 PET/CT.2. To compare the study findings obtained from $^{68}$Ga FAPI-04 PET CT and $^{18}$F-FDG PET/CT in a patient with cardiac sarcoidosis.3. To evaluate the diagnostic role of $^{68}$Ga FAPI-04 PET CT in differentiating cardiac and systemic sarcoidosis from lymphoma, tuberculosis, and other systemic inflammatory diseases. ***Materials and Methods:*** A patient suspected of having lymphoma and recently diagnosed with non-infective endocarditis was enrolled for the study. 4 millicuries (mCi) of Gallium-68 ($^{68}$Ga)-conjugated FAP inhibitor-04 (FAPI) were injected intravenously. A diagnostic whole-body imaging CECT was acquired, followed by PET images in 3D mode from the head to the upper thigh. Following appropriate dietary preparation a second PET/CT scan was scheduled after 3 days with $^{18}$F-FDG (0.1 mCi/Kg). ***Results:*** The images obtained from the left ventricular myocardium showed significant heterogeneous $^{68}$Ga-FAPI uptake throughout the myocardium with a maximum standardized uptake value (SUVmax) of 20.4, compared to FDG which showed uptake in the apico-anterior region with SUVmax of 16.6. Additionally, the images obtained from $^{68}$Ga-FAPI PET CT showed a mediastinal lymph node uptake pattern more characteristic of sarcoidosis. Non-specific FDG uptake in the brain, inflammatory cervical lymph nodes, and degenerative bone changes, seen using $^{18}$F-FDG, were not seen in $^{68}$Ga-FAPI PET CT, further aiding in a more accurate disease diagnosis. ***Conclusion:*** The life-threatening complications associated with cardiac sarcoidosis underscore the importance of early diagnosis and management. Increasing role FDG PET/CT in patients with systemic and cardiac sarcoidosis has proven to be a valuable diagnostic tool[1]. Advent of novel radiopharmaceuticals such as $^{68}$Ga-FAPI has significantly enhanced the potential of PET imaging. By selectively targeting cardiac fibroblast cells with high FAP expression [2], $^{68}$Ga-FAPI exhibits increased specificity in detecting myocardial involvement in sarcoidosis. In this case study $^{68}$Ga-FAPI PET CT was helpful in accurately diagnosing cardiac sarcoidosis with higher specificity compared to $^{18}$F-FDG PET CT, with higher target-to-background ratio, and independence from euglycemic state maintenance being observed as additional benefits. Further investigations are warranted to fully explore its clinical utility. ***References:*** [1]. Keijsers RGM, Grutters JC. In Which Patients with Sarcoidosis Is FDG PET/CT Indicated. J Clin Med. 2020 Mar 24;9(3):890. [2]. Siebermair J, Kessler L, Kupusovic J, Rassaf T, Rischpler C. Cardiac fibroblast activation detected by 68Gallium-FAPI-46 positron emission tomography-magnetic resonance imaging as a sign of chronic activity in cardiac sarcoidosis. ***Aim/Introduction:*** A 63-year-old man with a history of hematologic disorder, idiopathic Multicentric Castleman Disease(iMCD) who has been treated with Siltuximab for 3years encountered a growing mass in his right shoulder.A contrast ultrasound-guided biopsy was performed and the histological diagnosis was sclerosing epithelioid fibrosarcoma,a rare soft tissue sarcoma. Conventional imaging(CT and MRI)reported a solid lesion and multiple adenopathies of the right shoulder's region,but could not distinguish whether they were of sarcomatoid origin or from Castleman Disease.A high expression of fibroblast activation protein(FAP) was observed in multiple sarcomas,indicating an enormous potential for PET/CT using 68Ga-radiolabeled inhibitors of FAP (FAPI)[1]. ***Materials and Methods:*** Therefore,the patient was addressed to our Nuclear Medicine Department to be enrolled in a prospective interventional study and perform both a [18F]F-FDG and a [68Ga]Ga-FAPI-46 PET/CT. The patient underwent a [18F]F-FDG PET/CT at 60minutes from the radiotracer injection with a Field of View extended from the vertex to the toes; a [68Ga]Ga-FAPI-46 PET/CT was performed the following day and images were acquired both at 10and 60minutes. ***Results:*** The [18F]F-FDG PET/CT showed intense uptake of a solid lesion involving the right pectoralis region, part of the right scapula,axilla,clavicle and the overlying skin,along with multiple right axillary lymph nodes and of the shoulder's region. In addition,it detected small nodules at both lungs reported as metastases and not previously detected at conventional imaging.The [68Ga]Ga-FAPI-46 PET/CT was concordant, presenting a higher SUVmax of the shoulder's lesion(8.8 for [18F]F-FDG and 20.2 for [68Ga]Ga-FAPI); furthermore,it also displayed a liver focality located at segment V-VI with SUVmax=4.7,unknown at previous imaging and suspicious for metastasis. ***Conclusion:*** Determine patients' management is often challenging; the standard of care of fibrosarcoma is surgical excision with adequate margins in association with radiotherapy. In this particular case,due to the size and location of the neoplasm, the radical surgical treatment would have been a forequarter amputation of the dominant upper limb, with huge affection of quality of life. [18F]F-FDG and [68Ga]Ga-FAPI PET/CTs had reported systemic disease: for this reason and for clinical condition,the patient was addressed to palliative radiotherapy after multidisciplinary evaluation and patient's consult. Overall, an accurate detection rate for new metastases or suspicious lesions to examine and a high tumour-to-background ratio are fundamental to address patients to the correct therapeutic process; hence, [68Ga]Ga-FAPI-46 PET/CT is considered a promising tracer for sarcomatoid malignancies. ***References:*** [1]Koerber,S.A.,Finck,R.,Dendl,K.et al.Novel FAP ligands enable improved imaging contrast in sarcoma patients due toFAPI-PET/CT.Eur J Nucl Med Mol Imaging48,3918-3924(2021). https://doi.org/10.1007/s00259-021-05374-4

### [68Ga]Ga-FAPI PET/CT: a Valid Aid in Breast Cancer Not Only for Malignancies Reporting

***G. Cuzzani***[1], *E. Fortunati*[1], *S. Telo*[2], *C. Nanni*[3], *P. Castellucci*[3], *A. Farolfi*[3], *S. Zanotti*[4], *S. Grendele*[5], *D. Rosini*[4], *M. Taffurelli*[4], *S. Fanti*[1,3];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Department, AUSL Romagna, Romagna, ITALY,* [3]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Breast Surgery, Department of Oncology and Hematological Diseases, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Breast Surgery, Department of Functional Oncology, AULSS 7 Pedemontana, Santorso Hospital, Vicenza, ITALY.*

***Aim/Introduction:*** [68Ga]Ga-FAPI is known to be a promising PET/CT imaging tracer,showing an advantage when compared to[18F]F-FDG in those tissues which present a natural diffuse FDG uptake,such as liver and brain; furthermore,it shows high performance in the detection of breast cancer malignancies[1]. This is a case of a 66-year-old woman who was diagnosed with invasive ductal carcinoma of the left breast and presented a homolateral axillary lymph node suspicious for malignancy at traditional imaging(ultrasound and mammography).At a physical examination the left nipple showed a small ulcer and bloody discharge,so a cytologic evaluation was performed.The patient was offered neoadjuvant chemotherapy subject to a staging [18F] F-FDG PET/CT. ***Materials and Methods:*** The patient was enrolled in a prospective interventional study ongoing in our Nuclear Medicine Department and underwent both a [18F]F-FDG and a [68Ga]Ga-FAPI-46 PET/CT. The two scans were performed seven days apart;images were acquired 60 minutes after the [18F]F-FDG injection, while for [68Ga]Ga-FAPI-46 image acquisition occurred at 10 minutes("early scan")and at 60 minutes("standard scan")from the radiotracer injection. ***Results:*** The [18F]F-FDG PET/CT showed intense uptake in the upper outer quadrant of the left breast(SUVmax=17.6),agreeing with traditional imaging on the localization of the primary tumour,and focal uptake of a left axillary lymph node(SUVmax=18.6)reported as nodal metastasis. The subsequent [68Ga]Ga-FAPI-46 PET/CT confirmed the known mammary and axillary findings(which presented increasing SUVs from the early to standard scan)but also reported focal uptake of the left nipple(early SUVmax=8.3,standard SUVmax=7.7).In addition,[68Ga]Ga-FAPI-46 revealed mild uptake of the lateral-posterior arch of the sixth right rib(early SUVmax=5.5,standard SUVmax=5.7)which was reported to be more likely a benign formation according to the bone remodeling appearance at CT images,such as an enchondroma or fibrous dysplasia.The cytologic evaluation of the nipple's bloody discharge later resulted in "absence of malignancy" and it was reported as adenoma(which needed surgery despite being a benign condition),while the rib finding was confirmed stable at a CT scan performed seven months later. ***Conclusion:*** It is important to keep in mind that oncologic and collateral findings are equally common,therefore expertise and pathology are essential for the right diagnosis;knowing the causes of FAPI uptake is fundamental for an accurate image interpretation and to avoid false positives.This case is an example of how [68Ga] Ga-FAPI-46 PET/CT identified two additional findings which were negative at a prior [18F]F-FDG PET/CT and could have easily been mistaken for breast cancer metastases. ***References:*** [1]Kömek,-Can,Güzel,Oruç,Gündoğan,Yildirim,Kaplan,Erdur,Yıldırım,Çakabay.68Ga-FAPI-04 PET/CT,a new step in breast cancer imaging:a comparative pilot study with the18F-FDG PET/CT.Ann Nucl Med.2021Jun;35(6):744-752.doi:10.1007/s12149-021-01616-5. ## OP-883

### Comparative PET/CT imaging in a patient with metastatic clear cell renal cell carcinoma: 68Ga-NY104 versus 68Ga-PSMA versus 18F-FDG

***W. Zhu***, *X. Li, Y. Zhang, Y. Li, L. Huo;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** $^{68}$Ga-NY104 is a novel small molecule tracer targeting carbonic anhydrase IX (CAIX), which is overexpressed in clear cell renal cell carcinoma (ccRCC). $^{68}$Ga-PSMA PET/CT has also been proven effective in RCC imaging due to neovascularization. However, no comparative study has been done to compare the two imaging modalities. ***Materials and Methods:*** A 53-year-old male had radical nephrectomy due to ccRCC of left kidney in 2008. In 2022, an avidly-enhancing right kidney mass was found on ceCT during follow-up, as well as multiple other lesions in the liver, abdominal wall, pancreas, and seminal vesical. $^{68}$Ga-NY104 and $^{68}$Ga-PSMA PET/CT was performed for restaging given the suspicion of metastatic ccRCC. A comparative $^{18}$F-FDG PET/CT was also performed. The study was approved by the institutional review board of Peking Union Medical College Hospital (approval NO. ZS-3089 and ZS-2532). Metastatic ccRCC was later confirmed by biopsy of the abdominal wall lesion. ***Results:*** A total of 10 PET-positive lesions were identified on either of the three PET scans, including 1 right kidney lesion, 1 hepatic lesion, 1 pancreatic lesion, 2 abdominal wall lesions, 1 seminal vesicle lesion, 2 pulmonary lesions (0.6cm), 1 abdominal lymph node, and 1 left thigh lesion. On $^{68}$Ga-NY104 PET/CT, all lesions were PET positive, demonstrating intensive uptake (SUVmax 27.5). On $^{68}$Ga-PSMA PET/CT, only 6 lesions (1 hepatic, 1 pancreatic, 2 abdominal wall, 1 seminal vesicle, and 1 left thigh lesion) showed substantial uptake (SUVmax 12.9). On $^{18}$F-FDG PET/CT, only mild uptake was noted in 4 lesions (1 right kidney, 1 pancreatic, 1 abdominal wall, and 1 seminal vesicle lesion) with SUVmax of 4.5. For all lesions, $^{68}$Ga-NY104 demonstrated much higher tumor uptake and tumor-to-background ratio than $^{68}$Ga-PSMA and $^{18}$F-FDG. ***Conclusion:*** $^{68}$Ga-NY104 PET/CT is a powerful tool to evaluate metastatic ccRCC and has the potential to surpass $^{68}$Ga-PSMA and $^{18}$F-FDG.

## OP-884

### [99mTc]Tc-HYNIC-TOC as an alternative to [123I]mIBG for Neuroblastoma Staging, a Comparative Case Series

***K. Hlongwa***, *A. Brink, O. Kolade, A. Alnabulsi, S. More;*
*Red Cross War Memorial Children's Hospital and*
*University of Cape Town, Cape Town, SOUTH AFRICA.*

***Aim/Introduction:*** Neuroblastoma is the most common solid extracranial malignant paediatric tumour and is of neuroectodermal origin. Molecular imaging plays a key role in staging, evaluation of response to therapy, and follow-up. [$^{123}$I] mIBG has played an essential role in evaluating neuroblastoma patients with prognostic significance. Neuroblastomas have demonstrated expression of somatostatin receptors and successfully imaged with somatostatin analogue (SSA), [$^{68}$Ga] Ga-DOTA-TATE. During the COVID-19 pandemic, the supply of [$^{123}$I]mIBG was challenging, and in our hospital, access to PET/CT for paediatric patients is limited and not on-site. Therefore, our multi-disciplinary team opted to image patients with [$^{99m}$Tc] Tc-HYNIC-TOC and [$^{123}$I]mIBG once it became available to see the feasibility of using SSA in times of the unavailability of [$^{123}$I]mIBG. ***Materials and Methods:*** Paediatric patients referred for initial staging of neuroblastoma during 2021 and 2022 COVID pandemic were scanned with [$^{99m}$Tc]Tc-HYNIC-TOC and [$^{123}$I]mIBG within a 2-week interval of each other prior to chemotherapy. Consent was obtained from the parents prior to imaging. Images were reviewed by 2 Nuclear Physicians and a nuclear medicine registrar. Information regarding the N-myc amplification was also recorded for each patient. ***Results:*** Six patients were imaged with [$^{99m}$Tc] Tc-HYNIC-TOC and 3 were excluded due to incomplete imaging or chemotherapy prior to [$^{123}$I]mIBG imaging. Three patients were included in the review with respective ages of 4, 1 year 7 months, and 2 years 4 months. There was 100 % concordance in the imaging findings of [$^{99m}$Tc]Tc-HYNIC-TOC and [$^{123}$I]ImIBG in the 3 patients. Two patients with well-differentiated disease and N-myc

gain had positive [$^{99m}$Tc]Tc-HYNIC-TOC and [$^{123}$I]mIBG scans, one demonstrated localised disease and the other had metastases. One patient with differentiating disease and N-myc gain had negative [$^{99m}$Tc]Tc-HYNIC-TOC and [$^{123}$I]mIBG scans. ***Conclusion:*** Our limited case series demonstrates the potential for easily accessible and affordable [$^{99m}$Tc]Tc-HYNIC-TOC as an alternative to [$^{123}$I]mIBG for staging neuroblastoma in a resource-limited setting. Prospective large-scale studies will be necessary in order to validate these findings.

## OP-885

**[18F]F-SynVesT-1 PET In a Rare Case of Paraneoplastic Neurological Syndrome Associated With Isolated Anti-amphiphysin Antibodies**

***Y. Tang***, *L. Xiao, J. Yang, S. Hu;*
*Xiangya Hospital Central South University, Changsha, CHINA.*

***Aim/Introduction:*** Paraneoplastic neurological syndrome (PNS) is a rare immune-mediated neurological disorder that can be challenging to diagnose and treat. PNS related to anti-amphiphysin autoantibody, a 128 KD nerve terminal protein located on the synaptic vesicles, usually presented as stiff person syndrome. [$^{18}$F]F-SynvesT-1 is a novel radioligand for PET imaging targeting synaptic vesicle glycoprotein 2A (SV2A), which could observe the effect of anti-amphiphysin antibodies directly on the nervous system in patients with PNS. ***Materials and Methods:*** A 48-year-old man has suffered from progressive unresponsiveness and slurred speech for 10 months. Neuropsychological examination revealed inadequate numeracy, memory, and disorientation with dysarthria. The patients got 13/30 on Montreal Cognitive Assessment (MoCA). Routine laboratory, cerebrospinal fluid (CSF) analyses, and brain magnetic resonance imaging (MRI) were normal. Serological workup with paraneoplastic encephalitis panel showed positive evidence of anti-amphiphysin. ***Results:*** [$^{18}$F]F-FDG PET and [$^{18}$F]F-FDG PET/MRI images showed hypometabolism throughout the bilateral frontal and temporal lobes asymmetrically, while [$^{18}$F]F-SynvesT-1 PET and [$^{18}$F]F-SynVesT-1 PET/MRI showed a more restricted area of low uptake in these two lobes. Ambulatory EEG recording showed slow waves in the bilateral frontotemporal regions. Meanwhile, systemic [$^{18}$F]F-FDG PET did not identify any occult neoplasm. After being diagnosed with PNS, the patient's symptoms improved significantly with lymphatic plasma exchange and glucocorticoid therapy. ***Conclusion:*** Both [$^{18}$F]F-FDG and synaptic vesicle protein PET imaging can provide a diagnostic basis for localization for PNS. [$^{18}$F]F-SynVesT-1 PET is more specific than [$^{18}$F]F-FDG PET which plays an important role in the evaluation of PNS, not only an insight into disease characteristics and treatment directions.

***Aim/Introduction:*** Neurotensin receptor-1 ($NTS_1$) is a G-protein coupled receptor overexpressed in several cancer types including pancreatic adenocarcinoma, triple negative breast cancer and others. We have previously reported that [$^{68}$Ga]Ga-JMV6659 (DOTA-APAc-Lys-Lys-Pro-Tyr-Ile-TMSAla-OH) as a promising peptide-based radiopharmaceutical for NTS1 imaging. In this work, we evaluated the impact of N-terminal radiometal modification of JMV6659 for theranostic purpose. As [$^{68}$Ga]Ga-JMV6659 showed also blood uptake, this finding was also deeply evaluated. ***Materials and Methods:*** JMV6659 was radiolabeled with $^{111}$In and $^{161}$Tb ($^{89}$Zr and $^{177}$Lu ongoing). The resulting radiopharmaceuticals were investigated regarding their affinity, internalization, membrane bound fraction and efflux using colon cancer HT-29 cells. Cultured as 2D and 3D (organoids), HT-29 were also used to quantify the uptake of the radiopharmaceuticals. Finally, biodistribution of [$^{111}$In]In-JMV6659 was investigated in nude mice 24h after subcutaneous injection of HT-29 cells. ***Results:*** Saturation binding curves showed a preserved high affinity (nanomolar range) of [$^{111}$In]In-JMV6659 towards NTS1 with a $K_d$ value of 3.91±2.70nM. [$^{161}$Tb]Tb-JMV6659 displayed a somewhat lower affinity with a $K_d$ of 21.06±6.61 nM. [$^{111}$In]In-JMV6659 and [$^{161}$Tb]-JMV6659 exhibited high and specific $NTS_1$-mediated internalization which was maximum at 1h (68.17±5.97 and 82.97±3.12%, respectively) and slightly decreased to 54.48±9.59% and 60.74±12.00 at 4h. Contrarily, the membrane-bound fraction was 12.87±2.57 and 3.94±3.86%, respectively, at 1h and increased up to 25.43±7.38 and 23.00±5.43% at 4h. Human lymphocytes showed weak nonspecific binding of [$^{111}$In]In-JMV6659, whereas a higher specific binding was observed on human neutrophils up to 2h. Human plasma proteins bound [$^{111}$In]In-JMV6659 at about 2%IA/mg.On the monolayer HT-29 cells, uptake of [$^{111}$In]In-JMV6659 was up to 6051.6±634.2 Bq vs 2093.5±182.7 Bq for [$^{161}$Tb]Tb-JMV6659 when 800 kBq (8MBq/mL) were applied. On spheroids, the uptakes were respectively 460.4±46.9 Bq and 473.5±132.4 Bq at the same concentration.On biodistribution, uptake of [$^{111}$In]In-JMV6659 in HT-29 tumors was still 0.41±0.07 %ID/g at 24h. All other organs, except kidneys (8.92±5.55 %ID/g), were cleaned from radioactivity at 24h. To verify the receptor-mediated specificity, blocking experiments were performed using excess of neurotensin. Only uptake in HT-29 tumor was significantly displaced (0.41±0.07 %ID/g vs 0.19±0.09 %ID/g). Blood sampling was also performed at 2h, 4h and 24h to elucidate the underlying kinetics. At 2h, uptake in blood was 1.04±0.36 %ID/mL and decreased to 0.24±0.13 %ID/mL at 4h. At 24h, no significant signal was detected in blood. ***Conclusion:*** Radiolabeled JMV6659 stands as promising radiotherapeutic analogue suitable for targeted radionuclide therapy of NTS1-positive tumors.

***Aim/Introduction:*** PSMA targeted alpha therapy (TAT) agents such as [$^{225}$Ac]Ac-PSMA-617 have shown great efficacy in treating mCRPC patients. However, dose limiting adverse effects such as renal toxicity and xerostomia have limited their potential. We have demonstrated that reducing the effective specific activity (ESA) of the PSMA-TRT agent [$^{177}$Lu]Lu-PSMA-617 via co-injection of PSMA-11 can significantly reduce salivary gland and renal uptake while maintaining PSMA+ tumor uptake in mice. To determine if [$^{225}$Ac]Ac-PSMA-617 uptake in these off-target organs is due to passive accumulation or PSMA expression in these sites, we made a comparative analysis of PSMA expression in human and mouse tissue to see if ESA reduction could limit salivary gland and renal uptake in humans undergoing PSMA-TAT, aligning with our findings in mice. ***Materials and Methods:*** Analyzed PSMA using immuno-histochemistry (IHC), quantitative autoradiography (QAR) and western blot (WB) in samples collected from the kidneys, salivary glands (SG), and lacrimal glands (LG) of both

mouse and human cadavers. IHC was performed on paraffin embedded 5 µm slides using anti-PSMA antibody (Proteintech, 13163-1-AP). QAR was performed on 10µm fresh frozen tissue sections incubated with 0.5µCi of [$^{177}$Lu]Lu-PSMA-617 for 1h and quantified using autoradiography film. Tissues were homogenized and analyzed for PSMA and actin by WB using anti-PSMA (Cell Signaling, 12702) and anti-actin (Cell Signaling, 5152) antibodies. ***Results:*** QAR analysis revealed, [$^{177}$Lu]Lu-PSMA-617 mean uptake (pCi/mm$^3$) of 23.28 ± 0.51 in LNCaP , 5.29 ± 0.02 in LG, 6.23 ± 1.42 in parotid, 3.67 ± 0.20 in submandibular, 3.40 ± 1.56 in kidney (cortex), 1.08 in muscle of human tissue and 0.95 ± 0.05 in SG, 16.4 ± 2.61 in Kidney of mouse tissue. IHC analysis revealed percentage PSMA positive cells of 89.92 ± 4.03 in LNCaP xenograft, 61.71 ± 7.02 in LG, 65.96 ± 0.63 in parotid, 68.48 ± 4.53 in submandibular, 41.80 ± 3.12 in kidney (cortex), 19.11 ± 7.05 in muscle of human tissue and 36.12 ± 9.39 in SG, 53.58 ± 2.04 in kidney (cortex) of mouse tissue. WB analysis revealed significantly higher PSMA expression in LNCaP xenografts compared to SG, LG and kidney of human tissue. ***Conclusion:*** Our preliminary data demonstrated PSMA is prominently expressed in SG, LG and kidneys in human tissue and actively binds to PSMA-TRT agents. Therefore developing methods to limit off-target toxicity of PSMA-TRT agents becomes crucial. ***References:*** Kalidindi TM et al., Eur J Nucl Med Mol Imaging, PMID: 33495926. [1]*Molecular Partners AG, Schlieren, SWITZERLAND,*
[2]*Paul Scherrer Institute, Villigen, SWITZERLAND.*

***Aim/Introduction:*** DARPins (Designed Ankyrin Repeat Proteins) are small binding proteins that combine short systemic half-life, ideal binding properties and high stability. DARPin molecules with very high affinity and specificity can be generated against a broad range of tumor targets. We have previously shown that increased DARPin affinity correlates with elevated tumor uptake and extended tumor retention in mouse models suggesting that radiolabelled binders with picomolar affinity will lead to tumor uptake levels meaningful for therapeutic applications. The robust architecture of DARPins provides high thermal stability, which is beneficial for labelling with radionuclides that require harsh conditions, and which enables engineering approaches that are not compatible with other protein scaffolds. The limitation of small-sized, protein-based targeting agents originates from their renal clearance pathway, which leads to a strong kidney accumulation of coupled residualizing radionuclides resulting in kidney toxicities. To overcome this problem, we have undertaken an extensive engineering campaign to optimize the surface of the DARPin scaffold for reduced kidney reabsorption. ***Materials and Methods:*** Several surface-optimized DARPin variants were engineered against different tumor targets and were analysed for their biophysical properties. Building on the absence of cysteines in the DARPin scaffold, we generated single-cysteine versions for site-specific conjugation to different linker/chelators using maleimide chemistry. Molecules radiolabelled with different radionuclides (e.g., Indium-111, Lutetium-177) were analysed for their in vivo biodistribution properties in different xenografted tumor models. Furthermore, tumor penetration of candidates was analysed by immunohistochemistry on tumor sections. ***Results:*** In vitro characterization showed that engineered DARPin molecules maintained good biophysical properties and high affinities to the target antigen. In vivo biodistribution studies with surface-engineered DARPins showed strongly improved profiles as compared to parental binders. Kidney accumulation was reduced by up to 90% at four hours post injection, while tumor uptake was not affected. This effect was confirmed with different DARPin candidates suggesting a general applicability of the approach. Additionally, orthogonal kidney protecting strategies have been identified that showed superior effects than commonly used nephro-protectants. Combining the different strategies on Her2 binding candidates resulted in an additive effect and an improvement of the tumor-to-kidney ratio from 1:34 to 1:3 in preclinical mouse models. Refinement of the applied strategies to further optimize the tumor-to-kidney ratio are currently ongoing. ***Conclusion:*** The presented results show that our proprietary "Radio DARPin Therapy" platform represents an attractive solution for the development of next-generation RLTs. Several programs in indications with high unmet medical need are currently underway.

***Aim/Introduction:*** To study the effectiveness and normal tissue toxicity of a nanoparticle depot (NPD) embedded with [$^{198}$Au]Au-gold nanoparticles ([$^{198}$Au]Au-NPD) for intratumoral β-particle radiotherapy of a 4T1 murine mammary carcinoma tumour in immunocompetent BALB/c mice and for causing an abscopal effect on a distant non-irradiated tumor. ***Materials and Methods:*** [$^{198}$Au]AuNP were synthesized by sodium citrate reduction of H[$^{198}$Au]AuCl$_4$ and stabilized with lipoic acid-polyethylene glycol, then characterized by UV/Vis spectroscopy, Transmission Electron Microscope (TEM) and Dynamic Light Scattering (DLS). 4 × 10$^{11}$ [$^{198}$Au]AuNP were embedded in a calcium alginate seed (ϕ 0.8×4mm). Subcutaneous 4T1 tumors were initiated in BALB/c mice in the right shoulder (T1) at 7 days (d) before treatment and in the left flank (T2) outside the β-particle range at 1 d prior to treatment. Mice (n=5) received no treatment or intratumoral implantation in T1 of two non-radioactive Au-NPD, one (3.0 ± 0.5 MBq) or two (4.5 ± 0.6 MBq) [$^{198}$Au]Au-NPD. Tumor size (T1 and T2) and body weight were monitored 3 times/week. At 14 d post treatment, mice were sacrificed. Blood biochemistry and hematology were analysed. T2 was immunostained for CD4$^+$ and CD8$^+$ cells and flow cytometry was performed for CD45$^+$, CD3$^+$, CD4$^+$, CD8$^+$ and PD-1$^+$ Tumour Infiltrated Lymphocytes (TILs). ***Results:*** Spherical 23 nm [$^{198}$Au]AuNP were synthesized (>99% yield) and embedded into a NPD. Intratumoral implantation of one

or two [$^{198}$Au]Au-NPD increased T1 doubling-time (DT) by 1.8-fold (7.6±0.6 d) and 3.4-fold (14.9±3.7 d), respectively vs. no treatment (4.3±0.3 d, p<0.0001). DT of T2 was increased by treatment of T1 with one or two [$^{198}$Au]Au-NPD (3.9±1.0 or 4.1±1.1 d) vs. no treatment (3.0±0.5 d, p<0.0001). Treatment of T1 with two Au-NPD did not inhibit T1 or T2 growth (DT=4.7±0.6, 3.1±0.6 d, respectively). Body weight, blood biochemistry and hematology showed no normal tissue toxicity. Treatment of T1 with two Au-NPD, one or two [$^{198}$Au]Au-NPD decreased CD45$^+$, CD45$^+$CD3$^+$, CD45$^+$CD3$^+$CD8$^+$, CD45$^+$CD3$^+$CD4$^+$ TILs in T2 by 45-86 %. T1 treatment with two Au-NPD or one [$^{198}$Au]Au-NPD decreased PD-1 mean fluorescence intensity (MFI) on CD45$^+$CD3$^+$CD8$^+$ TILs by 33% or 43%, and on CD45$^+$CD3$^+$CD4$^+$ TILs by 34% or 42%, respectively. T1 treatment with two [$^{198}$Au]Au-NPD decreased PD-1 MFI on CD45$^+$CD3$^+$CD8$^+$ TILs by 33%, but increased on CD45$^+$CD3$^+$CD4$^+$ TILs by 23%. ***Conclusion:*** Intratumorally implanted [$^{198}$Au]Au-NPD inhibited 4T1 growth, and caused an abscopal effect on a distant tumor, possibly mediated by PD-1 expression on CD45$^+$CD3$^+$CD8$^+$ and CD45$^+$CD3$^+$CD4$^+$TILs.

## OP-899

### Radioactive immuno-imaging and radioimmunotherapy of 131I-labeled human single-chain variable fragment antibodies against anaplastic thyroid cancer in tumor-bearing nude mice

***Q. Liu***[1], *H. Pang*[2];
[1]*the Second Affiliated Hospital of Chengdu Medical College, China National Nuclear Corporation 416 Ho, Chengdu, Sichuan, CHINA,* [2]*The First Affiliated Hospital of Chongqing Medical University, Chongqing, P.R. China, Chongqing, Sichuan, CHINA.*

***Aim/Introduction:*** Anaplastic thyroid carcinoma has a high degree of malignancy and lacks effective treatment, as the tumor tissue does not respond to radioactive iodine therapy. With the continuous development of immunotherapy, we investigated the use of 131 iodine-labeled antibodies, to explore a new treatment method. ***Materials and Methods:*** Total RNA was extracted from the lymphatic tissue near the anaplastic thyroid carcinoma which was used to amplified VH and VL fragments with RT-PCR, and joined with their linkers. VH and VL were used to produce the scFv fragments by the way of splicing-overlap-extension PCR. The scFv gene was cloned in pCANTAB-5E plasmid, and the recombinant phagemids were transformed to susceptible E. coli TG1. Enzyme-linked immunosorbent assay (ELISA) was used to detect the expression of scFv. The expression and relative molecular mass of soluble scFv were tested by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and western blotting, respectively. The chloramine T method was used to label scFv with $^{131}$I. $^{131}$I-scFv was injected via the tail vein into nude mice to analyze the distribution of $^{131}$I-scFv in body tissues and organs. Static single photon emission-computed tomography (SPECT) imaging was performed at 12, 24, 48, and 72 h after injection to observe the intratumoral accumulation of radioactivity. The treatment group is divided into 4 groups. The tumor volume change was observed the tumor inhibition rate was calculated. The survival time of each mouse was also recorded. The tumor tissue was removed from each mouse within 1 h after death, and made pathological sections and observe under electron microscopy. ***Results:*** The human anaplastic thyroid carcinoma phage antibody library was constructed successfully. Phage ELISA results showed specific binding to ARO cells. SDS-PAGE and western blotting showed that the relative molecular mass of soluble scFv was approximately 29 kD. The labeling rate was 91.66% and the radiochemical purity was 93.1 ± 0.32%. SPECT imaging showed that 131I-scFv selectively accumulated in tumor tissue. The target/non-target (T/NT) value was highest and clearest at 48 h, and SPECT/CT image fusion results were in agreement with the biodistribution results. The survival times of the four groups of tumor-bearing nude mice were 39.5, 43.0, 54.5, and 55.0 d. ***Conclusion:*** Human single chain variable fragment antibodies against ATC were successfully generated. We found that 131I-scFv provided a more effective diagnosis and treatment method for the clinical treatment of anaplastic thyroid carcinoma.

## OP-900

### Preparation of 47SC-labeled DOTA-RGD4 tetramer and preliminary preclinical study on its application in iodine-refractory differentiated thyroid carcinoma

***X. Jiang***;
*Second Affiliated Hospital of Chengdu Medical College (China National Nuclear Corporation 416 Hospital), chengdu, CHINA.*

***Aim/Introduction:*** Thyroid cancer is the most common malignant endocrine tumour and its incidence has been increasing in recent years. The 10-year survival rate of radioactive iodine-refractory differentiated thyroid cancer (RAIR-DTC) is only 10%, which is a key challenge in the clinical management of thyroid cancer. The αvβ3 is highly expressed in thyroid cancer, suggesting that radiolabeling can target αvβ3. Arg-Gly-Asp (RGD) may be a new strategy for the integration of RAIR-DTC treatment. In this study, $^{47}$Sc-labelled 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetate (DOTA)-RGD tetramer ($RGD_4$) was used for the first time to explore its efficacy in the treatment of RAIR-DTC. ***Materials and Methods:*** In this study, $^{47}$Sc labelling of DOTA-$RGD_4$ was efficiently performed. LogP values, in vivo and in vitro metabolic stability, cellular uptake and specific binding of the labelled product were determined. The tumour targeting ability and therapeutic potential of the radiotracer was investigated in CAL-62 mice, while imaging studies were performed at different time intervals (2 4 24 48 72h) by SPECT/CT. ***Results:*** The radiochemical yield of $^{47}$Sc-labelled DOTA- $RGD_4$ was >90% and the radiochemical purity was >99%. the LogP value was -2.376. the radiotracer showed good in vivo, in vitro and metabolic stability, with a specific binding rate of >95%. the SPECT/CT and biodistribution studies showed that the radiopeptide accumulated heavily in the tumour, with maximum tumour uptake at 4 hours post-injection and a tumour background ratio of 8.13±3.67. The drug was excreted mainly by the urinary route. The treatment results suggested that not only was tumour growth inhibited but also significant tumour shrinkage was observed following administration of this radiopharmaceutical to mice. ***Conclusion:*** Preclinical data indicate that $^{47}$Sc-DOTA-$RGD_4$ is highly efficient and stable in vitro and vivo, and that SPECT imaging and biodistribution data demonstrate significant tumor uptake and specificity, allowing for effective treatment of RAIR-DTC and other cancers overexpressing αvβ3 integrin receptors, as well as for staging and follow-up imaging.

## OP-901

### PSMA-Targeted Single Domain Antibody Fragment NB7: Preliminary Evaluation as a Scaffold for Targeted α-particle Therapy of Prostate Cancer

***T. Huynh***[1], *Y. Feng*[1], *R. Meshaw*[1], *X. Zhao*[1], *L. Rosenfeld*[2], *N. Papo*[2], *M. Zalutsky*[1];
[1]*Duke University, Durham, NC, UNITED STATES OF AMERICA,* [2]*Ben-Gurion University of the Negev, Beer-Sheva, ISRAEL.*

***Aim/Introduction:*** Single domain antibody fragments (sdAbs) are an attractive platform for targeted α-particle therapy (TAT) because of their ~15 kDa size, high stability, fast normal tissue clearance and excellent tumor targeting and penetration. We developed a PSMA-targeted sdAb, NB7, with high affinity and a different

binding site on PSMA than the small molecule PSMA-targeted agents. Herein, we report the in vitro and in vivo evaluations of radiohalogenated NB7 conjugates using residualizing prosthetic agents designed for use with radioiodine and $^{211}$At. ***Materials and Methods:*** NB7 sdAb was labeled using both the 1,3,5 and 1,3,4 isomers of N-succinimidyl guanidinomethyl [*I]iodobenzoate ([$^{125,131}$I]SGMIB), and their astatinated analogues [$^{211}$At]SAGMB s. Binding affinity, cell uptake and internalization were evaluated using PSMA+ PC3 PIP and PSMA- PC3 flu prostate cancer cells. A paired-label biodistribution study was performed to compare 1,3,4-[$^{131}$I]SGMIB-NB7 and 1,3,5-[$^{125}$I]SGMIB-NB7 conjugates (both without His6-tag) in athymic mice with subcutaneous PSMA+ PC3 PIP xenografts. A single-label study was performed with 1,3,5-[$^{125}$I] SGMIB-NB7His (with a His6-tag at the C-terminus) in the same animal model. ***Results:*** [$^{131}$I]SGMIB-NB7 showed high binding affinity (6.4 ± 2.0 nM), PSMA-specific cell uptake (51.6 ± 0.6 % at 2 h), and high internalization (30-70% internalization at 2 h). Good tumor uptake (7.2 ± 1.5 %ID/g at 1 h) and fast kidney clearance (3.2% ID/g at 4 h) was seen in PSMA+ PC3 PIP xenografts. Notably, less than 3% ID/g uptake was seen in salivary gland and lacrimal gland at 1h, which cleared quickly (< 1% ID/g at 4 h). Paired-label biodistribution found no distinctions between SGMIB isomers. No discernible differences were observed for radioiodinated NB7 conjugates with/without a His6 tag at the C-terminus. Similar to the radioiodinated conjugates, [$^{211}$At]SGMAB-NB7 demonstrated high PSMA-specific uptake in PSMA+ PC3 PIP cells (41.5 ± 1.5 % at 2 h). ***Conclusion:*** $^{125,131}$I-labeled and $^{211}$At-labeled NB7 conjugates via these guanidino bearing prosthetic agents demonstrated excellent PSMA-specific binding, cell uptake and internalization in PSMA+ PC3 PIP cells. Radioiodinated NB7 showed good tumor uptake, rapid kidney clearance and low retention in salivary glands and lacrimal glands. Our results suggest that NB7 offers a potentially valuable alternative scaffold for PSMA-targeted therapy with a size and pharmacokinetic profile intermediate between small molecule PSMA inhibitors and intact antibodies. Further evaluation of $^{211}$At-labeled for TAT is underway.

## OP-902

### 177Lu-labeled aflibercept for theranostic application in renalcancer models

***L. Kang***, *Z. Chen, Q. Yang, Y. Qiu, W. Huang, L. Song, X. Sun;*
*Peking University First Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Aflibercept, a chimeric recombinant protein, can sequester all isoforms of VEGF-A, PlGF, and VEGF-B, therefore affecting pathological and physiological angiogenesis. In this study, the role of $^{177}$Lu-labeled aflibercept was investigated for SPECT imaging and treatment in renal cancer models. ***Materials and Methods:*** Aflibercept was conjugated with 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling with $^{177}$Lu ($t_{1/2}$ = 6.65 d). After the renal cancer Renca tumor-bearing mice model was established, SPECT imaging and biodistribution studies were performed after the injection of $^{177}$Lu-DOTA-aflibercept. Further, five experimental groups of five mice each were formed and then treated as follows by tail vein injection: $^{177}$Lu-DOTA-aflibercept, $^{177}$Lu-DOTA-IgG (human non-specific), $^{177}$Lu, aflibercept, and PBS. Measurements of tumor size were conducted every other day. Tumor sizes and body weight were measured within 14 days post-injection. Mice injected with CY5.5-aflibercept (n=4), CY5.5-IgG (n=4), and CY5.5-aflibercept-block (n=4) were imaged for optical imaging. Finally, histological analysis was performed to examine VEGF expression in tumors and hematological analysis was for evaluating the toxicity of therapy. ***Results:*** The labeling yields were more than 90% for $^{177}$Lu (n=5). The SPECT imaging of $^{177}$Lu-aflibecept showed that the tumor uptake of Renca tumor reached the highest on the fifth day. Ex vivo biodistribution results validated and quantified the planer imaging results. According to the results of fluorescence imaging, Cy5.5-aflibercept group mice showed significant accumulation in tumors, which was significantly higher than the control group and blocking group. The results showed that for the treatment group of $^{177}$Lu-aflibercept, significant inhibition of tumor growth was observed. The standardized tumor volume of $^{177}$Lu-aflibercept is only 180.4 ± 107.8% at 14 days, much smaller than PBS group (PBS=1064.3 ± 706.0%; P=0.002) and other treatment groups ($^{177}$Lu=461.9 ± 36.4%, $^{177}$Lu-IgG=370.9 ± 176.4%, aflibercept=331.6 ± 101.1%). Immunofluorescence images showed positive signals of VEGF and CD31 expression in cells of different groups after treatment. The $^{177}$Lu-aflibercept group had the least VEGF expression positive signals. However, there was no significant difference in CD31 expression signals between different groups. Therefore, the effectiveness of the treatment was demonstrated in our study. Besides, the bodyweight of $^{177}$Lu-aflibercept did not change significantly and there was no significant long-term blood toxicity, indicating the safety of radiolabeled aflibercept in vivo. ***Conclusion:*** $^{177}$Lu-labeled aflibercept displayed a significant VEGF-positive tumor affinity and effective tumor therapy without significant toxicity. Therefore, $^{177}$Lu-labeled aflibercept could be further investigated in the theranostic field of renal cancer in the clinic.

## OP-903

### Development of cobalt-55 labelled neurotensin antagonist NOTA-SR142948 for cobalt-58m NTSR1 targeted radionuclide therapy

***W. Lin***[1], *G. O. Fonseca Cabrera*[2], *E. Aluicio Sarduy*[1], *T. E. Barnhart*[1], *Z. Li*[2], *Z. Wu*[2], *J. W. Engle*[1];
[1]*University of Wisconsin Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*University of North Carolina at Chapel Hill, Chapel Hill, NC, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Neurotensin receptors (NTSR) are known for stimulating tumor proliferation through neurotensin (NTS) activation and are expressed in a variety of cancers including breast, pancreatic, prostate, colon and non-small cell lung cancers. NTS antagonists have achieved greater in vivo tumor uptake than NTS agonist-based ligands due to their improved metabolic stability, leading to phase I/II clinical trials in humans. We investigated the therapeutic potential of SR142948 conjugated with NOTA chelator for cobalt-58m targeted radionuclide therapy (TRT) via its diagnostic congener, cobalt-55, using NTSR1-positive HT29 human colorectal adenocarcinoma cells as the cancer model. ***Materials and Methods:*** Cobalt-55 ($^{55}$Co) was produced via deuteron irradiation of iron-54 targets and purified with ion exchange/extraction chromatography. Trace metals were quantified with microwave plasma - atomic emission spectroscopy (MP-AES). NOTA-SR142948 ("SR") was labelled with $^{55}$Co (pH 4.5, 1 h, 55°C, 2 mg/mL sodium gentisate). Labelled compounds were purified using HLB solid-phase extraction columns following HPLC purification and subsequently dried under argon flow before reconstitution in PBS to <10% ethanol. Radioanalytical-HPLC was used to determine the radiochemical purity of the labelled compounds. [$^{55}$Co]Co-SR binding saturation and internalization assays were evaluated using HT29 cells in triplicate, and surface bound activity was removed with stripping buffer (0.1 M citrate pH 2). Female nude mice (N=4) were

xenografted with a 1:1 mixture of $10^6$ HT-29 cells and Matrigel, and then PET imaged after 7 days. NTSR1-negative CaCo2 tumors were xenografted contralaterally. Each mouse received 2.1 MBq [$^{55}$Co]Co-SR. Pharmacokinetic profiles were acquired by PET imaging at 1, 4, 9 and 24 h post injection. Major organs and tissues were quantified at 24 h post injection to confirm image-derived uptake values. ***Results:*** Apparent molar activity of [$^{55}$Co]Co-NOTA was 146±18 MBq/nmol (N=2) end of the bombardment and verified by MP-AES. HPLC verified quantitative [$^{55}$Co]Co-SR radiolabelling at 74 MBq/nmol (37 MBq/nmol at time of injection) and sodium gentisate effectively mitigated radiolysis. >35% of bound [$^{55}$Co]Co-SR activity was internalized by HT29 cells after 3 h of incubation and measured NTSR1 $K_D$ = 3±2 nM. PET imaging with [$^{55}$Co]Co-SR showed predominantly renal clearance with high, persistent tumor uptake (14±1 %ID/g at 24 h) and high tumor-to-organ ratios (>6 for kidney). ***Conclusion:*** In vitro and in vivo data from [$^{55}$Co]Co-SR show promising results for [$^{58m}$Co]Co-SR NTSR1 TRT. Future work will assess the subcellular compartmentalization of the internalized activity and evaluate the cytotoxicity of [$^{58m}$Co]Co-SR for HT29 cells before translation to in vivo therapy studies.

### OP-904

**Single-time-point [68Ga]Ga-DOTATATE-PET/CT for model-based prediction of the time-integrated activity of [177Lu]Lu-DOTATATE during therapy**

***V. Vasic***[1,2], *J. Gustafsson*[3], *E. Yousefzadeh-Nowshahr*[1,2], *A. Beer*[1], *K. Sjögreen Gleisner*[3], *G. Glatting*[1,2];
[1]*Department of Nuclear Medicine, Ulm University Medical Centre, Ulm, GERMANY,* [2]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, Germany, Ulm, GERMANY,* [3]*Medical Radiation Physics, Lund University, Lund, Sweden, Lund, SWEDEN.*

***Aim/Introduction:*** Prediction of the time-integrated activity (TIA) based on single-time-point (STP) pre-treatment PET/CT could simplify patient-specific [$^{177}$Lu]Lu-DOTATATE therapy. The knowledge integrated into a physiologically based pharmacokinetic (PBPK) model, together with a [$^{68}$Ga]Ga-DOTATATE measurement and Bayesian information of the corresponding patient population, could suffice for a prediction of the TIA for [$^{177}$Lu]Lu-DOTATATE biokinetics during therapy. The objective is to evaluate the accuracy of the TIA calculation using STP and Bayesian information. ***Materials and Methods:*** Data from 12 patients (8 males, 4 females; (65±12) years) with well-differentiated metastatic neuroendocrine tumours (NETs) from the Iluminet trial (1,2) were eligible for the study. Patients received (1.7±0.4) pmol and (197±48) MBq of [$^{68}$Ga]Ga-DOTATATE and (10.26±0.09) nmol and (7.46±0.07) GBq of [$^{177}$Lu]Lu-DOTATATE. Accurate dosimetry as presented previously (1) was performed on four total-body planar gamma-camera images acquired at 1 h, 24 h, 96 h, and 168 h p.i. and one SPECT/CT at (22±1) h p.i. For the study, one PET/CT image (63±5) min p.i. was used, and a whole-body PBPK model was developed and implemented in SimBiology/MATLAB. First, Bayesian values were estimated from an initial fit with all measured data (diagnostic+therapy). Second, reference parameters were obtained using PET/CT, scintigraphic measurements and Bayesian information. Finally, two fits of STP pre-treatment PET/CT using Bayesian information were performed: a) using the reference parameters as start values and b) using the Bayes values as start values. The deviation from the reference TIA value was evaluated for the most relevant organs and lesions in percent. ***Results:*** In case a), median [min, max] of the deviation of the TIA from reference TIA in kidney, spleen, liver, tumour and total body without bladder activity are 0.2[0, 0.4]%, 0.2[0, 0.4]%, 1.2[0.7, 4.6]%, 0.4[0, 1.1]%, 0.8[0.4, 1.3]%, respectively. In case b) the deviation is higher: 13[2, 46]%, 13[1, 44]%, 50[17, 194]%, 20[6, 284]%, 18[8, 91]% for kidney, spleen, liver, tumour and total body without bladder activity, respectively. ***Conclusion:*** With good (i.e. the reference) starting values, it is - in principle - possible to predict the TIA values of therapy with a deviation of less than 5% when using the STP pre-treatment PET/CT fit. Subsequent tests aim to find the optimal start values to achieve a prediction TIA that is very close to the reference TIAs. ***References:*** 1. Stenvall et al., EJNMMI Res. 2022;12:75 2. Sundlöv et al., Eur J Nucl Med Mol Imag. 2022;49:3830-3840

### OP-905

**Accuracy of predicted kidney's absorbed doses in [177Lu]Lu-PSMA-617 therapy using single-time-point data and non-linear mixed effect modelling**

***D. Hardiansyah***[1], *E. Yousefzadeh-Nowshahr*[2], *F. Kind*[3], *A. J. Beer*[2], *J. Ruf*[3], *G. Glatting*[2], *M. Mix*[3];
[1]*Universitas Indonesia, Depok, INDONESIA,* [2]*Ulm University, Ulm, GERMANY,* [3]*University of Freiburg, Freiburg, GERMANY.*

***Aim/Introduction:*** In molecular radiotherapy, individual absorbed dose estimation is desirable [1]. However, this is not often performed in the clinic as it needs multiple-time-point imaging data [2]. Therefore, in this study, we investigated the accuracy of the predicted kidney's absorbed doses in [$^{177}$Lu]Lu-PSMA-617 therapy using single-time-point (STP) data from SPECT/CT and non-linear mixed-effects (NLME) modelling. ***Materials and Methods:*** Kidney's biokinetic data of [$^{177}$Lu]Lu-PSMA-617 were collected from sixty-three patients at TP1=(1.8±0.8) h, TP2=(18.7±0.9) h, TP3=(42.7±1.0) h, TP4=(66.3±0.9) h, and TP5=(160.3±24.2) h post injection using SPECT/CT. Population-based model selection with NLME (NLME-PBMS) [3] was performed to select the best function from a set of sum-of-exponential (SOE) functions. In total, nine SOE functions with four to seven parameters were included in the analysis. The best function from the NLME-PBMS analysis was selected based on the goodness-of-fit test and Akaike weight. Reference absorbed doses (rADs) were calculated using the best function and all-time-point data. STP absorbed doses (sADs) were calculated by fitting the best function parameters using STP data at different time points. The accuracy of the STP dosimetry was analysed using the absolute value of the relative deviations (RDs) and root-mean-square errors (RMSEs) between sADs and rADs. ***Results:*** A function with six adjustable parameters, i.e. $A_1e^{-(\lambda1+\lambda phys)t}+A_2e^{-(\lambda2+\lambda phys)t}-A_3e^{-(\lambda3+\lambda phys)t}-(A_1+A_2-A_3)e^{-(\lambda bc+\lambda phys)t}$, was selected as the best function with an Akaike weight of about 100%. STP dosimetry using TP3=(42.6±1.0) h showed the lowest (mean±SD) of the RDs of (6±8)% and (median [min, max]) of the RDs of (2 [0.03, 39])%. The RMSEs of the STP dosimetry at TP1, TP2, TP3, TP4 and TP5 were 23%, 16%, 10%, 20%, and 53%, respectively. Four outlier patients for STP at TP3 (outside the (mean±2SD) of the RD) were found in our study with RD values between 23% and 39%. ***Conclusion:*** STP dosimetry with SPECT/CT measurements at TP3=(42.6±1.0) h

post injection may be used to accurately determine kidney ADs using the NLME method and population-based model selection. NLME modelling allows using functions with more parameters than measured per patient. ***References:*** [1] Glatting G, Bardiès M, Lassmann M. Z Med Phys. 2013;23:262-9. ## OP-906

### Accuracy and Uncertainty Analysis of Reduced Time Point Imaging Effect on Time-Integrated Activity for [177Lu]Lu-DOTA-TATE PRRT in Clinical Patients and Realistic Simulations

***A. Peterson***[1,2], *D. M. Mirando*[3], *Y. K. Dewaraja*[1];
*[1]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, [2]Wayne State University, Detroit, MI, UNITED STATES OF AMERICA, [3]MIM Software Inc, Beachwood, OH, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Factors including scheduling can lead to undesirable imaging time points (TP) for determining time-integrated activity (TIA) and the resulting impact on [$^{177}$Lu]Lu-DOTA-TATE dosimetry accuracy is not well-known. We use 4TP $^{177}$Lu-SPECT/CT data to perform a comprehensive analysis of the error and variability in TIA when employing reduced TP methods. ***Materials and Methods:*** The study includes 28 patients with neuroendocrine tumors who underwent SPECT/CT imaging at approximately 4, 24, 96, and 168 hours post-therapy (p.t.) following the first cycle of [$^{177}$Lu]Lu-DOTA-TATE. The healthy liver, kidney, spleen, and up to 5 index tumors were delineated for each patient. Time-activity curves were fit with exponentials to the 4TP data as a reference. Various combinations of 2 and 3TPs were fit to determine optimal imaging schedules and associated errors. 2 common methods of single time point (STP) TIA estimation were also evaluated. A simulation study was performed with data generated by sampling curve fit parameters from log-normal distributions and adding realistic measurement noise. In clinical and simulation studies, error and variability in TIA estimates were estimated with various sampling schedules. ***Results:*** The optimal imaging time period for STP TIA estimates was 3-5 days (71-126h) p.t. for tumor and organs (6-8 days (144-194h) p.t. for one STP method for spleen). Optimal STP estimates give mean percent errors (MPE) within ±5% and SD<9% across all structures with largest magnitude error and highest variablility for kidney (MPE=-4.1%,SD=8.4%). The optimal sampling schedule for 2TP estimates is 1-2 days (21-52h) p.t. followed by 3-5 days (71-126h) p.t. for kidney, tumor, and spleen and for 3TP estimates it is 1-2 days (21-52h) p.t. followed by 3-5 days (71-126h) p.t. and 6-8 days (144-194h) p.t. for all structures. Using the optimal schedules, the largest MPE for 2TP estimates is 1.2% for spleen and highest variability is tumor with SD=5.8% while for 3TP estimates the largest MPE is 2.5% for spleen and highest variability is tumor with SD=2.1%. Simulated results corroborate the clinical findings with similar errors and indicate many sub-optimal schedules also exhibit low error and variability. A tool has been made available online to explore error and variability associated with user-provided sampling schedules[1]. ***Conclusion:*** Reduced TP methods achieve acceptable average TIA errors over a range of sampling schedules while maintaining low uncertainty. This information can improve the feasibility of dosimetry for [$^{177}$Lu]Lu-DOTA-TATE and elucidate the uncertainty associated with non-ideal conditions. ***References:*** [1]Peterson AB. Reduced TP Error Checker. 2023. https://doi.org/10.5281/zenodo.7843928.

## OP-907

### Non-Uniqueness of Multiexponential Time-Activity Curves in Few-Timepoint Theranostic Workflows Can Increase Dosimetric Error

***D. Balfour***, *J. Sage, J. Willaime, D. Boukerroui; Mirada Medical Ltd., Oxford, UNITED KINGDOM.*

***Aim/Introduction:*** Recent literature has shown interest in reducing the number of timepoints in theranostic workflows. Many such studies use parametric, multiexponential time-activity curve (TAC) models to obtain the time-integrated activities (TIAs) required for dosimetry. Such methods then have more parameters than measurements. Mathematically, this leads to an infinity of possible curves that can solve the fitting problem, each with a different TIA. A unique curve is selected randomly by the solver or determined by some prior information, but it is not commonplace for the choice to be explicitly discussed or analysed. The non-uniqueness of the solution in situations where there are fewer timepoints than model parameters is demonstrated here and its impact on TIA estimation is assessed. ***Materials and Methods:*** A curve stripping TAC fitting method [1] was adapted and solutions analytically derived for a 3 timepoint workflow. The TAC was modelled as a 4-parameter bi-exponential decay consisting of rapid and slow washout terms since these contribute most to dosimetric accuracy. With only 3 measurements, 1 parameter remained underdetermined. A prior, $\rho \in ]0,1[$, was introduced to characterise this unknown: it represented the ratio of contributions between the two washout terms at the second timepoint. The physical assumptions of the model, such as ensuring the rapid washout curve decayed faster, were analysed to obtain constraints on the range of valid values for ρ, parameterising the family of valid solutions. The equivalent range of valid TIA values was then calculated. To demonstrate on realistic data, 2 [Lu-177]-DOTATATE theranostic patients [2] were segmented and locally rigidly registered to produce a set of activity measurements for the liver at 3 timepoints. For comparison, the TIA was also estimated using trapezoidal integration extrapolated with physical-only decay. ***Results:*** The family of valid TACs was determined by identifying the upper and lower bounds on ρ. All curves between these bounds are plausible. Patient 1 had liver TIA values between 18.4 and 19.6 MBq·h/ml, (6.1% maximal underestimation) and patient 2 had TIA values between 23.9 and 24.5 MBq·h/ml (2.7% maximal underestimation). By comparison, the trapezoidal TIAs were 18.76 and 18.79 MBq·h/ml, respectively. ***Conclusion:*** Curve non-uniqueness in parametric TAC integration is a source of error not usually accounted for in uncertainty analysis. Robust means to select a unique curve is required to ensure accurate dosimetry. This can be achieved using good-quality statistical priors. ***References:*** [1] Jackson et al. (2020) https://doi.org/10.1002/mp.14243 [2] Uribe et al. (2021) https://doi.org/10.2967/jnumed.121.262748

## OP-908

### Estimating Biochemical PSA Dynamics after Radioligand Therapy with [177Lu]Lu-PSMA-I&T Using a Population Pharmacokinetic/Pharmacodynamic Model

***H. Siebinga***[1,2], *B. J. de Wit - van der Veen*[1], *D. M. V. de Vries - Huizing*[1], *J. J. M. A. Hendrikx*[1,2], *A. D. R. Huitema*[2,3,4];
*[1]Department of Nuclear Medicine, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS, [2]Department of Pharmacy and Pharmacology, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS, [3]Department of Clinical Pharmacy, University Medical Center Utrecht, Utrecht University, Utrecht, NETHERLANDS, [4]Department of Pharmacology, Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** To predict response to [$^{177}$Lu]Lu-PSMA treatment, tumor exposure-response relationships need to be established. Pharmacokinetic/pharmacodynamic (PKPD) modelling is suitable to assess this association. Therefore, a population PK model for [$^{177}$Lu]Lu-PSMA-I&T using SPECT/CT was developed and related to PSA dynamics after therapy with a PKPD approach. ***Materials and Methods:*** A population PK model was developed using dosimetric SPECT/CT data of 79 patients who received multiple cycles [$^{177}$Lu]Lu-PSMA-I&T (7.4 GBq with 2- or 6-week interval). The PK model consisted of 5 compartments; blood, salivary glands, kidney, tumors and combined remaining tissues. Covariates were tested to explain interindividual variability. The final PK model was expanded with a PD compartment (sequential fitting approach) representing PSA dynamics. Patient PSA records were collected up to 82 weeks after the last $^{177}$Lu-cycle. To explore the exposure-response relationship, individually estimated [$^{177}$Lu]Lu-PSMA-I&T tumor concentrations were related to PSA changes over time. ***Results:*** The population PK model adequately described observed data in all compartments. A significant declining uptake in tumors during later cycles was identified, where the average tumor uptake rate decreased to 72%, 50% and 43% in cycle 2, 3 and 4, respectively, compared to cycle 1. In addition, a cycle-to-cycle variability of 37% (RSE 20.8%) on tumor uptake was estimated and tumor volume was identified as a relevant covariate on tumor uptake, where a two-times higher volume resulted in a 2.07-fold increased tumor uptake rate.Observed PSA increase was described by an exponential growth rate (0.000118 $h^{-1}$). Therapy-induced PSA decrease was related to estimated tumor concentrations (MBq/L) by an $E_{MAX}$-model (($E_{MAX}$*concentration)/($EC_{50}$+concentration)) and individual PSA concentrations were adequately captured. A threshold of 116 MBq/L in tumors was determined to result in no PSA change, i.e. a minimum tumor uptake required for a PSA decrease during treatment (though this provides no information on eventual treatment response). Based on simulations of this PKPD model (n=500), 56% and 23% of the patients are expected to show no increase and >50% decrease in PSA 6 weeks after treatment (4 cycles of 7.4 GBq with 6-weeks interval), respectively. ***Conclusion:*** Our population PK model accurately described observed radioactivity in salivary glands, kidneys and tumors after [$^{177}$Lu]Lu-PSMA-I&T treatment and revealed a declining tumor uptake over cycles. The PKPD model adequately captured individual PSA observations and identified population response rates and tumor dose thresholds. This PKPD-approach may help to compare therapeutic regimes, individualize dosing and identify patients in whom radioligand therapy is likely to fail.

## OP-909

### Population-based model selection for iodine kinetics in benign thyroid disease

***D. Hardiansyah***[1], *A. Riana*[1], *H. Hänscheid*[2], *M. Lassmann*[2], *G. Glatting*[3];
[1]*Universitas Indonesia, Depok, INDONESIA,* [2]*University Hospital Würzburg, Würzburg, GERMANY,* [3]*Ulm University, Ulm, GERMANY.*

***Aim/Introduction:*** Model selection is crucial in individual dosimetry of molecular radiotherapy [1,2]. Recently, we demonstrated the superiority of population-based model selection with non-linear mixed-effects model (NLME-PBMS) over conventional methods [3]. However, NLME-PBMS has not been applied to determine the optimal mathematical model for benign thyroid disease. Our study aims to utilise NLME-PBMS to accurately calculate target tissue time-integrated activity (TIAs) in $^{131}$I therapy for benign thyroid disease. ***Materials and Methods:*** Biokinetic data (% administered activity) of $^{131}$I-therapy in target tissue were obtained from seventy-three patients with Graves' disease/toxic nodular goitre/non-toxic goitre. Time-activity data from uptake measurements were collected at 2, 6, 24, 48, and 96 (N=53) or 120 (N=20) h after oral capsule administration of $^{131}$I. Twenty-two sum-of-exponentials (SOE) functions with two to nine parameters (including the EANM SOP function [4]) were used for the model selection. The parameters of the SOE functions were fitted to the all-time-points biokinetic data in the NLME framework. The SOE function most supported by the data was selected based on the Akaike weight [2]. ***Results:*** The SOE function with five parameters, i.e. $f_{5b}=(A_1+A_2)e^{-(\lambda1+\lambda phys)t}-(A_1)e^{-(\lambda2+\lambda phys)t}-(A_2)e^{-(\lambda3+\lambda phys)t}$ was selected as the function most supported by the data. The Akaike weight of the best function was 99.99%. The estimated fixed effect ("parameter mean value in the population") of parameters $A_1$, $A_2$, λ1, λ2, and λ3 were 0.2, 0.3, $1.9\times10^{-3}$/h, $5.7\times10^{-2}$/h and $5.7\times10^{-1}$/h, respectively. The variances of the random effect ("width of parameter distributions in the population") of parameters $A_1$, $A_2$, λ1, λ2, and λ3 were 0.2, 0.4, 0.4/$h^2$, 0/$h^2$ and 0.2/$h^2$, respectively. The estimated fractional standard deviation of intra-individual variability of the function most supported by the data was 0.059. The optimal function from the model selection performed better than the function from EANM SOP based on the Akaike weight (99.99% vs $3.5\times10^{-40}$%). ***Conclusion:*** An optimal mathematical model (SOE with five fit parameters) was determined for calculating TIAs in $^{131}$I therapy dosimetry for tumours based on NLME and model selection. The optimal mathematical model f5b has two more parameters than the EANM SOP function, which could lead to more accurate TIAs. The sum of 3 exponential terms corresponds to a compartmental model consisting of 3 compartments. ***References:*** [1]. Hardiansyah, D., et al., EJNMMI Phys, 2021. 8(1): p. 82. [2]. ## OP-910

### 131I Thyroid lesion dosimetry with quantitative imaging

***E. Richetta****, C. Cutaia, A. Codegone, V. Garbaccio, R. Pellerito, M. Stasi;*
*Ordine Mauriziano Hospital, Turin, ITALY.*

***Aim/Introduction:*** Post $^{131}$I treatment of metastatic thyroid cancer lesion dosimetry is recommended by the Italian (DLgs 101/20) and European (EU 59/2013) laws to verify the target exposure. To this aim quantitative imaging is useful to standardize the dosimetric process. In this study the SPECT-CT quantification tool is validated and compared to the standard dosimetic method. ***Materials and Methods:*** The quantification software was installed on SPECT-CT for $^{131}$I quantitative imaging (matrix 256x256, 64 views, 20s/view, attenuation-scatter corrected, 2.4 mm voxel-size). Dose were calculated both on standard iterative algorithm (IT) and quantitative (xSPECT) images for results comparisons. A $^{131}$I known liquid source was employed for homogeneous phantom (22 kBq/ml) and spheres phantoms (cylinder 130 ml and 6 spheres, 7.9 MBq/ml) acquisitions to verify the activity calculation accuracy and to build recovery coefficients (RC) partial volumes effect (PVE) curves. Lesion dosimetry was performed on 10 patients and compared (23 lesions, 3 SPECT-CTs (24 h, 48h, > 96 h), biexponential fit with uptake phase, MIRD sphere model). ***Results:*** For IT images the 3.38E-5 MBq/counts absolute calibration factor was found, while for xSPECT a 0.87 volume sensitivity factor was adopted. In the homogeneous phantom activity accuracy was within -3.6% and -4.7 % for IT and xSPECT respectively. Discrepancies between the two activity calculation methods were in mean (±1dev.st) -3%

±2.9% confirming the effectiveness of the quantification tool. RC curves were significantly different for the two algorithms (IT and xSPECT respectively): 130 ml (1,1), 26.5 ml (0.93, 0.90), 11.4 ml (0.86, 0.68), 5.5 ml (0.72, 0.43), 2.6 ml (0.54, 0.25), 1.1 ml (0.33, 0.13), 0.5 ml (0.16, 0.07). For 10 patient lesion dosimetry was performed. Lesion volumes were small (100% < 35 ml, 43 % < 10 ml) and required PVE corrections. Percentage differences between IT and xSPECT were in mean (±1dev.st) -2%±26%, +3%±20% and 4.9%±22% for activity, cumulated activity and mean dose respectively. ***Conclusion:*** The quantification software is an effective tool for $^{131}$I lesion dosimetry in order to standardize and simplify the dosimetric workflow. Further investigation on 3D voxel dosimetry could better explain variations founded on mean dose results with MIRD sphere model.

## OP-911

### Evaluation of images from patients treated with 224Ra-CaCO3-microparticles for peritoneal metastases - can 224Ra be quantified using SPECT/CT?

***S. Grønningsæter***[1], *L. G. Mikalsen*[1,2], *J. Blakkisrud*[1], *M. Revheim*[1,3], *S. Westrøm*[4], *S. Selboe*[1], *Ø. Bruland*[5,6], *S. Larsen*[7], *C. Stokke*[1,8]; *[1]Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [2]Department of Life Sciences and Health, Oslo Metropolitan University, Oslo, NORWAY, [3]Faculty of Medicine, University of Oslo, Oslo, NORWAY, [4]Oncoinvent AS, Oslo, NORWAY, [5]Department of Oncology, Oslo University Hospital, Oslo, NORWAY, [6]Institute of Clinical Medicine, Oslo University Hospital, Oslo, NORWAY, [7]Department of Gastroenterological Surgey, Oslo University Hospital, Oslo, NORWAY, [8]Department of Physics, University of Oslo, Oslo, NORWAY.*

***Aim/Introduction:*** In an ongoing Phase 1 study, SPECT-based quantification was evaluated after injecting $^{224}$Ra adsorbed in calcium carbonate microparticles ($^{224}$Ra-$CaCO_3$-MP) to patients with peritoneal metastasis from colorectal cancer. The imaging results were compared with the estimated amount of activity in patients based on non-imaging approaches. ***Materials and Methods:*** Two days after cytoreductive surgery (CC-0) with hyperthermic intraperitoneal chemotherapy treatment (CRS-HIPEC), patients were injected intraperitoneally with approximately 7 MBq $^{224}$Ra-$CaCO_3$-MP, diluted in isotonic solution. Whole body planar images and SPECT/CT scans were acquired using a Siemens Symbia Intevo Bold gamma camera at approximately 3, 24, and 120 hours after injection. Imaging was performed using a 20% energy window centred at 240 keV, with two 5% scatter windows, mainly capturing emissions from $^{212}$Pb and daughters. Reconstruction of SPECT images was conducted with an OSEM Flash3d reconstruction algorithm with scatter correction, CT based attenuation correction, and 30×2 iterations×subsets. A homogenous water phantom had previously been used to find the calibration factor (176.1 counts/kBq). Whole-body probe measurements were obtained at 3, 24 and 120 hours and blood samples at 3, 6, 24, 48 and 120 hours. Kinetic modelling, based on the amounts of activity in blood and an adapted model using ICRP publication 137 models for unbound radium and lead, was used to estimate the amount of activity leaving the peritoneal cavity. The SPECT/CT images were used for quantification of activity, based on segments drawn in 3dSlicer covering the whole abdomen. The non-imaging based approach considered the injected activity, corrected for wash-out based on external probe measurements. ***Results:*** Six patients were included, with five patients completing all of the three imaging acquisitions. The kinetic model estimating that 15-25 % of the activity left the peritoneal cavity, and this was also supported by visual inspection of the images. Comparing the activity measured by SPECT to the non-imaging approaches resulted in that 74-104% of the known activity was captured at day 1, 73-137% at day 2, and 64-190% at day 6. ***Conclusion:*** Quantitative SPECT/CT imaging of $^{224}$Ra, primarily based on $^{212}$Pb emissions, might be adequate for quantifying $^{224}$Ra, although the accuracy was found to decrease with the amount of activity. For the six patient investigated, most of the activity was contained in the peritoneal cavity, covered by a single SPECT bed position. Cavitary (or regional) treatment may represent an idealised situation for $^{224}$Ra SPECT quantification compared to radiopharmaceuticals intended for distribution throughout the body.

## OP-912

### 90Y Voxel S-Values updated Monte Carlo database including Internal Bremsstrahlung and new analytical model extending the evaluation to any voxel size

***D. Pistone***[1,2], *L. Auditore*[1,2], *A. Italiano*[2,3], *E. Amato*[1,2,4]; *[1]Department of Biomedical and Dental Sciences and of Morphofunctional Imaging (BIOMORF), University of Messina, Messina, ITALY, [2]INFN, National Institute for Nuclear Physics, Section of Catania, Catania, ITALY, [3]Department of Mathematical and Computer Science, Physical Sciences and Earth Sciences (MIFT), University of Messina, Messina, ITALY, [4]Health Physics Unit, University Hospital "Gaetano Martino", Messina, ITALY.*

***Aim/Introduction:*** Voxel S-Values (VSVs) are widely employed for 3D internal dosimetry of radionuclide therapies, but databases are available for a limited set of voxel sizes. Additionally, it was recently highlighted that Internal Bremsstrahlung (IB) accompanying β-decay, up to now neglected in dosimetry, including VSVs calculation, can play a significant role in the energy deposition for some β-emitters, such as $^{90}$Y. This study aimed at calculating via Monte Carlo (MC) simulation updated $^{90}$Y-VSVs including IB, and developing an analytical model to extend the VSV estimation to any voxel dimension of practical interest. ***Materials and Methods:*** GATE (Geant4 Application for Tomographic Emission) MC simulations were implemented for multiple voxelized geometries of soft tissue, with cubic voxel size d from 2 to 6 mm, in steps of 0.5 mm. For each geometry, the central voxel was set as a homogeneous source of $^{90}$Y decays and IB photons, and the $^{90}$Y-VSVs were computed with and without the additional IB contribution. The analytical model was developed by first fitting the VSVs, including IB as a function of the "normalized radius" $R_n$ = R/d (R = distance from the central voxel), and then fitting the obtained parameters as a function of d. ***Results:*** Comparing MC-derived VSVs including and neglecting IB, differences between +25% and +30% were found for R larger than the maximum range of $^{90}$Y β-particles, testifying the significant contribution of IB to the photon tails of VSVs. Comparing the VSVs from the proposed analytical model with MC ones including IB, agreement within ±5% was found in the central voxel and for the photon tails, increasing the accuracy given by the previous model by Amato et al. 2012 [1]. ***Conclusion:*** The updated $^{90}$Y-VSVs proposed in this study include for the first time IB, increasing the accuracy with respect to existing databases. The new analytical model, implemented in a simple spreadsheet, constitutes a user-friendly and fast approach to calculate $^{90}$Y -VSVs for non-standard voxel dimensions. ***References:*** [1] Amato E et al. Med. Phys. 2012; https://doi.org/10.1118/1.4757912

### OP-913

**Texture Analysis of 68Ga-DOTATOC PET/CT Images For the Prediction of Outcome in Patients With Neuroendocrine Tumors**

***S. Pellegrino***[1], *R. Fonti*[1], *R. Bologna*[1], *M. Panico*[1], *R. Morra*[2], *G. Palmieri*[2], *M. Giuliano*[2], *S. De Placido*[2], *S. Del Vecchio*[1];
*[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.*

***Aim/Introduction:*** The aim of our study was to test whether texture analysis of 68Ga-DOTATOC PET/CT images can predict clinical outcome in patients with neuroendocrine tumors (NET). ***Materials and Methods:*** Fifty patients with neuroendocrine tumors who had undergone 68Ga-DOTATOC PET/CT were included in the study. Primary tumors were localized in the gastroenteropancreatic (39), bronchopulmonary (8) and other anatomical districts (3). Patients were subjected to a mean follow-up period of 19 months (range 1-40 months). All primary lesions were segmented using an automated contouring program setting a threshold for SUV at 2.5 and then they were subjected to texture analysis using LIFEx program. Among all the extracted features, we selected CoV (SD divided by SUVmean), HISTO Skewness, HISTO Kurtosis, HISTO Entropy-log$_{10}$, GLCM Entropy-log$_{10}$, GLCM Dissimilarity and NGLDM Coarseness for further analysis. SUVmax, SUVmean, Receptor Expressing Tumor Volume (RETV) and Total Lesion Receptor Expression (TLRE) were also determined. Univariate and multivariate analyses of clinical and imaging variables were performed using Cox proportional hazards regression. Survival analysis was performed using Kaplan-Meier method and log-rank tests. ***Results:*** Fifty primary lesions were analyzed. Mean values of the conventional and volumetric parameters SUVmax, SUVmean, RETV and TLRE were 24.96±20.47, 8.42±6.58, 26.51±38.82 mL and 295.69±717.61 g, respectively. Moreover, mean values of the texture features CoV, HISTO Skewness, HISTO Kurtosis, HISTO Entropy-log$_{10}$, GLCM Entropy-log$_{10}$, GLCM Dissimilarity and NGLDM Coarseness were 0.52±0.21, 1.18±0.42, 4.04±1.30, 0.92±0.33, 1.71±0.57, 2.83±2.43 and 0.02±0.01, respectively. Survival analysis was performed including clinical variables (age, gender, grading, early or advanced stage), imaging parameters (SUVmax, SUVmean, RETV and TLRE) and texture features (CoV, HISTO Skewness, HISTO Kurtosis, HISTO Entropy-log$_{10}$, GLCM Entropy-log$_{10}$, GLCM Dissimilarity and NGLDM Coarseness). At univariate analysis, overall survival (OS) was predicted by age (p=0.0034), SUVmax (p=0.0128), SUVmean (p=0.0059), CoV (p=0.0090), HISTO Entropy-log$_{10}$ (p=0.0123), GLCM Entropy-log$_{10}$ (p=0.0126) and GLCM Dissimilarity (p=0.0086). At multivariate analysis, only the texture feature GLCM Entropy-log$_{10}$ was retained in the model for prediction of OS ($\chi^2$=7.047, p=0.0079). Finally, survival analysis showed that patients with GLCM Entropy-log$_{10}$ >1.28 had a significantly better OS as compared to patients with GLCM Entropy-log$_{10}$ ≤1.28 ($\chi^2$=7.1075, p=0.0077). ***Conclusion:*** Texture analysis of 68Ga-DOTATOC PET/CT images, by revealing the heterogeneity of somatostatin receptor expression, can predict the clinical outcome of NET patients.

### OP-914

**Association Between Absorbed Dose Heterogeneity and Metabolic Response in HCC Patients Undergoing Transarterial Radioembolization with Y-90 Resin Microspheres**

***N. Coskun***[1], *M. Kartal*[2], *A. Erdogan*[2], *E. Ozdemir*[1];
*[1]Ankara Bilkent City Hospital, Ankara Yildirim Beyazit University, Ankara, TÜRKIYE, [2]Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Voxel-based dosimetry is known to be associated with improved response rates in the treatment of hepatocellular carcinoma (HCC) through transarterial radioembolization (TARE) using glass microspheres. However, the voxel-based dosimetric approach for resin-based microspheres has not been extensively studied and the significance of dosimetric heterogeneity remains unclear. In this study, we aimed to determine the dose thresholds associated with metabolic response and evaluate the predictive potential of intratumoral dose heterogeneity in HCC patients undergoing TARE with resin-based microspheres. ***Materials and Methods:*** We conducted a retrospective screening of patients diagnosed with HCC who underwent TARE using Y-90-loaded resin microspheres in our center between January 2021 and January 2023. Voxel-based dosimetric analysis was performed on post-treatment Y-90 PET/CT images to calculate the average absorbed tumor dose, the percentage of targetted tumor volume, and the minimum doses to consecutive volume percentages within the tumor. The metabolic response of the lesions was determined 3 months after treatment by F-18 FDG PET/CT imaging according to PERCIST criteria. Lesions with complete or partial response were deemed responsive, while lesions that remained stable or progressed were deemed non-responsive. The relationship between the calculated dosimetric parameters and the response to treatment was evaluated using independent samples T-test and ROC analysis. ***Results:*** Thirty-five lesions targeted with 22 TARE sessions in 19 patients (15 males, 4 females, mean age 60±13 years) were included in the study. Objective metabolic response was observed in 57% of the lesions (n=20). Average tumor dose, the percentage of targeted volume, and minimum absorbed doses at 20% to 95% of tumor volume were significantly higher in responsive lesions. The minimum absorbed dose at 50% of tumor volume demonstrated the most prominent difference between responsive and non-responsive lesions. The optimal cut-off values for average tumor dose, targetted tumor percentage, and minimum dose at 50% of tumor volume were 94.6 Gy (sensitivity 73%, specificity 70%, AUC 0.72), 94% (sensitivity 73%, specificity 55%, AUC 0.64), and 91 Gy (sensitivity 80%, specificity 80%, AUC 0.80), respectively. ***Conclusion:*** Our findings suggest that not only the average tumor dose but also the heterogeneous distribution of the absorbed dose within the tumor is associated with metabolic response in HCC lesions treated with resin microspheres. The use of multicompartmental, voxel-based dosimetry can provide a reliable insight into dosimetic heterogeneity. These findings, if confirmed by prospective, randomized studies, may contribute to the development of more effective treatment approaches using resin-based Y-90 microspheres.

### OP-915

**Development of clinical-radiomic model on baseline FDG-PET images in non-small-cell-lung cancer patients, referred to radical lung surgery**

***L. Travaini***, *G. Zuccotti, F. Botta, S. Netti, M. Casiraghi, M. Ferrari, A. Gaeta, P. Rocca, F. Mattana, S. Fracassi, A. Barone, G. Buonsanti, G. Petralia, L. Spaggiari, F. Ceci;*
*EUROPEAN INSTITUTE OF ONCOLOGY, Milano, ITALY.*

***Aim/Introduction:*** : to investigate the association of radiomic features (RFs) extracted from baseline 18F-FDG PET/CT (FDG-PET) with Overall Survival (OS) in a population of early Non-Small Cell Lung Cancer (NSCLC) patients. ***Materials and Methods:*** between 01/2015 and 12/2021 patients with stage I, II and IIIa NSCLC who underwent FDG-PET before surgery were evaluated. OS was the primary endpoint of the analysis. The dataset was randomly split into a training set and a test set consisting of 70% and 30% of the subjects, respectively. The radiomic score (RS) of each patient was determined as a linear combination of the RFs and the coefficient determined with a multivariable Cox LASSO model on the training set. Three prognostic models were evaluated: the clinical model containing only clinical information, the radiomic model containing only the radiomic score, and the clinical-radiomic model containing both clinical information and the radiomic score. The models were compared using the C-index calculated on the training and on the test cohort. Finally, Pseudo Likelihood Ratio Test (PST) was performed to explore any differences in the C-indexes of the clinical and clinical-radiomic model, respectively, on the training set. ***Results:*** three hundred ninety-six (n=396) patients met the inclusion criteria. Median follow-up was 39 months (19-59 months interquartile range IQR) on censured overall sample. The median lesion size was 40 mm (InterQuartile Range (IQR): 29-55). In the clinical model, age and pT were significantly associated with OS. However, the model showed sub-optimal fit, as the C-index was 0.60 in the training and a 0.56 in the test set. The radiomic model showed similar results, with higher performance compared with the clinical model (training C-index=0.73; validation C-index=0.59). The highest training performance was obtained by combining the clinical and radiomic model: training C-index=0.74 and validation C-index=0.58. The performance of the clinical-radiomic model was significantly higher ($p \leq 0.001$) compared to the performance of the clinical model alone in the training set. Conversely, there was no significant difference in the performance of the radiomic and clinical-radiomic models. ***Conclusion:*** our preliminary results confirm the better performance of the clinical-radiomic model compared to the others considered separately. Considering the sub-optimal performance of the model, the inclusion of CT data and the contouring of PET images with different methods is necessary to improve the performance of this radiomic approach.

## OP-916

### Texture Analysis of 18F-FDG PET/CT Images for the Prediction of Outcome in Patients with Multiple Myeloma

***S. Pellegrino***[1], *D. Origlia*[1], *C. Vallone*[1], *R. Della Pepa*[2], *S. Del Vecchio*[1], *R. Fonti*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY,* [2]*Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.*

***Aim/Introduction:*** Multiple myeloma (MM) is characterized by uncontrolled growth of monoclonal plasma cells which can infiltrate the bone marrow in both focal and diffuse manner. This peculiarity makes staging and prognosis of this disease rather difficult. The aim of our study was to test whether texture analysis of 18F-FDG PET/CT images can predict survival in MM patients. ***Materials and Methods:*** Forty-six MM patients underwent 18F-FDG-PET/CT before treatment. We used an automated contouring program for segmenting the hottest focal lesion (absolute threshold for SUV at 2.5) and a lumbar vertebral body for assessment of diffuse bone marrow involvement. The conventional imaging parameters SUVmax and SUVmean and texture features such as Coefficient of variation (CoV), HISTO Skewness, HISTO Kurtosis, GLCM Entropy-log10, GLCM Dissimilarity and NGLDM Coarseness were obtained. Patients were treated and then subjected to a mean follow-up period of 51 months. ***Results:*** We examined 46 focal lesions (FL) and 46 lumbar vertebrae for assessment of diffuse involvement (DI). The mean values of all variables obtained from FL were higher than those extracted from DI, in particular SUVmax (11.05±8.30 vs 3.00±0.96), SUVmean (4.89±2.21 vs 1.80±0.57) and GLCM Dissimilarity (4.29±2.73 vs 0.96±0.31). At follow-up 24 patients died of myeloma and were compared to the 22 survivors for overall survival (OS) analysis. Univariate analysis showed that FL SUVmax (p=0.0453), FL SUVmean (p=0.0463), FL CoV (p=0.0211) and DI SUVmax (p=0.0538) predicted OS. At multivariate analysis only FL CoV and DI SUVmax were retained in the model (p=0.0154). ROC curve analysis showed that the best discriminating FL CoV and DI SUVmax values for OS prediction were 0.44 and 3.88, respectively. Kaplan-Meier method and log-rank testing showed that patients with FL CoV below the cutoff had significantly better OS than those with FL CoV above the cutoff (p=0.0003), as well as patients with DI SUVmax below the cutoff versus those with DI SUVmax above the cutoff (p=0.0006). Combining FL CoV and DI SUVmax by using their respective cutoff values, a statistically significant difference was found between the resulting four survival curves (p=0.0001). Indeed, patients with both FL CoV and DI SUVmax below their respective cutoff values had the most favorable prognosis, as opposed to those having FL CoV and DI SUVmax above their respective cutoff. ***Conclusion:*** Conventional and texture parameters derived from 18F-FDG PET/CT analysis can predict the clinical outcome of MM patients by assessing the heterogeneity and aggressiveness of both focal and diffuse infiltration.

## OP-917

### Inter-institutional validation of a [18F]-FDG PET radiomic signature to predict the location of tumor recurrence after re-irradiation in head and neck cancer in an independent cohort

***A. Beddok***[1,2], *K. Grogg*[2], *L. Rozenblum*[3,2], *C. Nioche*[1], *F. Orlhac*[1], *H. Shih*[4], *T. Marin*[2], *I. Buvat*[1], *G. El Fakhri*[2];
[1]*Institut Curie, PSL Research University, University Paris Saclay, Inserm LITO, Paris, FRANCE,* [2]*Gordon Center for Medical Imaging, Massachusetts General Hospital, Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [3]*Department of Nuclear Medicine, AP – HP Hôpitaux Universitaires La Pitié Salpêtrière - Charles Foix, Sorbonne Université, Paris, FRANCE,* [4]*Department of Radiation Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** A [18F]-FDG PET (PET) radiomic signature for predicting the location of locoregional recurrence (LR) after re-irradiation (reRT) was previously derived* in patients with head and neck cancer (HNC) identifying radiomic features characterizing the signal heterogeneity in the re-irradiated target volume as predictive factors. The aim of this study was to test the performance of this model in an independent cohort of patients from a separate institution. ***Materials and Methods:*** A validation cohort of 36 re-irradiated HNC patients at Massachusetts General Hospital was created ("Boston's cohort"). All patients had a PET scan before reRT, including 27 patients with a second LR. For each patient, the re-irradiated GTV (rGTV) was segmented using SUV>3 threshold extended with a 1 mm margin. Radiomic features were extracted from rGTV using LIFEX software v7.3.17 (2x2x2mm spatial resampling, fixed bin size of 0.157 SUV units). The second LR was categorized as "in-field" if 100% of its volume was in the

rGTV's 95% isodose ("outside" if < 20%). In the initial published study* using 23 HNC patients (Paris's cohort), the prediction model was created using the first principal component (PC) of a PC analysis involving four features: SUV_min, SUV_Kurtosis, GLCM_Correlation, and GLCM_Contrast. In the present work, each subject was characterized by these features, projected as a supplementary individual onto the Paris' PC, and assigned to one of the two groups using the same cut-off as the one identified in the Paris' cohort. Balance accuracy (BA) assessed the model's performance. Permutation test evaluated significance. ***Results:*** Among the 27 patients, 15 had "in-field" and 12 had "outside" second LR. The ranges of values for the four features were not significantly different between the Paris and Boston cohorts (Wilcoxon rank test: p>0.05). BA was 79% with 6 patients misclassified (one "outside" classified as "in-field", and five "in-field" classified as "outside"), corresponding to a positive predictive value (PPV) of 91%. These results were significantly higher than those from the permutation experiment (p<0.05) and close to the 84.5% BA obtained in the Paris's cohort using cross-validation. ***Conclusion:*** This study confirms in an independent cohort of patients that before reRT, a previously derived PET radiomic signature can identify patients that will relapse "in-field" after re-irradiation with a high PPV. If the robustness of the model is confirmed, PET radiomics could facilitate the identification of patients that might benefit from in-field boost in a reRT scheme. ***References:*** *Beddok et al. EJNMMI 2023 PMID: 36282298

## OP-918

### Multi-imaging adaptive radiotherapy for locally advanced head and neck cancer: preliminary results from the RadiomicART study

***F. Gelardi***[1,2], *C. Franzese*[1,3], *M. Teriaca*[3], *M. Badalamenti*[3], *M. Roghi*[3], *D. Dei*[1,3], *C. Giannitto*[4], *M. Rodari*[2], *M. Scorsetti*[1,3]; [1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), ITALY,* [2]*Department of Nuclear Medicine, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY,* [3]*Department of Radiation Oncology, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY,* [4]*Department of Diagnostic Imaging, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY.*

***Aim/Introduction:*** Radiation therapy, alone or in combination with chemotherapy, is the primary non-surgical treatment for locally advanced head and neck cancer (HNC). Despite the introduction of innovative modulated techniques, radiation-related toxicity is still an issue affecting patients' quality of life. Adaptive Radiotherapy (ART) can tailor the treatment plan to improve the distribution of the therapeutic dose according to radiation-induced changes from the initial simulation. We present the preliminary results from the RadiomicART study, aiming at an advanced multi-imaging-based analysis approach to predict outcome and toxicity in HNC patients treated with ART. ***Materials and Methods:*** We prospectively enrolled patients with locally advanced HNC eligible for RT in our institution. All patients underwent CT, [18F]FDG PET/CT, and MRI before RT. We delineated the target volumes on CT and adjusted them on PET/CT and MRI. The total dose delivered was 66/60/54Gy in 30 fractions, using the VMAT-simultaneous integrated boost technique. After three weeks, imaging was repeated to allow adaptive planning. We defined GTV-T and GTV-N by plotting primary tumour and lymph nodes separately. We compared disease characteristics in terms of semiquantitative parameters on PET/CT and of radiomics features on MRI between the original and adaptive plans. We assessed the correlation between imaging changes and patients' baseline characteristics. ***Results:*** We included 30 patients with HNC (median age 69 years, M:F=22:8, 50% with history of smoking). The most common site of primary tumour was oropharynx (19/30), and HPV was found in 15/30 patients. The median GTV-T and GTV-N at baseline versus at re-planning were 22 versus 20 cc, and 5.7 versus 5.5 cc, respectively. PET/CT analysis showed a significant difference in both SUVmax and SUVmean between baseline and interim scan for both primary tumour (SUVmax 18.31 vs 9.76, p<0.0001; SUVmean 9.57 vs 5.6, p<0.0001) and pathological lymph nodes (SUVmax 11.24 vs 6.85, p=0.0004; SUVmean 5.34 vs 3.74, p=0.0005). The reduction in GTV-T and GTV-N was also statistically significant (p<0.0001 and 0.04, respectively). In the primary tumour, Δ-GTV was significantly associated with gender (p=0.006), while Δ-SUVmean correlated with HPV presence (p=0.035). MRI analysis showed a significant association between the median absolute deviation of Δ-radiomics features and smoking (p<0.05), HPV presence (p<0.005), and primary tumour (p<0.005). ***Conclusion:*** Preliminary results showed significant imaging differences between the original and adaptive RT plans and specific correlations with patient characteristics. These findings suggest a potential role for advanced image analysis in treatment planning and outcome prediction in HNC patients.

## OP-919

### Application of an artificial intelligence-based tool in [18F]FDG PET/CT for the assessment of bone marrow involvement in multiple myeloma

***C. Sachpekidis***[1], *O. Enqvist*[2], *J. Ulén*[3], *A. Kopp-Schneider*[1], *L. Pan*[1], *A. Jauch*[4], *M. Hajiyianni*[5], *L. John*[5], *N. Weinhold*[5], *S. Sauer*[5], *H. Goldschmidt*[5], *L. Edenbrandt*[6], *A. Dimitrakopoulou-Strauss*[1]; [1]*German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [2]*Department of Electrical Engineering, Chalmers University of Technology, Department of Electrical Engineering, Chalmers Uni, SWEDEN,* [3]*Eigenvision AB, Eigenvision AB, SWEDEN,* [4]*Institute of Human Genetics, University of Heidelberg, Heidelberg, GERMANY,* [5]*Department of Internal Medicine V, University Hospital Heidelberg and National Center for Tumor Diseases (NCT), Heidelberg, GERMANY,* [6]*Department of Clinical Physiology, Region Västra Götaland, Sahlgrenska University Hospital, Department of Clinical Physiology, Region Västra G, SWEDEN.*

***Aim/Introduction:*** To validate a novel three-dimensional deep learning-based tool on PET/CT images for automated assessment of the intensity of BM metabolism in multiple myeloma (MM) patients. ***Materials and Methods:*** Whole body [18F]FDG PET/CT scans of 35 consecutive, previously untreated MM patients were studied. All patients were investigated in the context of an open-label, multicentre, randomised, active-controlled, phase 3 trial (GMMG-HD7). Qualitative (visual) analysis classified the PET/CT scans in three groups based on the presence and number of focal, [18F]FDG-avid lesions as well as the degree of diffuse [18F]FDG uptake in the BM. The proposed automated method for BM metabolism assessment is based on an initial CT-based segmentation of the skeleton, its transfer to the SUV PET images, subsequent application of different SUV thresholds, and refinement of the resulting regions using postprocessing. Six different SUV thresholds were applied for definition of pathological tracer uptake in the skeleton and -using the resulting masks- subsequent calculation of the whole body metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in each patient. Correlation analysis was performed between the automated PET values and the results of visual PET/CT analysis as well as histopathological, cytogenetical and clinical data of the patients. ***Results:*** BM segmentation and calculation of MTV and TLG after application of the deep learning tool was feasible in all

patients. A significant positive correlation ($p<0.05$) was observed between results of visual analysis of the PET/CT scans for the three patient groups and the MTV and TLG values after employment of all six [$^{18}$F]FDG uptake thresholds. Further, we could demonstrate a significant, moderate, positive correlation between bone marrow plasma cell infiltration and plasma levels of β2-microglobulin with the automated quantitative PET/CT parameters MTV and TLG, after utilization of the following four thresholds: (1) liver SUVmedian x 1.1 (axial skeleton), gluteus SUVmedian x 4 (extremities), (2) liver SUVmedian x 1.5 (axial skeleton), gluteus SUVmedian x 4 (extremities), (3) SUVmax ≥ 2.5, and (4) SUVmax ≥ 2.5 (axial skeleton), SUVmax ≥ 2.0 (extremities). ***Conclusion:*** The automated, volumetric, whole body PET/CT assessment of BM metabolic activity in MM is feasible with the herein applied method and correlates with clinically relevant parameters in the disease. This methodology offers a potentially reliable tool in the direction of optimization and standardization of PET/CT interpretation in MM. Based on the present promising findings, the deep learning-based approach will be further evaluated in future prospective studies with larger patient cohorts.

## OP-920

### Development and validation of 18F-PSMA PET/CT-based radiomics model to predict biochemical recurrence-free survival following radical prostatectomy

***T. Li***, *K. Zhao, X. Su;*
*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, CHINA.*

***Aim/Introduction:*** Biochemical recurrence (BCR) following radical prostatectomy (RP) is a significant concern for patients with prostate cancer. Reliable prediction models are needed to identify patients at risk for BCR and facilitate appropriate management. This study aimed to develop and validate a radiomics model based on preoperative 18F-PSMA PET/CT for predicting BCR-free survival in patients undergoing RP for prostate cancer. ***Materials and Methods:*** A total of 236 patients with histologically confirmed prostate cancer who underwent RP were retrospectively analyzed. All patients had a preoperative 18F-PSMA PET/CT scan. Radiomics features were extracted from the primary tumor region in PET/CT images. A radiomics signature was developed using the least absolute shrinkage and selection operator (LASSO) Cox regression model. The performance of the radiomics signature in predicting BCR-free survival was assessed using Harrell's concordance index (C-index) and compared with clinicopathological variables. The model was externally validated in an independent cohort of 98 patients. ***Results:*** The radiomics signature comprised ten features and demonstrated a C-index of 0.74 (95% CI: 0.66-0.82) in the training cohort and 0.71 (95% CI: 0.61-0.81) in the validation cohort. The radiomics signature remained an independent predictor of BCR-free survival in multivariable analysis (HR: 2.48, 95% CI: 1.47-4.17, $p < 0.001$). The addition of the radiomics signature to a base model containing clinicopathological variables significantly improved the prediction performance (C-index: 0.78, 95% CI: 0.70-0.86, $p < 0.001$). ***Conclusion:*** We developed and validated a novel 18F-PSMA PET/CT-based radiomics model that can predict BCR-free survival following RP in prostate cancer patients. This model may be useful in identifying patients at a higher risk of BCR, thus enabling personalized risk stratification and tailored management strategies.

## OP-921

### Radiomic analysis of pre-surgery FDG-PET images in early-stage Non-Small Lung Cancer patients can improve outcome stratification

***L. Travaini***, *G. Zuccotti, M. Ferrari, M. Casiraghi, F. Botta, M. Colandrea, F. Mattana, C. Zanini, L. Gilardi, M. Calabrese, F. Bellerba, L. Spaggiari, G. Petralia, F. Ceci;*
*European Institute Of Oncology, Milano, ITALY.*

***Aim/Introduction:*** to investigate the association of radiomic features (RFs) from baseline 18F-FDG PET/CT (FDG-PET) and diagnostic CT images with Overall Survival (OS) and Progression Free Survival (PFS) in early-stage Non-Small-Cell-Lung-Cancer (NSCLC) patients. ***Materials and Methods:*** NSCLC patients staged by baseline FDG-PET and CT before radical surgery at our Institute were retrospectively enrolled. All patients had at least 48 months of follow-up. For each patient the largest lesion was contoured manually on CT images and semiauthomatically on PET images with 2 methods (Nestle method, LifeX package; PET Tumour Segmentation PTS tool, 3DSlicer package). Ninety-three PET RFs and 137 CT RFs were extracted with Pyradiomics tool (for PET, extraction was performed for each segmentation). Feature selection was previously performed (univariate ANOVA) to exclude features significantly affected by acquisition parameters (scanner model, injected activity/weight, frame duration, injection-acquisition interval for PET; kV and reconstruction algorithm for CT). Radiomic scores for OS and PFS were created by Multivariable Cox Regression LASSO Model; clinical and clinical-radiomic models were obtained by Multivariable Cox Regression Model. The performances of the different models (radiomic, clinical and clinical-radiomic, based on CT RFs and/or PET RFs with different PET segmentations) for each endpoint were assessed (C-index, 5-fold internal cross validation) and compared (Likelihood Ratio Test (LRT) and pseudo-LRT). ***Results:*** one-hundred and twenty patients (n=120) fulfilled the inclusion criteria. In the clinical model age, neoadjuvant and adjuvant therapy were independent predictors of OS (training C-index=0.70; validation C-index=0.71). The radiomic score significantly separated high- vs. low-risk OS sub-cohorts when including CT features. The best performance was obtained with the combination of CT features and PET features with PTS method ($p=0.0015$, training C-index 0.78, validation C-index 0.80) and was significantly higher compared to the clinical model alone ($p<0.001$). Sex, pT and adjuvant therapy were independent predictors of PFS in the clinical model (training C-index=0.66; validation C-index=0.61). Significantly better results for PFS prediction were obtained when combining clinical and radiomic data, the highest performance being obtained with the PET radiomic score from PTS segmentation method: training C-index=0.74 and validation C-index=0.72 ($p<0.001$ for the comparison with clinical model alone). ***Conclusion:*** radiomic analysis applied to baseline FDG-PET and CT images in early-stage NSCLC appears to be a reliable approach for stratifying patients with more favorable vs. less favorable outcome after radical lung surgery.

## Inflammation & Infection Committee - TROP Session: COVID-19: Isn't it over yet?

### OP-922

**Noninvasive imaging of inflammatory processes by macrophage-directed PET-tracers during a SARS-CoV-2-infection in cynomolgus macaques (Macaca fascicularis)**

***M. Stammes***[1], *G. Koopman*[1], *T. Wagner*[2], *B. Traenkle*[2], *P. Kaiser*[2], *A. Maurer*[3], *J. Schwenck*[3], *U. Rothbauer*[3], *M. Kneiling*[3], *D. Sonanini*[3];
[1]*BPRC, Rijswijk, NETHERLANDS,* [2]*University of Tübingen, Reutlingen, GERMANY,*
[3]*Eberhard Karls University, Tübingen, GERMANY.*

***Aim/Introduction:*** Monitoring the presence and dynamic distribution of distinct immune cell populations are key in understanding the impact of disease processes in the body. Macrophages are critically involved in the pathogenesis of COVID-19. In addition, it has been indicated that a SARS-CoV-2 infection leaves an inflammatory imprint in the macrophage compartment and thus alters effector functions of macrophages which subsequently might lead to the "long-COVID" syndrome. One option to monitor macrophages by noninvasive in vivo PET imaging is to target the mitochondrial translocator-protein (TSPO) which has already proven its ability to visualize SARS-CoV-2-associated pulmonary inflammation. However, imaging of $^{18}$F-TSPO is limited by its low specificity and/or its preferential binding of anti-inflammatory macrophages. Recently, a specific nanobody targeting the myeloid cell population including proinflammatory macrophages was developed and radiolabeled with $^{64}$Cu enabling PET imaging. The aim of this study was to validate the applicability of the newly developed tracer by visualizing the inflammation processes in non-human primates during a SARS-CoV-2 infection with immunoPET. ***Materials and Methods:*** Six female cynomolgus macaques were infected with SARS-CoV-2 and subsequently followed for two months. PET-CTs were obtained before and after infection covering the head, thorax, and abdominal region. Swabs and blood were repeatedly taken to determine the course of the infection. ***Results:*** All animals were positive for SARS-CoV-2 in the swabs on various timepoints pi. The initial development of pulmonary lesions was already detected at the first CT, performed 2 days post infection (pi). TSPO PET-CTs showed an increased uptake in both the anatomically affected and unaffected lungs tissue whereas the PET-CTs of the new nanobody tracer only revealed an increased tracer uptake in the mediastinal lymph nodes of all animals from the first scan obtained after infection. Notably, the increased nanbody tracer uptake in the spleen and bone marrow of all animals was more pronounced at three weeks pi (average $SUV_{mean,spleen}$ pre-infection 3.69 vs 5.87 pi, average $SUV_{mean,bonemarrow}$ pre-infection 2.09 vs 3.22) and even further increased for the spleen at seven weeks pi with a $SUV_{mean,spleen}$ of 7.53. ***Conclusion:*** This study illustrates that the new nanobody tracer can serve as a versatile probe for monitoring individual immune responses during the course of SARS-CoV-2 infection. In comparison to TSPO we detected individual differences in bonemarrow and spleen uptake. These studies might potentially give an insight in the inflammatory processes and the immune mechanisms involved for continuous symptoms and the onset of long-Covid.

### OP-923

**Role of 18F-FDG PET/CTin detecting residual or recurrent diseaseafter surgery in patients with rhino-orbito-cerebral mucormycosis: a pilot study**

***A. Phulia***[1], *I. Singh*[1], *R. Kumar*[2];
[1]*Maulana Azad Medical College, New Delhi, INDIA,* [2]*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** Coronavirus disease 2019 (COVID-19) pandemic has brought an unwelcome increase in the incidence of life-threatening opportunistic infections like mucormycosis. The use of steroids in COVID-19 patients and the presence of uncontrolled diabetes as comorbidity has led to an increase in the incidence of invasive rhino-orbito-cerebral mucormycosis. Anatomical imaging modalities have limitations in detecting residual/recurrent disease in the post-surgical setting due to distortion of normal anatomy and associated post-treatment changes. The current study aims to assess the role of 18F-FDG PET/CT, to detect residual or recurrent rhino-orbito-cerebral mucormycosis in the post-surgical setting. ***Materials and Methods:*** A total of 33 COVID-19 patients with a confirmed diagnosis of rhino-orbito-cerebral mucormycosis, who have already undergone surgical debridement and now presenting with suspicion of residual or recurrent disease on clinical and/or imaging findings were included in this study. These patients underwent 18F-FDG PET/CT at least 4 weeks after the previous surgical debridement. Lesions with increased FDG uptake compared to the adjacent region and/or physiological uptake of the liver were considered positive for residual or recurrent disease. Regions of interest (ROI) were drawn around the area of abnormal uptake for measurement of semi-quantitative parameters such as standardized uptake value (SUV). All patients with positive PET/CT results underwent a KOH swab or biopsy for confirmation of the diagnosis. In cases where a KOH swab or biopsy could not be done or in cases of equivocal results, patients were assessed using clinical and/or imaging follow-up. ***Results:*** A total of 33 patients (males, 29; females 4) with a mean age of 53.27 ± 10.97 were enrolled in the study. 18F-FDG PET/CT was positive in 21 (64%) and negative in 12 (36%) patients. Based on the reference standard, 20 were true positives, 12 were true negatives, and the remaining 1 was a false positive. Four patients underwent re-operation and biopsies from all these patients were positive for residual/recurrent disease. The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 100% (95% CI: 83% - 100%), 92% (95% CI: 64% - 100%), 95% (95CI: 75% - 99%), 100% and 97% (95% CI: 84% - 100%) respectively. ***Conclusion:*** 18F-FDG PET/CT is highly sensitive and specific for the detection of residual or recurrent disease in rhino-orbito-cerebral mucormycosis patients after surgery. It can be a valuable tool to further evaluate the effectiveness of antifungal therapy and treatment response and assess the need for further interventions.

### OP-924

**Covid-19. Before and after in the diagnosis of pulmonary embolism in nuclear medicine. Our experience.**

***C. Ruiz Corbalán***, *A. Leiva Montejo, A. De Agrela Serrao, D. Cáceres Silva, M. Castellón Sanchez, L. Mohamed Salem, J. Navarro Fernadez, T. Rodriguez Locarno, A. Hernandez Martinez, L. Frutos Esteban, J. Contreras Gutierrez;
Arrixaca, Murcia, SPAIN.*

***Aim/Introduction:*** The aim of this paper is to show the changes introduced in our department in pulmonary perfusion studies for the diagnosis of pulmonary embolism (PE) after the appearance

of COVID-19 and results observed when they are complemented with SPECT-CT. ***Materials and Methods:*** This is a retrospective, descriptive, observational, retrospective study. Between 2020 and 2022, 333 patients attended our department due to suspected PE for pulmonary ventilation-perfusion scintigraphy. Given the epidemiological situation, it was not possible to perform ventilation studies. Only pulmonary perfusion studies were performed and, in case of doubts, they were complemented with SPECT-CT. Planar studies were classified as high or low probability of PE or non-diagnostic. SPECT-CT studies were classified as compatible or not compatible with PE, being compatible studies those which showed one segmental defect or two subsegmental defects without intraparenchymal alterations visualized with CT. The information obtained was analyzed in an Excel database. ***Results:*** From the total amount of cases, 14.7% of planar studies were non-diagnostic. When they were complemented with SPECT-CT, this proportion was reduced to 4.8% per year. SPECT-CT was performed in 110 studies. 85% of cases showed concordance with planar images, 1% disagreed and 14% of non-diagnostic studies were confirmed as compatible for PE. ***Conclusion:*** Due to the epidemiological situation, pulmonary ventilation studies were replaced by only-perfusion SPECT-CT to complement planar images. Thus, we observed that non-diagnostic studies were reduced. Thanks to hybrid imaging, we made more reliable diagnoses and stopped talking in terms of probability. Since June 2022, in our department, planar lung perfusion imaging and SPECT-CT have been performed in all patients with suspected PE unless the patient's baseline condition prevents it.

## OP-925

### Results of V/Q SPECT in the evaluation of pulmonary Long COVID - a two-year analysis of the pandemic

***J. Lepej***[1,2], *I. Marin*[1,2], *K. Lepejová*[3], *I. Kuglová*[1], *A. Obušeková*[1], *I. Polčová*[1], *O. Zahornacký*[4], *M. Duránik*[5];
[1]*Institut of Nuclear and Molecular Medicine, Košice, SLOVAKIA,* [2]*Clinic of Nuclear Medicine UPJŠ LF and INMM, Košice, SLOVAKIA,* [3]*Department of Clinical Biochemistry, Haematology and Immunology - Cumulus s.r.o., Košice, SLOVAKIA,* [4]*Clinic of Infectious Diseases and Travel Medicine, UPJŠ and UNLP, Košice, SLOVAKIA,* [5]*Faculty of Medicine University P.J. Šafarik, Košice, SLOVAKIA.*

***Aim/Introduction:*** Pulmonary embolism (PE) is one of the manifestations of long COVID (LC), caused by the SARS-CoV2 virus or as a complication after vaccination. In the second year of the pandemic, V/Q scan indications due to dyspnea and pathological D-dimer (DD) levels increased by 40%. The aim of our research was to analyze these results. ***Materials and Methods:*** During the first 2 years of the pandemic, 1036 lung V/Q SPECT examinations were performed at our institution after inhalation of $^{81m}$Kr and perfusion of $^{99m}$Tc-MAA as a second step. Patients were divided into 3 groups: A) 281 with COVID-19 and after vaccination, as controls without COVID-19 there were two groups B) 389 (in 2021) and C) 366 (in 2020). Results were compared with medical records and available DD levels. ***Results:*** In group A) PE was present in 58/240 (24.2%) examined for LC and 12/41 (29.3%) in acute cases of PE after vaccination. The incidence of PE in the control groups was higher: B) 130/389 (33.4%) and C) 173/366 (47.3%) for a more targeted indication of examinations. DD levels increased with PE severity in all groups except PE after COVID-19. Patients from group A) had a history of cancer more often (7.9% LC and 9.8% vaccinated) than controls B) and C), only 1.2%. The proportion of chronic smokers with pulmonary embolism was lower in group A) COVID-19 (9%) than in control group C (24%). More than 38.1% of the 29.3% of smokers in the study had match V/Q defects. ***Conclusion:*** V/Q SPECT has been a useful tool for detecting PE in patients with long covid and post-vaccination. The pandemic had serious consequences for the health of the population and the level of healthcare in Slovakia, and we draw attention to some of them.

## OP-926

### Incidental Acute COVID-19 Infection during Radioligand Therapy

***A. Mishra****, R. P. Baum, C. Müller, C. Landvogt;*
*Curanosticum, Wiesbaden, GERMANY.*

***Aim/Introduction:*** Over 977 inpatient radioligand therapies (RLT) were performed between February 2020 and April 2023. As per COVID-19 pandemic regulations, indications for inpatient admission included negative rapid antigen test and absence of COVID-19 related symptoms such as fever, coughing, loss of smell and/or taste as well as contact with COVID-19 positive patient in the preceding 14 days. All patients also underwent polymerase chain reaction (PCR) test before admission. In 12 patients, PCR test was came out to be positive on the second day of admission. ***Materials and Methods:*** Upon admission, patients underwent history taking (including vaccination status), physical examination and blood tests (CBC, renal & liver panel, tumor markers). Antibody titers (BAU/ml) against SARS-CoV-2 were measured in all patients. In our hospital setting, PCR tests require between 12-24 hours to declare results (after sample collection). 14 patients, who were COVID-positive were treated without knowledge of the positive PCR test. RLT was performed under monitoring of vitals. Single-photon emission computed tomography (SPECT/CT) was performed one day after treatment. Positive patients were discharged after 24 hours (German regulations demand 48 hours stay) under appropriate radiation safety measures (the remaining radiation was < 1 mSv per year at one-meter distance from the patient). All patients were discharged in stable cardio-pulmonary conditions. Abbreviations (Patient Characteristics Table): M - male, F - female, NET - neuroendocrine tumor, PCa - prostate cancer, Lu - Lutetium, Ac - Actinium, Ct -cycle threshold. ***Results:*** RLT performed on PCR positive patients with NET, PCa, signet ring cell carcinoma and clear cell sarcoma (Ac-225 FAP-3BP-3940) were completely uneventful. Daily monitoring of vitals was unremarkable. High uptake of the radiotherapeutic in the metastases and normal physiologic biodistribution was noted in the SPECT/CT scans. ***Conclusion:*** Due to global logistics of radiopharmacy delivery, patients for RLT are planned usually weeks in advance. Our data indicate that PSMA radioligand therapy as well as radiopeptide therapy (as well as FAP PTRT) can be performed in asymptomatic COVID-positive patients - without any sequelae. Therefore, COVID-19 infection is not a limiting factor for performing RLT.

## OP-927

### FDG PET CT in the Neurological manifestations of COVID-19

***N. Seniaray***[1], *R. Verma*[1], *R. Ranjan*[2], *E. Belho*[1], *H. Mahajan*[1];
[1]*Mahajan Imaging & labs, New Delhi, INDIA,* [2]*Department of Neurology, Sir Ganga Ram Hospital, New Delhi, INDIA.*

***Aim/Introduction:*** To determine role of 18F-FDG PET/CT in neurological manifestations of corona virus 2 (SARS- CoV-2). ***Materials and Methods:*** A retrospective analysis of 38 patients with CNS involvement attributable COVID-19 infection and who had history of COVID-19 infection within 3 months of appearance of symptoms. All the subjects were clinically and radiologically (MRI) analyzed and were further segregated into MRI positive (n=18) and negative (n=20) subjects. All the subjects underwent whole body 18F-FDG PET/CT scan with a dedicated brain sequence on

a separate day. Additional F-DOPA PET CT/ TRODAT SPECT CT was done in few patients. The FDG uptake patterns were recorded and areas of hypo/hypermetabolism that were two standard deviations from the mean were considered as abnormal. ***Results:*** Out of 18 MRI positive subjects, 12 had findings suggestive of ischemic stroke with diffusion restriction and characteristic angiographic abnormalities, 4 subjects had concurrent Rhino-cerebral Mucor mycosis with associated changes on MRI and FDG PET scan. 2 Subjects had space occupying T2 hyper intense lesions on MRI, diagnosed as focal demyelination which was non FDG and F-DOPA avid. Out of 20 subjects with non contributory MRI 12 had clusters of hypermetabolism in the pre frontal, dorso-lateral frontal, insular and cingulate cortices and 8 subjects had posterior cortical-subcortical and cerebellar hypermetabolism on FDG PET images. Antibodies to COVID-19 was found in the serum of 33 and CSF of 5 subjects. ***Conclusion:*** FDG PET CT may help in certain neurological manifestations of COVID-19, especially with non contributory MRI, thereby expediting the subsequent clinical management.

***Aim/Introduction:*** A considerable number of individuals suffer from long COVID or post-COVID syndrome: complaints such as debilitating fatigue and cognitive complaints persisting months to years after COVID-19 infection. Neuro-inflammation might be involved in its pathophysiology. The PET tracer [$^{18}$F] DPA-714 binds with high affinity to translocator protein (TSPO) that is brought to expression on activated microglia, enabling visualization of neuro-inflammation in vivo. Our main goal was to assess [$^{18}$F]DPA-714 binding in post-COVID individuals with and without persistent complaints compared to pre-pandemic healthy controls.[1] ***Materials and Methods:*** In this ongoing study, 20 post-COVID individuals underwent a 60-minutes dynamic [$^{18}$F]DPA-714 PET scan with arterial blood sampling. All individuals were high affinity binders (HABs) according to their TSPO genotype. Subjects additionally completed questionnaires, neuropsychological evaluation and MRI. Individuals reporting subjective complaints on the Checklist-Individual-Strength (CIS) concentration (≥18) and fatigue (≥35) subscales, were classified as individuals with persistent complaints. PET data were analyzed using a reversible two-tissue compartment model with additional blood volume parameter, from which binding potential ($BP_{ND}$; $k_3/k_4$) was used to assess [$^{18}$F]DPA-714 binding.[2] Regions-of-interest (ROIs) included brainstem, thalamus, orbitofrontal, temporal, cerebellar and global gray matter. We assessed prevalence of post-COVID individuals (with and without complaints) with elevated $BP_{ND}$ (≥1.5SD relative to pre-pandemic controls). ANOVA adjusted for age and sex was used to assess differences in $BP_{ND}$. ***Results:*** Seventeen subjects with persistent complaints ([mean±SD] 26±7 months after infection, age 52±7 years, 8 female) and 3 without (16±10 months after infection, age 47±2 years, 2 female) were included. Data from 3 pre-pandemic controls (age 55±4 years, 1 female, all HAB) was available as reference. In line with our classification, CIS-concentration and -fatigue scores were higher in individuals with persistent complaints versus without (concentration: 26±6 vs 11±3, fatigue: 45±8 vs 15±6, respectively). Five out of 20 post-COVID individuals showed elevated binding relative to the pre-pandemic controls (global $BP_{ND}$: 2.44±0.32 versus 1.35±0.11, p=0.013), with elevated binding across all ROIs. Global elevated [$^{18}$F]DPA-714 binding was present in 2 out of 3 post-COVID individuals without persisting complaints, compared to 3 out of 17 individuals with persisting complaints. ***Conclusion:*** Our results so far show globally elevated [$^{18}$F]DPA-714 binding (>1.5SD above pre-pandemic controls) in approximately 25% of post-COVID individuals, which in this group with only limited numbers -especially of patients without persistent symptoms- does not clearly relate to reporting of persistent symptoms. ***References:*** [1]Hagens et al. J Neuroinflammation (2018), [2]Golla et al. (2015) Journal of Cerebral Blood Flow & Metabolism

## OP-929

### Little recovery of brain metabolic impairment in patient with persistent long COVID: a [18F]FDG PET study

***T. Horowitz****, P. Dudouet, E. Kaphan, T. Radulesco, S. Gonzalez, S. Cammilleri, A. Menard, E. Guedj;*
*APHM, Marseille, FRANCE.*

***Aim/Introduction:*** Imaging studies have proposed [$^{18}$F]FDG PET as a biomarker in neurological post COVID condition (long COVID), showing a characteristic brain hypometabolic pattern, including the limbic regions, brainstem and cerebellum. It remains unknown whether such metabolic changes may recover during follow-up of patients with prolonged symptoms. The aim of this [$^{18}$F]FDG PET study is to evaluate longitudinal brain metabolic changes in the follow-up of long COVID subjects with persistent

symptoms. ***Materials and Methods:*** We retrospectively included all subjects who underwent two brain [18F]FDG PET for long COVID in our department between June 2020 and November 2022 named PET1 and PET2 (56 subjects, mean age 51.1 years, range 24-71 years; 36 women). They all sustained the WHO criteria of long COVID, with a biologic prove of SARS-CoV-2 infection for 49/56. All subjects presented persistent symptoms of Long COVID at the time of the second PET,explaining its realization. The 56 long COVID subjects were compared to 51 healthy controls (mean age 51.2, range 22-78 years; 33 women). On average, PET1 and PET2 were performed respectively 7 and 16 months after acute COVID. Whole-brain voxel-based analysis compared PET1 and PET2 to healthy subjects (p-voxel <0.001 uncorrected, p-cluster <0.05 FWE-corrected); and PET1 to PET2 (first with this same threshold; and thereafter with a less constraint p-voxel < 0.005 uncorrected, p-cluster <0.05 uncorrected). ***Results:*** All subjects had persistent symptoms of long COVID, globally stable during the follow-up. Long COVID subjects at PET1 and PET2 showed significant hypometabolism in the previous reported pattern (limbic regions, brainstem and cerebellum). On the 14,068 hypometabolic voxels that were identified on PET1, 6503 voxels were found hypometabolic on PET2 (46%). On the 7,732 hypometabolic voxels that were identified on PET2, 6,094 had been found on PET1 (78%). Comparing PET1 and PET2, no findings remained significant after correction of multiple comparison for the cluster by FWE method. With a less constraint statistical threshold, two clusters presented a significant improvement at PET2 located within the pons and the right cerebellar vermis, showing respectively 8.4 and 5.2 % improvement at PET2, 9 months thereafter in average. ***Conclusion:*** Subjects with persistent symptoms of long COVID exhibit durable brain metabolic changes, even more than two years after onset of symptoms. Further studies are needed to evaluate the PET evolution in patients with clinical recovery.

## OP-930

### Extracerebral findings from [18F]DPA-714 PET/CT using a long axial field of view PET scanner in post-COVID

***D. Visser***[1,2], *X. Palard-Novello*[1,2,3], *M. Yaqub*[1,2], *E. van der Giessen*[1,2], *M. den Hollander*[1,2], *A. D. Windhorst*[1,2], *S. C. J. Verfaillie*[4], *F. Barkhof*[1,2,5], *H. Knoop*[4], *B. N. M. van Berckel*[1,2], *S. S. V. Golla*[1,2], *N. Tolboom*[6], *R. Boellaard*[1,2];

***Aim/Introduction:*** A considerable number of individuals suffer from long COVID with an unclear underlying pathophysiology. The PET tracer [18F]DPA-714 binds with high affinity to translocator protein (TSPO) that is brought to expression on inflammatory microglia. The aim of this study is to explore simplified kinetic parameters of [18F]DPA-714 uptake in various extracerebral organs in participants with persistent fatigue and cognitive complaints after COVID infection using a long axial field of view (LAFOV) PET scanner. ***Materials and Methods:*** Seventeen participants with long COVID, high-affinity binders for TSPO, were included. Questionnaire data on the Work and Social Adjustment Scale (WSAS) and pain-subscale of the RAnd-36 item Health Survey were available. Each participant received ~250 MBq [18F]DPA-714 directly followed by a 60 minutes acquisition on the Quadra PET/CT scanner. Patlak linearization was applied to estimate the net influx rate ($K_i$) in muscle and bone, and Logan linearization was performed to estimate the distribution volume ($V_T$) in adrenal gland, kidney, liver, lung, myocardium, pancreas, spleen, and thyroid. One volume of interest (VOI) was manually defined in each organ for all participants. Participants with high $K_i$ or $V_T$ compared to the other participants (with visual confirmation of diffuse uptake) were considered specific cases. ***Results:*** There were four participants with high diffuse [18F]DPA-714 uptake in three different organs. Two of which had a high muscle uptake with a significant increase of $K_i$ (+213% and +112%, respectively, compared to the mean of the other participants muscles $K_i$), which was seen in most muscle groups throughout the body. Both participants had higher (=worse) WSAS scores (40 and 36, respectively, vs a mean of 17 (SD=11) for the other participants) and the participant with the highest muscle $K_i$ had the lowest (=worst) RAnd36-pain score (0 vs a mean of 66 (SD=27) of the other participants). Another participant had high lung uptake with a significant increase of $V_T$ (+219%) compared to mean lung $V_T$ of the other participants. The CT images of this participants lungs showed diffuse ground glass opacity and dense focal opacities. One participant had a high thyroid uptake with a significant increase of $V_T$ (+166%) compared to the mean thyroid $V_T$ of the other participants. ***Conclusion:*** Some participants had increased diffuse uptake in certain organs. This study warrants further research regarding the clinical interpretation of these findings and exhibits the potential role of LAFOV PET scanners to extract meaningful extracerebral findings for brain studies.

### 68Ga-FAPI PET/CT novel diagnostic tool in sarcoma.

***H. Lanzafame***[1,2], *R. Hamacher*[2,3], *I. A. Mavroeidi*[2,3], *K. M. Pabst*[1,2], *N. Hirmas*[1], *L. Kessler*[1,2], *T. Bartel*[1,2], *S. Leyser*[1,2], *F. Barbato*[1,2], *M. Schuler*[2,3], *S. Bauer*[2], *J. T. Siveke*[2,3,4], *K. Herrmann*[1,2], *W. P. Fendler*[1];
[1]*Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [2]*German Cancer Consortium (DKTK), Partner site University Hospital Essen, Essen, GERMANY,* [3]*Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, GERMANY,* [4]*Bridge Institute of Experimental Tumor Therapy, West German Cancer Center, University Hospital Essen, Essen, GERMANY.*

***Aim/Introduction:*** Several bone sarcomas (BS) and soft-tissue sarcomas (STS) demonstrate high Fibroblast activation protein-α (FAP) expression on tumor cells and associated fibroblasts. Here we aimed to investigate the diagnostic performance of FAP-directed [68Ga]Ga-FAPI PET/CT in BS and STS and compared it to 2-[18 F]

FDG PET/CT. ***Materials and Methods:*** Patients with BS or STS undergoing [68Ga]Ga-FAPI PET/CT for staging or restaging were enrolled in a prospective observational trial. A group of patients also underwent 2-[18 F]FDG PET/CT. Number of detected lesions and uptake (SUVmax) for T, N, visceral metastases (VM) and bone metastases (BM) were recorded and analyzed. Non-parametrical t-test was employed for semiquantitative analysis. The association between [68Ga]Ga-FAPI uptake intensity and histopathologic FAP expression was analyzed with Spearman r correlation. Eligibility for FAP-directed radioligand therapy was defined as SUVmax>10 for all tumor regions. ***Results:*** We included 200 sarcoma patients (65 BS, 135 STS), of which 32(16%) were low, 141(70.5%) were high-grade sarcomas and 27(13.5%) sarcoma entities for which grading doesn't apply (N/A). [68Ga]Ga-FAPI vs. 2-[18 F]FDG detected a total of 1174 (81%) vs. 1023 (71.5%) lesions. On a per-region basis, [68Ga]Ga-FAPI vs. 2-[18 F]FDG PET demonstrated higher detection efficacy for T 144 (100%) vs. 124 (86%) lesions and M 1167(97%) vs. 1026(86%) lesions. We reported [68Ga]Ga-FAPI vs. 2-[18 F]FDG higher sensitivity (96.03% vs. 88.41%), specificity (87.8% vs. 60.0%), PPV (98.8% vs. 95.2%), NPV (67.92% vs. 38.10%) and overall accuracy (95.31% vs. 88.36%). Higher [68Ga]Ga-FAPI vs. 2-[18 F]FDG radiotracer uptake was recorded in low grade (10.36±8.5 vs. 7.08±4.5, p=0.01) and N/A (22.32±12.2 vs. 8.58±10.8, p=0.004) tumors. Higher uptake was specifically noted in patients with SFT (T SUVmax 23.49±11.9 vs. 4.45±8.7, p=0.0005; VM SUVmax 17.04±28.7 vs. 3.79±2.0, p=0.0001) and myxoid liposarcoma(T SUVmax 5.61±12.2 vs. 3.53±2.1, p=0.04). [68Ga]Ga-FAPI uptake values and histopathologic FAP expression score (n = 89) showed a moderate positive correlation (Spearman r = 0.43; p < 0.0002). 63 of 128 (49.2%) patients with metastatic sarcoma (18(45%) other, 16(76.1%) SFT, 11(36.6%) liposarcoma, 6(40%) leiomyosarcoma, 4(22.2%) chondrosarcoma, 4(13.3%) UPS, 2(25%)ewing, 1(6.25%) osteosarcoma, 1(11.1%) chordoma) were deemed eligible for FAP radioligand therapy due to intense FAP expression. ***Conclusion:*** In patients with sarcoma, [68Ga]Ga-FAPI PET demonstrated higher tumor uptake and detection rate as well as near equal accuracy when compared with 2-[18 F]FDG PET. FAP expression was sufficient for radioligand therapy in about half of sarcoma patients based on [68Ga]Ga-FAPI PET.

## OP-933

### Head-to-head Comparison of [68Ga]Ga-FAPI04 and [18F]-FDG PET/CT Imaging in Recurrent/Metastatic Solitary Fibrous Tumor Patients

***R. Wang***[1,2,3], *J. Wang*[1,2,3], *G. Wang*[1,2,3], *L. Li*[1,2,3], *Z. Zhu*[1,2,3], *X. Chen*[4,5,6], *J. Zhang*[4,5,6];
[1]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, CHINA,* [2]*State Key Laboratory of Complex Severe and Rare Diseases, Beijing, CHINA,* [3]*Beijing Key Laboratory of Molecular Targeted Diagnosis and Therapy in Nuclear Medicine, Beijing, CHINA,* [4]*Departments of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [5]*Nanomedicine Translational Research Program, NUS Center for Nanomedicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [6]*Clinical Imaging Research Centre, Centre for Translational Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** Solitary fibrous tumours (SFTs) are rare mesenchymal origin tumors, that typically arise in the central nervous system or body cavities, such as the pleura or peritoneum. While generally benigh, SFTs pose a risk of recurrence and metastasis, with limited effective treatment options. [18F]-FDG PET/CT is widely used for evaluating systemic involvement and lesion metabolism in recurrent/metastatic tumors. The aim of this study is to compare the performance and effectiveness of conventional [18F]-FDG PET/CT and the fibroblast activating protein inhibitor [68Ga]Ga-FAPI04 PET/CT in patients with recurrent / metastatic solitary fibrous tumors. ***Materials and Methods:*** A total of 20 SFT patients with suspected recurrence/metastatic lesions were enrolled in this prospective study. Participants underwent both [18F]-FDG and [68Ga]Ga-FAPI04 PET/CT within two days using the same hybrid PET/CT scanner. The number of lesions detected by both PET/CT scans and the maximum standardized uptake value (SUVmax) of lesions were recorded. If patients had more than five lesions, five were randomly selected for further comparison. The Wilcoxon signed rank test was used for statistical analysis. ***Results:*** In the 20 SFT patients, [68Ga]Ga-FAPI04 PET/CT detected significantly more lesions than [18F]-FDG PET/CT (266 vs. 146, $p < 0.05$). In terms of lesion uptake values, [68Ga]Ga-FAPI04 PET showed a higher mean SUVmax than [18F]-FDG (11.0 ± 9.0 vs. 5.1 ± 2.5, $p < 0.001$). Due to the low expression of FAP in normal organs, [68Ga]Ga-FAPI04 PET/CT demonstrated superior tumor/background ratios in the brain and liver, which compensated for the lack of lesion masking caused by physiological [18F]-FDG uptake in these organs. ***Conclusion:*** This is the first prospective study to compare two radiotracers head-to-head in patients with SFT. Although the sample size is relatively small, [68Ga]Ga-FAPI04 showed better ability to detect recurrent/metastatic lesions in these patients. Given the current lack of effective treatments for many recurrent/metastatic SFT patients, high FAP expression in this type of tumour is expected to become a potential therapeutic target for SFT patients.

## OP-934

### Prognostic value of fluorodeoxyglucose positron emission tomography derived metabolic parameters and textural features in soft tissue and bone sarcomas

***N. Aydin***, *G. Mütevelizade, G. Gümüşer, E. Sayıt Bilgin;*
*Celal Bayar University, Manisa, TÜRKIYE.*

***Aim/Introduction:*** Bone and soft tissue sarcomas are a large group of several heterogeneous tumors of mesenchymal origin that may occur at any age. The aim of this study was to evaluate the prognostic value of PET-derived metabolic features and textural parameters of primary tumors in sarcoma patients. ***Materials and Methods:*** The imaging findings of 48 patients (31 male and 17 female; age 41.1 ± 24.2 years) who underwent 18-fluorodeoxyglucose positron emission tomography (PET)/computed tomography for primary staging prior to therapy between 2017 and 2022 were retrospectively evaluated. PET metabolic data and textural features of primary tumors were obtained. Cox proportional hazards regression models were used to identify predictors for progression-free survival and overall survival. Survival curves were estimated by using the Kaplan-Meier method. ***Results:*** Distant metastases were detected in primary staging in 13 patients (27.0 %). The median follow-up duration after diagnosis was 21 months (range: 1-64 months). In the Kaplan-Meier analysis, the presence of distant metastasis, Morphological_Asphericity and Histogram_Entropy_Log10 were found as independent predictors for progression-free survival and Morphological_Compacity were found as independent predictors for overall survival. ***Conclusion:*** In addition to the presence of distant metastasis at initial diagnosis, textural features of primary tumors may be used as prognostic biomarkers to identify patients

with worse prognosis in soft tissue and bone sarcomas. ***References:*** Song H, Jiao Y, Wei W, Ren X, Shen C, Qiu Z, et al. ### Assessing bone metabolism in chronic kidney disease-mineral bone disease (CKD-MBD) using 18F-NaF PET/CT Imaging

***M. Usmani***[1], *N. Ahmed*[2], *F. Marafi*[3], *G. Gnanasegaran*[4], *T. Van den Wyngaert*[5];
[1]*Sultan Qaboos Comprehensive Cancer Care and Research center (SQCCCRC), Muscat, OMAN,* [2]*Jack Brignall PET/CT Centre, Castle Hill Hospital, Cottingham, UNITED KINGDOM,* [3]*Jaber Al-Ahmad Molecular Imaging Center, Kuwait, kuwait, KUWAIT,* [4]*Royal Free Hospital NHS Trust, London, UNITED KINGDOM,* [5]*Antwerp University Hospital, Antwerp, BELGIUM.*

***Aim/Introduction:*** Disorders of mineral metabolism and bone disease are common complications in chronic kidney disease (CKD) patients and are associated with increased morbidity and mortality. The study aims to assess regional and total bone metabolic activity in CKD patients using $^{18}$F-NaF PET and correlation between semiquantitative indices of $^{18}$F-NaF and blood parameters. ***Materials and Methods:*** Seventy-two subjects (mean age, 61.8±13.8 years) were included in this study. Out of 72 subjects, 24 patients had ESRD (GFR <15 mL/min/1.73 m$^2$), 38 had CKD (GFR between 60-15 mL/min/1.73 m$^2$), and the remaining 10 were control subjects with normal renal function (mean age: 65.3±11.5). All subjects underwent $^{18}$F-NaF PET-CT with a dose activity of 0.06mCi/Kg. Regional and total skeletal metabolism were assessed with mean SUVs in a skeletal volume of interest (VOI), bone to soft tissue index (B/S), global SUV mean (GSUV mean) of the whole bone, and global uptake in the femoral neck. ***Results:*** There is a significant difference in femoral neck metabolism in CKD and ERSD groups 5.09±1.98 versus 6.76±2.25 in the right femur and 5.4±2.2 versus 6.86±2.47 in the left femur in comparison to control with has SUV mean of 4.66±1 in the right (p=0.003) and 4.31±0.96 in the left femur (p=0.006). Bone to soft tissue index in the femur was 3.79±1.8 in CKD and 4.6±2.48 in ESRD (p=0.016). The global SUV mean ($GSUV_5$) was 8.27±1.20 in ESRD, 7.7±0.86 in CKD, and 8.7±0.65 in healthy subjects (p=0.006). While $GSUV_2$ was measured as 5.06±0.91 in ESRD, 4.58±0.57 in CKD, and 4.92±0.41 in controls (p=0.026). There is also a significant difference in SUV mean in lumbar vertebrae (L1-L4) among CKD, ESRD, and controls. There was a moderate correlation between fluoride activity in the $^{18}$F-NaF PET scan and blood parameters such as ALP and PTH. In addition, the $^{18}$F-NaF uptake parameters were significantly different in low versus high bone turnover state and potentially discriminate low turnover from high turnover states of renal osteodystrophy. ***Conclusion:*** The assessment of total skeleton and regional metabolism and bone turnover in CKD patients is feasible with $^{18}$F-NaF PET. The difference in NaF uptake in CKD compared to controls could be related to a change in bone turnover in CKD patients. More studies with large sample sizes are needed to confirm our findings and establish the normal range of regional and total skeletal metabolism in CKD patients and its wider clinical implications.

[1]*Clínica Universidad de Navarra, Navarra, SPAIN,*
[2]*Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** In this study, we aimed to determine whether $^{99m}$Tc-HDP-SPECT/CT (SPECT/CT) provides additional information to Magnetic Resonance Imaging (MRI) using standard sequences, in patients with axial pain. We also evaluated the response to steroid injections in facet joint arthropathy (FJA) guided by SPECT/CT findings. ***Materials and Methods:*** We retrospectively studied 193 patients with clinical history of axial pain evaluated with both SPECT/CT and MRI within a maximum interval of 180 days. Imaging reports for each technique were reviewed and pathological findings were recorded. Patients with FJA and clinical follow-up were included in the analysis. The response to targeted interventional pain treatment was classified according to the degree of pain improvement (effective: decrease >50%; partial: decrease <50%; and ineffective: no improvement). Descriptive statistical analysis was performed. ***Results:*** One-hundred-ninety-three were included (63.7% females; 36.3% male, mean age was 55.7 ± 15.3 years). Although the number of total pathological findings on MRI were higher than observed on SPECT/CT (339 vs. 268; p<0.01; t-Student) SPECT/CT was superior to MRI in FJA detection (84/268 vs 51/339), (Table 1). Fifty-five patients (28%) with FJA were treated with steroids guided by SPECT/CT. Injections were effective in 50.9% (28/55) of patients, 38.2% (21/55) reached partial response, and the injections were ineffective in 10.9% (6/55). A subset of 20 patients with previous history of partial (12/20) or ineffective (8/20) response to non-image guided steroid injection was referred to a repeated injection after SPECT/CT. In 62.5% (5/8) of subjects with previous ineffective response turned to effective, and 66.6% (8/12) of subjects with partial response reached effective response after SPECT/CT-guided repeated injection. ***Conclusion:*** While MRI shows more detailed information about anatomy and pathological processes, our preliminary findings showed a superiority of SPECT/CT in the detection of FJA. Moreover, SPECT/CT imaging can also help to guide therapeutic interventions not only in treatment naïve patients but also in those with previous non-image-guided steroid treatment.

### The value of Tc-99m-DPD bone scintigraphies in patients with alkaptonuria. A promising imaging tool for disease monitoring?

***D. Schmitt***[1], *S. vom Dahl*[2], *K. Mattes-György*[1], *E. Novruzov*[1], *M. Dabir*[1], *S. David*[2], *K. Jan Philipp*[1], *T. Lüdde*[2], *M. Busch*[2], *E. Mamlins*[1], *F. Giesel*[1];
[1]*Department of Nuclear Medicine, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY,* [2]*Clinic for Gastroenterology, Hepatology and Infectious Diseases, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY.*

***Aim/Introduction:*** Alkaptonuria is a rare autosomal recessive disorder with a lack of the enzyme homogentisate-1,2-dioxygenase (appearance of 1:250.000-500.000). Benzochinone derivates of homogentisate accumulate inter alia in collagenous structures

such as cartilage and can lead to severe osteoarthropathy (ochronosis) and significant joint involvement which can be detected in isotope bone scans. In particular, with the EMA-approval of novel pharmaceuticals such as nitosinone, solid evidence-based data need to be generated. The diagnostic value of Tc-99m-bone scans as a response monitoring tool in the course of ochronotic disease involvement has not yet been structurally evaluated - mostly due to a lack of evidence based data. With our monocentric, retrospective study, we aimed to analyze the potential of bone scans as a monitoring tool in the course of alkaptonuria. ***Materials and Methods:*** Our medical center provides healthcare for the largest national cohort of patients with the diagnosis of alkaptonuria. We involved a total of 21 patients in our study, and analyzed the changes of tracer distribution patterns in long term follow-up bone scans (n=9, f: 4, m: 5, age at primary isotope scan: 22-68 years, median 53 years, time difference between bone scans: min. 12 months, max. 35 months). Within this group, 8 patients received nitosinone treatment at the time of the follow-up bone scan (duration of nitosinone treatment: min. 10 months, max. 24 months, daily dose 2-10 mg/dl). We investigated distribution patterns of the angiographic, blood pool and delayed phase and SPECT images in bone scintigraphies as well as the changes in the follow-up. ***Results:*** Most frequent findings were an ochronosis of the spine as well as affected large joints (especially shoulders). On nitosinone treatment most cases showed an improvement of these leading findings in the follow-up (5 out of 8 patients) or were constant (2 out of 8 patients). At the same time, a progress of not yet or slightly affected large joints was seen (4 out of 8 patients). ***Conclusion:*** Tc-99m-bone imaging appears to be an important tool to monitor the ochronotic or inflammatory/degenerative changes in the course of alkaptonuria. In particular, Tc-99m-bone scans might play a key role for the monitoring of nitosinone therapy. ***References:*** Cortes Hernandez J, Ruiz-Olivia Ruiz F, Alonso Colmeneres JI, Alvarez Ruiz S, Caton Santaren B, Alcorta Armentia MP. Ochronotic arthropathy: the value of bone scintigraphy in alkaptonuria. Rev Esp Med Nucl 2004; 23:189-192.

### $^{99m}$Tc-NTP15-5, proteoglycan tracer: Phase I trial (CARSPECT)

***M. Chanchou***[1], *P. Auzeloux*[1], *N. Sas*[1], *T. Billoux*[1], *S. Levesque*[1], *E. Thivat*[1], *E. Jouberton*[1], *E. Miot-Noirault*[2], *M. Galmier*[2], *M. Couderc*[3], *S. Mathieu*[3], *X. Durando*[1], *F. Cachin*[1];
[1]*Centre Jean Perrin/UMR1240 INSERM (IMoST)/UCA, Clermont-Ferrand, FRANCE,* [2]*UMR1240 INSERM (IMoST)/UCA, Clermont-Ferrand, FRANCE,* [3]*CHU/UCA, Clermont-Ferrand, FRANCE.*

***Aim/Introduction:*** $^{99m}$Tc-NTP 15-5, a radiotracer developed by UMR 1240 INSERM IMoST UCA, targets cartilage proteoglycans. Its affinity for healthy cartilage and its pathological variations were demonstrated in preclinical models. The main objective of this phase I study (CARPECT: NCT04481230) is to determine the injected activity of $^{99m}$Tc-NTP 15-5 to obtain the best visual contrast of articular fixation on healthy cartilage, without any toxicity. The secondary objectives are quantitative analyzes of the fixation on the cartilage, biodistribution and pharmacokinetic of the tracer. ***Materials and Methods:*** Patients with unilateral knee osteoarthritis or breast cancer treated with anti-aromatase were included between November 2020 and June 2022. Three levels of activity were studied (5, 10 and 15 MBq/kg). The study design was constructed to include a maximum of six patients. A visual score measured tracer uptake in 31 joints on planar scintigraphies performed at 30 min, 2 h, 4 h and 6 h p.i: 1: uptake < diaphyseal uptake; 2: uptake = diaphyseal uptake; 3: uptake > diaphyseal uptake. A score equal to 3 at 2 h p.i for at least 80% of the joints validated the studied activity. The 3D uptake quantification, performed on SPECT-CT from the lumbosacral regions to the knees, covered 16 joint and periarticular regions. 3D Background activity was measured on bone and muscle. Pharmacokinetics, biodistribution and dosimetry of the tracer were analyzed on scintigraphic imaging and urine and blood samples. Tolerance was rated by the NCICTC 4.0 scale. ***Results:*** Five patients were finally injected with $^{99m}$Tc-NTP 15-5. 15 MBq/Kg level was the best level to display at least 80% of the joint with a score 3 at 2h p.i. 2D/3D analysis showed physiological periarticular uptake, urinary and enterohepatic elimination of the tracer from the 30th minute. Cartilage/background ratio were high for five articular interfaces. No toxicity has been reported. ***Conclusion:*** These results demonstrate high accumulation of $^{99m}$Tc-NTP 15-5 on articular cartilage and periarticular structures. Phase II trials will evaluate this tracer in the exploration of cartilage pathologies. Grant: I-Site CAP 20-25; ANR 15-CE18-003.

### Comparison and Clinical Significance of Hybrid Imaging and Planar Bone Scintigraphy in Patients With Oncological Lesions

***P. Korol***[1], *O. Shcherbina*[1], *M. Tkachenko*[2];
[1]*Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE,* [2]*Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE.*

***Aim/Introduction:*** To compare and evaluate retrospectively the value of hybrid fusion single-photon emission computed tomography with (SPECT/CT) imaging versus planar scintigraphy in assessing possible bone metastases ***Materials and Methods:*** 185 cancer patients with malignant tumors of the breast, prostate, thyroid gland (123 women and 62 men) were studied. Bone scintigraphy including SPECT/CT and planar scintigraphy was performed in all patients. We first analyzed flat images, then the images merged and focused on the added value of the merged images. Diagnostic validity for each lesion was individually assessed. On planar images, we classified as sure (malignant, benign) or indeterminate lesions ***Results:*** The clinical analysis included 185 cancer patients (123 women, 62 men, mean age 57.2 ± 9.5 years). Planar images show 381 lesions: 334 were significant. (182 bone metastatic lesions and 199 benign lesions) and 48 were uncertain. After viewing the combined images: for self-confident lesions: there were six benign lesions that became suspicious based on low-dose CT. Nearly everything indeterminate became more certain of the diagnosis with 51 benign lesions and 34 metastases. In addition, the combined images also showed 39 lesions, no visualized on planar images ***Conclusion:*** The results show increased diagnostic confidence obtained with fused SPECT/CT images compared to planar images in differentiation malignant from benign bone lesions.

### Molecular PET/CT mapping of rhACE2 distribution and quantification in organs: a helper for SARS-CoV-2 targeting therapy

***Z. Wang***[1,2], *C. Zhao*[3], *C. Li*[4], *Q. Liu*[5], *H. Zhu*[6,5], *Y. Liu*[1];
[1]*School of Basic Medical Science, Southwest Medical University, Luzhou, CHINA,* [2]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Key Laboratory for Research Evaluation of Radiopharmaceuticals (National Medical Products Administration), Department of Nuclear Medicine, Peking University Cance, Beijing, CHINA,* [3]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Biochemistry and Molecular Biology, Peking University Cancer Hospital and Institute, Beijing, Beijing, CHINA,* [4]*Department of Nuclear Medicine,First Affiliated Hospital of Hebei North University, Zhangjiakou, CHINA,* [5]*Institute of Biomedical Engineering, Peking University Shenzhen Graduate School, Shenzhen, CHINA,* [6]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Key Laboratory for Research and Evaluation of Radiopharmaceuticals (National Medical Product Administration), Department of Nuclear Medicine, Peking University Ca, Beijing, CHINA.*

***Aim/Introduction:*** Non-invasive and repeated monitoring of rhACE2 distribution and content in organs using the ACE2-specific nuclide probe $^{68}$Ga-HZ20. ***Materials and Methods:*** In this study, we optimized the labeling conditions of the probes and evaluated their safety; a mice organ in situ rhACE2 high aggregation model was constructed for the first time, and in vivo real-time PET imaging of rhACE2 was performed using ACE2-specific positron emission tomography agent $^{68}$Ga-HZ20. The distribution and uptake of probes were analyzed, and the model was validated. ***Results:*** This radiotracer exhibited reliable radiochemical properties in vitro and maintained a high affinity for rhACE2 in vivo. In terms of probe uptake, $^{68}$Ga-HZ20 showed a good target-to-nontarget ratio, and the correlation between the uptake value of the probe and the dose of rhACE2 was >90% in either model, which was rapidly cleared from the circulatory system and excreted by the kidneys and urinary system. No organs were damaged after the injection of high doses of probes. ***Conclusion:*** This technology non-invasively and repeatedly monitors the content and distribution of rhACE2 in vivo, which is helpful to clarify the resident capacity of rhACE2 in organs and analyze the preventive ability of rhACE2 against SARS-CoV-2 and the therapeutic ability for COVID-19.

## EPS-274

### Evaluating a suite of anti-FAP nanobody constructs as PET imaging agents.

***J. Gallant***, *Z. T. Rosenkrans, K. L. Ott, N. Y. Luo, A. S. Thickens, R. Hernandez, A. M. LeBeau;*
*University of Wisconsin, School of Medicine and Public Health, Madison, WI, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Metastatic castration resistant prostate cancer (mCRPC) is a uniformly lethal disease. Underlying the challenges to generate effective therapies for mCRPC is the disease's heterogeneity and the lack of methods for monitoring disease progression that are capable across all mCRPC subtypes. Fibroblast activation protein alpha (FAP) has been identified as an antigen with ubiquitous expression across all mCRPC subtypes (1). We have developed a suite of high affinity, FAP targeting nanobodies and nanobody based constructs as useful PET imaging tracers in preclinical models of mCRPC. Here, we present a direct comparison of FAPI-46 and a lead single domain FAP nanobody (F7, $K_D$ =9nM) as imaging agents. Further, we present a dimeric nanobody (F7HD, $K_D$ =29pM) and nanobody-Fc fusion protein (F7Fc, $K_D$ =38pM) characterizing their potential as additional imaging agents. ***Materials and Methods:*** Xenografts using a FAP-expressing engineered prostate cancer cell line (CWR-R1-EnzR$^{FAP}$) were supplanted in the hind flank of nude mice. Three anti-FAP nanobody based constructs were radiolabeled with $^{64}$Cu and evaluated as PET/CT imaging agents for their ability to rapidly localize at the tumor site, the single domain nanobody was compared to $^{68}$Ga-FAPI-46. Images were acquired as soon as 1h post injection and with the highest molecular weight construct imaged up until 48h post-injection. Injected dose per gram quantities were determined for non-specific and tumor-specific tissues. ***Results:*** The single domain F7 nanobody was able to rapidly localize to tumor tissues with increased uptake as compared to FAPI-46, 1.1% ID/g vs 0.5% ID/g at 1h post-injection. The F7 dimer was rapidly taken up in tumor tissue with maximal uptake at 4h, 1.43% ID/g, that was retained at 24h, 1.267% ID/g. Additionally, F7Fc demonstrated rapid uptake at 4h (7.5% ID/g) and continued to accumulate. Signal was retained in tumor tissue through 24h and 48h, 15.23% ID/g and 14.93 % ID/g respectively. Minimal on-target, off-disease accumulation was seen with expected uptake in organs suggestive of the construct's routes of excretion, blood uptake was cleared rapidly in all constructs. ***Conclusion:*** All the examined FAP nanobody based constructs show promise as PET imaging agents with uptake kinetics comparable to a small molecule approach. Additionally, the nanobody-based constructs demonstrate tunable pharmacokinetics, suggesting the possibility of using these constructs as theranostic agents. ***References:*** 1. Hintz HM, Gallant JP, Vander Griend DJ, Coleman IM, Nelson PS, LeBeau AM. ## EPS-275

### Close but no cigar? In vitro properties of small molecule PD-L1 ligands assessed by real-time radioligand binding in comparison to peptides and antibodies.

***C. Donat***[1], *F. Krutzek*[1], *K. Zarschler*[1], *K. Kopka*[1,2,3], *S. Stadlbauer*[1,2];
[1]*Helmholtz Centre Dresden-Rossendorf, Dresden, GERMANY,* [2]*Technical University Dresden, Dresden, GERMANY,* [3]*National Center for Tumor Diseases, Dresden, GERMANY.*

***Aim/Introduction:*** Programmed cell death ligand 1 (PD-L1) can be overexpressed in solid cancers, exerting an immunosuppressive effect. Clinically, breakdown of immune blockade through PD-L1 specific antibodies has been employed with good success rates. However, only 30% of the patients are responders and heterogenous PD-L1 expression can render biopsies unreliable. Noninvasive molecular imaging can overcome this, given suitable radiotracers. However, the binding mode of different PD-L1 ligand classes can vary, making assessment of in vitro properties an important step in radioligand evaluation and translation. We employed real-time radioligand binding and heterogeneous interaction modelling to test different PD-L1 radiotracer candidates.

***Materials and Methods:*** Four PD-L1 ligand classes were investigated: peptide (WL12[1]), monoclonal antibody (atezolizumab), antibody fragment (7CZD[2]) and two small molecules ([$^{64}$Cu]Cu-1/2 ), based on a biphenyl binding motif. All molecules were radiolabelled with copper-64, and PC3 cells, overexpressing human PD-L1 employed as substrate. Cells were incubated with the radioligands, and bound radioactivity measured using the LigandTracer system. Using increasing concentrations followed by buffer only, allowed to determine binding kinetics. Data were additionally analysed for heterogenous molecular interactions (InteractionMap®). ***Results:*** Real-time binding of the small molecules was best fitted using a 1:1 model , accounting for a concentration dependent bulk effect. In albumin presence, association was relatively slow and dissociation moderate, yielding a $K_D$ in the higher nM range (1: 276; 2: 54.3 nM). Binding without albumin showed faster association, resulting in a lower $K_D$ (1: 2.08 (±0.36); 2: 20.9 (±5.44) nM), indicating a structure-dependent interaction with albumin. Binding of peptide and antibody was best fitted using a 1:1 model. $K_D$ was very low for [$^{64}$Cu]Cu-WL12: 0.79 nM (±0.42) and [$^{64}$Cu]Cu-atezolizumab: 0.36 nM (±0.22), without an albumin effect. [$^{64}$Cu]Cu-7CZD binding showed similar kinetics, best fitted using a 1:1 model, accounting for ligand depletion, yielding a $K_D$ of 0.35 nM (±0.09). InteractionMap® analysis for small molecules reported two moderate binding interactions, one presumably caused by albumin. Without albumin, only one major binding interaction was observed, similar to peptide and antibody. [$^{64}$Cu]Cu-7CZD showed two moderate binding interactions, without albumin presence. ***Conclusion:*** Tested PD-L1-specific radiolabelled compounds showed suitable but variable in vitro kinetics, likely caused by reported differences in binding modes. Real-time radioligand binding provides advantages over traditional endpoint assays and together with heterogenous interaction analysis, can help define suitable structure-activity relationships for new PD-L1 radiotracers. ***References:*** 1. ### Al18F-DX600-BCH

***J. Ding***[1], *Q. Zhang*[1], *J. Jiang*[1], *N. Zhou*[1], *Z. Yu*[1], *Z. Wang*[1], *X. Meng*[1], *T. Liu*[1], *F. Wang*[1], *z. Lu*[1], *X. Yang*[2], *Z. Yang*[1], *P. Du*[1], *Z. Hua*[1];
[1]*Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Peking University First Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Angiotensin-converting enzyme 2 (ACE2), as a transmembrane protein, is the main entry point for certain coronaviruses including the new coronavirus SARS-CoV-2 to enter cells. ACE2 is also highly expressed in colorectal cancer, gastric cancer, and malignant proliferation of pancreatic cancer et al. By synthesizing the molecular imaging probe Al$^{18}$F-DX600-BCH which is high-affinity ACE2 for PET imaging, it is hoped that the expression of ACE2 in body can be detected in real time, specifically and non-invasively, and the therapeutic effect monitoring can be achieved. ***Materials and Methods:*** The radioactive probe Al$^{18}$F-DX600-BCH was obtained. The radiochemical purity was analyzed by radio-HPLC, and the in vitro stability was studied by incubating in each buffers. Blood samples of normal mice were collected to determine the pharmacokinetic curve of Al$^{18}$F-DX600-BCH in blood. The mice were sacrificed at 5 time points after injection and the organs of interest were taken out for biodistribution experiments. Normal mice and rats underwent small animal PET scans and IHC staining was obtained from rat organ sections. A total of 10 volunteers were enrolledand received PET/CT 1 hour and 2 hours after injection or dynamic PET/CT during 0-330 seconds (NCT04542863). ***Results:*** The radiochemical yield of the manually prepared Al$^{18}$F-DX600-BCH without attenuation correction was 20.4% ± 5.2%, the purified radiochemical purity was greater than 99%, and it was stable in vitro within 4 hours. The pharmacokinetic curve showed that the concentration of Al$^{18}$F-DX600-BCH in the blood decreased rapidly (the half-lives of the distribution phase and clearance phase were 2.12 min and 25.31 min, respectively). Both the biodistribution and PET imaging results of small animals showed that Al$^{18}$F-DX600-BCH was highly accumulated in the kidney (SUVkidney/normal > 50), and the rat image showed specific uptake of the probe in the testis (SUVtestis/normal > 10). The results of IHC staining of rats showed that kidney, gastrointestinal (++) and bronchial (+++) cells were ACE2 positive, which was consistent with the published human expression distribution of ACE2. In clinical PET imaging, strong radioactivity accumulation was observed in various organs of the genitourinary system including the kidney (SUVrenal cortex = 32.00, SUVtestis = 4.56), and moderate radioactivity accumulation was observed in several cases of conjunctiva and nasal mucosa. ***Conclusion:*** This work reported for the new probe Al$^{18}$F-DX600-BCH targeting ACE2, and conducted preliminary preclinical experiments and a total of 8 clinical transformations, demonstrating the potential and possibility of non-invasive mapping of ACE2.

## EPS-277

### Development of a dual-modality imaging probe targeting SSTR2 via a trifunctional chelate

***D. Chapeau****, S. Beekman, Y. Seimbille;*
*ErasmusMC, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Surgical resection is still the mainstay of treatment for patient with localized malignant diseases. SPECT or PET/CT imaging has the potential to assess resectability, while new imaging techniques, such as fluorescence-guided surgery (FGS), can facilitate tumor visualization and margins delineation during surgery. Both imaging techniques require the use of a labeled molecule. The probe should ideally contain a radionuclide for preoperative nuclear imaging and a fluorescent dye for intraoperative image-guided surgery. Thus, a chemically identical molecule is administered to the patient for both applications. A trifunctional chelate (TFC) based on a modified DOTA-GA was synthesized and then coupled to the SSTR2-agonist octreotate and a cyanine dye.[1] Then, we studied the influence of the dual-labeling on the biochemical proprieties of the SSTR2-targeted probe. ***Materials and Methods:*** Our chelate, dubbed eTFC-01, was synthetized in 5 steps. Then, the chelate was coupled onto the protected linear peptide at the N-terminus on resin, followed by the cyclization in liquid phase. The cyanine dye (sCy5) was finally conjugated using copper-free click chemistry. In vitro competitive binding assays with [$^{111}$In]In-DOTA-TATE were performed using U2OS cells over-expressing human SSTR2. The fluorescent peptide was labeled with $^{111}$In in sodium acetate buffer for 20 minutes at 90°C and analyzed by iTLC and radio-HPLC. $LogD_{7.4}$ and stability in PBS and serum were also determined. ***Results:*** eTFC-01 and the probe were successfully synthesized with an overall yield of 2% and 5%, respectively. The SSTR2-targeted probe was successfully labeled with $^{111}InCl_3$ with a radiochemical yield and purity exceeding 98%. It showed good stability in the labeling solution, PBS buffer (98% at 24 h) and mouse serum (98% at 1 and 4 h, and 86% at 24 h). The $^{111}$In labeled probe was hydrophilic, as determined by the LogD value (-0.7 + 0.04). The probe exhibited a

two-fold higher $IC_{50}$ value for SSTR2 than DOTA-TATE (8.8 nM vs. 4.1 nM, respectively). ***Conclusion:*** Favorable stability and binding to SSTR2 were obtained with the probe, confirming that addition of the fluorescent dye coupled to eTFC-01 did not significantly affect the binding properties. In vivo studies are underway to study the pharmacokinetics of the probe. eTFC-01 is a promising scaffold for the development of dual-labeled probes. ***References:*** 1. Ghosh, S. C. et al. Synthesis of a Fluorescently Labeled 68Ga-DOTA-TOC Analog for Somatostatin Receptor Targeting. ACS Med. Chem. Lett. 8, 720-725 (2017).

## EPS-278

### Conjugation of different chelators to a HER2 targeting single domain antibody for Ga-68 and Lu-177 radiolabelling

***B. Altunay***, *L. Obradović, F. M. Mottaghy, A. T. J. Vogg; University Hospital RWTH Aachen, Aachen, GERMANY.*

***Aim/Introduction:*** Several single-domain antibodies (sdAbs) have been investigated as non-invasive probes for addressing HER2 receptors, since they offer the advantage of a more accurate determination of the HER2 status compared to monoclonal antibodies and have been shown to be safe and suitable in cancer diagnosis and treatment. Here, two different HER2 targeting sdAb-chelator conjugates were labelled with $^{68}$Ga and $^{177}$Lu and investigated with regard to their stability, cell binding capabilities and biodistribution in vivo. ***Materials and Methods:*** The activated chelators based on DTPA and DOTA-GA were mixed with the HER2 targeting sdAb, NM-02, in three different ratios each. The purified sdAb-chelator complexes were labelled with $^{68}$Ga and optimized in terms of solvents, pH and temperature. The ideal chelator-sdAb ratios for DTPA and DOTAGA were determined by cell uptake studies with their labelled conjugates. The two complex conjugates labelled with $^{68}$Ga and $^{177}$Lu were analysed for their labelling kinetics, serum stability, shelf life and cell uptake rate. Biodistribution studies were performed in breast cancer xenografted mice. ***Results:*** Cell uptake studies indicated for both conjugates the ratio of sdAb to chelator of 1/20 to be the most appropriate. The optimized RCC was 56.1 ± 5.2 %, 71.1 ± 3.5 %, 66.4 ± 5.4% and 66.5 ± 1.5% for [$^{68}$Ga]Ga-DOTA-GA-NM-02, [$^{68}$Ga]Ga-DTPA-NM02, [$^{177}$Lu]Lu-DOTA-GA-NM-02, and [$^{177}$Lu]Lu-DTPA-NM02, respectively. While no difference was observed in the shelf-life at room temperature for the $^{68}$Ga labelled sdAbchelator conjugates (RCP 76% after 5 hours), for $^{177}$Lu labeled DOTA-GA complex an 11.6% higher stability was observed after 144 hours compared to the DTPA complex (RCP 80.1% vs. 68.7%). In human serum, a stability of 95% after 4 hours was detected for the $^{68}$Ga labelled sdAbchelator conjugates. For the $^{177}$Lu labelled conjugates, after 48 hours a RCP of 99% was observed. Since $^{68}$Ga and $^{177}$Lu radiolabelled DOTA-GA-NM-02 (102.6 ± 8.1 and 82.6 ± 7.3 %ID/g) showed a higher cell uptake after 4 hours compared to labelled DTPA-NM-02 (69.5 ± 3.2 and 55.5 ± 7.7 %ID/g), the DOTA-GA conjugate was further used for animal studies. Biodistribution data confirmed the specific uptake of the sdAb-chelator conjugate in the HER2-positive tumor 4 hours after the injection. ***Conclusion:*** The $^{68}$Ga/$^{177}$Lu labelled DOTA-GA-NM-02 (1/20) conjugates showed the best radiochemical stability and highest cell uptake rate in HER2-positive cells. The in vivo images indicated that the newly synthesized tracer [$^{68}$Ga]Ga-DOTA-GA-NM-02 may be an effective non-invasive probe to detect the HER2 status in patients with breast cancer.

## EPS-279

### More than sweet: TRAP-based Sugar Trimers for Functional Liver Imaging with 68Ga

***M. A. Zierke***[1], *C. Rangger*[1], *K. Samadikhah*[2], *A. Schmid*[2], *R. Haubner*[1];
[1]*Nuclear Medicine, Innsbruck, AUSTRIA,* [2]*Werner Siemens Imaging Center, Tübingen, GERMANY.*

***Aim/Introduction:*** TRAP-based multimers have shown to be efficient imaging tools for targets such as PSMA[1] and integrin $\alpha_v\beta_6$[2]. Based on this chelator, we now report the synthesis of a small library of trimeric sugar conjugates targeting the asialoglycoprotein receptor (ASGR). ASGR is a c-type lectin, which is selectively expressed on functional hepatocytes and hence, allows imaging of the functional liver reserve. Variations in sugar type and linker length generated a set of four different ligands (T0G3, T3G3, T3N3 & T3U3) that were labelled with $^{68}$Ga and tested for their suitability as imaging agents for this receptor. ***Materials and Methods:*** All compounds were synthesized using CuAAC followed by demetallation of the resulting Cu-complex. Trimers featured either Galactose (T3G3), N-Acetylgalactose (T3N3) or Glucose (T3U3) with a $PEG_3$-Linker or Galactose without linker (T0G3). Radiolabelling was accomplished within 15 min at 95°C in a 5 M HEPES buffer (pH=5.8). In vitro evaluation included octanol/buffer distribution (logD), protein binding, and metabolic stability studies in human blood serum (incubation for 2, 30, 60, and 120 min at 37°C). For biodistribution experiments, healthy BALB/c mice were used. Animals were dissected 10, 30 and 60 min p.i. and accumulation of the tracers was measured (n=3). Additionally, the most promising candidate T3N3 was studied with PET/MR. ***Results:*** All compounds could be labelled in high yields and were obtained in high radiochemical purity (>97%). LogD values ranged from -3.8 to -4.3 indicating high hydrophilicity. Low to moderate protein binding and high stability in human blood serum was found. In biodistribution studies, T3N3 showed the highest liver accumulation, followed by T3G3. Lowest liver uptakes were found for T0G3 and T3U3. For T3N3 60 min dynamic scans allowed a clear delineation of the functional liver tissue. ***Conclusion***: Choice of the sugar is essential for target specificity. Introduction of spacers between the chelator and the sugar is required to obtain optimal binding geometries to the receptor. Multimerization of Galactose and N-Acetylgalactose on the TRAP-platform is a convenient way to access liver specific PET radiopharmaceuticals targeting the ASGR. ***References:*** [1] Wurzer et al. Mol Pharm, 2018. [2] Quigley et al. EJNMMI, 2022.

## EPS-280

### Novel Dual-Modality Imaging Agents Targeting the CCK2 Receptor by Chelator Scaffolding

***G. GARIGLIO***[1], *K. Bendová*[2], *M. Hermann*[3], *M. Petrik*[2], *E. von Guggenberg*[1], *D. Putzer*[4], *C. Decristoforo*[1];
[1]*Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA,* [2]*Faculty of Medicine and Dentistry, Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, CZECH REPUBLIC,* [3]*Department of Anesthesiology and Critical Care Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA,* [4]*Department of Radiology, Medical University Innsbruck, Innsbruck, AUSTRIA.*

***Aim/Introduction:*** The outcome of cancer surgery benefits from preoperative imaging and intraoperative real-time guidance. Dual-modality probes, combining positron emission tomography (PET) with fluorescence imaging (FI) capabilities in the same molecule, can be used for both applications and therefore are

of high clinical relevance [1]. We herein present a pair of PET/FI agents addressing the tumours expressing the cholecystokinin-2 receptor (CCK2R): [$^{68}$Ga]Ga-SulfoCy5.5-TRAP-(PEG4MGS)$_2$ (1) and [$^{68}$Ga]Ga-SulfoCy5.5-FSC-(PEG4MGS)$_2$ (2). In these probes, the SulfoCy5.5 fluorophore and two units of the stabilised Minigastrin targeting peptide are individually coupled to the chelator acting as core scaffold, specifically TRAP-Pr for (1) and Fusarinine C (FSC) for (2). ***Materials and Methods:*** The synthetic strategy to both labelling precursors started with the derivatization of the chelator to enable bioconjugation of the other components by the CuAAC click reaction and concluded with the removal of coordinated metals. $^{68}$Ga-labelling was accomplished within 10 min at pH 3 and 95°C for (1) and at pH 4.4 and RT for (2). In vitro characterisation included the evaluation of lipophilicity ($LogD_{7.4}$), protein binding and stability in human serum. Binding affinity ($IC_{50}$) and internalisation assays were performed by using AR42J and A431 cells expressing the CCK2R. Biodistribution experiments in healthy BALB/c mice were undertaken to evaluate pharmacokinetics up to 4h p.i. Biodistribution, PET and fluorescence imaging studies in A431 xenografted BALB/c mice were conducted to assess the tumour targeting in vivo. ***Results:*** $^{68}$Ga-labelling resulted in > 97% radiochemical purity (radio-HPLC) for both precursors. Hydrophilic properties, rapid binding to serum proteins (> 55% after 1h) and high CCK2R affinity ($IC_{50}$ < 1 nm) were observed. Specific receptor-mediated internalisation was found in cell uptake studies and in confocal fluorescence microscopy experiments. Biodistribution data indicated slow clearance from blood pool for both tracers. Higher accumulation in kidneys was found for (1), with (2) exhibiting a distinct liver and spleen uptake. First studies in xenografted mice with (1) showed CCK2R-positive tumour visualisation by both PET/CT (1-3h p.i.) and fluorescence imaging (24-48h p.i.); biodistribution results indicated moderate, but specific tumour uptake (6.5% ID/g 2h p.i.). ***Conclusion:*** In this study we successfully prepared a pair of analogous PET/FI agents based on TRAP-Pr or FSC scaffolds. Their comparison indicated that these chelators have distinct influences on the biodistribution. Promising in vitro and in vivo targeting properties were shown by (1). Further optimisation may improve the pharmacokinetic profiles of these tracers. ***References:*** [1] Yuen R, et al. Pharmaceutics 2022, 14(3), 645.

## EPS-281

### Construction and immnoPET imaging of an iodine-labeled specific antibody for targeting MMP2 detection in pan-cancer

***X. Ma***, *T. Liu, H. Zhu, Z. Yang;*
*Peking university, Beijing, CHINA.*

***Aim/Introduction:*** A poor prognosis in cancer patients is closely related to tumor invasion and metastasis, which is affected by many factors. A prerequisite for tumor metastasis is the breakdown of the extracellular matrix (ECM), which is a natural cellular barrier. Matrix metalloproteinase-2 (MMP2) has a unique enzymatic activity with the ability to break through the ECM, which may promote tumor metastasis. The aim of this study is to provide guidance for the noninvasive detection of MMP2 in pan-cancer. ***Materials and Methods:*** Flow cytometry (FCM), Western blot (WB), and Immunofluorescence (IF) were used to verify the expression of MMP2 on the surface of human colon cancer cells LS174T, human non-small cell lung cancer cells A549, patient derived gastric cancer xenograft (PDGCX), human pharyngeal squamous cell carcinoma cells FADU, and human pancreatic cancer cells ASPC1. $^{124/125}$I-anti-MMP2 was prepared using N-bromine succinimide (NBS) as oxidant and purified by PD-10 column. The physicochemical properties, affinity, metabolic characteristics, biodistribution and immunoPET imaging of $^{124I/125}$I-anti-MMP2 were performed. $^{124}$I-IgG and $^{18}$F-FDG were used as controls. Finally, the correlation analysis between tumor uptake and MMP2 expression level was established. ***Results:*** LS174T, A549, PDGCX and FADU cells showed high MMP2 expression, while ASPC1 showed low expression of MMP2.The radiochemical purity was over 99% and maintained over 93% in saline or 5% Human Serum Albumin (HSA) for more than 9 d. The EC50 values of anti-MMP2 and $^{nat}$I-anti-MMP2 were 4.98±0.59 ng/mL and 5.19±0.45 ng/mL, respectively.The $K_d$ value of $^{125}$I-anti-MMP2 to MMP2 protein was 3.653 nM, while that of $^{125}$I-IgG was 19.54 nM.$^{125}$I-anti-MMP2 showed significantly higher uptake in MMP2 high-expression cells than that in MMP2 low-expression cells (P<0.001). The biological half-life of distribution and clearance phases were 1.467 h and 37.05 h, respectively. $^{125}$I-anti-MMP2 showed high initial uptake in blood pool and liver, and the uptake was decreased with time.In vivo immunoPET imaging showed that the tumor-to-muscle ratio of $^{124}$I-anti-MMP2 were higher than that of $^{124}$I-IgG and $^{18}$F-FDG (P<0.01) in MMP2 (+) tumors. The expression levels of MMP2 in cells and tumors had positive correlation with $SUV_{max}$ values (P<0.01). ***Conclusion:*** $^{124}$I-anti-MMP2 is a promising imaging technique for delineating MMP2 positive tumors. It has great potential in early diagnosis, targeted population selection of the patients.

## EPS-282

### Novel fluorinated Osimertinib analogue for medical nuclear imaging of EGFRm-positive non-small cell lung cancer

***Y. Brief***, *H. Grievink, G. Abourbeh, E. Mishani, O. Shamni;*
*Cyclotron & Radiochemistry unit, Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, ISRAEL.*

***Aim/Introduction:*** Non-small cell lung cancer (NSCLC) comprises the majority of lung cancer cases. Activating mutations in NSCLC patients (delE746-A750 exon 19, L858R exon 21) are found in genes coding for the tyrosine kinase (TK) domain of the epidermal growth factor receptor (EGFR), occurring in 10-30 % of NSCLC patients. Osimertinib, a third-generation EGFR TK-inhibitor (TKI) is a first-line therapy for NSCLC patients harbouring activating EGFR mutations (EGFRm). Osimertinib exhibited higher selectivity and lower toxicity than earlier EGFR-TKI's, and targets the acquired resistance mutation (T790M), often emerging in these patients. The current study aimed to develop an 18f-fluorine radiolabeled positron emission tomography probe to identify EGFRm tumors, based on Osimertinib's chemical structure. ***Materials and Methods:*** The non-radiolabeled fluorine-19 reference standard, F-OS was designed and synthesized via N'-alkylation at a region not involved in EGFR binding and was fully characterized. The potency and selectivity of F-OS were evaluated in vitro using the methylene blue IC50 assay and human NSCLC cell lines, of which three possessed different EGFRm (HCC827, NCI-H1975, and NCI-H3255), and one was the wild-type EGFR (QG56). [$^{18}$F]F-OS was synthesized using a fully automated 90-minute process. In vivo PET/ MRI studies were conducted using xenografts (NCI-H1975 and QG56 cell lines) and analyzed using preclinical image post-processing software. ***Results:*** F-OS was obtained at a chemical yield of 20 % (purity > 99%). F-OS binding profile toward various EGFR forms ($IC50_{F\text{-}OS}$ in cell lines: HCC827 (49), NCI-H1975 (29), NCI-H3255 (12) and QG56 (6440) nM) were comparable to that of Osimertinib ($IC50_{Osimertinib}$ in cell lines: HCC827 (2), NCI-H1975 (4), NCI-H3255

(2) and QG56 (1880) nM), and corresponded to other reported IC50 values. [$^{18}$F]F-OS was obtained at a low radiochemical yield (~1 %, radiochemical purity > 99 %, n=7), yet sufficient for the preclinical PET/ MRI study. [$^{18}$F]F-OS was evaluated in-vivo PET/ MRI study using NSCLC xenografts harboring EGFRm-(L858R/ T790M) or WT EGFR. A significant two-fold accumulation increase in the EGFRm xenografts (n=5) was observed, contrary to the WT EGFR xenografts (n=3). furthermore, a three-fold tumor/muscle [$^{18}$F]F-OS uptake ratio was observed for the EGFRm, compared to the WT EGFR-mice. ***Conclusion:*** This study aimed to develop a PET probe for identifying EGFRm-positive NSCLC tumors. F-OS potency and selectivity suggest a comparable binding profile to Osimertinib to different EGFR-forms expressing cell lines. [$^{18}$F] F-OS accumulation in the EGFRm xenografts warrants thorough PET/ MRI investigation to elucidate [$^{18}$F]F-OS potential as a nuclear imaging probe to identify EGFRm tumors.

## EPS-283

### FAPI-functionalised melanin nanoparticles for PET/MRI/ PA imaging of glioma

***L. Wen***, *H. Wang, S. Yang, X. Long, C. Zheng, D. Jiang;*
*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

***Aim/Introduction:*** Fibroblasts activated protein (FAP), a membrane-bound enzyme, is up-regulated in tumor-associated fibroblasts in more than 90% of epithelial tumor and low or no expression in healthy tissues. Hence, we aim to investigate the feasibility of using an ultra-small-sized, FAP specific, organic melanin nanoparticles (MNP) for photoacoustic imaging (PAI), magnetic resonance imaging (MRI), and positron emission tomography (PET) imaging of glioma. ***Materials and Methods:*** The specific nanoparticles, FMN, was constructed by ultrasonic fragmentation method and chelated with the MR contrast agent $Mn^{2+}$ and PET radionuclide $^{64}$Cu for PA/MR/PET imaging. FMNs were fully characterized for morphology and toxicity in vitro. The specificity of ($^{64}$Cu, Mn)-FMN was completed with U87MG and A549 cell lines to assessed via western blot, immunohistochemical staining, and cell uptake. In vivo pharmacokinetic and multimodal imaging efficacy of ($^{64}$Cu, Mn)-FMN were evaluated in healthy Kunming and/or subcutaneous tumor-bearing mice. ***Results:*** FMN was regular morphology with 10.47 ± 1.44 nm of hydrodynamic diameters, and exhibited excellent biocompatibility and biodegradability. The U87MG cells expressed high levels of FAP, while A549 cells expressed low levels of FAP. Additionally, ($^{64}$Cu, Mn)-FMN exhibited excellent high specificity and stability in vitro. In vivo pharmacokinetic test results showed that the biological half-life of distribution phase and scavenging phase were 0.086 h and 1.907 h, respectively. In U87MG tumor-bearing mice, the PA signal and $T_1$-weighted signal gradually increased with time, and peaked at 24 h after the nanoprobe injection. Micro-PET/ CT imaging and semi-quantitative analysis showed that the nanoprobe accumulated in the U87MG tumors, which was significantly higher than that of A549 tumors. ***Conclusion:*** We have successfully fabricated a MNP-based nanoprobe for PET, MR, and PA imaging of tumor FAP expression. The study revealed that ($^{64}$Cu, Mn)-FMN nanoprobe has the great potential as multimodal imaging candidate agent in U87MG tumor-bearing mice. ***References:*** [1] Garin-Chesa P, Old LJ, Rettig WJ. ### Preclinical PET imaging with 89Zr-labelled oxMIF-specific antibody delineates subcutaneous tumours in colorectal murine models

***F. Bachmann***, *A. Puchol Tarazona, I. Mirkina, M. Thiele, A. Schinagl;*
*OncoOne Research & Development GmbH, Vienna, AUSTRIA.*

***Aim/Introduction:*** The oxidized isoform of the macrophage migration inhibitory factor (oxMIF) selectively occurs in tumour tissues and thus represents an attractive target to image tumours[1,2]. A bioengineered anti-oxMIF monoclonal antibody with improved pharmacokinetics, biodistribution and safety profile, compared to a previously clinically tested anti-oxMIF antibody[3] was generated. Here, the suitability of this 2$^{nd}$ generation anti-oxMIF antibody - ON102Ab - for positron emission tomography (PET) was evaluated. ***Materials and Methods:*** The ability of ON102Ab to trigger Fc-mediated responses was evaluated cell-based assays. The potential of ON102Ab to induce cytokine release from huPBMCs was assessed by using cytometric bead assays. Balb/c nude mice bearing subcutaneous HTC116 tumours received an i.v. injection of infrared dye-labelled ON102 and whole-body images were taken for up to 7 days. In addition, after conjugating ON102Ab with the chelator DFO* and radiolabelling with $^{89}$Zr, the antibody was injected into murine colorectal cancer models, and whole-body PET images were collected 4, 7 and 10 days p.i. ***Results:*** Bioengineering extended the half-life of the antibody, enhanced tumour uptake and extended the retention in the tumour for over 10 days, overall improving the tumour-to-body AUC ratio in an HTC116 subcutaneous murine model. ON102Ab showed a favourable safety profile, as it did not induce any ADCC, ADCP, or CDC, nor triggered release of IL-6, TNF-α or MCP-1 from PBMCs in vitro. Administration of $^{89}$Zr-ON102 in syngraft and xenograft murine models of colorectal cancer caused no signs of toxicity and allowed to delineate the tumours by PET. ***Conclusion:*** ON102Ab is a 2$^{nd}$ generation anti-oxMIF-mAb with improved biological properties. $^{89}$Zr-ON102 accumulated in the tumours of murine colorectal cancer models allowing the selective imaging of the tumour tissue by PET scanning. This highlights the suitability of oxMIF as a tumour-specific target for theranostic interventions and the potential of $^{89}$Zr-ON102 as a safe diagnostic tool for the detection of malignant solid tumours in humans. ***References:*** 1. ## EPS-285

### Preparation and preclinical evaluation of anti ROR1 labeled with 64Cu as a Radioimmunoconjugate for ROR1+ breast cancer Imaging

***B. Alirezapour***[1], *H. Rabbani*[2];
[1]*Nuclear Science and technology research Institute (NSTRI), Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Antigen and Antibody Engineering Department, Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Radioimmunoscintigraphy (RIS) has attracted considerable clinical application in tumor detection. Receptor-tyrosine-kinase-like orphan receptor 1 (ROR1) is extensively expressed during embryogenesis but it is absent within most mature tissues. However, expression of ROR1 has been reported in multiple human malignancies including breast cancer. So breast cancer radioimmunoscintigraphy targeting ROR1 expression is an attractive object in molecular imaging especially nuclear medicine researches. In this study, we have developed an efficient indirect labeling method of anti-ROR1 with $^{64}$Cu ($T_{1/2}$ = 12.8 h, β+ = 17%, β– = 39%, EC = 43%) through using NOTA (p-SCN-Bn-NOTA) bi-functional chelator and performed preliminary bio distribution studies in mouse bearing breast adenocarcinoma. ***Materials and Methods:*** Anti-ROR1 was conjugated with NOTA (Macrocyclics B-605), the average number of the chelator conjugated per mAb was calculated and total concentration was determined by spectrophotometrically. NOTA- anti-ROR1 was labelled with $^{64}$Cu then Radiochemical purity and immunoreactivity by A549 cell line and serum stability of $^{64}$Cu-NOTA-anti-ROR1 were determined. The biodistribution studies and radioimmunoscintigraphy were performed in female BALB/c mouse bearing breast adenocarcinoma tumor ($^{64}$Cu-NOTA- Anti-ROR1 i.v., 100 µl, 20±5 µg mAb , 6, 12, 24 and 48 h). ***Results:*** $^{64}$Cu-NOTA-anti-ROR1 was prepared (RCP >98% ± 0.9, Specific activity 4.3 ± 0.7 µCi/µg). Conjugation reaction of chelator (20 molar excess ratio) to antibody resulted in a product with the average number of chelators attached to a mAb (c/a) of 2.7 ± 0.4. Labeling yield with $^{64}$Cu in 400µg concentration of bioconjugate was 98.6% ± 1.1. Immunoreaction of $^{64}$Cu-NOTA- anti-ROR1 complex towards ROR1 antigen was determined by RIA and the complex showed high immunoreactivity towards ROR1. In vitro and in vivo stability of radioimmunoconjugate was investigated respectively in PBS and blood serum by RTLC method. In vitro stability showed more than 92% ± 2.2 in the PBS and 81% ± 2.7 in the serum over 24 h. The Immunoreactivity of the radiolabeled anti-ROR1 towards A549 cell line was found to be 0. 82. The biodistribution of $^{64}$Cu-NOTA-anti-ROR1 complex in the mice with normal and breast tumor at 6, 12, 24 and 48 h after intravenous administration, expressed as percentage of injected dose per gram of tissue (%ID/g). Biodistribution and imaging studies at 24 and 48 h post-injection revealed the specific localization of complex at the site of tumors. ***Conclusion:*** $^{64}$Cu-NOTA- anti-ROR1 is a potential compound for molecular imaging of PET for diagnosis and follow up of ROR1 expression in oncology

## EPS-286

### Radiosynthesis and preclinical evaluation of [Zr89]mAb1 and [Zr89]mAb2 as PET tracers for B7:H3-positive tumors

***B. Fernandes***[1], *F. Basuli*[2], *C. P. Olkowski*[1], *D. Nambiar*[1], *S. Adler*[3], *G. L. Griffiths*[3], *F. I. Lin*[1], *P. Choyke*[1];
[1]*Molecular Imaging Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD, UNITED STATES OF AMERICA,* [2]*Chemistry and Synthesis Center, National Heart, Lung, and Blood Institute, National Institutes of Health, Rockville, MD, UNITED STATES OF AMERICA,* [3]*Clinical Research Directorate, Frederick National Laboratory for Cancer Research Frederick, Frederick, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Targeting the tumor microenvironment with antibody-based immunotherapies has emerged as an important strategy in the treatment of cancer. B7-H3 is a transmembrane protein expressed by several solid cancers with low expression by normal tissues, which makes it a suitable antigen for targeted therapies (including radioimmunotherapy). Several anti-B7-H3 antibodies exhibit high affinity for their target and have demonstrated antitumorgenic activity already in their non-radiolabeled form. This study aimed to validate the tumor-targeting potential of two radiolabeled anti-human B7-H3 monoclonal antibody candidates (MacroGenics, Inc, Rockville, MD) and to compare the in vivo biodistribution by positron emission tomography imaging in mice bearing human B7-H3-expressing tumors. ***Materials and Methods:*** [Zr$^{89}$]mAb1 and [Zr$^{89}$]mAb2 were synthesized using the desferrioxamine labeling methodology. In vitro studies determined the affinity binding of both radiotracers as well as their internalization efficiency at 37**℃**. In vivo studies evaluated the biodistribution of the radiotracers in healthy mice or mice bearing MC38 tumors expressing human B7-H3. Animals were intravenously injected with either [Zr$^{89}$]mAb1 or [Zr$^{89}$]mAb2mAb2 for biodistribution assessments at 24h, 48h, and 72h post-injection. Radiotracer uptake in the animals' organs was expressed as percent injected dose per gram (%ID/g). A Shapiro-Wilk normality test was applied to all data before analysis. Differences between groups were evaluated using a two-sided t-test (parametric data) and Mann-Whitney test (non-parametric data) and considered significant when $p<0.05$. ***Results:*** The specific activity, radiochemical yield, and radiochemical purity of [Zr$^{89}$]mAb1 were 122±22 MBq/nmol, 91±3%, 98±0.4%, respectively, and that for [Zr$^{89}$]mAb2 was 139±29 MBq/nmol, 92±1%, and 98±1%, respectively. In assays with human B7-H3 expressing cell lines, [Zr$^{89}$]mAb1 and [Zr$^{89}$]mAb2 bound with similar Kd at 4**℃** (5.6 and 3.2 nM, respectively). However, [Zr$^{89}$]mAb2 showed 55% internalization (p=0.004) while [Zr$^{89}$]mAb1 showed none (p=0.3412). In vivo biodistribution studies in healthy mice showed significantly higher excretion of [Zr$^{89}$]mAb1 than [Zr$^{89}$]mAb2 by kidneys at 48h (p=0.008), and 72h (p=0.008), while [Zr$^{89}$]mAb2 presented significantly higher uptake than [Zr$^{89}$]mAb1 in lymph organs such as spleen (p=0.016) and lymph nodes (p=0.032) at 48h. Biodistribution assessment in tumor-bearing mice showed significantly faster excretion of [Zr$^{89}$]mAb1 compared to [Zr$^{89}$]mAb2 at the three time points (24h, p=0.008; 48h, p=0.008; 72h, p=0.008). By contrast, [Zr$^{89}$]mAb2 uptake in tumors (36±15 %ID/g) was 119% higher (p=0.032) than that of [Zr$^{89}$]mAb1 (16±8 %ID/g) at 48h. ***Conclusion:*** Radiolabeled anti-human B7-H3 antibodies, [Zr$^{89}$]mAb1 and [Zr$^{89}$]mAb2, exhibited high tumor uptake in human B7-H3 tumor-bearing mice. However, [Zr$^{89}$]mAb2, which presented greater internalization capacity, exhibited higher tumor uptake.

## EPS-287

### A Zirconium Coordination Platform for Positron Emission Tomography Traceable Cargo Delivery

***H. Hong***, *X. Jiao, X. Li, Y. Cong, J. Hu, Y. Jiang;*
*Nanjing University, Nanjing, CHINA.*

***Aim/Introduction:*** Metal coordination materials, e.g. metal-organic frameworks (MOF), can be used for delivery of many drug cargos to address their solubility issues. Our group previously established zirconium-89 containing MOFs for targeted delivery and positron emission tomography (PET) imaging of breast tumors[1,2]. The aim of this study is to produce a $^{89}$Zr containing coordination platform with drug cargo as the bridging molecules instead of traditional

"drug loading" strategy, and this cargo delivery platform can be readily visualized by PET imaging. ***Materials and Methods:*** A solvothermal method was used to build a MOF platform composed by $ZrCl_4$ and hematoporphyrin monomethyl ether (HMME, used here as a model drug). Surface functionalization with polymer molecules and tumor-homing peptide ligands was conducted. The structure of $^{89}$Zr-HMME was investigated by TEM, XRD, XPS etc. The in vivo pharmacokinetic behavior of $^{89}$Zr-HMME was systematically studied, and the complex biological effects of $^{89}$Zr-HMME against melanoma were also evaluated (such as sonodynamic therapy effect, immunological responses etc.). ***Results:*** $^{89}$Zr-HMME had an isotope loading capacity of up to 50 MBq/μg with superior radiochemical stability. The $^{89}$Zr-HMME conjugates had diameters of 100-160 nm by TEM and hydrodynamic diameters of 200-250 nm. Potent tumor uptake was observed for $^{89}$Zr-HMME in B16F10 (~9 %ID/g at 2 h p.i.) while the blood circulation time for $^{89}$Zr-HMME was ~6.5 min. In addition, $^{89}$Zr-HMME could trigger strong sonodynamic effects and tumor killing in B16F10, alter the immune microenvironment in tumors (e.g. $CD4^+$, $CD8^+$ T cell infiltration etc.), and decelerate the tumor invasion. The detailed biological mechanisms were revealed. ***Conclusion:*** This $^{89}$Zr-HMME coordination platform can serve as a useful tool for PET-traceable cargo delivery into different types of tumors and trigger combinational tumor therapies. ***References:*** 1. Chen et al. ACS Nano. 2017,11(4):4315-4327. 2. J Nanobiotechnology. 2022, 20(1):494.

## EPS-288

### Organotrifluoroborate sugar conjugates for a guided boron neutron capture therapy: radioisotopic exchange reactions for PET imaging

***A. Erhard***[1], *L. Confalonieri*[2], *D. Imperio*[2], *M. Balcerzyk*[1], *L. Panza*[2]; [1]*Centro Nacional de Aceleradores, Sevilla, SPAIN,* [2]*University of Eastern Piedmont Amedeo Avogadro, Novara, ITALY.*

***Aim/Introduction:*** Sugars are a versatile tool for targeting malignant cells, using [$^{18}$F]FDG as a prototype. Boron neutron capture therapy (BNCT) is a cancer treatment that relies on irradiation with thermal neutrons of cancer cells previously loaded with [$^{10}$B]-containing compounds. The recent introduction of accelerators as a neutron source for clinical use prompts the planning of delivery compounds enriched with boron able to be traced in real time. We report the synthesis of a new class of sugar derivatives conjugated to a trifluoroborate moiety as potential theranostic agents, their stability and cytotoxicity studies, together with [$^{18}$F] radiolabeling optimization and in vivo preliminary microPET imaging. ***Materials and Methods:*** Synthesis of compounds with the generic structure: monosaccharide-linker-ammonium trifluoroborate group was based on a nucleophilic substitution or involving a click reaction. Toxicity was assessed on human fibroblasts by treatment with increasing concentrations (0.001-1mM) and MTT assay. Stability of the trifluoroborate group was analyzed through [$^{19}$F] NMR spectroscopy, using BPA as reference. Radiolabeling was performed by dissolving the compound in an acidified [$^{18}$F]-fluorine solution and warmed at 85ºC, 20 minutes, followed by purification with Alumina cartridge. Radiolabeling stability was analyzed in vitro by radio-TLC. The radiolabeled compound was then injected into healthy Balb/C mice for microPET/CT imaging ( [$^{18}$F]FDG as control). ***Results:*** Compounds were synthesized and purificated (>95% purity by NMR). At a concentration of 1mM, our selected compound (Glc1) induced a reduction of cell viability at all times. Stability of Glc1 showed an hydrolisis behaviour with half-life value of 72 hours. Radiolabeling procedure provided a conversion of 49.88% and after purification, radiochemical purity was 97.2% At 37ºC we found that [$^{18}$F]F-Glc1 was stable for 1 hour in human plasma and for 100min in physiological solution. Preliminary results of the incorporation of [$^{18}$F]F-Glc1 in healthy mice by microPET/CT indicated that the radiopharmaceutical was metabolized in the liver, it did not pass the blood-brain barrier and was not metabolized in the heart, showing differences with [$^{18}$F] FDG biodistribution. ***Conclusion:*** Synthesis of sugars containing the -$BF_3$ moiety is feasible in a simple, efficient and rapid manner. Radiolabeling with [$^{18}$F]F was succesfully achieved on one derivative and the radiopharmaceutical was demonstrated to be enough stable both in vitro and in vivo when injected into mice for imaging. On the other hand, this compound appears to be quite toxic for BNCT applications. The discovery of a potencial theranostic candidate for BNCT remains a big challenge for researchers.

## EPS-289

### Preclinical characterization of novel radiolabeled and fluorescent-labeled Fibroblast Activation Protein (FAP)-targeting ligands using gamma counting, SPECT imaging and Cryo-Fluorescence Tomography (CFT)

***J. Hesterman***[1], *A. Novicki*[1], *K. Orcutt*[1], *S. DiMagno*[1], *S. Hillier*[1], *S. Patel*[1], *A. Amor*[1], *B. Burke*[2], *S. Archibald*[3], *J. Wright*[3], *J. Domarkas*[3], *J. Heimann*[2], *V. Yost*[2], *E. White*[4], *C. Stokes*[4], *M. Silva*[4], *A. Cordova*[4], *S. Toddes*[4], *J. Babich*[1], *J. Hoppin*[1]; [1]*Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA,* [2]*Invicro, Needham, MA, UNITED STATES OF AMERICA,* [3]*University of Hull, Hull, UNITED KINGDOM,* [4]*Emit Imaging, Baltimore, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** FAP PET followed by fluorescent-FAP guided surgical resection offers great potential in clinical practice, particularly given the lack of pan-cancer fluorescent imaging agents for surgery. This study evaluated the relative biodistribution of a ZW800-1 fluorescent-labeled and a $^{67}$Cu-labeled NOTA-conjugated FAP compound of otherwise analogous structure. The biodistribution of the FAP imaging candidate compounds was captured across multiple techniques, including radiolabeled gamma counting (GC), radiolabeled whole-body SPECT (SPECT), and whole-body ex vivo cryo-fluorescence tomography (CFT). ***Materials and Methods:*** RTX-1363 and RTX-1341 are structurally similar compounds built on a trifunctional scaffold. Both exhibit sub-nanomolar enzymatic inhibition for human FAP ($IC_{50}$s: 50 and 85 pM, respectively) with good selectivity (FAP/PREP >50). The major structural difference is replacement of $N_3O_2$ NOTA chelate in RTX-1363 with optical dye ZW800-1 in RTX-1341. [$^{67}$Cu]RTX-1363 was prepared by adding RTX-1363 in DMSO to a solution of $^{67}$Cu in 0.05M HCl and adjusting the pH to 5.5 using 3N NaOAc. Radiochemical purity was confirmed to be >95% using RP-HPLC. A 1ug mass dose of either [$^{67}$Cu]RTX-1363 or [ZW800-1]RTX-1341 was administered in 200 uL via tail-vain injection to U-87 MG tumor-bearing mice. Three animals were imaged using SPECT/CT at 1H and 24H post-administration. Additional animals were sacrificed at 1H or 24H post-administration for gamma counting or CFT imaging. Regions of interest were segmented from SPECT and CFT images, including tumor, knee joint, liver, and kidney. ***Results:*** Consistent biodistribution was observed across compounds through qualitative assessment and quantitative analysis. No significant differences in macro tissue distribution were noted at any time point. SPECT imaging enabled within-subject quantitative longitudinal assessment while CFT imaging provided high resolution whole-body information both anatomically and

functionally, yielding insights such as the local distribution of the ligand on the surface of the bone and heterogeneity of tumor composition and distribution. Quantitative analysis is presented, indicating strong agreement in longitudinal intensity values relative to liver in tumor, knee joint, and kidney across modalities. ***Conclusion:*** Qualitative and quantitative agreement is observed in biodistribution between ZW800-1 fluorescent labeled and $^{67}$Cu radiolabeled compounds using gamma counting, whole-body SPECT and whole-body CFT. High-resolution ex vivo CFT imaging provided insights into local ligand distribution complementing low-resolution longitudinal in vivo SPECT data. Physiochemically similar characteristics between zwitterionic dye ZW800-1 and the Cu-$N_3O_2$ complex likely contributed to similarities in tissue biodistribution, further emphasizing the ability of CFT to complement radiolabeled techniques for compound screening in appropriately selected ligand systems.

## EPS-290

### 68Ga-NOTA-ACN376 imaging as a non-invasive approach to diagnose CLDN18.2-positive tumors

***c. yan***[1,2], *Z. Hua*[3], *Z. Hua*[3], *Z. Hua*[3];
[1]*Beijing cancer hospital, Beijing, CHINA,* [2]*Guizhou University Medicine College, Guizhou, CHINA,*
[3]*Beijing Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction:*** (Claudin18.2) CLDN18.2 is highly expressed in primary malignant tumors such as gastric cancer, pancreas and esophagus,and has become another emerging target for anti-tumor since HER2. We constructed a molecular probe targeting CLDN18.2 nanobodies, performed PET/CT imaging in model animals, and evaluated its affinity and specificity for CLDN18.2-positive tumors in model animals. ***Materials and Methods:*** Nanobody ACN376 was coupled with NOTA-Mal chelating agent by site-specific modification, the $^{68}$Ga-NOTA-ACN376 probe was obtained by $^{68}$Ga labeling, and its quality control was carried out. The affinity of $^{68}$Ga-NOTA-ACN376 to CLDN18.2 protein was determined by ELISA experiment. Cell binding experiments were performed using transfected CLDN18.2 high-expression AGS-CLDN18.2 cells and AGS cells. Blood pharmacokinetics studies were performed on $^{68}$Ga-NOTA-ACN376 to explore the rate of clearance in plasma. Micro-PET imaging and biodistribution of tumor-bearing mice were used to verify the targeting and specificity of the probe. ***Results:*** The radiochemical purity of $^{68}$Ga-NOTA-ACN376 was 98.56 ± 0.78% (n=5) and the specific activity was 24.7 ± 3.26 GBq/μmol. The equilibrium dissociation constant value was 27.85 nM. Cell binding experiments showed that excess ACN376 and CLDN18.2-targeted monoclonal antibody (TST001) could effectively block the uptake of probe by AGS-CLDN18.2 cells. The distribution half-life of the probe in vivo was 1.83 min, and the clearance half-life was 22.77 min, indicating that the probe had rapid in vivo distribution, metabolism and clearance rate. In Micro-PET imaging, the tumor/muscle ratio in the AGS-CLDN18.2 model 1 h after probe injection was significantly higher than that in the negative model and the blockade group (34.86 ± 4.68 vs. 15.00 ± 2.13 vs. 11.01 ± 2.09, p<0.005). Biodistribution studies showed that the uptake of 68Ga-NOTA-ACN376 in the AGS-CLDN18.2 model was significantly higher than that in the negative AGS model group (6.61 ± 0.41 %ID/g vs. 0.39 ± 0.13 %ID/g, p<0.0001). ***Conclusion:*** A series of in vitro and in vivo experimental results showed that $^{68}$Ga-NOTA-ACN376 was successfully synthesized with excellent physicochemical properties and stability, fast in vivo distribution, clearance rate, and high affinity and specificity to CLDN18.2 antigen. $^{68}$Ga-NOTA-ACN376 was rapidly cleared in mice, which can effectively improve the target/background ratio, thereby reducing the internal exposure to non-target organs such as blood. Preliminary preclinical studies have shown that this probe has good affinity, targeting and specificity for human CLDN18.2, providing a potentially highly sensitive and non-invasive detection method for CLDN18.2-positive tumors.

## EPS-291

### 61Cu-PSMA PET in prostate cancer: development and selection of the first radioligand for clinical translation

***T. Basaco Bernabeu***[1], *R. Mansi*[1], *L. Del Pozo*[1], *S. Zanger*[1], *M. Blagoev*[2], *R. H. Gaonkar*[1], *L. McDougall*[1], *A. Johayem*[2], *L. Jaafar-Thiel*[3], *M. Fani*[1];
[1]*Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND,* [2]*Department of Nuclear Medicine, University Hospital of Zürich, Zürich, SWITZERLAND,* [3]*Nuclidium AG, Basel, SWITZERLAND.*

***Aim/Introduction:*** Prostate cancer is the most frequently diagnosed cancer among men in Europe. The high demand for PSMA PET tracers is likely to increase further with the broadening of PSMA PET indications. The preferred PET radioligand [$^{68}$Ga]Ga-PSMA-11 is facing critical supply challenges. In addition, the approved $^{18}$F-labeled PSMA ligands (e.g. [$^{18}$F]PSMA-1007) show significant differences in biodistribution and lack of a therapeutic companion. Thus, we propose using of the cyclotron-produced Copper-61 ($t_{1/2}$=3.34h, $E_{\beta^+ max}$=1216keV) for PSMA PET imaging. $^{61}$Cu can be produced in large scale, like $^{18}$F, and enables delayed imaging compared to $^{68}$Ga. Moreover, it forms a theranostic couple with the β$^-$-emitter $^{67}$Cu. Herein, we report the development of the first $^{61}$Cu-PSMA ligands and compare their performances to [$^{68}$Ga]Ga-PSMA-11 and [$^{18}$F]PSMA-1007. ***Materials and Methods:*** We developed [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T and [$^{61}$Cu]Cu-NODAGA-PSMA-I&T and compared them versus [$^{68}$Ga]Ga-PSMA-11 and [$^{18}$F]PSMA-1007. In vitro (lipophilicity, affinity, cellular uptake and distribution) and in vivo (dynamic PET/CT imaging and biodistribution at 1h and 4h post-injection) studies were performed using LNCaP cells and LNCaP-xenografted nude mice. ***Results:*** [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T and [$^{61}$Cu]Cu-NODAGA-PSMA-I&T were prepared at an apparent molar activity of 24 MBq/nmol and radiochemical purity ≥97%. Their PSMA-affinity was in the nanomolar range ($IC_{50}$=11.2±2.3 and 9.3±1.8 nM, respectively). Both were more lipophilic (logD=-2.69±0.44 and -2.95±0.08, respectively) than [$^{68}$Ga]Ga-PSMA-11 (-3.89±0.19) and [$^{18}$F]PSMA-1007 (-3.04±0.06). All radioligands showed similar cellular uptake with 50:50 distributions between surface-bound and internalization at 1h/37°C. [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T and [$^{61}$Cu]Cu-NODAGA-PSMA-I&T accumulated in LNCaP tumors and PSMA-positive tissues (kidneys, adrenals, spleen and salivary glands), but to different extends. [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T had ~10-fold higher blood values and predominant accumulation in the abdomen and the liver. At 1h p.i., [$^{61}$Cu]Cu-NODAGA-PSMA-I&T showed the highest tumor uptake (14.0±5.0 %IA/g), compared to [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T (6.06±0.25, p=0.006), [$^{68}$Ga]Ga-PSMA-11 (10.2±1.5, p=0.097) and [$^{18}$F]PSMA-1007 (9.70±2.57, p=0.080). The highest tumor uptake was also seen for [$^{61}$Cu]Cu-NODAGA-PSMA-I&T at 4h p.i. (10.7±3.3 %IA/g), compared to [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T (4.88±0.63, p=0.0014) and [$^{18}$F]PSMA-1007 (6.28±2.19, p=0.0145). Tumor-to-non tumor ratios were superior for [$^{61}$Cu]Cu-NODAGA-PSMA-I&T versus [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T, and equally good or better versus [$^{68}$Ga]Ga-PSMA-11 and [$^{18}$F]PSMA-1007. Tumor-to-non tumor ratios

were further improving from 1h to 4h. PET/CT imaging of all radiotracers confirmed the biodistribution data. PET/CT images of $^{61}CuCl_2$ showed accumulation of the uncomplexed $^{61}Cu$ in the liver and intestine, similar to [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T. ***Conclusion:*** [$^{61}$Cu]Cu-NODAGA-PSMA-I&T had seemingly better biodistribution, pharmacokinetics and imaging properties than [$^{61}$Cu]Cu-DOTAGA-PSMA-I&T. It showed similar distribution to [$^{68}$Ga]Ga-PSMA-11 and [$^{18}$F]PSMA-1007, while showing advantages for delayed imaging. [$^{61}$Cu]Cu-NODAGA-PSMA-I&T was selected for clinical translation of the first $^{61}$Cu-PSMA PET.

## EPS-292

### Preclinical 68Ga-EMP100 PET Imaging to quantify c-Met Expression in non-small cell lung cancer (NSCLC)

***A. Prignon***[1,2], *T. Rusu*[2,1], *R. Anita*[2], *C. Portal*[3], *J. Cadranel*[2]; [1]*Sorbonne University, UMS28, LIMP, Paris, FRANCE,* [2]*THERANOSCAN Clinical Research Group of the Pneumology and Thoracic Oncology Department Tenon Hospital AP-HP, Paris, FRANCE,* [3]*Edinburgh Molecular Imaging, Edinburgh, UNITED KINGDOM.*

***Aim/Introduction:*** The c-Met receptor tyrosine kinase (TK) is the cell surface receptor for hepatocyte growth factor (HGF). The c-Met/HGF axis is aberrantly activated in many cancers, particularly in NSCLC. A PET imaging agent targeting c-Met receptor could better select patients for c-Met targeted therapy compared to other routinely used techniques such as MET gene amplification by next generation sequencing (NGS) or immunohistochemistry (IHC). ***Materials and Methods:*** To non-invasively quantify c-Met levels, we developed a robust and automated radiolabelling of a c-Met targeted peptide with gallium-68, $^{68}$Ga-EMP100, and evaluated its in vivo distribution, pharmacokinetics, and c-Met specificity in preclinical models of non-small cell lung cancer (NSCLC) with variable c-Met expression. MET gene amplification and IHC c-MET scoring were assessed on corresponding tumours. IHC was also conducted on tissue microarrays (TMAs) obtained from therapy naïve patients. ***Results:*** The synthesis on a fully automated system was performed successfully. The overall decay-corrected radiochemical yield was > 60% and radiochemical purity was ≥ 95% (iTLC and radioHPLC), with a sufficient specific activity in MBq/nmol for mice injection.Five different mouse models were developed using squamous (EBC-1) and adenocarcinoma (H1993, H1648, A549 and HCC827) NSCLC cell lines.$^{68}$Ga-EMP100 provided high-contrast PET images within 40 minutes of administration. Interestingly, $^{68}$Ga-EMP100 detected variable c-Met levels according to quantitative uptake analysis in tumour performed in mean % of injected dose/g, or SUV Max in g/mL, confirmed by ex vivo analysis at 1h p.i. MET copy number was not really correlated with semiquantitative IHC measures of c-MET expression in tumours. IHC permits only to discriminate really low expression in A549 model (1+) compared to the others which were found highly positive (3+). Elements of target validation in humans were also obtained through the IHC analysis of TMAs, were 36% of adenocarcinomas, 24% of sarcomatoid carcinomas and 9% of squamous cell carcinomas were found as high c-Met overexpressing. ***Conclusion:*** The potential of PET imaging using $^{68}$Ga-EMP100 was successfully demonstrated through direct comparison of its performance against currently used gold standards such as genetic tests and IHC analysis of biopsied tissues, allowing a full body quantitative assessment of the c-Met overexpression. This may represent a game changer in the clinicopathological staging of patients and their selection for c-Met targeted therapies such as antibody drug conjugate or internal systemic radiotherapy. Further studies are warranted to explore the relationship between molecular imaging and response to these specific therapies.

## EPS-293

### Early detection of CD38using a novel 68Ga-labeled peptidein lymphoma murine models

***L. Kang***[1], *Q. Yang*[1], *X. Li*[2], *L. Song*[1], *W. Huang*[1], *X. Sun*[1], *Z. Wang*[2]; [1]*Peking University First Hospital, Beijing, CHINA,* [2]*National Center for Nanoscience and Technology, Beijing, CHINA.*

***Aim/Introduction:*** Lymphoma is a heterogeneous disease with different clinical manifestations and prognosis. Despite conventional chemotherapy and radiotherapy, many subtypes of lymphoma are highly aggressive. CD38 is highly expressed on the surface of B-derived lymphoma cell, making it a characteristic tumor biological target of lymphoma, especially in multiple myeloma. CD38 peptide can overcome limitations of antibodies and achieve precise imaging of tumor sites, providing the possibility for early diagnosis of tumors and dynamic monitoring of immunotherapy. In this study, the diagnosis role of $^{68}$Ga-labeled CD38-targeted peptide was investigated for PET imaging in lymphoma murine models. ***Materials and Methods:*** After obtaining amino acid sequence through screening of combinatorial chemistry peptide library based on microchip, we synthesized CD38 peptide, PF381, by solid phase synthesis using standard Fmoc scheme. Surface plasmon resonance (SPR) method was used to detect the affinity between PF381 and human CD38 protein. PF381 was conjugated with 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling with $^{68}$Ga ($t_{1/2}$ = 67.7 min). $^{68}$Ga-PF381 was determined using high performance liquid chromatography (HPLC). PET imaging was performed after injection of $^{68}$Ga-PF381 after the lymphoma tumor-bearing murine model was established. Further, we conducted biodistribution analysis 30 minutes after injection to analyze the differences in radioactive distribution and uptake of CD38 positive tumor Ramos and negative tumor U266. ***Results:*** The SPR signal of PF381 gradually increased with the increase of protein concentration, and the KD value reached $10^{-8}$ M, indicating that PF381 has a strong affinity for CD38. For HPLC, the radiolabeling efficiency of $^{68}$Ga-PF381 was nearly 70%. PET imaging of $^{68}$Ga-PF381 showed that, significant radioactive concentration was observed 30 minutes after injection in Ramos tumor model, and lasted until 80 minutes. In U266 tumor model, no significant radioactive concentration was observed at all time points. The above results of imaging suggest the high uptake of tumors from radiolabeled PF381. The biodistribution results showed that, the uptake of Ramos tumors (0.75 ± 0.03%ID/g) is higher than that of U266 tumors (0.26±0.08%ID/g, P<0.01), which was consistent with PET imaging results. ***Conclusion:*** We developed a novel peptide targeting CD38 and proved $^{68}$Ga-labeled PF381 had rapid targeting and good tumor penetration ability. Therefore, $^{68}$Ga-labeled PF381 could achieve high sensitivity in vivo imaging of small lymphomas.

## Case Report Session 4 - TROP Session: FDG PET and Conventional Imaging: Still Surprising!

### OP-943

**Pre- and post-CAR-T therapy FDG PET/CT images and limitations of the Deauville Criteria: A Pictorial Essay**

***S. Kwon***[1], *S. Ha*[1], *J. Min*[2], *J. O*[1], *Catholic University Lymphoma Group (CULG);*
[1]*Seoul St Mary's Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Only a few studies presenting FDG PET/CT findings in DLBCL after chimeric antigen receptor (CAR) T-cell therapy have been published to date. This study aims to describe the patterns of post-CAR-T FDG PET/CT. ***Materials and Methods:*** Patients with DLBCL with F-18 FDG PET/CT before and after CD-19 targeted CAR-T (tisagenlecleucel) infusion were reviewed. Clinical factors were collected, including demographics, initial stage, prior-treatment history, and CAR-T-related factors (use of bridging therapy, tocilizumab, adverse events including ICANS and CRS). The authors assessed PET/CT taken before, 1-month after, and 3-months after CAR-T infusion (pre, 1-mo, 3-mo PET/CT) and recorded the Deauville score (DS), SUVmax of the hottest lesion, SUVmean of non-lymphomatous organs (spleen, bone marrow, liver, and blood pool), and location of the recurrent lesions. Lesions with DS>3 were considered viable lesions. The location of new recurrent lesions in post-CAR-T PET/CT outside previous lymphoma sites was designated as unexpected recurrence sites. ***Results:*** A total of 15 patients were included (median age 61.5, range 38-83, M:F=9:6). 9 patients (60 %) were stage IV at diagnosis. Fifteen patients underwent bridging chemotherapy. Six patients underwent 1-mo, and eight patients had 6-mo PET/CT. In pre-CAR-T PET/CT, viable lymphoma lesions were seen in 12 patients (80 %), while the remaining 3 patients (20 %) showed no definite viable lesion in pre-CAR-T PET/CT. Five patients showed only nodal disease; the remaining ten had extra-nodal diseases. A total of 8 (53.3 %) patients showed progression in post-CAR-T PET/CT (2 patients in 1-mo and six patients in 3-mo PET/CT images). All three patients without viable disease in pre-CAR-T PET/CT manifested as CAR-T failure. SUVmax/liver ratio of the hottest recurrent lesion was 0.7 ~ 15.5. Most recurrent lesions showed DS 5 uptakes, except for one patient with a new DS 2 lesion in the right cheek (SUVmax/liver ratio: 0.7), which was biopsy proven to be a lymphoma lesion. The patient underwent salvage chemotherapy, but the disease progressed with unexpected extensive lymphomatosis peritoneii. The percent change of spleen-to-liver ratio (SLR) between pre- and 1-mo PET/CT ranged from -40 % to 33%. The percent change of SLR and 1-mo SLR did not show a significant difference between the patients with or without CAR-T failure. ***Conclusion:*** The unfavorable outcome following CAR-T infusion can manifest as diverse Deauville scores in pre- or post-CAR-T PET/CT images. ***References:*** Early FDG-PET response predicts CAR-T failure in large B-cell lymphoma. Blood Adv. 2022;6(1):321-326.

### OP-944

**Dramatic treatment response images of a metastatic lung adenocarcinoma case with Osimertinib treatment on 18F-FDG PET/CT**

***B. Ince***, *A. Namazova, M. Bodur, S. Asa, L. Uslu-Besli, S. Sager, H. Sayman, K. Sonmezoglu;*
*Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** We present $^{18}$F-FDG PET/CT images of a patient diagnosed with metastatic lung adenocarcinoma who responded dramatically to treatment with Osimertinib. Osimertinib is a third-generation epithelial growth factor receptor-tyrosine kinase inhibitor (EGFR-TKI) and is the first treatment option for patients with lung adenocarcinoma with exon 19 deletions or exon 21 L858R mutations. It is also indicated in patients who have become resistant to other EGFR-TK inhibitors. It is known that $^{18}$F-FDG PET/CT is an early predictor of outcomes and individual prognosis of patients with advanced lung adenocarcinomas receiving first-line EGFR-TKI therapy. ***Materials and Methods:*** The patient was administered 0.15 mCi/kg FDG intravenously. PET/CT imaging was obtained from the vertex and upper thigh at 60th minute after the injection. ***Results:*** A 50-year-old nonsmoker male patient was diagnosed with poorly differentiated adenocarcinoma by bronchoscopic biopsy of the upper lobe of the left lung. Initial $^{18}$F-FDG PET/CT imaging showed a consolidated hypermetabolic mass lesion of the primary malignancy covering most of the parenchyma of upper lobe of the left lung, metastatic hypermetabolic peribronchial thickening in the right lung and lower lobe of the left lung, and hypermetabolic metastatic lymph nodes in the right hilar, bilateral axillary, left supraclavicular, and right lower cervical regions. Biopsy of the left supraclavicular lymph node revealed adenocarcinoma metastasis. After molecular genetic testing of the primary tumor revealed an exon 19 deletion in the EGFR gene, the patient was treated with 80 mg/day Osimertinib. $^{18}$F-FDG PET/CT imaging performed after 12 weeks of treatment showed a significant morphologic and metabolic response of the primary malignant tumor in the left upper lobe and metastatic peribronchial thickening in the left lower lobe. Complete response was observed in the remaining metastatic lesions. ***Conclusion:*** We presented $^{18}$F-FDG PET/CT images of the case with a dramatic response to Osimertinib treatment. ***References:*** 1. ## OP-945

### Imaging Plasmacytoid Dendritic Cell Neoplasm with FDG PET/CT: Atypical Presentation of a Rare Disease in a Child

***M. Ben Nasr***, *O. Ben Hamida, R. Belayouni, C. Mhiri, I. Slim, I. Meddeb, A. Mhiri;*
*Salah Azaiez Institute of Tunis, Tunis, TUNISIA.*

***Aim/Introduction:*** Blastic plasmacytoid dendritic cell neoplasm (BPDCN), previously called "CD4/CD56 hematodermic neoplasm", is a rare hematolymphoid neoplasm with a very poor prognosis. The disease has rarely been described in the paediatric population and is characterized by cutaneous involvement in most cases with hematological dissemination. Given the low number of cases described, the role of FDG PET/CT in this disease is very little known. We herein present a case of a 14-year-old girl with BPDCN to highlight the utility of FDG PET/CT for staging and treatment follow-up in this rare entity. ***Materials and Methods:*** A 14-year-old girl with no history consulted for progressive poly-arthralgia without fever. Clinical examination revealed skin infiltrate of the left abdominal region with bilateral axillary lymphadenopathy. Initial blood count showed microcytic anemia. Skin biopsy showed massive tumour infiltration of the dermis by blastic cells and the immunohistochemical study was compatible with acute dendritic leukemia with tumour cells expressing CD4, CD56 and TCL1. Myelogram and bone marrow biopsy were performed, confirming massive blastic invasion. The computed tomography (CT) demonstrated cervical, axillary, and inguinal lymphadenopathy, hepatosplenomegaly and a multi nodular thickening of the anterolateral abdominal wall. The patient underwent FDG PET / CT for initial staging and follow up. FDG PET/CT imaging was performed 60 minutes after the intravenous injection of 148 MBq (4 mCi) of 18F-FDG with BIOGRAPH vision PET CT Siemens. ***Results:*** The exam revealed multiple hypermetabolic bilateral lymph nodes of the cervical, axillary, mediastinal, intra and retro-peritoneal regions. It showed a mild FDG-avid cutaneous lesions, osteo-medullary involvement, and unknown FDG-avid nodules in both mammary glands. The SUVmax varied between 2 and 4,6 (SUV of the liver was measured as 2.2). Treatment was initiated in collaboration with hematologists and oncologists. The patient received two cycles of induction chemotherapy combined with corticosteroid therapy. Two months later, FDG PET/ CT showed no hypermetabolic lesion with a total regression of the lymph nodes, bone marrow, cutaneous and mammary involvement. The child achieved complete remission and hematopoetic stem cell transplantation was proposed. ***Conclusion:*** FDG PET/CT has been widely used in staging, restaging and response assessment of lymphoma. Likewise, for acute leukemia patients, FDG PET/CT can also help determine the extent of the disease and assess the therapeutic response. This case demonstrates the usefulness of FDG-PET for staging and assessment of the treatment response in an extremely rare type of paediatric leukemia.

## OP-946

### Utility of 18F-FDG PET/CT in Rhabdomyosarcoma of Prostate

***S. Jain***[1], *H. Goyal*[2];
[1]*All India Institute of Medical Sciences, Bhopal, INDIA,* [2]*Jipmer, Puducherry, INDIA.*

***Aim/Introduction:*** Rhabdomyosarcoma (RMS) of the prostate is a rare and aggressive malignancy that typically occurs in children and young adults. Literature evaluating the role of 18F-FDG PET/CT imaging in management of Prostatic RMS is scarce. FDG PET/CT imaging can help in the staging, restaging, and monitoring response to therapy. We present two cases of Prostatic RMS demonstrating the utility of 18F-FDG PET/CT in staging and treatment response, with one demonstrating complete metabolic response. ***Materials and Methods:*** In both cases, 18F-FDG was administered intravenously followed by acquisition of the whole body PET/CT from base of skull to mid thigh after 60 minutes of injection. ***Results:*** Case 1: A 19 year old man, who presented with low backache and loin pain was diagnosed with embryonal type RMS of prostate. Whole body 18F-FDG PET/CT scan revealed FDG-avid soft tissue mass lesion involving the prostate with involvement of supraclavicular, retroperitoneal and pelvic lymph nodes. Metastatic involvement of the right iliac bone was also noted. On follow-up 18F-FDG PET/CT scan after receiving 6 cycles of chemotherapy (VAC regimen - vincristine, actinomycin-D, and cyclophosphamide), complete metabolic response in these lesions was noted. Case 2: A 17 year old boy, who presented with difficulty in micturion was diagnosed with spindle cell type RMS of Prostate. 18F-FDG PET/CT was performed which revealed heterogeneously increased FDG uptake in heterogeneously enhancing soft tissue attenuation mass replacing the prostate gland, and infiltrating the urethra, posterior wall of the bladder, the seminal vesicles, and bilateral ureters. Loss of fat planes with pelvic sidewall and bilateral obturator internus muscles was also noted. Involvement of pelvic lymph nodes was seen with increased FDG uptake in right external iliac, bilateral internal iliac node, pre-sacral, and left inguinal lymph nodes. Liver (Segment VI) and skeletal (T10 vertebra, L1-L2 vertebrae, Sacrum, and neck of the right femur) metastasis were also noted with increased FDG uptake. In view of widespread metastatic involvement noted on F18-FDG PET/CT, the patient was subsequently started on chemotherapy (VAC regimen). ***Conclusion:*** 18F-FDG PET/CT imaging plays an important role in the evaluation of patients with RMS of the prostate. It is a valuable tool for the staging, restaging and treatment response assessment, and guide in effective treatment planning. ***References:*** Saltzman AF, Cost NG. ## OP-947

### When Histopathology is Wrong and Bone Scintigraphy is Right - an Exemplary Case of a Rare Genetic Metabolic Disease (Familial Expansile Osteolysis) Repeatedly Mistaken for Fibrous Dysplasia and Paget's Disease

***D. Filipan***[1], *E. Koumakis*[2,3], *V. Cormier-Daire*[4], *T. Funck-Brentano*[5], *F. Paycha*[6];
[1]*University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA,* [2]*Centre de Référence des Maladies Osseuses Constitutionnelles, Service de Rhumatologie, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE,* [3]*INSERM UMR 1163, Institut Imagine, Hôpital Necker, Paris, FRANCE,* [4]*Service de Génétique Clinique Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE,* [5]*Service de Rhumatologie & BIOSCAR UMR 1132, INSERM, Université Paris Cité, Paris, FRANCE,* [6]*Service de Médecine Nucléaire, Hôpital Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE.*

***Aim/Introduction:*** Juvenile Paget's disease (JPD) is a rare genetic bone disease characterized by greatly increased bone turnover, skeletal pain, fractures, and deformity. There are two known somatic mutations, causing JPD1 and JPD2, the latter also known as familial expansile osteolysis (FEO). ***Materials and Methods:*** We present the case of a 45-year-old female patient with chronic knee pain. Past medical history revealed hearing loss at the age

of 5 (from bilateral aplasia of the stapes), multiple dental implants before the age of 30 for fragile and falling teeth, and resection of a bone deforming lesion of the upper jaw at the age of 15 for which histopathology report indicated fibrous dysplasia. X-ray imaging of the knees demonstrated bilateral patellofemoral arthropathy and suspicion of fibrous dysplasia of the lower end of the right femur. Dual-energy X-ray absorptiometry evidenced severe osteoporosis. Blood tests revealed elevated bone-specific alkaline phosphatase, osteocalcin and serum C-terminal telopeptide. The patient was referred for a [99mTc]bisphosphonates scintigraphy. Acquisition workflow included full body planar scan completed by SPECT/CT fields-of-view of skull, upper and lower limbs. There was an extensive polyostotic disease with increased skeletal global uptake at 1.3 times normal value, focalized on cranial vault, left maxilla, both clavicles, right humerus, distal end of both femurs and proximal 2/3 of left tibia. CT portion of hybrid imaging found expansion of the bone, bowing of long bones, scoliosis of the spine, cortico-medullary dedifferentiation of the tibiae and local Pagetic-type deformation (clavicles, humeri, right femur). There were no SPECT/CT criteria for fibrous dysplasia. Such pattern was judged consistent with an atypical polyfocal Paget's disease phase II/III with asynchronous appearance and predominance on the peripheral skeleton. ***Results:*** Elevated bone turnover markers coupled with paediatric age-onset abnormalities, Pagetic-type deformations and demineralization prompted a genetic analysis. A heterozygous mutation of TNFRSF11A gene was identified, encoding receptor activator of nuclear factor-kappa B (RANK) and thus confirmed FEO. No evidence of fractures or clinically relevant bone pain permitted an initial watch-and-wait approach, but the patient subsequently developed inflammatory thoraco-lumbar pain correlated to significant increase in bone turnover marker levels, so bisphosphonates infusion was initiated with good clinical and biological results. ***Conclusion:*** This case illustrates the complexity of a correct diagnosis in adults with rare constitutional bone diseases and shows that integrative bone SPECT/CT pattern analysis coupled with quantitative skeletal turn over may act as a problem-solver in properly diagnosing dysostoses such as JPD2.

## OP-948

### Delayed Onset Angiosarcoma Arising from a Femur Infarct Pictured by [99mTc]bisphosphonates SPECT/CT and [18F]FDG-PET/CT: Caution with Tumour Necrosis and Haemorrhage Phenomena in Molecular Imaging analysis!

***D. Filipan***[1], *N. Saleh*[2], *R. Kaci*[3], *F. Paycha*[2];
[1]*University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA,* [2]*Service de Médecine Nucléaire, Hôpital Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE,* [3]*Service d'Anatomie et de Cytologie Pathologiques, Hôpital Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE.*

***Aim/Introduction:*** Angiosarcoma of bone is extremely rare (less than 1% of all bone sarcomas), with rapid, aggressive progression and a very poor prognosis. It may arise within a bone infarct and is typically characterized by multifocal lesions in tubular bones (usually femur). ***Materials and Methods:*** A 70-year-old male presented with subacute painful left thigh. Past medical history revealed acute myeloid leukaemia (AML) treated 20 years prior (without total body irradiation), including long-term corticosteroid therapy with multiple bone infarcts sequelae. Radiographs detected a lytic bone lesion on a previous infarct of the left femoral diaphysis. CT scan of the left thigh confirmed an osteolytic lesion centred on the medullary cavity with permeative bone destruction of the cortex (Lodwick-Madewell type III), associated with spiculated periosteal reaction and extra-compartmental extension: two extra-osseous juxta-lesional soft-tissue masses. The patient was referred for a [99mTc]bisphosphonates scintigraphy, combining full body planar scan and additional SPECT/CT fields-of-view of the lower limbs. There was increased heterogeneous circumferential uptake (magnitude: 2xN) of the left femoral diaphysis at the site of cortical bone destruction. An [18F]FDG-PET/CT scan spotted the tissular infiltration of the vastus intermedius muscle exhibiting intense hypermetabolism (SUVmax 43, tumour metabolic volume 56 $cm^3$). An ultrasound-guided biopsy was performed. Immunohistochemical (IHC) analysis described tumoral proliferation in vessel-forming clusters, with intense staining by the anti-CD31/anti-ERG antibodies, and Ki67 50%. IHC stains were consistent with epithelioid angiosarcoma. Pre-operative MRI of the left thigh showed a T1 iso-signal and heterogeneous T2 hypersignal mass displaying early irregular contrast enhancement. ***Results:*** Multimodality cross-sectional imaging categorized the sarcoma as Enneking stage IIB (G2T2M0). The patient underwent en-bloc resection. Pathology report confirmed a high-grade epithelioid angiosarcoma: haemorrhagic, necrotizing (>50%), poorly delimited tumour with cortical bone destruction, medullary canal infiltration, soft tissue invasion and positive surgical margins. Follow-up [18F]FDG-PET/CT scan 2 months later elicited intensely hypermetabolic soft tissue satellite mass at surgical site (SUVmax 52), associated with hypermetabolic hepatic and bone metastases. The patient did not receive chemotherapy due to poor general condition and died 1 month later. ***Conclusion:*** Massive tumoral necrosis and haemorrhagic zones caused faint intra-osseous radiopharmaceuticals uptake, but [18F]FDG depicted soft-tissue expansion more accurately than MRI. Diagnosing bone angiosarcoma is challenging especially when competing diagnoses are bone angiosarcoma secondary to bone infarction, extra-medullary recurrence of AML, and chemotherapy-associated lymphoma of bone. Case-reporting exceptional bone sarcomas is crucial in not underestimating their incidence and gathering key imaging features to improve a dismal prognosis.

## OP-949

### Facial asymmetry unmasked by bone scintigraphy

***L. Sobral Torres****, A. OLiveira, P. Soeiro;*
*Centro Hospital Universitário de São João, Porto, PORTUGAL.*

***Aim/Introduction:*** Bone scintigraphy with single photon emission computed tomography (bone SPECT) is commonly used to diagnose condylar hyperplasia (CH). Nevertheless, facial asymmetry and mandibular malocclusion have multiple other causes also identifiable by this technique. We present an unsuspected case of fibrous dysplasia of the maxilla mimicking CH in which bone SPECT was fundamental revealing the aetiology and thus impacting the treatment approach. ***Materials and Methods:*** A 14-year-old girl presented with painless and progressive left laterognathia with malocclusion. Physical examination revealed left temporomandibular joint sounds associated with rightward deviation of the chin and a difference between the inter-incisive midlines. Routine blood tests were normal and no bone disease family history was noted. The main diagnostic hypothesis was CH. To assess the possibility of surgical treatment a 3-phase bone scintigraphy of the head with SPECT was performed using [$^{99m}$Tc]Tc-hydroxymethylene diphosphonate (HDP). ***Results:*** The bone scan revealed no condylar asymmetry of either perfusion or uptake of the radiopharmaceutical. Relative condylar uptake was within normal parameters, consistent with inactive growth (less than 10% difference). However, markedly increased uptake was observed in the left maxillary sinus. On transmission computed tomography (CT), the uptake matched an osteoblastic lesion occupying almost the entire left maxilla and part of the zygomatic bone. Biopsy

confirmed a benign fibro-osseous lesion consistent with fibrous dysplasia. ***Conclusion:*** A 3-phase bone scintigraphy with SPECT can identify the precise location of areas of abnormal osteoblastic activity and help diagnose the aetiology of facial asymmetry and dental malocclusion. Further improvement of this technique can be achieved by combining SPECT with transmission images. ***References:*** Higginson JA, Bartram AC, Banks RJ, Keith DJW. ## OP-950

### Unexpected Finding of Myeloma in Myocardial Perfusion Imaging Study with 99mTc-sestamibi

***P. Cichocki***[1], *A. Płachcińska*[2], *Z. Adamczewski*[1];
[1]*Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND,* [2]*Department of Quality Control and Radiation Protection, Medical University of Lodz, Lodz, POLAND.*

***Aim/Introduction:*** Multiple myeloma (MM) is a disease involving abnormal proliferation of plasma cells. $^{18}$F-FDG PET is the primary radioisotope imaging technique used in diagnosis of MM. However, $^{99m}$Tc-sestamibi is also known to accumulate in some malignant tumors (eg. breast, lung or thyroid cancers), including MM lesions. ***Materials and Methods:*** A 73-year-old man with a history of chronic coronary artery disease (CAD), myocardial infarction, myocardial dysfunction (EF=25%), atrial fibrillation, 1st degree atrioventricular block and implantation of cardioverter-defibrillator (ICD) was referred for myocardial perfusion imaging (MPI) as part of routine monitoring of CAD progression. Patient also had a history of stage G3b chronic kidney disease (CKD) and left side nephrectomy due to kidney cancer. MPI was performed using Infinia Hawkeye 4 gammacamera in a two-day REST/Regadenoson protocol after injection of 999 MBq of $^{99m}$Tc-sestamibi each day. ***Results:*** MPI study revealed a post-infarction scar with moderate stress-induced ischemia. However, technologist reported abnormal uptake of $^{99m}$Tc-sestamibi in bones visible in both studies during image reconstruction. Poor radiopharmaceutical quality was ruled out by quality control. Patient was referred for further diagnosis with the suspicion of MM. Follow-up investigation revealed findings typical for MM: 1) several osteolytic lesions in bones visible in skull X-ray as well as chest, abdomen and pelvis CT scans (most lesions in the chest area were corresponding to abnormal findings in $^{99m}$Tc-sestamibi SPECT), 2) low hemoglobin concentration (9,7 g/dL), 3) high creatinine level (414 µmol/L; 4,68 mg/dL; eGFR (BIS1) 17 mL/min/1,73m2), 4) high calcium level (2,97 mmol/L), 5) presence of monoclonal spike on serum protein electrophoresis, 6) presence of free lambda light chains in urine sample. Patient was scheduled for further diagnosis and treatment in hematology clinic, but unfortunately contracted type A influenza before transfer and did not survive the infection. ***Conclusion:*** Non-specific accumulation of $^{99m}$Tc-sestamibi in malignant tumors can lead to accidental findings with potentially high clinical significance, and should not be overlooked or dismissed as an artifact or poor radiopharmaceutical quality. In this case, symptoms of MM were masked by CAD and CKD, which could have significantly delayed the diagnosis if not for the unexpected findings in MPI. It is important for technologists to pay attention to unusual uptake patterns in the chest area during quality control and reconstruction of images in routinely performed MPI, since they are no longer visible on fully reconstructed and masked tomographic slices and polar maps used for myocardial perfusion assessment.

## OP-951

### Ga-68 DOTATOC PET/CT and I-123 MIBG scan in a refractory case of pediatric neuroblastoma: imaging biomarkers with complete mismatch and implications for patient management

***L. Vija***[1], *A. Latgé*[1], *M. Gambart*[1], *L. Guillon*[2], *S. Brillouet*[1], *D. Vallot*[1], *L. Dierickx*[1], *S. Zerdoud*[1], *F. Courbon*[1];
[1]*Institut Claudius Regaud-Oncopole, Toulouse Cedex 9, FRANCE,* [2]*CHU Toulouse, Toulouse Cedex 9, FRANCE.*

***Aim/Introduction:*** Scintigraphy with Iodine-123 MIBG taken up by noradrenaline transporters (NAT) and Ga-68 DOTATATE with high uptake for somatostatin receptor subtype 2 (SSTR2) are used to select patients for molecular radiotherapy with Iodine-131 MIBG and Lu-177 DOTATATE. We compared the differential biodistribution of these two imaging biomarkers in a 6 year old patient with bone metastatic left adrenal neuroblastoma undergoing assessment for eligibility for molecular radiotherapy with Iodine-131 MIBG or Lu-177 DOTATATE as this patient progressed on bone metastases after three lines of chemotherapy and local irradiation of a lesion of the vertex. ***Materials and Methods:*** I-123 MIBG scintigraphy was performed on a Discovery NM/CT670 gamma camera with both planar and SPECT/CT of the whole body at 24h post injection. Ga-68 DOTATATE PET CT was performed on a Discovery Omni Legend PET/CT system (GE Healthcare) at 50 minutes after intravenous injection of 37 MBq of Ga-68 DOTATATE according to BMI and pediatric guidelines. ***Results:*** Both PET and scintigraphy scans were evaluated to assess the extent of bone marrow disease using the International Society of Pediatric Oncology European Neuroblastoma (SIOPEN) (scoring from 0-72). On I-123 MIBG scan the bone scoring was 19/72 whereas on Ga-68 DOTATOC PET the bone extent was more important, with a score of 34/72. However there was a complete mismatch between focal bone areas with intense uptake on MIBG scan versus SSTR2 expression intensity lower than the liver on Ga-68 DOTA PET, versus lesions with no uptake or faint uptake on MIBG scan and intense uptake on Ga-68 DOTA PET. Only one lesion of the vertex and another of the right femur were concordant and intense in both imaging methods. ***Conclusion:*** This case report shows biological heterogeneity in the expression of NAT and SSTR2, so that both imaging methods are complementary and useful to guide the choice of the most adequate molecular radiotherapy. Increased SSTR2 expression might be related to more aggressive lesions. Heterogeneous clonal evolution related to genomic instability might be responsible for the mismatch.

**An exploratory study on the mechanism of pralatrexate killing gemcitabine-resistant pancreatic cancer cells**

***W. Weng***, *J. Hong, D. Jiang, B. Chen, S. Zheng;*
*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

***Aim/Introduction:*** Pancreatic cancer is one of the most lethal malignant tumors in human beings, and its low survival rate and poor prognosis have become a public health problem to be solved urgently. Although gemcitabine, a first-line treatment for pancreatic cancer, can improve the survival benefit and related clinical symptoms of patients with advanced pancreatic cancer, the drug resistance of patients to gemcitabine during treatment often leads to adverse clinical outcomes. For patients with gemcitabine-resistant pancreatic cancer, it is urgent to explore new chemotherapy drugs. In previous large-scale drug screening, we found that pralatrexate has a strong killing effect on gemcitabine-resistant pancreatic cancer cells and is safe for use in nude mice.The purpose of this study was to explore the anti-tumor mechanism of pralatrexate on gemcitabine-resistant pancreatic cancer cells, in order to provide new methods and ideas for solving the problem of gemcitabine-resistant pancreatic cancer. ***Materials and Methods:*** A new acquired gemcitabine-resistant cell line BXPC-GEM-20 was established from the parental pancreatic cancer cell line. BXPC-GEM-20 cells were treated with different concentrations of pralatrexate and the changes of related pathway proteins were detected by western blotting. ***Results:*** Western blotting showed that the expressions of AMPK,AKT,mTOR,p-mTOR were decreased, while the expressions of p-AMPK and LC3A/B were increased. ***Conclusion:*** Pralatrexate can down-regulate the expression of AKT and activate phosphorylation of AMPK, resulting in the downregulation of mTOR protein, thus increasing the expression of autophagy related protein LC3 A/B and promoting autophagy.Pralatrexate increases autophagy by down-regulating the expression of AMPK and AKT, which may be one of the mechanisms of pralatrexate killing gemcitabine-resistant pancreatic cancer cells.

### EP-0002

**Androgen-induced cell cycle arrest in prostate carcinoma cells as a potential risk for pseudoprogression during diagnosis with prostate-specific membrane antigen (PSMA) radiopharmaceuticals and treatment failure with PSMA radioligands. An in vitro study.**

***B. Meller***[1], *P. Thelen*[2], *V. Unterkircher*[3], *J. Bucerius*[1], *L. Trojan*[2], *C. O. Sahlmann*[1], *F. Bremmer*[3];
[1]*University Medical Center Göttingen, Clinic of Nuclear Medicine, Göttingen, GERMANY,* [2]*University Medical Center Göttingen, Clinic of Urology, Göttingen, GERMANY,* [3]*University Medical Center Göttingen, Institute of Pathology, Göttingen, GERMANY.*

***Aim/Introduction:*** Cell cycle arrest (CCA) is a well-known reason for radiotherapy treatment failure. It is expected that CCA might also affect the outcome of radioligand therapy. In the context of PSMA-ligand diagnostics and therapy, there is still little known about the relationship between PSMA expression and the cell cycle of prostate cancer cells (PC). Therefore, we investigated the effect of androgens (AN) on the cell cycle of prostate cancer cell lines and their uptake of PSMA radiopharmaceuticals as a model for the discontinuation of antiandrogen therapy. ***Materials and Methods:*** Two different human PC cell lines LNCaP und VCaP (ATCC) were used. In LNCaP the castration resistance (CR) bases on androgen receptor (AR)-mutations (AR-T878A) while in VCaP a wild type (WT) AR overexpression has been observed. VCaP were grown permanently with testosterone (T, revCRPC) or without T (CRPC). RevCRPC-cultures represent therefore the androgen sensitive cell type, CRPC the castration resistant VCaP (CRPC). All three cell lines were 48 h incubated with respectively 1 nmol/L T, dihydrotestosterone (DHT) and R1881 as well as 5nmol/L 3β-androstanediol (A) and 3α-A , Thereafter, the Ga-68-PSMA-11 uptake after 3 h as well as the percentage of the cells in the different phases of the cell cycle were determined. ***Results:*** In the AR-mutated LNCaP the incubation with AN did not influence the radiopharmaceutical uptake significantly. In androgen-sensitive revCRPC the uptake of Ga-68-PSMA-11 increased >30 % ($p < 0.05$) after AN withdrawal. In CRPC the incubation with testosterone doubled the uptake ($p<0.05$). The incubation with 3αA, R1881 und DHT resulted in an increase of the radiopharmaceutical uptake-of >400 % ($p<0.01$). This increase was associated with an increase of cell fraction in CCR in G0/G1 ($p<0.05$) and a significant decrease ($p<0.005$) of the cell fraction in the other phases of cell cycle. ***Conclusion:*** The expression of PSMA in WT AR-cell lines can be significantly influenced by changes in AN supplementation. The association of a higher radiopharmaceutical uptake with a cell cycle arrest point to a cell cycle dependent expression of PSMA with potential consequences for imaging and therapeutic approaches in vivo.

### EP-0003

**Synthesis and in vitro evaluation of a small molecule $^{99m}$Tc-G2C-CBM as potential PD-L1 imaging agent**

***Z. Chen***[1,2,3], *D. Zhu*[1,4], *C. Lu*[1,2,3];
[1]*Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA,* [2]*NHC Key Laboratory of Nuclear Medicine, Wuxi, CHINA,* [3]*Jiangsu Key Laboratory of Molecular Nuclear Medicine, Wuxi, CHINA,* [4]*Department of Radiopharmaceuticals, School of Pharmacy, Nanjing Medical University, Nanjing, CHINA.*

***Aim/Introduction:*** The checkpoint blockade immunotherapy of PD-1/PD-L1 has become a potent treatment strategy for cancers. However, the objective response rate of this immunotherapy is below 30%, which is expected to be improved. Expression level of PD-L1 play a key role in the guidance of immunotherapy, which could be quantified by noninvasive imaging with radiotracers. In this study, we develop a $^{99m}$Tc labeled small molecule compound for PD-L1 imaging. ***Materials and Methods:*** The labeling precursor N - [2 - (3-cyanobenzene-1-methoxy) - 4 - (2- bromo-3-phenylbenzyloxy) - 5-chlorobenzyl] - N-sericylglycylglycylcysteine (G2C-CBM) was synthesized from 2-bromo-3-iodotoluene in a seven-step reaction sequence. Using $SnCl_2$ as reducing agent, and in the presence of sodium glucoheptonate, a series of studies were performed to optimize labeling efficiency of $^{99m}$Tc-G2C-CBM. The radiolabeling yield (RLY) and radiochemical purity (RCP) of $^{99m}$Tc-G2C-CBM were determined by high performance liquid

chromatography (HPLC). The in vitro stabilities of $^{99m}$Tc-G2C-CBM was determined every 1h at room temperature. The partition coefficient of $^{99m}$Tc-G2C-CBM was determined in n-octanol and phosphate buffer (PB) (pH 7.4) and the uptake of $^{99m}$Tc-G2C-CBM was performed in PD-L1 positive cell (A375-hPD-L1) and PD-L1 negative cell (A375). ***Results:*** The chemical structures of the labeling precursor and its intermediates were verified by IR, $^{1}$HNMR and MS. RLY and RCP of $^{99m}$Tc-G2C-CBM were over 93% at selected condition. $^{99m}$Tc-G2C-CBM was stable up to 6 h in phosphate-buffered solution (PH=7.4) and radiochemical purities was over 90% at selected condition. Partition coefficient (lgP) of $^{99m}$Tc-G2C-CBM was 1.31 at pH 7.4 of the phosphate buffer. The uptake of $^{99m}$Tc-G2C-CBM in A375-hPD-L1(25.84%) cell is significantly higher than that in A375(4.09%) cell after co-incubated for 4 hours. ***Conclusion:*** $^{99m}$Tc-G2C-CBM is probably a potential SPECT PD-L1 imaging agent and further study is needed.

## EP-0004

### Robustness of radiomic features in dopamine transporter imaging with single photon emission tomography

***V. Laskov***[1,2], *P. Choniawko*[1,2], *D. Rotbauer*[2];
[1]*University Hospital Kralovske Vinohrady, Department of Radiology and Nuclear medicine, Prague, CZECH REPUBLIC,* [2]*Third Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC.*

***Aim/Introduction:*** In this study, we are assessing the robustness of radiomic features in dopamine transporter imaging (DaT) with single photon emission tomography (SPECT) with different reconstruction parameters using an anthropomorphic head phantom with tissue heterogeneity of our own production. ***Materials and Methods:*** We made an anthropomorphic head phantom with tissue heterogeneity, produced using a personal 3D printer. Polylactide was used as the 3D printing material for soft tissue with 82% infill. Bone was subsequently reproduced by pouring liquid plaster (plaster powder and water ratio 2:1) into the cavity of the phantom. A new cavity in the supposed region of basal ganglia was made. A cotton ball with 10 MBq of DAT SPECT radiotracer (123I-Ioflupane) was inserted. 10 MBq corresponds to the approximal brain 5% uptake after 3-4 hours from the injection. Scans were performed on the two-detector hybrid camera with acquisition parameters corresponding to international guidelines for DaT SPECT imaging. Low-dose computer tomography scan of the phantom was performed in order to calculate the attenuation correction(AC) map. SPECT reconstruction was performed on a clinical workstation using OS-EM iterative reconstruction with and without AC, and FBP algorithms. OS-EM reconstructed data had no post-filtering applied. FBP data were prefiltered using a Butterworth filter.Reconstructed data was uploaded to LifeX software, for our proposed analysis 165 radiomics features were extracted from the region of interest separately for each reconstruction and attenuation correction variant.Statistical analysis was made in RStudio software using Intraclass Correlation Coefficient(ICC) function from psych. package. Statistical significance was determined for $p<0.05$. ***Results:*** Overall radiomic features in different reconstruction parameters showed a moderate repeatability rate with ICC 0.636 ($p<0.01$, 95% CI (0,577-0,696). For each group of radiomic features, repeatability was different, with the highest repeatability rate (ICC 0.998 ($p<0.01$, 95% CI [0,997-1]) in GLRLM features, and the lowest repeatability rate (ICC 0.636 ($p<0.01$, 95% CI [0,500-0,780]) in intensity based features. ***Conclusion:*** We have identified that overall radiomics features extracted from DaT SPECT show a moderate repeatability rate within different reconstruction parameters. These results make radiomic features suitable for clinical practice and human studies, but awareness of feature selection should be held, as some groups of radiomic features are more repeatable and thus more robust than others. Descriptors of the relationships between image voxels (GLCM, RLM, SZM, NGTDM) derived textures show an excellent rate of repeatability, which gives them the highest potential for future studies in patients with Parkinsonism and clinical translation.

## EP-0005

### Sinomenine Hydrochloride enhances Trametinib-induced iodide-handling gene expression and radioiodine uptake

***J. Zhang****, A. Yang;*
*The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, CHINA.*

***Aim/Introduction:*** Radioiodine therapy is one of the main treatments after surgery for differentiated thyroid cancer (DTC). However, the downregulation of iodide-handling gene presents difficulties for radioiodine therapy in DTC cells. Thyroid cancer frequently exhibits activation of the RAS/RAF/MEK/ERK pathway. Targeted therapy has been applied in the treatment of advanced, metastatic, radioiodine-refractory thyroid cancer. Our previous study has found sinomenine hydrochloride (SH) can promote redifferentiation and radioiodine uptake in DTC. We hypothesized that addition of SH could be a rational complement to MEK inhibitor trametinib in treating thyroid cancer. ***Materials and Methods:*** The experiments focused on DTC cells, including BCPAP and TPC-1. RT-qPCR was performed to determine the expression of NIS genes after SH and trametinib addition. NIS, p-ERK, t-ERK protein were detected by Western blot after treatment with different concentrations of SH. Use γ counter to detect changes in cellular iodide uptake. ***Results:*** We observed upregulation of ERK expression with SH treatment, an effect abrogated by trametinib. SH increased the expression of NIS mRNA and protein at different concentrations. Further studies revealed that the expression of NIS mRNA and protein was significantly increased in the combination treatment group compared with the SH treatment alone or trametinib alone. Radioiodine uptake was also increased in the combination therapy group. ***Conclusion:*** Combination of SH and trametinib induces DTC cells redifferentiation and radioiodine uptake. It will lay the theoretical foundation for future clinical research and application.

## EP-0006

### "In house" radiolabeling of anti-PD-L1 monoclonal antibodies with 111-Indium for in vivo imaging

***F. Silva***[1], *R. Lopes*[1], *A. S. Capacho*[1], *M. Fortunato*[1,2], *S. Vaz*[1], *F. Oliveira*[1], *C. João*[1], *D. Costa*[1];
[1]*Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*Nova School of Science and Technology, Lisbon, PORTUGAL.*

***Aim/Introduction:*** At present, the assessment of cancer immune checkpoint inhibitors expression, such as PD-L1, is obtained via biopsy followed by immunohistochemistry. However, biopsies may be unduly aggressive due to the anatomical location of the tumor, and may not translate entire tumor burden disease heterogeneity. The combination of Immunology and Radiopharmacology has the potential for developing new diagnostic strategies aimed at improving patient selection for immunotherapy, predicting early responses and side effects. This work aims to radiolabel, in house, anti-PD-L1 monoclonal

antibodies (MPDL3280A and 6E11) with Indium-111 ($^{111}$In), in order to obtain their in vivo whole-body imaging distribution. Its success will provide essential knowledge and expertise for subsequent radiolabeling of other monoclonal antibodies for clinical applications. ***Materials and Methods:*** An excess (50:1) of a DTPA derivative was used to conjugate to MPDL3280A and 6E11, and radiolabeling procedures were performed by reacting the DTPA-containing antibodies with $^{111}InCl_3$. In vitro stability studies of the radiolabeled antibodies were performed in the presence of 0,9% NaCl and cell culture media, DMEM and RPMI. Assessment of the PD-L1 binding capability of the antibodies was performed through cell cytometry studies in human (MCF7 and H2444) and murine (E0771, LLC, B16F10, MOPC315, MOPC315.BM) cancer cell lines, and cellular uptake studies on high (H2444 and MOPC315) and low (MCF7 and LLC) PD-L1 expressing cells. ***Results:*** DTPA was conjugated to the antibodies and the $^{111}$In-labeled MPDL3280A and 6E11 were obtained with >95% radiochemical purity. In vitro stability studies showed that after 48 h of incubation both antibodies retained >90% of the coordinated $^{111}$In. Flow cytometry analysis demonstrated a higher expression of the anti-PD-L1 antibodies on the H2444 and MOPC315 cell lines, intermediate expression on the E0771, LLC, B16F10, and MOPC315.BM cells and no expression on MCF7 cell lines. For the cellular uptake studies, $^{111}$In-MPDL3280A-DTPA displayed the highest uptake in H2444 cells, with 10.48% I.D./$10^6$ cells at 24 h post incubation, compared with low expressing PD-L1 MFC7 cells (0.45% I.D./$10^6$ cells). For $^{111}$In-6E11-DTPA, the uptake difference was less accentuated, with 2.35% I.D./$10^6$ cells at 24 h for the higher PD-L1 expressing MOPC315 cells; however, it was noteworthily higher when compared with the low PD-L1 expressing LLC cell line (0.42% I.D./$10^6$ cells). ***Conclusion:*** $^{111}$In-labeled MPDL3280A and 6E11 were successfully obtained and the resulting antibodies showed significant binding affinity towards higher PD-L1 expressing cancer cell lines, which makes them promising candidates for potential imaging of PD-L1 expression in vivo.

## EP-0007

### The high affinity angiotensin AT2 receptor agonist, C21, inhibits proliferation and induces cell death in prostate cancer cells by an AT2 receptor-independent mechanism

***Y. Zhao***, *M. Marx, U. Lützen, M. Zuhayra;*
*Department of Nuclear Medicine, Molecular Imaging, Diagnostics and Therapy, UKSH, Kiel, GERMANY.*

***Aim/Introduction:*** Several studies carried out in different tumours indicate that activation of the angiotensin type 2 ($AT_2$) receptor inhibits cell proliferation and initiates apoptosis. In the present study, we investigated in prostate - specific membrane antigen (PSMA) positive prostate carcinoma (PCa), LNCaP cells: 1) the expression of $AT_2$ receptors, 2) the effect of the activation of the $AT_2$ receptor on proliferation and apoptosis, 3) the role of the $AT_2$ receptor in the PSMA-expression. The effects detected in LNCaP cells were compared with those obtained in PC3 cells, PSMA-negative PCa cells. ***Materials and Methods:*** Selective stimulation of $AT_2$ receptors was achieved by a 24 h exposure of cells either to angiotensin II (Ang) II ($10^{-7}$ M) in the presence of the selective $AT_1$ receptor antagonist, losartan ($10^{-6}$ M), or to the high-affinity $AT_2$ receptor agonist, C21 ($10^{-6}$ M). PD 123177 ($10^{-6}$ M) was used as the selective $AT_2$ receptor inhibitor. The expression of $AT_2$ receptors and PSMA were quantified by Western blotting. The cell growth and cell death were analysed by WST-1 assay and LDH-release into the culture medium, respectively. Histological assessment of cell proliferation was accomplished by observation of cresyl violet stained cells using an inverted light microscope. ***Results:*** Both, LNCaP and PC3 cells express the AT2 receptor. Stimulation of the membrane $AT_2$ receptors with Ang II + losartan in LNCaP cells did not inhibit cell proliferation nor did it induce cell death. However, the $AT_2$ receptor agonist, C21, which interacts with both, the membrane and intracellular $AT_2$ receptors, significantly reduced cell proliferation and increased LDH release, indicating that C21 induced cell death. Experiments employing cresyl violet staining confirmed the cell death-promoting effects of C21. The effects of C21 were more pronounced in PSMA-positive LNCaP cells than in PSMA-negative PC3 cells. Inhibition of $AT_2$ receptors in LNCaP cells by PD123177 did not affect the effects of C21. The $AT_2$ receptor inhibitor actually potentiated the cell death-promoting effects of the agonist as evidenced by further enhanced LDH release. In addition, C21 reduced the expression of PSMA in LNCaP cells. ***Conclusion:*** We demonstrate that the C21 induces rapid cell death in LNCaP cells most probably via activation of intracellular $AT_2$ receptors. The down-regulation of PSMA expression might point to a possible mechanism responsible for the observed effects of C21. Our results indicate that treatment of PCa with C21 may reduce the progression of the disease.

## EP-0008

### Microleakage evaluation of new composite resins for posterior teeth: bioactive resins vs bulk fill resins

***A. Pires Lourenço***[1,2,3], *C. M. Marto*[2,3,4], *A. Coelho*[2,3,4], *M. V. Pinto*[4], *P. Neves*[4], *I. Amaro*[2,3,4], *J. Sousa*[4], *M. Marques Ferreira*[2,3,5], *E. Carrilho*[2,3,4], *M. Laranjo*[1,2,3], *A. M. Abrantes*[1,2,3], *M. F. Botelho*[1,2,3], *A. B. Paula*[2,3,4];
*[1]Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Institute of Biophysics, Faculty of Medicine, Coimbra, PORTUGAL, [2]Univ Coimbra, Center for Innovative Biomedicine and Biotechnology (CIBB), Coimbra, PORTUGAL, [3]Clinical Academic Center of Coimbra (CACC), Coimbra, PORTUGAL, [4]Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO); Institute of Integrated Clinical Practice and Laboratory for Evidence-Based Sciences and Precision Dentistry, Faculty of Med, Coimbra, PORTUGAL, [5]Univ Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO); Institute of Endodontics and Laboratory for Evidence-Based Sciences and Precision Dentistry, Faculty of Medicine, Coimbra, PORTUGAL.*

***Aim/Introduction:*** Posterior tooth restorations are a sensitive technique that depends on the type of adhesive systems and composite resins used. There are some recent resins that intend to reduce the sensitivity of the technique either by using larger increments with less polymerization shrinkage (bulk fill resins) or by direct adhesion to the tooth structure without the need of the adhesive system (bioactive resins).The aim of the present study was to compare microleakage in restorations using a new bioactive resin Surefill One™, SDR®flow bulk fill resin and Spectra™ST conventional nanohybrid resin. The null hypothesis is that there are no microleakage variations between the various resins studied. ***Materials and Methods:*** An in vitro study was carried out using fifty-two premolars and molars extracted for orthodontic reasons. Identical preparations were thus performed in all of them (Class V with 4 mm mesio-distal, 3 mm occluso-gingival and 3 mm in depth) and divided into different experimental groups: 1 positive control, 1 negative control and 3 tests with bioactive composite resin (Surefill One™), bulk fill flow resin (SDR®flow), and conventional nano-hybrid composite resin (and Spectra™ST). Through quantitative techniques using Nuclear Medicine, it

was possible to evaluate microleakage using a radioactive isotope, technetium. Radioactivity emitted by the specimens was detected by a gamma camera. The different groups were compared using the ordinary one-way ANOVA and Tukey's test for multiple comparisons. ***Results:*** The results of the experimental study point to statistically significant differences between the test groups ($p = 0.002$), with increased microleakage in the bioactive composite resin group. The negative control group has the lowest microleakage. The positive control presents the highest microleakage with statistically significant differences compared to all other groups, Surefill ($p<0.05$), SDR ($p<0.001$) e Spectra ($p<0.001$). In the test groups, the conventional nanohybrid resin ($p<0.001$) and the bulk fill resin ($p<0.001$) showed statistically lower microleakage values than the bioactive resin. There were no statistically significant differences between the nanohybrid resin and the bulk fill resin, both presenting low microleakage values. ***Conclusion:*** The microleakage technique with Nuclear Medicine is validated by the results of the positive and negative control groups. The application of adhesive systems prior to the composite resin remains recommended. Bioactive resins do not have sufficient adhesiveness to perform well on posterior teeth. Bulk fill resins present similar results to conventional nano-hybrid resins, thus presenting a clinical advantage due to use in larger increments, reducing appointment times and technique sensitivity.

## EP-0009

### [99mTc][Tc-HYNIC-scFvD2B] vs [99mTc][Tc(CO)3(scFvD2B-HisTag)] for the imaging SPECT of prostate cancer: preliminary in vitro studies

***C. Gobbi***[1], *L. Melendez-Alafort*[2], *B. Spolaore*[3], *N. Salvarese*[1], *D. Carpanese*[2], *V. Rossi*[2], *A. Rosato*[2,4], *G. Fracasso*[5], *C. Bolzati*[1];
[1]*Institute of Condensed Matter Chemistry and Energy Technologies - National Research Council, Padua, ITALY,* [2]*Istituto Oncologico Veneto IOV-IRCSS, Padua, ITALY,* [3]*Department of Pharmaceutical and Pharmacological Sciences, University of Padua, Padua, ITALY,* [4]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padova, ITALY,* [5]*Department of Biomedical Sciences, University of Padua, Padua, ITALY.*

***Aim/Introduction:*** scFvD2B is a single-chain variable fragment of the IgGD2B antibody, specific for the extracellular domain of prostate membrane antigen (PSMA), overexpressed in prostate cancer (PCa). Its small size allows a greater penetration into the tumour tissue and a faster elimination from blood than whole antibodies. With its short biological half-life, it can be coupled with short half-life radionuclide (e.g. $^{99m}$Tc) to be used as imaging agent[1].In this study succinimidyl-HYNIC hydrochloride (S-HYNIC) was randomly conjugated to scFvD2B and then labelled with $^{99m}$Tc; additionally the corresponding scFvD2B-HisTag, was site-specifically tagged with $[^{99m}Tc][Tc(CO)_3(OH_2)_3]^+$ thanks to the presence of the hexahistidine-tag motif on its C-terminal portion. The two radioimmunoconjugates (RIC) were characterized and their in vitro stability and affinity to the PSMA receptor in PCa cell lines were compared. ***Materials and Methods:*** 2 mg/ml of native scFvD2B was conjugated to S-HYNIC (1:10 molar ratio). Radiosynthesis was carried out at 37°C for 1 hour, adding $[^{99m}Tc][TcO_4]^-$ (500-720 MBq) to a vial containing HYNIC-scFvD2B (70-150 µg), $SnCl_2$ and EDDA/Tricine mixture as coligands.scFvD2B-HisTag (100-150 µg) was incubated with $[^{99m}Tc][Tc(CO)_3(OH_2)_3]^+$ (500-720 MBq; obtained with the IsoLink® kit) at 37°C for 2 hours.Both RICs were purified by gel filtration. Stability was evaluated by HPLC after incubation at 37°C for 24h in different media and transchelating agents. Cell studies were assed in PSMA(+) cell line (LNCaP and PC3-PIP) and PC3(-) as negative control. ***Results:*** $[^{99m}Tc]$[Tc-HYNIC-scFvD2B] was obtained with a RCY up to 50%, instead the RCY of $[^{99m}Tc][Tc(CO)_3$(scFvD2B-HisTag)] was in the range of 23-43%. After purification, RCP were higher than 95% for both RICs. They were stable in media over the investigation time.For $[^{99m}Tc]$[Tc-HYNIC-scFvD2B] cell uptake and internalization values were: 7% and 6% in LNCaP; 12% and 10% in PC3-PIP; 1,5% and 0,5% in PC3. While for $[^{99m}Tc][Tc(CO)_3$(scFvD2B-HisTag)], cell uptake and internalization were: 6% and 4% in LNCaP; 30% and 15% in PC3-PIP; and 3% and 0,7% in PC3. Blocking studies with an excess of native scFvD2B confirmed the specificity of RICs for PSMA-receptor. ***Conclusion:*** $[^{99m}Tc]$[Tc-HYNIC-scFvD2B] and $[^{99m}Tc][Tc(CO)_3$(scFvD2B-HisTag)] were stable and produced in high RCP. $[^{99m}Tc][Tc(CO)_3$(scFvD2B-HisTag)] internalization in PC3-PIP was higher than that observed for $[^{99m}Tc]$[Tc-HYNIC-scFvD2B], but in LNCaP they were comparable. In vivo studies for both RIC are now in progress. Acknowledgement to AIRC (IG-2020 ID 24528) for financial support. ***References:*** 1. Mitri et al. 2021 Adv. Nat. Sci: Nanosci. ## EP-0010

### 161Tb-PSMA-I&T and177Lu- PSMA-I&T treatment in T23 and ST4787 prostate cancer cell lines - a model representative of177Lu-PSMA-resistant prostate cancer phenotype

***M. Kirienko***, *E. Jachetti, R. Sulsenti, C. Pascali, A. Bogni, M. Colombo, E. Seregni;*
*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY.*

***Aim/Introduction:*** Our objective was to evaluate the effect on cell proliferation of $^{161}$Tb-PSMA-I&T and $^{177}$Lu- PSMA-I&T in cell lines representative of castration resistant prostate adenocarcinoma (T23) and neuroendocrine prostate cancer (ST4787). ***Materials and Methods:*** We used two murine cell lines T23 and ST4787 transfected to overexpress human PSMA utilizing puromycin (PURO) selection based lentiviral system (T23-Folh1-PURO and ST4787-Folh1-PURO). PSMA expression was then checked by western blot. Tumor cells (7500 cells for ST4787 and 5000 cells for T23 in 1 mL medium with supplements) were seeded in plates. After adhesion and washing, the cells were incubated in 1ml medium with supplements containing $^{161}$Tb-PSMA-I&T or $^{177}$Lu-PSMA-I&T (0.1–10 MBq/mL), respectively, or just medium. In the first set of experiments the radiopharmaceutical-containing medium was left standing for the whole incubation time, while it was removed after 4 hours in the second set. The tumor cells were left to grow for 7 days. Tumor cell viability was assessed through cell count with Image J and it was quantified as percentage of cell count of control (untreated) cell samples. The results were analyzed for statistical significance by One-way ANOVA with Turkey's multiple comparisons test. ***Results:*** Both T23-Folh1-PURO and ST4787-Folh1-PURO, tested after infection and after at least two passages of puromycin selection, were positive for PSMA.In the first experiment, the reduction of viability of T23-Folh1-PURO and ST4787-Folh1-PURO tumor cells after exposure to $^{161}$Tb-PSMA-I&T and $^{177}$Lu-PSMA-I&T was observed not earlier than 7 days using 10MBq/ml. A viability reduction for T23-Folhl-PURO cells was observed also using 5 MBq/mL of $^{161}$Tb-PSMA-I&T, while $^{177}$Lu-PSMA-I&T did not provoke any change. In the second experiment, both cell lines resulted resistant to both radiopharmaceuticals at all the tested activities (0.5-10 MBq/ml). ***Conclusion:*** We observed that PSMA-overexpressing tumor cells

may not respond to PSMA-targeting radiopharmaceuticals and postulated that the mechanism might have similarity with the clinical observations; indeed, up to approximately 30% of patients experience disease progression (1). Our model could be useful for studying the effects of PSMA-directed radioligand treatments to identify mechanisms of resistance to $^{177}$Lutetium-labelled compounds and to identify possible combination treatment strategies. $^{161}$Terbium-PSMA-I&T showed promising results in overcoming resistance. ***References:*** 1- Sartor et al. Lutetium-177-PSMA-617 for Metastatic Castration-Resistant Prostate Cancer. N Engl J Med 2021; 385:1091-1103

### αvβ3 integrin-selective RGDechi peptides labelled with [99mTc][Tc(N)(PNP)]- and [99mTc][Tc-HYNIC]- systems: an in vitro comparison

***C. Bolzati***[1], *C. Gobbi*[1], *N. Salvarese*[1], *A. Giorgio*[2], *D. Carpanese*[3], *V. Rossi*[3], *L. Melendez-Alafort*[3], *A. Rosato*[3,4], *M. Saviano*[5], *A. Del Gatto*[2], *L. Zaccaro*[2];
[1]*Institute of Condensed Matter Chemistry and Energy Technologies, ICMATE-CNR, PADOVA, ITALY,* [2]*Institute of Biostructures and Bioimaging, IBB-CNR, Napoli, ITALY,* [3]*Istituto Oncologico Veneto, IOV-IRCCS, PADOVA, ITALY,* [4]*Department of Surgery, Oncology and Gastroenterology, University of Padua, DiSCOG-UniPD, Padova, ITALY,* [5]*Institute of Crystallography, IC-CNR, Bari, ITALY.*

***Aim/Introduction:*** Recently, chimeric RGD-echistatin peptides, selective for $\alpha_v\beta_3$, have been proposed as antiangiogenic agents. Radiolabelled derivatives have also been proposed for the selective imaging of $\alpha_v\beta_3$ expressing tumours. The low serum stability of the forefather peptide, named RGDechi, led to the development of the more stable truncated derivates RGDechi[1-17] and ψRGDechi. In this study, the two peptides were labelled with technetium-99m via [$^{99m}$Tc][Tc(N)(PNPn)]- (PNPn=diphosphinoamine) and [$^{99m}$Tc][Tc-HYNIC]- (Tc-organohydrazine) systems. The radiolabelled peptides were compared in their in vitro stability and affinity to $\alpha_v\beta_3$ integrin in expressing cell lines. ***Materials and Methods:*** [$^{99m}$Tc(N)PNPn]-labelled peptides were efficiently prepared adopting the classical two-step procedure. The first-step is required to produce a mixture of reactive $[^{99m}Tc(N)]^{2+}_{int}$ precursors. In the second-step, the reactive $[^{99m}Tc(N)]^{2+}_{int}$ was transformed into the final compound by the rapid addition of the pertinent PNPn (water-soluble PNP3OH={[$(OHCH_2)_2PCH_2CH_2]_2NCH_2CH_2OCH_3$}); more lipophilic PNP43={[$(CH_3)_2PCH_2CH_2]_2NCH_2CH_2OCH_3$}), RGDechi peptide derivative, and phosphate buffer. [$^{99m}$Tc-HYNIC]-tagged peptides were obtained incubating, at 70°C for 20 min, the previously HYNIC-conjugated peptides with [$^{99m}$Tc][$TcO_4$]$^-$ in a vial containing $SnCl_2$ and EDDA/tricine as co-ligands. The stability of radiopeptides was evaluated by HPLC after incubation at 37°C in different media. Affinity to $\alpha_v\beta_3$ integrin was evaluated by cell uptake studies assed in WM-266-4 and 4T1 lines ($\alpha_v\beta_3$-positive), and HeLa ($\alpha_v\beta_3$-negative, with moderate $\alpha_v\beta_5$ expression). ***Results:*** Radiopeptides were prepared efficiently in each case. They were stable in PBS and to transchelating agents. [$^{99m}$Tc(N)PNPn]-labelled peptides showed good stability in cell culture medium, human and mouse sera, and mouse liver homogenate. In whole blood, [$^{99m}$Tc(N)PNPn(RGDechi[1-17])] were more stable than [$^{99m}$Tc(N)PNPn(ψRGDechi)]. In mouse kidney homogenate we observed a degradation for both compounds. Regarding [$^{99m}$Tc-HYNIC]-tagged peptides, their stability was low in many of the investigated milieu, including cell culture medium. Cellular studies show that only the [$^{99m}$Tc(N)PNPn(RGDechi[1-17])] series has a specific uptake in $\alpha_v\beta_3$-positive cells, the accumulation was significantly lower in HeLa cells, suggesting that [$^{99m}$Tc(N)PNPn(RGDechi[1-17])] radiopeptides are able to selectively bind $\alpha_v\beta_3$ integrin and not to cross-react with $\alpha_v\beta_5$. The amount of uptake/internalization was dependent on the nature of [$^{99m}$Tc(N)(PNPn)]-synthon. No specific bound was observed for [$^{99m}$Tc(N)PNPn(ψRGDechi)] series as well as for [$^{99m}$Tc-HYNIC]-tagged peptides. ***Conclusion:*** Stability and integrin affinity properties of RGDechi derivatives are strongly influenced by the adopted labelling technology. Among the tested compounds, only the [$^{99m}$Tc(N)PNPn(RGDechi[1-17])] series is adequately stable and has a specific uptake in $\alpha_v\beta_3$-positive cells. Thus, it was selected for further investigation. Acknowledgement to AIRC (IG-2020 ID 24528) for financial support.

## EP-0012

### Let's label biomolecules in mild conditions with the [99mTc][Tc(N)(PNP)]-system: the PNP3OH experience

***C. Bolzati***[1], *N. Salvarese*[1], *B. Spolaore*[2], *C. Gobbi*[1], *A. Vittadini*[1], *D. Forrer*[1], *S. Ghiani*[3], *A. Maiocchi*[4];
[1]*Institute of Condensed Matter Chemistry and Energy Technologies, ICMATE-CNR, PADOVA, ITALY,* [2]*Department of Pharmaceutical and Pharmacological Sciences, University of Padua, PADOVA, ITALY,* [3]*Bracco Research Centre, Bracco Imaging SpA, Torino, ITALY,* [4]*Bracco SpA, Milano, ITALY.*

***Aim/Introduction:*** The [$^{99m}$Tc][Tc(N)(PNP)]-technology has long been used to label biomolecules. The most important advantage of this technology is its high chemical flexibility; nevertheless, the usage of classical, quite lipophilic PNPs leads to the need of heating over extended times to reach high radiochemical yields. This represents a limit, because these conditions are not suitable for label temperature-sensitive biomolecules. Water-soluble phosphines are an attractive class of oxidatively stable ligands that generate stable hydrophilic chelates with good pharmacokinetics. Modification of the substituents on the P atoms induces the variation of electronic and sterical properties of the ligand, which affect its reactivity for the metal ions, influencing the reaction rate, and the stereochemistry of the final complex. Hence, the water-soluble PNP3OH, {[$(OHCH_2)_2PCH_2CH_2]_2NCH_2CH_2OCH_3$}, was designed and the effect of the substituents on the corresponding ws-[Tc(N)(PNP3OH)]$^{2+}$-framework was studied in silico through a series of density functional theory calculations and compared with those of alkyl PNP ligands (PNP3 and PNP43). The reactivity was then experimentally verified using the [$^{99m}$Tc][Tc(N)(PNP3OH)]-framework to label different biomolecules including: RGD peptides, biotin, and apomyoglobin as model protein.[1] ***Materials and Methods:*** Computational studies aimed at predicting the molecular geometry of the intermediate complexes $TcNCl_2$PNP, and of the free ligands were performed. PNP3OH was synthesized and characterized. The biomolecules mentioned above were conjugated with a terminal cysteine residue, cys~, to allow the coordination of the [$^{99m}$Tc][Tc(N)(PNP3OH)]-synthon. Radiosyntheses were performed using a two-step reaction. The receptor specificity of the radiolabelled biomolecules was assessed in-vitro in pertinent cell lines. ***Results:*** Structural variation on PNP alters the coordination geometry of the $TcNCl_2$PNP precursors and ligands arrangement around the metal, affecting the strength of the metal-P and metal-Cl bonding. Data show that the Tc-Cl bonds strength are weaker in [Tc(N)$Cl_2$(PNP3OH)] precursor than in the other $TcNCl_2$PNP. This makes the Cl atoms of [Tc(N)$Cl_2$(PNP3OH)] more prone to substitution and thus more reactive to nucleophilic attack by cys~. Experimental results confirm this behavior; the insertion of water-soluble groups on PNP actually improves the reactivity of [$^{99m}$Tc][Tc(N)(PNP3OH)]-framework

towards cys~. Radiosyntheses were performed efficiently under physiological conditions at RT in 30 min, using a concentration range of $10^{-5}$-$10^{-6}$ M of cys-conjugated biomolecules. All [$^{99m}$Tc][Tc(N)(PNP3OH)]-tagged biomolecules preserve their receptor targeting ability. ***Conclusion:*** Data support the effective application of the [$^{99m}$Tc(N)(PNP3OH)]-technology to the labeling of temperature-sensitive biomolecules. Acknowledgement to Bracco Imaging and AIRC (IG-2020 ID 24528) for financial support. ***References:*** 1. Bolzati et al. Mol. Pharm., 2022, 19, 3, 876-894

## EP-0013

### To study uptake of 18F-AVT-011 in different cell lines expressing p-glycoprotein.

***R. Thakur***[1], *M. Kumar*[1], *P. chaudhari*[2], *P. Kumar*[1];
[1]*National Institute of mental health and neurosciences, Bangalore, INDIA,* [2]*Advanced Centre for Treatment, Research and Education, Mumbai, INDIA.*

***Aim/Introduction:*** To study the uptake of 18F-AVT-011 in U87 (temozolomide sensitive) and LN18 cells (temozolomide resistant). ***Materials and Methods:*** 18F-AVT-011 was synthesized in our lab by a method published elsewhere[1]. The cell lines U87 (IC50 = 10-100μM) and LN18 (IC50 = 400-500 μM) were cultured in Dulbecco's modified eagle medium (DMEM). The MGMT levels and Pgp levels were evaluated by PCR and flow cytometry techniques respectively. The cells were detached using trypsin and then resuspended in equal proportion for the uptake study. Each test tube contained 1mL of cell suspension into which 10 μL (~ 0.74 MBq) of [18F]-AVT-011 was added and incubated for 15 min, 30 min, 60 min, and 120 min at 37ºC in a water bath. The blocking studies were performed by incubating the same cell suspension (1 mL) with 500-fold excess of Pgp blocking agent Tariquidar solution (5mM) for 30 min at 37ºC in a water bath and radioactivity was added as described above. The cell suspension was centrifuged. The pellet was washed thrice with normal saline, and the supernatant was collected separately in the other set of tubes. The radioactivity associated with cells and supernatant was counted in a gamma counter (Capnitec Inc), and the percentage of radioactivity bound to the cells was calculated. ***Results:*** $^{18}$F-AVT-011 was synthesized with radiochemical purity greater than 95%. methylation was more than 90% in U87 cells and ~ 4% in LN-18 cells. The Pgp levels were distinct in both cells. The Pgp levels were higher expressed in LN18 cells. The uptake of 18F-AVT-011 was 77.9 ± 0.5 % in U87 and 74.4 ± 2.9 % in LN18 cells at 15 min but it was 72.1 ± 1.7% in U87 and 9.6 ± 1.4% in LN18 and same was observed at 2 h. The radioactivity effluxed out of LN18 cells at a faster rate which may be due to the overexpression of Pgp. The blocking study showed an increase in the uptake of radioactivity after tariquidar blocking. ***Conclusion:*** $^{18}$F-AVT-011 may be a potential radiotracer for imaging Pgp activity. The validation through animal study is in progress. ***References:*** Kumar P, Thakur R, Acharya PC, Mohan HK, Pallavi UN, Maheshwari D, Mohammed K M A, Kumar A, Goud Nerella S, Joshi RK, Kumar M, Nagaraj C. Synthesis, characterization, and radiosynthesis of fluorine-18-AVT-011 as a Pgp chemoresistance imaging marker. Sci Rep. 2022 Nov 3;12(1):18584.

## EP-0014

### Dual-radionuclide detection for radiopharmaceutical studies

***J. Campeiro***, *C. D. van der Heide, J. de Swart, S. U. Dalm; Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Dual-radionuclide detection has a promising advantage for radiopharmaceutical studies. For example, research evaluating different targets expressed on prostate cancer (PCa) cells, i.e. prostate-specific membrane antigen (PSMA) and gastrin-releasing peptide receptor (GRPR), could benefit from a dual-radionuclide detection method to develop novel treatment strategies based on combined PSMA and GRPR treatment using radiopharmaceuticals labeled with different radionuclides. This is relevant as targeting both PSMA and GRPR might lead to treatment with improved efficacy and safety. However, distinguishing radionuclides, i.e. $^{111}$In, $^{177}$Lu and $^{161}$Tb, by their energy peaks of gamma rays when combined in one solution/system is hampered by the crosstalk and overlap between the energy spectra originating from each radionuclide. To enable simultaneous dual-radionuclide detection, a detector with good energy resolution or complex scatter and crosstalk correction methods are necessary. Our objective was to develop a simple method for simultaneous detection and discrimination of gamma radiation emitted by combinations of $^{111}$In, $^{177}$Lu and $^{161}$Tb. ***Materials and Methods:*** The radioactivity of a combined solution of $^{161}$Tb&$^{177}$Lu or $^{111}$In&$^{177}$Lu (1 kBq/mL per radionuclide) was measured in a HIDEX-AMG γ-counter and expressed as counts per minute (CPM). Narrow energy windows were defined to distinguish radionuclides by their energy peaks, i.e. for $^{161}$Tb&$^{177}$Lu 20-35 keV and 187-229 keV, and for $^{111}$In&$^{177}$Lu 400-480 keV and 102-124 keV, respectively. Moreover, the PSMA- and GRPR-expressing PCa PC3-PIP cell line was incubated with $10^{-9}$ M [$^{111}$In]In-NeoB and $10^{-9}$ M [$^{177}$Lu]Lu-PSMA-617 simultaneously or separately for 1 hour, whereafter cell uptake was determined using the above-mentioned energy windows. Data are expressed as percentage added dose (%AD). ***Results:*** Using the identified energy peaks for $^{161}$Tb, $^{177}$Lu and $^{111}$In we were able to distinguish the CPMs per radionuclide in solutions containing $^{161}$Tb&$^{177}$Lu or $^{111}$In&$^{177}$Lu. The same method also enabled effective determination of the radioactivity uptake per radiopharmaceutical after incubating PC3-PIP cells simultaneously with [$^{177}$Lu]Lu-PSMA-617 and [$^{111}$In]In-NeoB. Our first results showed no significant difference in uptake after combined or separate incubation (28.6±4.3 vs 34.8±4.0 %AD for [$^{177}$Lu]Lu-PSMA617 and 5.6±0.9 vs 7.2±0.3 %AD for [$^{111}$In]In-NeoB, respectively). ***Conclusion:*** Our preliminary studies demonstrated successful simultaneous $^{161}$Tb&$^{177}$Lu and $^{111}$In&$^{177}$Lu gamma ray detection in a PCa cell line; by identifying narrow energy windows specific for each radionuclide, we were able to distinguish between the radionuclide source and quantify the radioactivity uptake by the cells. This method will open new venues in preclinical radiopharmaceutical research e.g. allowing the investigation of therapies combining radiopharmaceuticals labeled with different radionuclides.

### Age Related Changes of Cellular Contributions in FDG Uptake Correlate with Metabolic Connectivity

***J. Gnörich***, *L. Bartos, A. Zatcepin, R. Schäfer, S. Kunte, P. Beumers, P. Bartenstein, N. Albert, S. Ziegler, M. Brendel; LMU Munich, Munich, GERMANY.*

***Aim/Introduction:*** 2-Fluorodesoxyglucose PET (FDG-PET) is frequently used to study glucose metabolism in mammalian brains. Alterations of glucose uptake in brain regions and brain networks occur during healthy aging. However, the cellular sources of age-related changes in FDG uptake and their impact on PET read outs during aging remain to be

elucidated. ***Materials and Methods:*** We investigated wildtype mice between 3 and 18 months of age using FDG-PET and fluorescence activated cell sorting (FACS) after in vivo tracer injection (scRadiotracing). FDG uptake per cell was quantified in isolated microglia, astrocytes and neurons. Cortical brain uptake and metabolic connectivity were determined by FDG-PET. ***Results:*** Neuronal FDG uptake strongly decreased at 18 months of age when compared to 3 and 12 months. Contrary, astrocytes and microglia showed increasing or stable FDG uptake between 12 and 18 months of age. Glucose uptake was dominated by astroglia at early (microglia predominance) and late ages (astrocyte predominance). Increases of FDG PET at late ages were explained by increasing astrocytic FDG uptake and metabolic connectivity was driven by the proportion of glucose uptake in astroglial cells. ***Conclusion:*** Trajectories of cellular glucose uptake during aging strongly differ between astroglia and neurons. Astroglial glucose uptake determines brain FDG-PET alterations and metabolic connectivity during aging.

## EP-0016

### Inhibition of PFKFB3 counteracts atherosclerosis via NLRP3/Casepase1/IL-1β pathway in macrophages

***M. Zhao***[1], *X. Wang*[2], *W. Wu*[1], *Y. Bai*[2], *X. Li*[3];
[1]*The Third Xiangya Hospital of Central South University, Changsha, CHINA,* [2]*Xiangya Hospital of Central South University, Changsha, CHINA,* [3]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Macrophages are woven into atherosclerosis occurrence and development. Inflammasome activation is a core mechanism contributing to the local high-inflammatory microenvironment in plaques. However, the trigger factor of inflammasome activation is unknown. ***Materials and Methods:*** Carotid atheroma specimens were collected from 17 patients with carotid stenosis who underwent carotid endarterectomy. High-fat western diet-treated ApoE-/- mice were selected to develop an atherosclerosis model, and a PFKFB3 inhibitor PFK158 was administered along with atherosclerosis modeling. Meanwhile, lipopolysaccharide (LPS) and TNF-γ were employed to differentiate bone marrow-derived macrophages(BMDMs) into M1-like phenotypes under either hypoxia or normoxia. The glycolytic activity was determined by in vivo 18F-FDG micro-PET/CT, ex vivo glucose uptake, and ECAR analysis; HIF-1α, PFKFB3, NLRP3, Caspase-1, and IL-1β expressions were quantified by using western-blot and real-time PCR. ***Results:*** PFKFB3 accumulations in human atherosclerotic plaques, in colocalization with NLRP3 expression and macrophages. PFK158 overruled atherosclerosis occurrence, reduced glycolytic activity, and NLRP3 inflammasome activation in murine atherosclerotic plaques. Mechanistically, hypoxia promoted glycolytic reprogramming and NLRP3 inflammasome activation in BMDMs. Blocking either HIF-1α or PFKFB3 downregulated NLRP3/Caspase-1/IL-1β pathway in hypoxic BMDMs. ***Conclusion:*** In brief, this study demonstrates that HIF-1α/PFKFB3/NLRP3 signal pathway is a crucial mechanism for inflammation activation in macrophages in atherosclerosis emergence. The targeting PFKFB3 may be a promising strategy for atheroprotection.

## EP-0017

### In vivo [18F]SMBT-1 imaging of reactive astrocytes in mouse models of Alzheimer's disease - temporospatial relationship with amyloid, tau and microgliosis

***R. Ni***[1], *Y. Kong*[2], *C. Maschio*[1], *B. Yao*[3], *J. Xiao*[2], *Q. Huang*[2], *Y. Guan*[2];
[1]*University of Zurich, Zurich, SWITZERLAND,* [2]*PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [3]*Radiopharmacy and Molecular Imaging Center, School of Pharmacy, Fudan University, Shanghai, CHINA.*

***Aim/Introduction:*** Reactive astrocytes and microgliosis play important roles in the pathophysiology of Alzheimer's disease (AD). Here, we aim to understand the association between reactive astrocytes, microgliosis, glucose metabolism, and amyloid-β in vivo in 5×FAD transgenic mice. ***Materials and Methods:*** PET with [$^{18}$F]SMBT-1 (monoamine oxidase-B) [1], [$^{18}$F]DPA-714 (translocator protein), [$^{18}$F]FDG and [$^{18}$F]florbetapir (Aβ) and [$^{18}$F]PMPBB3 (tau) [2] was carried out in 3- and 6-month-old male 5×FAD mice, and aged-matched wild-type mice. The brain regional referenced standard uptake value (SUVR) was computed with the cerebellum as reference region. Immunofluorescence staining was performed with antibodies against monoamine oxidase-B, glial fibrillary acidic protein, C3d, translocator protein, Iba1, Glut1 and amyloid-β in mouse brain slices. ***Results:*** [$^{18}$F]SMBT-1 SUVRs were higher in the cortex and brain stem of 3 and 6-month-old 5×FAD mice than age-matched wild-type mice. [$^{18}$F]DPA-714 SUVRs were higher in the 6-month-old 5×FAD mice than age-matched wild-type mice. [$^{18}$F]florbetapir SUVRs were higher in the brain stem, cortex, hippocampus and midbrain of 6-month-old 5×FAD mice than in age-matched wild-type mice. Although an amyloidosis model, 6-month-old 5×FAD mice showed increased [$^{18}$F]PMPBB3 SUVRs (tau) in the cortex and hippocampus compared to 3-month-old 5×FAD mice and age-matched wild-type mice. ***Conclusion:*** The findings provide in vivo evidence for reactive astrocytes and microgliosis at early stage in 5×FAD mice. ***References:*** 1. ## EP-0018

### A comparison of the biodistribution and the patient dose estimation of [18F]FEPP and [18F]FEAO, potential radiotracers for PET myocardial perfusion imaging

***K. Gotowicz***[1,2], *U. Karczmarczyk*[3], *S. Krajewski*[1], *E. Witkowska-Patena*[4], *L. Steczek*[1], *J. Towpik*[1], *P. Kozanecki*[1], *M. Mazur*[2], *M. Dziuk*[4,5], *J. Włostowska*[1], *C. Kozanecki*[1], *P. Garnuszek*[3];
[1]*Synektik SA, Research & Development Centre, Warsaw, POLAND,* [2]*Department of Chemistry, University of Warsaw, Warsaw, POLAND,* [3]*National Centre for Nuclear Researach, Radioisotope Centre POLATOM, Warsaw, POLAND,* [4]*Military Institute of Medicine - National Research Institute, Nuclear Medicine Department, Warsaw, POLAND,* [5]*Affidea Poland, Warsaw, POLAND.*

***Aim/Introduction:*** Positron emission tomography (PET) myocardial perfusion imaging (MPI) is an effective method for non-invasive evaluation of coronary obstruction in patients with suspected or established coronary artery disease. The aim of the study was to carry out a preclinical comparison of two potential PET-MPI radiotracers - [$^{18}$F]FEPP and [$^{18}$F]FEAO. ***Materials and Methods:*** The biodistribution of single intravenous administration of each $^{18}$F-labelled compound was assessed on healthy, male Wistar rats. The animals were in quarantine for at least 6 days before the examination and had access to water and food ad libitum. Rats were sacrificed in groups of three at 0.25, 0.5, 1, 2, 3 and 6 hour after injection for each tracer. Dissected organs/tissues of interest were weighed and measured for their radioactivity. The obtained data was extrapolated to humans using the simplest allometric scaling model. The effective doses in mSv/MBq were calculated using software for internal dose assessment OLINDA/EXM®, version 1.1. ***Results:*** The main organ of interest for cardiac tracers is the heart and surrounding organs like the liver and the lungs. The biodistribution studies showed that [$^{18}$F]FEAO uptake in the cardiac muscle was high and stable (3.02 %ID/g at 15 minute and 2.79 %ID/g at 6 hour post-injection) in contrast to [$^{18}$F]FEPP (1.84 %ID/g and 0.05 %ID/g, respectively). Both compounds were characterized by relatively low uptake in the liver (maximum 0.89 %ID/g and 0.90 %ID/g at 15 min, respectively). The uptake in the lungs was much higher for [$^{18}$F]FEAO and decreased rapidly over time (from 3.02 %ID/g at 15 min to 0.55 %ID/g at 6 h). The study showed that both radiotracers were eliminated predominantly by biliary excretion. The excretion was faster for [$^{18}$F]FEPP, therefore the estimated effective dose for human was lower for this tracer (0.00714 mSv/MBq) compared to [$^{18}$F]FEAO (0.0109 mSv/MBq). ***Conclusion:*** The myocardial [$^{18}$F]FEAO uptake was much higher and stable in time revealing more favourable biodistribution profile in comparison to [$^{18}$F]FEPP. It also showed modest radiation exposure, comparable to the other $^{18}$F-labelled compounds used in MPI [1]. Encouraging results merit tracer evaluation in further clinical studies. The study was funded by the National Centre for Research and Development, Poland, grant no. POIR.01.01.01-00-0089/15. ***References:*** [1] Maddahi J, et al. Phase I, first-in-human study of BMS747158, a novel $^{18}$F-labeled tracer for myocardial perfusion PET: dosimetry, biodistribution, safety, and imaging characteristics after a single injection at rest. ## EP-0019

### Early brain [18F]FDG PET imaging predicts the long-term behavioral impact of exposure to sublethal doses of organophosphates: a longitudinal study in mice exposed to NIMP, a sarin surrogate

***A. Soyer***[1], *A. Champault*[2], *S. Leterrier*[1], *C. Corvo*[1], *L. Breuil*[1], *B. Hosten*[1], *W. Saba*[1], *C. Leroy*[1], *A. Winkeler*[1], *G. Dal Bo*[2], *K. Thibault*[2], *N. Tournier*[1];
[1]*Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), CEA, CNRS, Inserm, Service Hospitalier Frédéric Joliot, Université Paris-Saclay, Orsay, FRANCE,* [2]*Institut de Recherche Biomédicale des Armées (IRBA), Bretigny-sur-Orge, FRANCE.*

***Aim/Introduction:*** Organophosphate compounds (OPs) are still widely used as pesticides. Moreover, the use of OP nerve agents such as sarin as warfare neurotoxicants remains a threat. The acute and often lethal effects of high-dose exposure to OPs are widely studied. However, long-term neuro-psychiatric impairment has been reported in subjects exposed to sublethal, often asymptomatic doses of sarin. The aim of this study was to perform a longitudinal monitoring of brain function and behavior in a validated mouse model of OP exposure. We hypothesized that [$^{18}$F]FDG PET imaging may provide an early neuroimaging biomarker to monitor the central nervous system impact of sublethal exposure to OPs. ***Materials and Methods:*** A longitudinal brain [$^{18}$F]FDG microPET study was conducted in male Swiss mice. All animals were scanned at baseline, at day 1, day 7 and 1 month after administration of a single sublethal dose of 4-nitrophenyl isopropyl methylphosphonate (NIMP, 0.315 mg/kg, s.c, 50% of the LD50, n=12), a sarin surrogate, or vehicle (n=4, control). [$^{18}$F]FDG was injected intraperitoneally in awake mice which were then transferred in a cage for 50 min to allow for brain uptake. Mice were then anesthetized using isoflurane to provide 20 min of static PET acquisition. SUV-normalized [$^{18}$F]FDG PET images were co-registered to a mouse brain template. Finally, 1 month after NIMP exposure, each mouse underwent behavioral tests to assess anxiety (elevated plus maze, EPM) and cognitive performance (Y-maze). ***Results:*** Compared to baseline, a significant decrease in regional [$^{18}$F]FDG uptake was observed in certain brain regions of NIMP-treated mice on days 1 and 7. The decrease in [$^{18}$F]FDG uptake was progressive and significant in the amygdala, midbrain and cortex ($p<0.001$). Normal [$^{18}$F]FDG brain uptake was restored at 1 month ($p>0.05$). Such decline in [$^{18}$F]FDG uptake was not observed in control mice ($p>0.05$). Behavioral study at 1 month did not evidence change in cognitive performance ($p>0.05$). However, a higher level of anxiety compared with control animals was observed (decreased time spent in the open arm, $p<0.05$). Individual analysis showed that the level of anxiety was significantly correlated with the decrease in [$^{18}$F]FDG uptake in the amygdala at day 7 (both parameters expressed as % versus control animals, $r^2=0.906$, $p<0.001$). ***Conclusion:*** This longitudinal study shows the dynamics of altered brain glucose metabolism after sublethal exposure to OPs. Our results suggest that early [$^{18}$F]FDG PET data may predict the long-term behavioral impact of OP exposure, at least for anxiety.

## EP-0020

### Comparison of intravenous and oral administration of [18F]MC225: a feasibility study in rats

***G. Salvi de Souza***[1,2], *J. W. Sijbesma*[1], *J. Doorduin*[1], *A. M. Marques da Silva*[3,4], *C. R. Furini*[2,5], *A. A. Lammertsma*[1], *C. Tsoumpas*[1], *G. Luurtsema*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*School of Medicine, PUCRS, Porto Alegre, BRAZIL,* [3]*Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, BRAZIL,* [4]*Medical Imaging & Data Analytics, San Diego, CA, UNITED STATES OF AMERICA,* [5]*Laboratory of Cognition and Memory Neurobiology, Brain Institute, PUCRS, Porto Alegre, BRAZIL.*

***Aim/Introduction:*** [$^{18}$F]MC225 is a positron emission tomography (PET) tracer to measure the P-glycoprotein (P-gp) function, which plays a dynamic role in the bioavailability of (orally) administered drugs [1]. Nearly all drugs are given orally and, therefore, oral administration of an appropriate PET tracer should be a useful method for investigating the absorption of tracers in the gut and its relation to bioavailability and uptake in other organs. This pilot study aimed to compare the brain uptake and distribution of [$^{18}$F]MC225 following oral and intravenous administrations in healthy rats. ***Materials and Methods:*** Six adult male Wistar rats were divided into two groups: a control group for intravenous administration of [18F]MC225 and a second group for oral administration of the tracer. The control group (n=3, 309±10 g), anaesthetised with a combination of ketamine and dexmedetomidine, received 37 MBq in a tail vein. The second

group (n=3, 324±5 g) received 10 MBq orally by gavage before being anaesthetised using the same protocol. Approximately 120 minutes post-administration, animals were euthanized and brains were dissected and blood was collected via heart punction. The brain regions evaluated were olfactory bulbs, left cerebral hemisphere, right cerebral hemisphere, midbrain, and cerebellum. Data obtained using a gamma counter were transformed into tissue to blood ratio (TBR) units. TBR values are presented as mean ± standard deviation. ***Results:*** Mean TBR values for the intravenous group were higher than those for the oral group across all regions evaluated: 2.02 ± 0.77 vs 1.30 ± 0.09 for the olfactory bulbs, 2.05 ± 0.39 vs 1.14 ± 0.02 for the left cerebral hemisphere, 2.10 ± 0.51 vs 1.16 ± 0.04 for the right cerebral hemisphere, 1.86 ± 0.34 vs 1.15 ± 0.09 for the midbrain, and 1.78 ± 0.43 vs 1.12 ± 0.07 for the cerebellum. The ratios between oral and intravenous TBR ranged from 0.54 to 0.64. ***Conclusion:*** Oral administration of [$^{18}$F] MC225 in healthy rats results in lower brain uptake (120 minutes after administration) compared with intravenous administration. However, oral administration still results in detectable tracer levels in the brain and, as such, it may have relevance for studying the gut-brain axis. Further dynamic imaging studies are needed to investigate the optimal oral administration protocol and the best interval for data acquisition. ***References:*** [1] Elmeliegy, Mohamed, et al. "Effect of P-glycoprotein (P-gp) inducers on exposure of P-gp substrates: review of clinical drug-drug interaction studies." Clinical pharmacokinetics 59 (2020): 699-714.

## EP-0021

### Short-term synaptic remodeling in a rat model of alcohol binge drinking assessed using [11C]UCB-J PET imaging

***C. CORVO***[1], *C. Leroy*[2], *S. Letterier*[2], *S. Goutal*[2], *F. Caille*[2], *A. Soyer*[2], *M. Goislard*[2], *S. Amargier*[2], *N. Tournier*[2], *W. Saba*[2];
[1]*Université Paris-Saclay, Inserm, CNRS, CEA, Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), ORSAY, FRANCE,* [2]*Université Paris-Saclay, Inserm, CNRS, CEA, Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), Orsay, FRANCE.*

***Aim/Introduction:*** Binge drinking (BD) is characterized by a massive alcohol consumption in a short period of time and is mainly seen amongst teenagers, at a vulnerable period of brain development and maturation. Deleterious effects of chronic alcohol on neuronal/synaptic density and function are well known. However, preclinical studies suggest that short-term alcohol consumption is associated with synaptic remodeling in certain brain regions that may underlie addiction[1]. We hypothesized that changes in synaptic density associated with BD could be non-invasively monitored using [$^{11}$C]UCB-J, a specific radioligand of synaptic vesicle glycoprotein 2 isoform A (SV2A). ***Materials and Methods:*** In the BD model, male adolescent rats (33 days) were administered with ethanol (5 g/kg, orally) or water (control) every 2 days for 14 days. Dynamic brain PET imaging was performed under isoflurane anaesthesia at day 15 with [$^{11}$C]UCB-J (i.v, 42.6±4.9MBq, 60 min acquisition, n=5-6 per group). In additional BD and control animals (n=6 per group), [$^{18}$F]2-fluoro-2-desoxy-sorbitol ([$^{18}$F]FDS) PET imaging (i.v, 37.3±4.1MBq, 30 min acquisition) was performed as a paracellular marker of blood-brain barrier (BBB) integrity. Using a brain template, SUV-normalized time-activity curves (TACs) of [$^{11}$C]UCB-J and [$^{18}$F]FDS were generated in brain regions, and in the left heart-ventricle. Brain uptake was estimated by the regional area-under-the-TACs (AUC, SUV.min). A two-way ANOVA was performed to compare groups. ***Results:*** Significant increase in [$^{11}$C]UCB-J uptake in the BD group compared with control animals ($p<0.05$) was observed in several brain regions including thalamus (+21±14%), accumbens (+26±17%), ventral tegmental area (+26±18%), amygdala (+26±17%) and striatum (+21±15%), whereas radioactivity in the heart ventricle remained unchanged (+10±25%, $p>0.05$). Compared with the control group, the uptake of [$^{18}$F]FDS in brain regions (+6±9%; $p>0.05$) and heart ventricle (+1±13%; $p>0.05$) were not significantly increased in the BD model, suggesting preserved BBB integrity. ***Conclusion:*** The higher uptake of [$^{11}$C]UCB-J in certain brain regions supports an importance for a short term synaptic remodeling in an adolescent rat model of BD. This increase in brain uptake not related related to any change in the peripheral exposure of [$^{11}$C]UCB-J or to any BBB disruption. The dynamics and long-term impact of BD on synaptic density can be further investigated using [$^{11}$C]UCB-J PET imaging in this model. ***References:*** [1] Kyzar et Pandey, « Molecular Mechanisms of Synaptic Remodeling in Alcoholism ».

## EP-0022

### Sex differences in [18F]-FDG uptake and behavioral impairment following repetitive mild traumatic brain injury (rmTBI)

***R. Moraga-Amaro****, M. Bankstahl, J. P. Bankstahl;
Hannover Medical School, Hannover, GERMANY.*

***Aim/Introduction:*** Repetitive mild traumatic brain injuries (rmTBI) can lead to chronic traumatic encephalophaty (CTE), an early-age chronic neurodegeneration syndrome. Because of the lack of reliable biomarkers at early stages of this disease, CTE represents a significant health problem associated with disability. Using validated animal models of CTE based on rmTBI, it is possible to find prognostic biomarkers for early detection and preventive therapy of this disease. In this study, we evaluated neurological, behavioural and brain metabolic changes in animals exposed to rmTBI, focusing in the influence of sex in these differences. ***Materials and Methods:*** 20 rats aged 14-weeks (n=10 females; n=10 males) underwent 3 mTBI sessions, consisting on a free fall brass weight (450g) on the head of animals under anesthesia, with 5-days intervals between them. Sham animals without head impact were used as controls. Short- and long-term changes in weight gain, and neurological severity score (NSS) were monitored through a period of 12-weeks. Changes in anhedonic-like behaviour was measured using the Saccharin preference test (SPT) at 1-week, 2-weeks and 12-weeks after CTE induction. Open Field (OFT) and Y-maze tests to measure anxiety-like and spatial memory were performed at 12-weeks after CTE induction. [$^{18}$F]-FDG uptake was evaluated using regional brain VOI atlas at 1-day, 1-week, 2-weeks and 12-weeks after rmTBI. All longitudinal data was analysed using a generalized estimated equation (GEE) model, using "sex", "treatment" and "timepoint" as factors. ***Results:*** Animals exposed to rmTBI, independent from sex, showed neurological impairments compared to sham animals, present up to 12-weeks after ($p<0.01$). RmTBI exposed males showed a reduction in saccharin consumption in the SPT after 2-weeks ($p<0.01$), an effect not present in females. OFT results showed no differences in anxiety-like behaviour. However, a decrease in locomotion was found in rmTBI females only ($p<0.05$). In addition, long-term memory impairments were found in male rats exposed to rmTBI ($p<0.001$), but not in female rats. Brain regional [$^{18}$F]-FDG $SUV_{gluc}$ analysis revealed an increase in brain metabolism ($p<0.05$) in the medula and frontal association cortex of rmTBI male rats at 2-weeks and 12-weeks respectively. However, a decrease of $SUV_{gluc}$ was found instead ($p<0.01$) in the amygdala, frontal association cortex, medial prefrontal cortex, and visual cortex of female rats exposed to rmTBI. ***Conclusion:*** This study showed

sex-related short and long-term neurological, behavioural and gluco-metabolic impairments after rmTBI exposure. Correlation analysis investigating interactions between behavioural and imaging data is ongoing.

## EP-0023

### Longitudinal [18F]-FDG PET Characterization of Alzheimer's Disease P301S Transgenic Mice

***L. García-Varela***[1,2,3], *A. Custodia*[4,3], *L. Barro Rico*[1,3], *N. Gomez Lado*[1,3], *J. Codesido*[2,3,5], *A. Cuartero*[5], *A. Fernández-Ferreiro*[5], *D. Romaus Sanjurjo*[4,3], *A. Ouro*[4,3], *T. Sobrino*[4,3], *P. Aguiar*[1,2,3];
[1]*Molecular Imaging and Pharmacokinetic Modelling Group, CIMUS, USC, Santiago de Compostela, SPAIN,* [2]*Nuclear Medicine and Molecular Imaging Group, University Clinical Hospital, IDIS, Santiago de Compostela, SPAIN,* [3]*Centro de Investigación Biomédica en Red en Enfermedades Neurodegenerativas (CIBERNED), Instituto de Salud Carlos III, Madrid, SPAIN,* [4]*NeuroAging Group (NEURAL), Clinical Neurosciences Research Laboratory (LINC), IDIS, Santiago de Compostela, SPAIN,* [5]*Pharmacology Group, University Clinical Hospital of Santiago de Compostela, IDIS, Santiago de Compostela, SPAIN.*

***Aim/Introduction:*** Although Alzheimer's Disease (AD) mouse models are valuable for studying tau accumulation throughout disease progression and testing novel treatments [1,2], conducting a thorough longitudinal characterization of these models before starting trials is crucial [3]. This study evaluated the brain glucose consumption of P301S transgenic mice throughout the development of AD pathology using [$^{18}$F]-FDG Positron Emission Tomography (PET). ***Materials and Methods:*** AD group consisting of P301S transgenic mice (PS19 line) (n=6) and age-matched control mice (n=3) underwent longitudinal [$^{18}$F]-FDG-PET/CT scans using an averaged dose of 0.23MBq/g by the tail vein. First, [$^{18}$F]-FDG-PET/CT scans were performed at the age of 3 months ($weight_{AD}$=18±1.05g and $weight_{control}$=21.17±0.58g), and subsequently, follow-up scans were performed at the age of 5 months ($weight_{AD}$=21.25±2.54g and $weight_{control}$=26±0.87g), 8 months ($weight_{AD}$=21.5±1.1g and $weight_{control}$=27.83±2.36g) and 11 months ($weight_{AD}$=19.3±2.08g and $weight_{control}$=30.33±2.08g). All images were processed and analyzed with PMOD v4.2 software and different Volumes of Interest (VOIs) were obtained from a mouse T2-MRI template (Ma-Benveniste-Mirrione). Standardized Uptake Values (SUV) were estimated in all the selected VOIs. Generalized Estimated Equation was used to estimate the significant changes between groups in all the PET scans and at different VOIs. ***Results:*** At 3 and 5 months of age, SUV values in the AD group were not significantly lower than the ones from the control group in any of the selected VOIs. However, at 8 months of age, SUV values of the AD group were lower than the ones of the control group in most of the selected VOIs. This decrease in the SUV was significantly different in the central gray ($SUV_{AD}$=1.67±0.09 vs $SUV_{control}$=2.07±0.06, p<0.001), hippocampus ($SUV_{AD}$=1.48±0.10 vs $SUV_{control}$=1.80±0.06, p=0.005), inferior colliculi ($SUV_{AD}$=1.51±0.10 vs $SUV_{control}$=1.79±0.05, p=0.017), midbrain ($SUV_{AD}$=1.56±0.08 vs $SUV_{control}$=1.98±0.07, p<0.001), superior colliculi ($SUV_{AD}$=1.58±0.10 vs $SUV_{control}$=1.90±0.05, p=0.006) and thalamus ($SUV_{AD}$=1.57±0.10 vs $SUV_{control}$=1.98±0.07, p=0.001). Regarding the 11 months, SUV of all selected VOIs were significantly lower in the AD compared to controls (45% reduction in whole-brain, p<0.001). Our findings are in line with the tau accumulation during AD [4], therefore decreased brain metabolism might be related to the development of AD and the gradual accumulation of tau protein in the brain. ***Conclusion:*** This study evaluates for the first time the longitudinal changes in brain glucose metabolism of P301S transgenic mice. The results showed significant differences in brain glucose metabolism in the hippocampus and thalamus already at 8 months of age, and significant differences in all the brain regions at 11 months. ***References:*** https://linkinghub.elsevier.com/retrieve/pii/S0896627316000532 https://www.frontiersin.org/articles/10.3389/fnagi.2021.761913/full https://www.mdpi.com/1422-0067/22/18/9727 https://pubs.acs.org/doi/10.1021/acschemneuro.2c00519

## EP-0024

### Applicability of early phase imaging with 18F-PI-2620 and 18F-Florbetaben in mouse models with Tau and Amyloid pathology

***A. Englert***, *L. Slemann, S. Hummel, L. Hörmann, L. Kunze, C. Palleis, K. Wind-Mark, S. Lindner, P. Bartenstein, S. Ziegler, N. Albert, J. Levin, M. Brendel, J. Gnörich;*
*LMU Klinikum Campus Großhadern, Munich, GERMANY.*

***Aim/Introduction:*** Clinical studies have shown that early perfusion-weighted $^{18}$F-PI-2620 scans (R1) are in no way inferior to $^{18}$F-FDG-PET as a predictor of neuronal damage. This provides an immense advantage, since one single $^{18}$F-PI-2620 scan can generate simultaneous information about tauburden and neuronal injury. To date however, no comparable study has yet investigated the value of tau-PET R1 in mouse models of neurodegenerative disease. Thus, we tested the applicability of early phase recordings in a PS19 tau mouse model by comparison of R1 between tracers with high ($^{18}$F-PI-2620) and low ($^{18}$F-GE-180) extraction from blood. ***Materials and Methods:*** N=16 transgenic PS19 and P301s mice with tau pathology and n=17 controls (WT mice) were investigated in this study. $^{18}$F-PI-2620 (9 vs 8) and $^{18}$F-GE180 (7 vs 9) scans were performed in a dynamic setting (0-60 min) with an average of 18±2 MBq using a Mediso PET/3T-MRI system. Processing of PET images was performed via PMOD. We computed R1 using simplified reference tissue modeling 2 (SRTM2) applying the striatum as a tau negative reference region. As an independent validation R1 of [$^{18}$F]Florbetaben-PET were correlated with striatum scaled (SUVR) quantification of [$^{18}$F]FDG-PET with amyloid pathology (21 vs 21). ***Results:*** R1derived from $^{18}$F-PI-2620 PET indicated a significant decrease of perfusion in hindbrain regions of PS19 mice compared to wild-type mice (i.e. inferior colliculi (- 18.3%, p=0.011). Contrary, there were no relevant differences in R1 of $^{18}$F-GE-180 PET between PS19 and wild-type mice. PI-2620 PET R1 showed a high agreement with [$^{18}$F]FDG-PET SUVR and for all brainregions obtained from Mirrione brain atlas (r=0.67, p=0.0016). ***Conclusion:*** Assessment of $^{18}$F-PI-2620 delivery can be used as a surrogate of perfusion deficits in PS19 mice. Analysis of $^{18}$F-GE-180 delivery in the same model served as a negative control and indicated that the use of R1 as a perfusion surrogate is specific for tracers with high blood extraction.

## EP-0025

### Brain Metabolic Effects of Coca-paste Acute Systemic Administration in Rats

***R. Ferrando***[1,2], *L. Reyes*[2], *J. Prieto*[3], *A. Paolino*[2], *A. Abin-Carriquiry*[4], *P. Oliver*[2], *E. Savio*[2], *M. Scorza*[3];
[1]*University of the Republic, Montevideo, URUGUAY,* [2]*Uruguayan Centre for Molecular Imaging (CUDIM), Montevideo, URUGUAY,* [3]*Departamento de Neurofarmacología Experimental, Instituto de Investigaciones Biológicas Clemente Estable., Montevideo, URUGUAY,* [4]*Departamento de Neuroquímica, Instituto de Investigaciones Biológicas Clemente Estable., Montevideo, URUGUAY.*

***Aim/Introduction:*** Coca-paste (CP) is the most consumed smoked cocaine in South America and its use is mainly associated with deprived populations. In comparison with cocaine hydrochloride (CH), CP elicits a prototypical clinical profile of fast and severe dependence and impulsivity, representing a challenge for public health. In addition to the route of administration, we hypothesize that cocaine purity and the presence of active adulterants (e.g., caffeine) explain some differences between CP and CH. The aim of this study was to investigate the effect of acute CP administration on regional cerebral glucose metabolism (rCGM) in rats and compare it with that of CH. ***Materials and Methods:*** Animals were intraperitoneally injected with saline (n=9), a CP seized sample (68.9% cocaine and 15.0% caffeine) (n=8), or CH (at equivalent doses of cocaine base) (n=8). After 5 min, rats were intravenously injected with 50-74 MBq of $^{18}$F-FDG, and 30 min later, they were anesthetized, and images were acquired for 60 min in a small-animal PET/CT camera. Reconstruction was performed with 3D-MLEM, and quantification was carried out using VOI analysis in PMOD and voxel-based analysis in SPM8. ***Results:*** In VOI analysis, rCGM was significantly decreased in cingulate gyrus, medial prefrontal, motor, and somatosensory cortex ($p<0.05$) of CP-treated animals compared with control and CH groups. SPM analysis showed greater cortical hypometabolism in CP administration compared to CH, as well as metabolic increases in the brain stem and cerebellum ($p<0.01$ uncorrected). ***Conclusion:*** The differences in rCGM between both treated groups can be due to an additive action of cocaine and caffeine in CP samples. Our findings can contribute to understanding the clinical profile of CP consumers.

### A study on the volume of preclinical xenograft tumours assessed by ultrasound imaging and MRI compared to calliper measurements

***J. Strand***[1], *C. Ceberg*[2], *M. Safi*[1], *S. Strand*[2], *F. Szczepankiewicz*[2], *D. Roth*[2];
[1]*Clinical Sciences, Oncology, Lund University, Lund, SWEDEN,*
[2]*Medical Radiation Physics, Clinical Sciences, Lund University, Lund, SWEDEN.*

***Aim/Introduction:*** Pre-clinical models for the evaluation of response to radiotherapy include subcutaneously inoculated xenografts. The standard method for measuring the subcutaneous tumour volume is by calliper measurements directly on the skin of the animals. The length and width of the tumour are measured, the depth is assumed to be approximately the same as the width, and the volume is calculated assuming an ellipsoid geometry. However, the growth of solid tumours after radiotherapy frequently deviates from this shape. On possibility would be to use ultrasound for tumors measurement, as it enabled rapid and more accurate measurements of superficial tumor volumes. The aim of this study was to investigate the accuracy of tumour-volume measurements by calliper and ultrasound compared to MRI as standard in xenografts before and after [$^{177}$Lu]Lu-PSMA-617 and external radiotherapy. ***Materials and Methods:*** Seven BALB/c mice underwent treatment with 14-17 MBq of [$^{177}$Lu] Lu-PSMA-617. Five BALB/c mice were treated at a small-animal external-beam radiotherapy-system that delivered an absorbed dose of 10 Gy. The tumours were measured at several timepoints before and after treatment using a digital calliper, ultrasound, and MRI. For the ultrasound method, the tumour lengths, widths, and depths were measured. For the calliper method, the lengths and widths were measured, and the depths were assumed equal to the widths. For both methods, tumour-volumes were calculated assuming an ellipsoid geometry. A 9.4 T system was used for MR imaging using a RARE sequence. Volumes were calculated from manual tumour delineation. Tumour measurements by calliper and ultrasound were mostly performed separate days from MRI imaging. To compare ultrasound and calliper against MRI, linear interpolation was performed in the time-volume curves to facilitate pairwise same-day comparisons. Volume-errors were calculated for ultrasound and calliper using MRI as the reference method and assessed with Wilcoxon tests. ***Results:*** Across all ultrasound-calliper volume-pairs, the median (inter-quartile range) volume was 0.16 $cm^3$ (0.24 $cm^3$) for ultrasound, and 0.50 $cm^3$ (0.42 $cm^3$) for calliper. The median (inter-quartile range) volume-error was -0.023 $cm^3$ (0.087 $cm^3$) for ultrasound, and 0.32 $cm^3$ (0.26 $cm^3$) for calliper. Both medians were significantly different from zero, with p=0.018 (ultrasound) and p=1.1 x 10-5 (calliper), respectively. ***Conclusion:*** The present study demonstrates that measurements of subcutaneously inoculated tumour volume in mice using ultrasound exhibit significantly higher accuracy than measurements made with callipers. Accurate tumour volume estimation is important for internal radiation dosimetry, and relevant for determining the therapy effect on tumour volume.

## EP-0027

### Construction and Preclinical Evaluation of a 68Ga-Labeled Single-chain Fragment Variable Targeting PD-L2 in Lung Cancer

***Y. Yao***, *N. Li;*
*Peking university cancer hospital, Beijing, CHINA.*

***Aim/Introduction:*** Programmed cell death-Ligand 1 (PD-L2), a ligand programmed cell death protein 1 (PD-1), is an immune checkpoint molecule closely related to the efficacy of immune checkpoint inhibitor therapy (ICI). The aim of this study is to design a novel tracer $^{68}$Ga-NOTA-scFvE6 targeting PD-L2 and perform preclinical evaluation to dynamically monitor PD-L2 expression and screen potential beneficiaries of ICI therapy. ***Materials and Methods:*** A human single-chain fragment variable (scFv) was generated by phage display and the selected scFv was expressed by prokaryotic expression system. $^{68}$Ga-labeling of NOTA-conjugated scFvE6 was carried out in NaAc-buffer at pH 4 (37°C, 10min). In vitro stability was analyzed using Radio-thin layer chromatography (Radio-TLC). The affinity of the scFvE6 were evaluated by Radio-ELISA. Pharmacokinetic experiments were used to evaluate the metabolic characteristics in vivo. Cellular uptake assays were performed using the transduced PD-L2 expressing lung cancer cell line A549 (A549-PD-L2) and wild-type A549 cells as negative control. The biodistribution experiment was used to detect the in vivo distribution of the tracer and the dosimetry estimation was conducted based on the results. Micro-PET/CT imaging was conducted with $^{68}$Ga-NOTA-scFvE6 and static images were recorded at 1 h and 2 h p.i. Immunohistochemical and HE staining studies were carried out using the tumor tissue of tumor-bearing mice. ***Results:*** The radiochemical yields of $^{68}$Ga-NOTA-scFvE6 were 42.76±2.37%

and the radiochemical purity (RCP) of the tracer was more than 99%. The tracer incubated in 0.01 M PBS and 5% HSA maintained relatively high stability (RCP>95%). Radio-ELISA showed that $^{68}$Ga-NOTA-scFvE6 had a high affinity for the PD-L2 protein (Kd = 21.10 nM). The half-lives of the distribution phase and elimination phase were 4.136 and 43.42 min, respectively. Cellular uptake experiments confirmed that the uptake of $^{68}$Ga-NOTA-scFvE6 in A549-PDL2 cells was higher than that in A549 cells at each time point. The dosimetry estimation by using Olinda software showed that the effective dose was 2.46E-02 mSv/MBq. Micro-PET/CT showed significant uptake in the tumor region of A549-PDL2 tumor-bearing mice at 1h and 2h post-injection (SUVmax = 0.75 ± 0.02 and 0.85 ± 0.06). Immunohistochemistry showed that A549-PDL2 was highly expressed in A549-PDL2 mice. ***Conclusion:*** $^{68}$Ga-NOTA-scFvE6 enables easy radiosynthesis and shows excellent in vitro and in vivo PD-L2 targeting characteristics. The high tumor uptake at early imaging time points demonstrates the feasibility of $^{68}$Ga-NOTA-scFvE6 for imaging of PD-L2 expression in tumors and is encouraging for further clinical applications of screening potential beneficiaries.

## EP-0028

### Preparation and evaluation of Evans blue modified aptamer probe targeting to EpCAM

***M. Zhang***, *J. Ye, Z. Xie, W. Yang, F. Kang, J. Wang;*
*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** Epithelial cell adhesion molecule (EpCAM) is a potential target for early diagnosis of tumors. SYL3C, as a DNA nucleic acid aptamer, is a specific ligand for EpCAM. However, due to the fact that the nucleic acid aptamer is easy to be degraded by nuclease in vivo, which results in problems such as poor stability, short half-life of blood circulation and poor metabolism of aptamer. In order to solve the above problems, this study intends to connect the truncated Evans blue (EB) to SYL3C, through which albumin can be carried on, thus the in vivo stability and metabolism of SYL3C could be improved, and due to the enhanced permeability and retention (EPR) effect the tumor uptake could be further increased. ***Materials and Methods:*** NMEB-SYL3C and NOTA-SYL3C were synthesized and labeled with $^{68}$Ga. The stability of $^{68}$Ga-NMEB-SYL3C and $^{68}$Ga-NOTA-SYL3C in PBS and mouse serum was investigated, respectively. Cell uptake studies of the two tracers were performed in EpCAM strongly positive cells (4T1) and negative cells (293T), respectively. PET imaging studies of the two tracers were carried out in the tumor mice bearing 4T1 at different time points. ***Results:*** The radiochemical purity of $^{68}$Ga-NMEB-SYL3C and $^{68}$Ga-NOTA-SYL3C was both more than 98% after purification. $^{68}$Ga-NMEB-SYL3C can be stable in PBS and mouse serum for 2 hours, while only about 60% and 80% of $^{68}$Ga-NOTA-SYL3C was intact in PBS and mouse serum at 1 h, respectively. The uptake of $^{68}$Ga-NMEB-SYL3C in 4T1 cells was slightly lower than that of $^{68}$Ga-NOTA-SYL3C, indicating that the EB modification could somewhat decrease the affinity of SYL3C to EpCAM. However, the cell uptake studies also showed that the total binding and internalization of $^{68}$Ga-NMEB-SYL3C in 4T1 cells were significantly higher than those in 293T cells, which suggested that although EB modification affected the affinity of SYL3C to EpCAM, the affinity and specificity of $^{68}$Ga-NMEB-SYL3C to EpCAM was still high enough. The PET imaging results showed that $^{68}$Ga-NOTA-SYL3C cleared fast in mice within 5 min p.i., and there was no tumor uptake at all. Meanwhile, the results of $^{68}$Ga-NMEB-SYL3C showed that the tumor could be clearly observed at 0.5 h p.i., with the uptake value gradually increased over time, and reached the highest level of 5% ID/g at 3 h p.i. ***Conclusion:*** Preliminary results showed that EB modification can effectively improve the stability and metabolic kinetics of SYL3C in vivo, and thus significantly enhance the uptake in tumor.

## EP-0029

### Evaluation of a Long-circulating PSMA-targeting Peptide in a Xenograft Model of Bone Metastatic Prostate Cancer.

***W. Lo***, *Y. Huang, M. Chen, A. Lu, S. Wang, L. Chen, S. Farn;*
*Institute of Nuclear Energy Research, Taoyuan, TAIWAN.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is a target for prostate cancer given its increased expression on the surface of the prostate cancer cells. In our previous study, we synthesized a novel PSMA-targeting peptide named PSMA-INER-56, which demonstrates prolonged biological half-life, high tumor accumulation and therapeutic efficacy. The objective of this study is to assess the therapeutic efficacy and biodistribution of $^{177}$Lu-PSMA-INER-56 in a xenograft model of bone metastatic prostate cancer. ***Materials and Methods:*** PSMA-INER-56 was radiolabeled with $^{177}$Lu and $^{111}$In, respectively, and analyzed using radio-TLC and HPLC. A xenograft model of bone metastases was established in NOD/SCID mice by intra-femoral injection of PSMA-positive prostate cancer cell line, LNCaP cells, mixed with Matrigel in a 1:1 ratio, with a total of 50,000 cells. For therapeutic efficacy assessment, the animals were treated with 29.6 MBq of $^{177}$Lu-PSMA-INER-56, and the tumor volume and distribution of the radiopharmaceutical were monitored using SPECT/CT imaging. Furthermore, to confirm the therapeutic effect on day 28 post-administration, 18.5 MBq of $^{111}$In-PSMA-INER-56 was utilized. ***Results:*** The labeling efficiency and radiochemical purity of both $^{177}$Lu-PSMA-INER-56 and $^{111}$In-PSMA-INER-56 were found to be above 95%, with retention times of 9.39 and 9.43 minutes, respectively. After 49 days of intra-femoral injection of LNCaP cells, the animal model with bone metastases was treated with a single administration of 29.6 MBq of $^{177}$Lu-PSMA-INER-56. The SPECT/CT imaging of $^{177}$Lu-PSMA-INER-56 revealed a tumor uptake of 18.8 %ID/g at 24 hours post-administration, and this high accumulation persisted up to 192 hours, with a remaining uptake of 19.7 %ID/g. Meanwhile, the tumor size gradually decreased from the initial measurement of 2.7 cm to 1.5 cm. At day 30 post-administration of $^{177}$Lu-PSMA-INER-56, diagnostic radiolabeled $^{111}$In-PSMA-INER-56 was used for therapeutic efficacy monitoring. SPECT/CT imaging revealed persistent high accumulation of the radiotracer in the tumor with a concentration of 20.0 %ID/g. Additionally, the tumor size decreased to 0.84 cm, suggesting a positive therapeutic response to the treatment with $^{177}$Lu-PSMA-INER-56. ***Conclusion:*** In conclusion, the use of $^{177}$Lu-PSMA-INER-56 in a xenograft model of bone metastatic prostate cancer showed promising results in terms of therapeutic efficacy. The radiopharmaceutical's high labeling efficiency, purity, and tumor accumulation, combined with its long-circulating properties, indicate its potential as an effective targeted therapy. ***References:*** Li, MH., Lo, SN., Chen, MW. et al. Molecular Imaging for Radiolabeling a PSMA-Targeted Long Circulating Peptide as a Theranostic Agent in Mice Bearing a Human Prostate Tumor. J. Med. Biol. Eng. 41, 360-368 (2021).

## EP-0030

### Goat milk-derived extracellular vesicle engineered for multimodal imaging of cancer stem cells

***Y. Gao***, *Y. Zhang, X. Lan, R. An;*
*Wuhan Union Hospital, Wuhan, CHINA.*

***Aim/Introduction:*** Colon cancer is one of the most common malignant tumors, with the fourth highest number of deaths due to cancer. CD44 is a common marker expressed on cancer stem cells (CSCs) from colon cancer, which can specifically bind to

hyaluronic acid (HA). In this study, goat milk-derived extracellular vesicle (GEV) where HA was modified to target CD44 was used as a nanoprobe to trace colon cancer stem cells, hoping to carry out PET/CT imaging of colon cancer stem cells in vivo. ***Materials and Methods:*** GEV was isolated from fresh goat milk by differential centrifugation, and then DSPE-PEG-$N_3$ and DSPE-PEG-HA were co-incubated with GEV to form $N_3$-GEV-HA. The nanoprobe were characterized by transmission electron microscope and dynamic light scattering. Confocal microscopy was used to determine the ability of the probe to bind to colon cancer cells. $N_3$-GEV-HA was injected into the subcutaneous model of colon cancer in mice through tail vein, and near infrared fluorescence (NIRF) imaging was performed at different time points to determine the best time for pre-targeting strategy. This strategy enables the probe to circulate fully in the body and accumulate in the tumor tissue and then use short half-life radionuclides for PET/CT imaging. $N_3$-GEV-HA was injected into mouse colon cancer model HT29 (high expression of CD44) and DLD1 (low expression of CD44) at the best pre-targeted time points. One hour and two hours after injection of $^{68}$Ga-L-NETA-DBCO, which can bind to $N_3$, the anesthetized mice were subjected to pre-targeting static imaging of miniature PET/CT based on "click chemistry". ***Results:*** GEV was successfully isolated from goat milk and modified. The lipid bilayer structure of the probe was confirmed by transmission electron microscope. Confocal experiment showed that the binding ability of $N_3$-GEV-HA to HT29 tumor cells was stronger than that of DLD1. NIRF images showed that the fluorescence signal of the tumor site in the active targeting group (HT29 with $N_3$-GEV-HA) was the strongest compared with the passive targeting group (HT29 with $N_3$-GEV) and the control group (DLD1 with N3-GEV-HA), and the fluorescence signal was the strongest at 24 hours. The PET/CT images in vivo also showed the same imaging results. No obvious signs of injury were found in the main organs of rats in each group. ***Conclusion:*** The study demonstrated that the CD44-targeted nanoprobe $N_3$-GEV-HA can specifically target to colon CSCs and achieve high quality PET/CT/NIRF imaging. It has a broad prospect of clinical translation.

## EP-0031

### Porphyrin-modified strategy contributes to aptamers' tumor targeting

***S. Yang***, *X. Lan, D. Jiang;*
*Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan 430022, China, Wuhan, CHINA.*

***Aim/Introduction:*** Single-stranded DNA (ssDNA) has the advantages of easy preparation and modification, high stability in vitro, and excellent biocompatibility compared with traditional drugs. It has been developed into various nucleic acid drugs, especially aptamers, which can specifically bind to corresponding tumor targets and have broad prospects for clinical translation. But the extremely rapid renal clearance greatly limits its application in tumor-targeted imaging and therapy. In this study, ssDNA was modified with a second-generation porphyrin photosensitizer (PPR), to significantly prolong its blood circulation and successfully overcome pharmacokinetic defects in tumor-targeted imaging of aptamers. ***Materials and Methods:*** All amine group modified ssDNA sequences were conjugated with PPR by amide condensation. A series of sample oligonucleotides with different base lengths were modified with PPR (including PPR-A20, PPR-A40, PPR-A60, and PPR-A80) and characterized by UV-Vis, fluorescence spectrum, mass spectrum, and high performance liquid chromatography (HPLC). By using PPR as a radiometal chelator, PPR-ssDNA were labeled with $^{68}$Ga in hydrochloric acid/sodium acetate buffer. All four $^{68}$Ga-PPR-ssDNAs were injected into healthy mice intravenously. Their blood circulation was calculated through microPET/CT images and was compared with unmodified ssDNA to determine the pharmacokinetic effects of the PPR modification method. Murine models of CT26 colon carcinoma were further used to test the tumor imaging capacity of PPR-ssDNA in vivo. ***Results:*** In this study, PPR was successfully modified on the amino terminal of ssDNA. UV absorption spectrum showed that the products had characteristic absorption peaks of ssDNA and PPR at 260 nm and 405 nm, respectively, and mass spectrum confirmed the successful synthesis. PET images and biodistribution studies in healthy mice showed significantly extended blood circulation of all four PPR-ssDNA when compared with unmodified counterparts, where PPR-A60 displayed the best blood retention at 29.16±1.19 %ID/g at 2 h post injection, 60 fold higher than $^{68}$Ga-A20 (0.5 %ID/g). PET imaging of CT26 colon carcinoma mice showed PPR-A60 displayed 3.1± 0.72%ID/g tumor uptake at 2 h after injection. ***Conclusion:*** The one-step PPR modification strategy has greatly overcome the pharmacokinetic defects of ssDNA. Our PET imaging further confirmed excellent tumor imaging of PPR-A60 in colon tumor-bearing mice. Given PPR is a FDA-approved photosensitizer, we strongly believe that PPR-modified aptamers can improve the tumor targeting/therapeutic effect of aptamers and have excellent clinical application prospects.

## EP-0032

### Tumours inducing cachexia driven by Fn14 show enhanced 18F-FDG uptake in mice versus tumours that do not induce cancer cachexia: a quantitative PET analysis

***I. Burvenich***[1,2], *L. Osellame*[1,2,3], *A. Rigopoulos*[1], *N. Hoogenraad*[3], *A. M. Scott*[1,2,4];
[1]*Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*School of Cancer Medicine, La Trobe University, Bundoora, AUSTRALIA,* [3]*Department of Biochemistry and Genetics, La Trobe Institute for Molecular Science, La Trobe University, Bundoora, AUSTRALIA,* [4]*Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA.*

***Aim/Introduction:*** Cachexia is a complex syndrome characterized by unintentional weight loss, progressive muscle wasting and loss of appetite. The anti-Fn14 antibody (002) targets the TWEAK receptor (Fn14) and can extend the lifespan of mice by restoring the body weight of mice[1]. Previously, we have shown that $^{18}$F-FDG PET imaging demonstrates increased glucose uptake over time in syngeneic tumour models that induce cachexia versus tumours that do not induce cachexia. Here we investigate $^{18}$F-FDG uptake in tumours of an Fn14 knock-out variant of the cachexia-inducing C26 tumour model (C26 Fn14 KO), and response to therapy with anti-Fn14 antibody 002 and perform quantitative PET analysis. ***Materials and Methods:*** At 1 hour after $^{18}$F-FDG (14.8 MBq) tail vein injection, $^{18}$F-FDG PET/MRI imaging was performed in cachexia-inducing tumour models [MEF-Fn14 and C26 tumour-bearing Nod SCID gamma (NSG) mice] versus models that do not induce cachexia (MEF, C26 tumour-bearing mice treated with 002 (10 mg/kg) and C26 FN14 KO tumour-bearing NSG mice). All animals were fasted for 3 hours prior to $^{18}$F-FDG injection and kept on a heat pad during the experiment. $SUV_{average}$ was calculated for all tumours via VOI analysis of PET/MRI overlay images using PMOD software. ***Results:*** $^{18}$F-FDG PET imaging demonstrated increased glucose uptake in cachectic MEF Fn14

versus non-cachectic MEF tumour-bearing mice ($SUV_{average}$ MEF Fn14, 3.3 ± 0.6; % maximum body weight, 74.06 ± 1.43 versus $SUV_{average}$ MEF, 1.0 ± 0.1; % maximum body weight, 94.91 ± 2.84, (n = 2)). Therapy with 002 was able to reduce $^{18}$F-FDG uptake in C26 tumours ($SUV_{average}$ of C26 treated with vehicle control, 2.1 ± 0.3; $SUV_{average}$ of C26 treated with 002, 1.3 ± 0.3; P < 0.05, n = 3). C26 Fn14 KO tumours did not induce body weight loss and did not show an increase in $^{18}$F-FDG tumour uptake over time. In non-cachectic mice bearing C26 Fn14 KO tumours, $^{18}$F-FDG tumour uptake was significantly lower (P < 0.01) (SUVaverage, 0.70 ± 0.09; % maximum body weight, 96.66 ± 0.85; n = 5) than in cachectic mice bearing C26 Fn14 WT tumours (SUVaverage, 1.73 ± 0.72; % maximum body weight, 87.33 ± 6.96; n = 9). ***Conclusion:*** Our results demonstrate that the Fn14 receptor activation is linked to glucose metabolism of cachexia-inducing tumours. A clinical trial with $^{18}$F-FDG PET in cachectic patients is currently ongoing. ***References:*** [1]Johnston AJ, et al. Targeting of Fn14 Prevents Cancer-Induced Cachexia and Prolongs Survival. Cell. 2015;162(6):1365-78.

## EP-0033

### 89Zr-anti-murine CD103 PET imaging for non-invasive assessment of immune checkpoint inhibitor therapy

***X. Fan***, *N. P. Holland, A. Plat, H. W. Nijman, P. H. Elsinga, M. d. Bruyn;*
*University of Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** The lack of a reliable biomarker to predict the treatment efficiency has hindered the promotion and application of Immune checkpoint inhibitors therapy. $CD103^+$ cells, as shown in multiple clinical studies, are significantly increased during successful immunotherapy across human malignancies, showing its potential to be a biomarker to predict the effect of therapy. ***Materials and Methods:*** $^{89}$Zr-anti-murine tracer was developed and tested in mouse model for the feasibility of CD103 PET imaging. To further explore the behavior of the tracer in vivo, Balb/c and C57bl/6 mice were injected with various doses of $^{89}$Zr-anti-murine CD103 tracer and $^{89}$Zr-isotype control tracer and were scanned multiple times followed by ex vivo bio-distribution. To investigate the potential of CD103 PET-imaging for therapy monitoring MC38 tumor-bearing C57BL/6 mice were treated with a series of dual checkpoint inhibitors. CD103 PET imaging was performed after treatment to assess tumoral uptake of the tracer, and tumor volume changes were subsequently monitored to determine response. ***Results:*** A novel anti-murine CD103 mAb tracer was successfully developed and validated in a healthy mouse model. In both animal models, $^{89}$Zr-anti-murine CD103 tracer shows a higher specific uptake in CD103+ cell-rich gastrointestinal tract compared to the control tracer. Ex vivo bio-distribution data further demonstrated that compared to the control tracer, there was a significantly higher tracer uptake in the small intestine, mesenteric lymph nodes, and axillary LNs. In the treatment study, all mice responded to treatment (7/7) and tumor size was significantly reduced after treatment. However, there was no difference of CD103 tracer uptake in tumors compared to isotype tracers, either with or without treatment. ***Conclusion:*** We developed and validated a novel mouse CD103 ImmunoPET tracer, providing a new tool for preclinical studies to help understand the systemic bio-distribution of the tracer and the mechanism of action of CD103+ cells in the tumor microenvironment. However, within the syngeneic mouse tumor model, there was no significant difference between the control tracer and the CD103 tracer. Due to the fact that MC38 bearing mouse model is a transplanted tumor, compared to the real human situation, tumor takes way shorter time to grow and accumulate the immune reaction. Moreover, the CD103+ tumor infiltrating cell T-cell population belongs to the tissue resident memory T-cell subpopulation, its infiltration at the tumor site may take more time. By using such syngeneic tumor model, we may not be able to observe changes in this unique subpopulation.

## EP-0034

### In vivo testing of a novel anti-B4GALNT1 nanobody as a potential theragnostic tool for osteosarcoma tumors.

***M. Collantes***[1], *N. Mendoza*[2], *J. Simón*[3], *F. Pareja*[3], *M. Ecay*[1], *G. Quincoces*[3], *M. García-Moure*[4], *A. J. Schuhmacher*[2], *I. Peñuelas*[3];
[1]*Translational Molecular Imaging Unit (UNIMTRA), Nuclear Medicine Department, Clínica Universidad de Navarra, Pamplona, SPAIN,* [2]*Instituto de Investigación Sanitaria Aragón, Zaragoza, SPAIN,* [3]*Radiopharmacy Unit, Department of Nuclear Medicine, Clinica Universidad de Navarra, Pamplona, SPAIN,* [4]*Solid TumorsProgram, CIMA-Universidad de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** Beta-1,4,N-acetylgalactosaminyltransferase-1 (B4GALNT1) is an enzyme involved in the biosynthesis of G(D2) glycosphingolipid and widely expressed by paediatric solid tumors, including osteosarcoma (OS). We have herein radiolabelled a nanobody designed to detect B4GALNT1+ tumors and investigated its use as a potential theragnostic tool. ***Materials and Methods:*** The nanobody (14 KDa, 80µg) was radiolabelled with 700 MBq of [99mTc][Tc(CO)3(H2O)3]+ using Isolink™ kits and the radiolabeled product purified by size exclusion chromatography. The binding specificity of the $^{99m}$Tc-nanobody was tested in vitro by incubating B4GALNT1+ and B4GALNT1- cell lines and measuring the cell-bound radioactivity in a gamma counter. In vivo microSPECT/CT studies were performed in three different mouse models: 1) A xenograft model (n=6) with B4GALNT1(+) and B4GALNT1(-) tumors implanted in contralateral flanks was imaged at 0.5,2,4h after $^{99m}$Tc-nanobody i.v. injection. Additionally, ex vivo measurement of radioactivity in relevant tissues was performed at 4h. 2) An orthotopic model of OS (n=4) and 3) a lung metastasis model of OS (n=4) were created injecting a patient-derived osteosarcoma cell line in tibial plateu or intravenously respectively. In both OS derived mouse models, the diagnostic performance of $^{99m}$Tc-NBody as compared to $^{18}$F-FDG was studied by simultaneous microSPECT/microPET/CT imaging. ***Results:*** Radiolabeling yield was> 80%, and radiochemical purity >97% after purification. In vitro studies demonstrated a specific uptake of the $^{99m}$Tc-nanobody in B4GALNT1(+) cells (p<0.005, ANOVA). The in vivo images in xenograft model showed a rapid and greater uptake in B4GALNT1(+) tumors as compared to B4GALNT1(-) ones at 30m p.i. (1.7±0.34 %ID vs. 0.20±0.07; 2-way ANOVA, p<0.0001) that didn't change over time (2-way ANOVA, p=0.208). Biodistribution images showed fast renal excretion at 0.5h and minimal uptake in other organs, confirmed by ex vivo measurements at 4h (kidney:78.8±12.5% ID/g, brain:0.07±0.01%ID/g, muscle:0.26±0.03%ID/g). The diagnostic performance of the $^{99m}$Tc-nanobody was clearly superior to $^{18}$F-FDG in the orthotopic model of osteosarcoma with a higher SUVratio respect contralateral hindlimb ($^{99m}$Tc-nanobody:4,26±1,7 vs. $^{18}$F-FDG:0,93±0.5; t-test p<0.05). In the lung metastasis model, $^{18}$F-FDG didn't detect any tumors, while the $^{99m}$Tc-nanobody was able to detect numerous metastasis confirmed by histopathological analysis. ***Conclusion:*** [99mTc][Tc(CO)3(H2O)3] radiolabeling of nanobodies is an effective technique for the quantitative study of their specificity, kinetics and biodistribution. This new designed nanobody against B4GALNT1 antigen could be a promising tool to be used in diagnosis and treatment of B4GALNT1(+) tumors like osteosarcoma.

## EP-0035

### Development of neurotensin analogues stabilized by Lys8-Lys9 reduction and linker modifications

***C. Morgat***[1,2], *S. Previti*[3], *S. Bodin*[1,2], *L. Balasse*[4], *E. Rémond*[3], *P. Garrigue*[4], *F. Debordeaux*[1], *B. Guillet*[4], *F. Lamare*[2], *D. Vimont*[2], *E. Hindié*[1,2], *F. Cavelier*[3];
[1]*Nuclear Medicine Department - University Hospital of Bordeaux, Bordeaux, FRANCE,* [2]*University of Bordeaux, CNRS, EPHE, INCIA, UMR 5287, Bordeaux, FRANCE,* [3]*Institut des Biomolecules Max Mousseron, IBMM, UMR 5247, CNRS, Université de Montpellier, ENSCM, Montpellier, FRANCE,* [4]*CERIMED, Aix-Marseille University, Marseille, FRANCE.*

***Aim/Introduction:*** Neurotensin receptors are G-protein-coupled receptors expressed in several cancers, often so in subsets of patients with aggressive/advanced disease. We have previously developed JMV6659 (DOTA-APAC-Lys-Lys-Pro-Tyr-Ile-TMSAla-OH), a neurotensin analogue targeting neurotensin receptor-1 ($NTS_1$). In this work we aimed at optimizing this lead compound in terms of selectivity and stability. ***Materials and Methods:*** APAC linker was replaced with $(\beta ala)_2$ in JMV7222; Lys-Lys was reduced in JMV7259; while JMV7258 combines the two modifications. The compounds were radiolabeled with $^{68}Ga$ and studied in vitro. The most promising compound was subjected to µPET/CT imaging. HT-29 cells were used. ***Results:*** All analogues displayed nanomolar affinity (~5nM) towards $NTS_1$ and good selectivity (> 100). Internalization was high at 1h (~60% of cell-associated radioactivity) with low membrane binding (~15%). [$^{68}$Ga]Ga-JMV7222, [$^{68}$Ga]Ga-JMV7259 and [$^{68}$Ga]Ga-JMV7258 showed improved plasma stability compared to [$^{68}$Ga]Ga-JMV6659. [$^{68}$Ga]Ga-JMV7258 has the highest stability at 45 min (85%). All analogues were highly externalized (up to 70% at 45 min), much more than [$^{68}$Ga]Ga-JMV6659. Following injection of [$^{68}$Ga]Ga-JMV7258 in nude mice bearing HT29-tumor, kidneys showed the highest uptake (33.6±14.7%ID/g at 2h), which was significantly displaced by SR48692, a $NTS_1$-antagonist (14.1±4.3 %ID/g, p<0.0001). Surprisingly, HT29 xenografts showed only weak uptake (1.53±0.45 %ID/g at 2h) which was only partially displaced by SR48692 (1.11±0.29 %ID/g). We noticed that all our newly developed analogues suffered from high and fast efflux. Moreover, they displayed lower binding to neurotensin receptor-2 ($NTS_2$) than [$^{68}$Ga]Ga-JMV6659. Importantly, following $NTS_2$-prestimulation in vitro with 1µM levocabastine (a selective agonist of NTS2), the efflux of [$^{68}$Ga]Ga-JMV7258 was decreased becoming similar to [$^{68}$Ga]Ga-JMV6659 (~40%). Also, in vivo, uptake was 2.5-fold higher when levocabastine was added. For mechanistic studies, both $NTS_1$ and $NTS_2$ blocking was tested and uptake was not significantly decreased (p=0.095) suggesting that an $NTS_1$-independent pathway exists to allow the entrance of $NTS_1$ analogues. This is supported by the signal recorded when stimulation of $NTS_2$ by levocabastine was applied after $NTS_1$ blocking and led to a significantly higher tumor uptake than in experiment with $NTS_1$ blocking alone (p<0.0001). All mice injected with levocabastine had high kidney uptake and did not eliminate [$^{68}$Ga]Ga-JMV7258. ***Conclusion:*** This work provides new insights in neurotensin receptor physiology and targeting. First, a low efflux is needed to expect high $NTS_1$-uptake; second, $NTS_2$ stimulation increases the intracellular retention of $NTS_1$-selective analogues suggesting the presence of $NTS_1/NTS_2$ heterodimers; third: murine kidneys express $NTS_2$; fourth: $NTS_2$ binding and efflux are mandatory parameters to investigate when developing $NTS_1$-analogues.

## EP-0036

### In vivo evaluation of luteinizing hormone-releasing hormone antagonists in triple negative breast tumor-bearing model by using SPECT/CT imaging

***M. Weng****, S. Farn;*
*Institute of Nuclear Energy Research, Taoyuan City, TAIWAN.*

***Aim/Introduction:*** Triple negative breast cancer (TNBC) that is lack of diagnostic and effective therapeutic agents was clinically considered a subtype with low survival rate of human breast cancer patients. As we know, probes or drugs specific for receptors of luteinizing hormone-releasing hormone (LHRH-R), which is reported as potential targets for TNBC, are still under investigation as yet. In previous study, we have evaluated an peptidic abarelix-based antagonist, DOTA-LHRH, which revealed specific uptake in TNBC tumors. In this research, a cetrorelix-based antagonist, DOTA-LHRH-C, has been newly developed and also proved an effective strategy for in vivo uses by SPECT/CT imaging. ***Materials and Methods:*** The LHRH antagonist was first conjugated with a DOTA chelator; after radiolabeled with In-111, the radiochemical purity (R.C.P.) was analyzed by a radio-TLC system. The TNBC cell, HCC 1806, were incubated and subcutaneously inoculated on ASID mice. After intravenous (i.v.) injection of $^{111}$In-DOTA-LHRH-C, HCC 1806-bearing mice were anesthetized and imaged at 1, 4 and 24 h by a SPECT/CT, respectively. The bio-distribution test of $^{111}$In-DOTA-LHRH in HCC 1806-bearing mice was also investigated at 1, 4 and 24 h, respectively. ***Results:*** The R.C.P. of $^{111}$In-DOTA-LHRH-C was determined >90% by radio-TLC. The SPECT/CT imaging data showed that $^{111}$In-DOTA-LHRH-C was first collected in liver, kidney and tumors and retained in those within 24 h. In results of bio-distribution, $^{111}$In-DOTA-LHRH-C was mainly collected in lung, kidney, liver and HCC 1806 tumors at 1, 4 and 24 h. The tumor-to-muscle count ratio (T/M) is calculated as 2.18 ± 0.68 and the tumor-to-brain count ratio (T/B) is 4.33 ± 1.05 at 24 h, respectively; it also demonstrates similar results in comparison with those of DOTA-LHRH. (T/M was 3.88 ± 0.34 and T/B is 17.23 ± 0.25 at 24 h, respectively.) ***Conclusion:*** This research has evaluated the characteristics of a cetrorelix-based antagonist for LHRH-R over-expressive tumors in vivo. We suggested that DOTA-LHRH-C for further diagnostic research and comparison with DOTA-LHRH in vitro and in vivo. We think they may provide innovative information for development of TNBC patient's treatment strategies in the future in Taiwan.

## EP-0037

### Enhancing PSMA-RLT efficacy with STING agonist in syngeneic models of prostate cancer

***B. Louis***[1,2], *M. Taddio*[1,2], *K. Rashid*[1,2], *E. Abt*[1,2], *E. Rosser*[1,2], *T. Le*[1,2], *K. Lueckerath*[3,4], *C. Radu*[1,2], *J. Czernin*[1,2], *C. Mona*[1,2];
[1]*University of California at Los Angeles, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, Ahmanson Translational Theranostics Division, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Jonsson Comprehensive Cancer Center, Los Angeles, CA, UNITED STATES OF AMERICA,* [3]*Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY,* [4]*German Cancer Consortium–University Hospital Essen, Essen, GERMANY.*

***Aim/Introduction:*** Results from the VISION phase 3 clinical trial showed that $^{177}$Lu-PSMA-617 radioligand therapy (RLT) led to reduction in serum prostate specific antigen levels and improved survival in disease progression[1]. There is therefore an urgent unmet need to identify mechanisms that can enhance and prolong the efficacy of RLT. Emerging combination approaches are exploring

synergies between immunotherapy and radiation. STimulator of INterferon Genes (STING) is an interesting target for anticancer therapy because of its role in immune activation. This pathway is triggered by cytosolic dsDNA ultimately leading to type I interferon (IFN) production and immune cells activation[2]. Based on this, we tested a combination regimen consisting of PSMA-RLT and STING agonist (diABZI) in two PCa cell lines. ***Materials and Methods:*** Relative expression of IFN-related genes was assessed in vitro by qPCR in RM1-PGLS and Myc-CaP cells after exposure to vehicle, diABZI (1uM) or irradiation (8Gy). C57BL/6 or FVB mice were subcutaneously inoculated with 0.1 x $10^6$ RM1-PGLS or 2 x $10^6$ Myc-CaP-hPSMA cells in 100 µl PBS/Matrigel (1:1). PSMA expression was quantified in vivo by PET/CT 1h after i.v. administration of 1.1 MBq 68Ga-PSMA-617. Tumor-bearing mice were treated with 40kBq $^{225}$Ac-PSMA-617 or diABZI alone (1.5 mg/kg), at a tumor volume of 75.4±34.6mm$^3$ for RM1-PGLS and 133.9±20.8mm$^3$ for Myc-Cap-hPSMA. The following day, mice in the combination group received diABZI while control and RLT mice received vehicle (PEG400, 40% in NaCl). Therapeutic efficacy (4 groups, n=12) was assessed by survival and tumor CT volumetry. ***Results:*** In vitro qPCR analysis of IFN-related genes showed that diABZI increased IFNβ expression in RM1-PGLS by 150-fold while Myc-CaP cells showed no response. In vivo, systemic diABZI combined with PSMA-RLT produced significant tumor growth control in the RM1-PGLS model and major improvement in survival. At day 20 following treatment, the mean tumor volume for control mice was 1.723±0.807cm$^3$ compared to 0.167±0.229cm$^3$ for RLT, 0.165±0.218cm$^3$ for diABZI, and 0.061±0.035cm$^3$ for the combination group. Tumor-free survival rates at day 75 were: control 0%, RLT 42%, STING agonist 67% and combination 100%. ***Conclusion:*** qPCR analysis of IFN-related genes showed a binary profile in the two PCa cell lines. Efficacy study in RM1-PGLS showed that the combination led to a better survival and highlighted the impact of such combination and value in increasing type 1 IFN production. Confirmatory results in the STING-non responsive cell line are ongoing. ***References:*** [1]Sartor et al., N Engl J. Med, 2021 [2]Deng et al., Immunity, 2014.

## EP-0038

### [18F](2S,4R)4-Fluoroglutamine illustrates ability to distinguish KRAS mutation in pancreatic carcinoma

***S. Liu***, *F. Liu, X. Xu;*
*Peking University Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction:*** KRAS is a crucial member of the RAS family, and plays a vital role in regulating various life processes of cell growth, such as proliferation, differentiation, apoptosis, etc. Approximately 90% of pancreatic ductal adenocarcinomas carry KRAS mutations, which are classified as driver mutations and lead to unbridled proliferative features of the cancer. Precision treatment for pancreatic cancer could improve prognosis and prolong survival for patients. As KRAS-driven cancer cells are highly dependent on glutamine, this study aims to identify the G12D and G12C mutations in KRAS using [$^{18}$F](2S,4R)4-Fluoroglutamine ([$^{18}$F]F-Gln) ***Materials and Methods:*** [$^{18}$F]F-Gln was radiolabeled through two-step radiosynthesis reported in a previous study. Mice model bearing tumor were establish to test its effectiveness, including PANC1 and MIA-PaCa-2 mice xenografts. Polymerase Chain Reaction was used to verify mutations in these tumors and cells. ***Results:*** The Polymerase Chain Reaction was used to detect mutations in PANC1 and MIA-PaCa-2 cells/tumors, which exhibited G12D and G12C mutations, respectively. In micro-PET/CT imaging, [$_{18}$F]F-Gln demonstrated significant uptake in PANC1 mice xenografts when compared with MIA-PaCa-2 mice xenografts. After outlining the tumor, the SUVmax value in PANC1 tumors was significantly higher than in MIA-PaCa-2 tumors (1.05 ± 0.01 vs 0.46 ± 0.06 at 30 min, 0.92 ± 0.05 vs 0.37 ±0.07 at 60 min, and 0.62 ± 0.10 vs 0.33 ± 0.05 at 120 min). Furthermore, the uptake of [$^{18}$F]F-Gln in tumors was highest at 30 min in both mouse models ***Conclusion:*** [$^{18}$F](2S,4R)4-Fluoroglutamine probe has the potential to non-invasively identify the mutation type and status of KRAS in vivo through whole-body PET imaging. This could provide precision diagnosis and prediction for pancreatic carcinoma patients, allowing for more targeted and effective treatments.

## EP-0039

### A novel 18F labeled TKI-PET tracer for targeting EGFR mutation

***S. Liu***, *F. Liu, Z. Yang;*
*Peking University Cancer Hospital, Beijing, CHINA.*

***Aim/Introduction:*** The Epidermal Growth Factor Receptor (EGFR) mutation comprises approximately 30% among Asian NSCLC patients (1). The most frequent mutation in the EGFR tyrosine kinase domain (Del 19 and exon 21 L858R) occur in 30%- 50% of Asian NSCLC patients(2). EGFR tyrosine kinase inhibitors (TKIs) were regarded as a recommended first-line therapy in EGFR mutations patients(3). The development of PET probe for EGFR could monitor mutation status and predict EGFR-TKI sensitivity/resistance. ***Materials and Methods:*** $^{18}$F-LF13 was radiolabeled through one-step radiosynthesis. Cell uptake and blocking assay were completed with the HCC827 and the HCC827 blocked with erlotinib to evaluate the specificity of the $^{18}$F-LF13 probe. The micro-PET/CT imaging of the $^{18}$F-LF13 probe were researched in HCC827 and H1975 model mice. ***Results:*** The radiolabeling yield of $^{18}$F-LF13 was 1.55 ± 0.38% using manual synthesis (n=5), and radiochemical purity was over 99%. The uptake in HCC827 cell line was obvious higher than HCC827 cell line blocked with erlotinib (1.29 ± 0.08 vs 0.31 ± 0.02 at 30min, 1.24 ± 0.02 vs 0.32 ± 0.03 at 60min). In micro-PET/CT imaging, $^{18}$F-LF13 showed good characteristics of targeting HCC827 tumor, which exhibited Del 19 mutation. The $^{18}$F-LF13 showed better aggregation in HCC827 tumor, compared with HCC827 tumor blocked with erlotinib (SUVmax: 1.62 ± 0.02 vs 0.89 ± 0.02 at 30min) and H1975 tumor (SUVmax: 1.62 ± 0.02 vs 0.72 ± 0.03 at 30min). This probe was eliminated through intestinal tract rapidly. ***Conclusion:*** $^{18}$F-LF13 probe was powerful to target EGFR del 19 mutation and potential to apply in monitoring EGFR mutation status in NSCLC patients. ***References:*** 1. ### Lenvatinib strengthened I-131-trastuzumab radioimmunotherapy in HER2 positive tumor model

***I. Lim***, *S. Cho;*
*Korea Cancer Center Hospital, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** The purpose of this study is to investigate whether lenvatinib strengthened I-131-trastuzumab radioimmunotherapy in HER2-overexpressing tumor. ***Materials and Methods:*** Trastuzumab was radiolabeled with I-131. The specific in vitro targeting efficacy of I-131-trastuzumab was

analyzed using Lindmo assay. Cytotoxicity was evaluated via colony formation. NCI-N87 cells were implanted subcutaneously in BALB/c mice. Mice were randomized into 5 groups after tumor reaching to 200 mm3: control group, lenvatinib group, trastuzumab group, I-131-trastuzumab group, lenvatinib and I-131-trastuzumab combination group. After that, tumor sizes were evaluated. Tumors were analyzed for HER2, CD34, E-cadherin. ***Results:*** Through the serum stability test, it was confirmed that I-131-trastuzumab showed a labeling yield of 95% or more even after 48 hours to maintain stable binding. Compared with monotherapy, the combination of I-131-trastuzumab and lenvatinib inhibited the proliferation and viability of HER2-overexpressing NCI-N87 cells, resulting in almost no colony formation. In the xenograft model it also observed inhibition of tumor growth ($p< 0.001$). After tumor excision, it was detected that the HER2 level and the CD34 expression decreased, and the expression of E-cadherin increased in the combination group compared to the control group through immunofluorescence staining. ***Conclusion:*** The combination of I-131-trastuzumab and lenvatinib improved therapeutic effect in HER2-overexpressing tumor. This combination protocol might be applied to the patients in the future.

## EP-0041

### GRPR-antagonists based on AU-RM26-M1 and their [111In]In-radioligands: Preclinical evaluation for prostate cancer imaging

***A. Abouzayed***[1], *K. Obeid*[1], *P. Kanellopoulos*[1], *A. Mattsson*[1], *B. A. Nock*[2], *V. Tolmachev*[1], *T. Maina*[2], *A. Orlova*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Molecular Radiopharmacy, NCSR Demokritos, Athens, GREECE.*

***Aim/Introduction:*** The gastrin-releasing peptide receptor (GRPR) is an important target for prostate cancer radiotheranostics, owing to its high-density expression in the majority of primary and metastatic cancer lesions. The aim of this study was to design and characterize three GRPR-antagonists based on the metabolically stable motif AU-RM26-M1 (DOTAGA-$PEG_2$-[$Sar^{11}$]RM26, [$Sar^{11}$]RM26: [D-$Phe^6$,$Sar^{11}$,$Sta^{13}$,$Leu^{14}$-$NH_2$]BBN(6-14), Sta: 3S,4S-4-amino-3-hydroxy-6-methyl-heptanoic acid), whereby positive charged residues were introduced in the linker, namely: AU-RM26-M2 ($PEG_2$-Pip, Pip: 4-amino-1-carboxymethyl-piperidine), AU-RM26-M3 ($PEG_2$-Arg) and AU-RM26-M4 (Arg-Arg-Pip). These analogues were labelled with In-111 and the effects of the above linker modifications on the biological profile of resulting radioligands were investigated. ***Materials and Methods:*** The three peptide-conjugates were synthesized by solid-phase peptide synthesis. They were radiolabelled with indium-111 and the resulting radioligands were evaluated for their GRPR binding specificity, cell-uptake and receptor affinity in human GRPR-positive PC-3 cells. The radioligands (30 kBq, 40 pmol) were injected in Balb/c nu/nu mice bearing PC-3 xenografts and their biodistribution compared at 4 h post-injection (pi). The metabolic stability of radiolabelled peptides was studied in mice 5 min pi. [$^{111}$In]In-AU-RM26-M2 was further studied in vivo at 24 h pi and SPECT/CT images were acquired. ***Results:*** All three analogues were radiolabelled with indium-111 with >95% radiochemical yields. The equilibrium dissociation constants ($K_D$) of the three radioligands were in the low nanomolar range (<1.8 nM). GRPR blocking resulted in significant reduction of uptake in PC-3 cells vs. controls. The percentage of internalized fractions of the radioligands during 4 h incubation at 37 °C were low (<16% of cell-associated activity), as consistent with an antagonist profile. The rank of metabolic stability in peripheral mice blood at 5 min pi was: [$^{111}$In]In-AU-RM26-M4 (83±2% intact) > [$^{111}$In]In-AU-RM26-M2 (78±2%, intact) > [$^{111}$In]In-AU-RM26-M3 (25±5% intact). Consistent with stability results, [$^{111}$In]In-AU-RM26-M4 displayed the highest tumour uptake at 4 h pi (11.8±4.9%IA/g), followed by [$^{111}$In]In-AU-RM26-M2 (7.1±2.4%IA/g) and [$^{111}$In]In-AU-RM26-M3 (2.5±0.6%IA/g). The pancreatic uptake was the highest for [$^{111}$In]In-AU-RM26-M4 (3.2±0.3%IA/g) followed by [$^{111}$In]In-AU-RM26-M2 and [$^{111}$In]In-AU-RM26-M3 (0.4±0.1%IA/g and 0.1±0.0%IA/g , respectively). However, the tumour-to-organ ratios at 4 h pi were the highest for [$^{111}$In]In-AU-RM26-M2, as it had lower uptake in most tissues than [$^{111}$In]In-AU-RM26-M4 and higher tumour uptake than [$^{111}$In]In-AU-RM26-M3. SPECT/CT images of [$^{111}$In]In-AU-RM26-M2 corroborated the biodistribution profile. ***Conclusion:*** This study revealed that the type and position of positively charged residues in the linker of AU-RM26-M1 can be fine-tuned to improve GRPR-affinity, cell uptake, stability, tumour uptake and overall pharmacokinetics of resulting [$^{111}$In]In-radioligands in mice, and potentially also in patients.

## EP-0042

### Using [89Zr]Zr-Oxine ex-vivo labelled macrophages and [89Zr]Zr-DFO-anti-F4/80 to investigate the effect of moderate-dose external beam radiation therapy on macrophage polarisation

***V. De Santis***[1], *A. Banu*[1], *S. Langdon*[1], *J. Cheng*[1], *M. Cleveland*[2], *M. Ma*[1], *S. Terry*[1];
[1]*King's College London, London, UNITED KINGDOM,* [2]*Glaxosmithkline, Stevenage, UNITED KINGDOM.*

***Aim/Introduction:*** Tumour progression is dictated by the tumour microenvironment and its immune status among other factors. Macrophages are known to be present in tumours in large numbers and their presence is associated with metastasis, tumour progression and poor prognosis as they are co-opted by the tumour to polarise from M1-like tumoricidal macrophages to M2-like, tumour associated macrophages (TAMs). Radiotherapy is a mainstay of many cancer therapy plans. It has been suggested that targeted EBRT doses can re-program TAMs to M1-like phenotypes. Herein, differential doses of EBRT were investigated for their effect on macrophage polarisation, distribution and abundance using PET tracers [$^{89}$Zr]Zr-Oxine labelled macrophages and [$^{89}$Zr]Zr-DFO-anti-F4/80. ***Materials and Methods:*** Macrophage polarisation was assessed using flow cytometry. The pan-macrophage marker F4/80 was used to distinguish populations of macrophages from other cell populations. CD80 was used to determine M1 polarisation and CD206 was used for M2 polarisation. Female Balb/c mice were inoculated with 4T1 tumour cells orthotopically. Tumours received targeted doses of 0, 0.2, 2 and 12 Gy. After 72 hours tumours were dissected and digested for analysis. Imaged mice received doses of 0 and 2 Gy. For imaging studies, tumour bearing mice were injected intravenously with $10x10^6$ [$^{89}$Zr]Zr-Oxine-labelled macrophages, [$^{89}$Zr]Zr-DFO-anti-F4/80 or [$^{89}$Zr]Zr-DFO-IgG2b 48 hours after irradiation. Animals injected with [$^{89}$Zr]Zr-DFO-anti-F4/80 and [$^{89}$Zr]Zr-DFO-IgG2b were imaged at 24 post injection. Those that received [$^{89}$Zr]Zr-Oxine labelled macrophages were imaged at 24h and 48h post injection. ***Results:*** FACS results from irradiated tumour digests showed a dose dependent decrease in F4/80 expression with the greatest difference occurring at 2 Gy. CD80 expression decrease significantly with 0.2 and 2 Gy doses. CD206 expression decreased with a 2 Gy dose, however this effect was non-significant. Biodistribution studies with [$^{89}$Zr]Zr-DFO-anti-F4/80 showed a significant difference in

tumour:blood ratio between 0 and 2 Gy ($P \leq 0.0022$). Imaging studies with [$^{89}$Zr]Zr-oxine labelled macrophages did not show a significant difference in tumour:blood ratio between 0 and 2 Gy at 24h. Observational n=1 data at 48h shows a 126% increase in tumour:blood ratio at 2 Gy compared to 0 Gy. ***Conclusion:*** It is plausible that low to moderate doses of external beam radiation therapy cause changes in polarisation, however more studies are required elucidate whether these effects will be more visible with [$^{89}$Zr]Zr-PET after waiting longer periods before imaging post-injection for the tracer to clear from the lungs and blood, potentially revealing any differences.

## EP-0043

### [68Ga]Ga-Bedaquiline - A Potential Diagnostic Radiotracer for Overexpressed Mitochondrial ATP Synthase Composing Proteins in Lung Carcinoma

***A. Chakraborty***[1], *M. Tawate*[1], *A. Mitra*[2], *S. Sahu*[1], *S. Lad*[1], *S. Rakshit*[1], *G. Dhotre*[3], *M. K. Ray*[1], *A. Damle*[1], *U. Pandey*[2], *S. Kulkarni*[1];
[1]*Bhabha Atomic Research Centre, Mumbai, INDIA,* [2]*Board of Radiation & Isotope Technology, Mumbai, INDIA,* [3]*Tata Institute of Fundamental Research, Mumbai, INDIA.*

***Aim/Introduction:*** Bedaquiline is a selective mitochondrial ATP synthase (MAS) inhibitor. The MAS plays dominant role in metabolism and progression of various cancers especially in lung metastasis. Bedaquiline inhibit the overexpression of MAS by binding to ε subunit of MAS. The present work thus envisages to establish a radiolabeling protocol for p-SCN-benzyl-DOTA conjugated bedaquiline with [$^{68}$Ga]$GaCl_3$. The quality control procedure was optimized. For the radioactive formulation, in-vivo bio-distribution studies in SCID mice bearing A549 xenografted tumor were carried out. The preclinical study of [$^{68}$Ga]Ga-DOTA-Bedaquiline, reported herein, provides confirmatory indications toward its potential for clinical translation. Potential of DOTA-benzyl-bedaquiline is being explored to radiolabel with Lutetium-177 for radionuclide therapy. ***Materials and Methods:*** After demthylation of -$OCH_3$ group in bedaquiline, propyl-amine derivatives of bedaquiline were synthesized using N-Boc-3-bromopropylamine and purified by column chromatography. The bedaquiline propyl-amine derivatives were conjugated with p-NCS-benzyl-DOTA at 1:10 molar ratios (pH~8.0) and purified by semi-preparative HPLC. The DOTA-benzyl-bedaquiline (50 µg) were radiolabeled with [$^{68}$Ga]$GaCl_3$ obtained from $^{68}$Ge/$^{68}$Ga generator. The [$^{68}$Ga]$GaCl_3$ were pre-concentrated and eluted with acidified NaCl. The radiolabeling was carried out in 1M $CH_3COONa$ buffer at 95°C for 20 minutes (pH~4.0). The reaction mixture thus purified using preconditioned C18 Sep-Pak, finally [$^{68}$Ga]Ga-DOTA-bedaquiline was eluted from C18 with ethanol (100%, 0.8 mL). The resultant [$^{68}$Ga]Ga-DOTA-bedaquiline was diluted with saline and filtered. RCP was ascertained by radio-TLC and radio-HPLC. Endotoxin limit was quantified by gel-clot BET assay. In-vitro stability was ascertained by evaluating RCP (radio-HPLC) at 2h post-radiolabeling on storage at room temperature (25°C). Human lung adenocarcinoma cell-lines A549, expressing MAS were used for in-vitro evaluation. In-vivo biodistribution and PET/CT imaging was carried out in SCID mice bearing tumor xenograft induced by A549 cell-lines. ***Results:*** Using ~0.93 GBq of [$^{68}$Ga]$GaCl_3$, 3-4 patients doses (~0.68 GBq) of [$^{68}$Ga]Ga-DOTA-bedaquiline were formulated with ~73% RCY. The pH was ~4.5, while RAC was ~50 MBq/mL. RCP (radio-TLC, $R_f$: 0.0-0.1) and (radio-HPLC, $R_t$: 14.0-15.5 minutes) were >98%. Product was sterile and endotoxin-free (EL: <25 EU/mL). Product was found to be stable upto 2h at 25°C with RCP >98%. [$^{68}$Ga]Ga-DOTA-bedaquiline showed rapid binding with A549 cell-lines (25%), reaching a plateau after 45m. In bio-distribution study, high retention of radioactivity were found in tumor (6.8% ID/gm), which is in corroboration with results obtained from PET/CT studies. ***Conclusion:*** Clinical doses formulation of [$^{68}$Ga]Ga-DOTA-Bedaquiline was successfully developed. Pre-clinical results demonstrate the promising potential of [$^{68}$Ga]Ga-DOTA-Bedaquiline for clinical translation in MAS overexpressed lung cancers patients.

## EP-0044

### Preclinical Evaluation of an Anti-Nectin-4 ImmunoPET Reagent in Tumor Bearing Mice

***y. Ren***[1], *Z. Yang*[2];
[1]*Guizhou University, Guiyang, CHINA,* [2]*Peking University Cancer Hospital and Institute, Beijing, CHINA.*

***Aim/Introduction:*** Nectin-4 is selectively overexpressed in a variety of cancers and is currently under clinical investigation as a therapeutic target. A radionuclide Zr-89 labeled monoclonal antibody against Nectin-4 (9MW282) was evaluated as an Immuno-positron emission tomography (ImmunoPET) reagent. Its ability to assay nectin-4 expression was evaluated using bladder cancer mouse models. ***Materials and Methods:*** 9MW282, which is specific for nectin-4, was conjugated to desferrioxamine (DFO) and then radiolabeled with solid target nuclide Zr-89. The final product $^{89}$Zr-DFO-9MW282 was identified by Radio-TLC and its stability was analyzed in vitro. A Nectin-4 positive bladder cancer model bearing SW780 tumor was established and the Nectin-4 tumor targeting of the probe was verified by PET imaging in small animals. ***Results:*** The conjugation of DFO to 9MW282 resulted in a ratio of approximately 0.87 DFO conjugates per antibody molecule. Radiolabeling with [$^{89}$Zr] resulted in a radiochemical purity of > 99% when purified by PD-10 column as determined by ITLC. After incubation in vitro with PBS and 5% HSA solution for 6 days, the radiochemical purity of the probe was still >90%. High binding affinity was found to bind to Nectin-4 with a dissociation constant of 9.79 nM. The specificity and target of the $^{89}$Zr-DFO-9MW282 for nectin-4 was investigated using subcutaneous xenografts. The corresponding immunoPET imaging demonstrated exceptional performance in nectin-4-overexpressing diagnosis. In detail, small animals PET imaging of the probe showed high tumor targeting ability in Nectin-4 positive SW780 model mice with an increased accumulation in SW780 tumor within 72 h p.i. (SUVmax: 4.24 ± 0.03). which was significantly higher than that in $^{89}$Zr-DFO-IgG control group (SUVmax: 1.13 ± 0.01, $p < 0.001$). When 500 µg cold ligand 9MW282 was injected, the uptake of $^{89}$Zr-DFO-9MW282 in the tumor was significantly decreased (SUVmax: 1.67 ± 0.04, $p < 0.001$). ***Conclusion:*** A novel radionuclide labeled immunoPET probe $^{89}$Zr-DFO-9MW282 has been successfully prepared, which presented good physical and biological properties. Its excellent Nectin-4 targeting ability in PET imaging provides visualization tools for the stratification and diagnosis for Nectin-4 overexpressed tumor.

## EP-0045

### Preclinical evaluation of 64Cu-DOTHA2-FAPI for PET Imaging of head and neck cancer

***I. Ben-Salem***[1], *E. Croteau*[1], *V. Dumulon-Perreault*[2], *N. Saidi*[1], *O. Sarrhini*[1], *S. Ait-Mohand*[1], *O. Bélissant*[1], *E. Turcotte*[1], *A. Oweida*[1], *B. Guérin*[1], *E. Rousseau*[1];
[1]*Département de médecine nucléaire et radiobiologie, Université de Sherbrooke, Sherbrooke, QC, CANADA,* [2]*Centre d'Imagerie Moléculaire de Sherbrooke (CIMS), Centre de Recherche du CHUS (CRCHUS), Sherbrooke, QC, CANADA.*

***Aim/Introduction:*** Fibroblast Activation Protein (FAP) is a cell surface protein that is overexpressed in cancer-associated fibroblasts, which are cells that promote tumor growth and spread. FAP has emerged as a promising target for cancer imaging and therapy due to its high expression in various tumor types and its minimal expression in normal tissues. FAP-targeted imaging has shown promise in preclinical and clinical studies for various types of cancer, including pancreatic, ovarian and breast cancer. Its ability to distinguish between cancerous and normal tissues could potentially aid in early cancer detection, diagnosis, and monitoring of treatment response. 64Cu-labeled chelator-linked FAP inhibitors (FAPIs) have been successfully applied to PET imaging of various tumor types. To broaden the spectrum of applicable PET tracers, we herein report the radiosynthesis and preclinical evaluation of 64Cu-DOTHA2-FAPI for the imaging of head and neck cancer. ***Materials and Methods:*** Squamous cell carcinoma MOC2 cells were used to study cellular uptake and internalization of 64Cu-DOTHA2-FAPI in vitro. For in vivo study, MOC2 cells were inoculated in the buccal mucosa of mice and developed into aggressive tumors within 2 weeks of injection. Tumor-bearing mice were imaged using PET with 64Cu-DOTHA2-FAPI at 1hr, 4hr and 24hr post-injection. After PET imaging, mice biodistribution were performed. To confirm the specificity of the radiotracer to its ligand, a blocking experiment using unlabeled FAPI was conducted. ***Results:*** 64Cu-DOTHA2-FAPI was stable ex vivo in plasma and reached cellular uptake and internalization up to 69.37 ± 1.17% injected activity (IA)/$10^6$ cells at 24 h post-injection (p.i.). PET imaging of 64Cu-DOTHA2-FAPI allowed visualization of the tumor with uptake mostly in its periphery. Biodistribution results showed relatively low accumulation in brain (0.32±0.001 %ID/g ), heart (2.21±0.009 %ID/g) and spleen (2.25±0.006 %ID/g). Tumor uptake was 7.28±0.01 with 64Cu-DOTHA2-FAPI, relatively low uptake of whole tumor could be explained by non-homogenous distribution of FAP+ cancer associated fibroblasts (FAP+ CAF) in tumor. Tumor uptake was lower in the blocked group (4.14±0.023 %ID/g, $p<0.05$) confirming the specificity of 64Cu-DOTHA2-FAPI to its FAP target. ***Conclusion:*** Our study demonstrates the potential of 64Cu-DOTHA2-FAPI for molecular imaging of oral cancer in an orthotopic mouse model. This radiotracer could be a promising tool for early detection and monitoring of head and neck cancers.

## EP-0046

### Evaluation of 89Zr-DFO-C23 in immuno-PET imaging of A549 xenograft models with high TIM3 expression

***J. Tao***[1], *Z. Zeng*[2], *H. Zhu*[3];
[1]*Peking University Cancer Hospital, Beijing, Beijing, CHINA,* [2]*Peking University Cancer Hospital, Beijing, CHINA,* [3]*Peking University Cancer Hospital and Institute, Beijing, CHINA.*

***Aim/Introduction:*** T cell immunoglobulin and mucin domain 3 (TIM3; HAVCR2) is a transmembrane protein that plays a negative regulatory role in T cell responses and is considered a promising target in tumor immunotherapy. In this study, a monoclonal antibody probe targeting TIM3 was developed and labeled by $^{89}$Zr nuclide, and the molecular probe was evaluated in vivo and in vivo by high-resolution positron emission tomography (Micro-PET/CT) technology, in order to develop a novel antibody probe targeting TIM3 to guide tumor immunotherapy targeting TIM3. ***Materials and Methods:*** The self-developed TIM3-targeting monoclonal antibody C23 was conjugated to DFO bifunctional chelating agent, and then radiolabeled with 89Zr, and purified by PD-10 desalination column to obtain $^{89}$Zr-DFO-C23 probe. The A549 cell line was transfected with human TIM3 full-length plasmids to obtain an A549-TIM3 cell line with high TIM3 expression. Flow cytometry was used to detect TIM3 expression in A549-TIM3 cells. In vitro the affinity of the $^{89}$Zr-DFO-C23 probe was evaluated by comparing the uptake of A549 and A549-TIM3 cells to the TIM3 target, and the stability of the probe was assessed in PBS and 5% HSA solution. The biodistribution and pharmacokinetic properties of the probe were studied by injection of $^{89}$Zr-DFO-C23 in vivo, and then $^{89}$Zr-DFO-C23 was injected intravenously in the tail and then subjected to static whole-body positron emission tomography (PET) scanning by Micro-PET/CT for 15 minutes at 4, 24, 48, 72 and 96 h, respectively, and the images were quantified by region of interest (ROI) to obtain the maximum uptake value (SUVmax). The targeting specificity of this molecular probe with TIM3 was studied. ***Results:*** In this study, $^{89}$Zr-DFO-C23 probe was successfully prepared, and the high expression of TIM3 in A549-TIM3 cells was confirmed by flow cytometry. Compared with the blockade group or the A549-negative group, the results of cell uptake showed that the $^{89}$Zr-DFO-C23 probe was significantly specific for TIM3. The results of small animal PET showed that the uptake of $^{89}$Zr-DFO-C23 probe in the A549-TIM3 model reached the maximum absolute uptake value at 48 h. It was consistent with the distribution of $^{89}$Zr-DFO-C23 in A549-TIM3-bearing mice. ***Conclusion:*** The $^{89}$Zr-DFO-C23 probe developed in this study showed obvious targeting specificity with TIM3 in vitro and in vitro evaluation. Indicates the potential for non-invasive monitoring of TIM3 expression in tumor immunotherapy.

## EP-0047

### Preparation and Application of Bioorganic Nanoparticle Enhanced PDL1 Targeted Small Molecule Probe

***C. He***, *L. Xia;*
*Beijing Institute of Cancer Prevention and Treatment, Beijing, CHINA.*

***Aim/Introduction:*** PDL1 can also be used as a specific target for the diagnosis and immunotherapy of solid tumors. A large number of drug studies show complexity and lack of evaluation criteria, a PET imaging method to non-invasively quantify PDL1 expression level would potentially help select patients for more effective treatment, and might be leveraged to study target engagement. The most reported small molecule imaging probes targeting PDL1 still have problems such as low imaging specificity, short residence time and single function. Here, we combined the biocompatible melanin nanoprobe with PD-L1-binding peptide WL12 to construct a new nanoprobe targeting PD-L1 for enhancing functionality by using nanotechnology. ***Materials and Methods:*** In this study, melanin nanoparticles were used as raw materials to couple WL12-SH onto nano carriers to obtain (WL12-PEG-MNPs-II, referred to as WPMNs). We used dynamic light scattering, transmission electron microscopy, Fourier transform infrared spectroscopy, and other methods to characterize the synthesized products; Labeling WPMNs with nuclide $^{124}$I and NOTA-WL12 with $^{68}$Ga was used to construct high expression PDL1 cell A549$^{PDL1}$. Cell uptake and kd experiments were conducted to verify the ability of $^{124}$I-WPMNs to target PDL1 in vitro. Micro-PET/CT imaging studies were conducted in A549$^{PDL1}$ bearing mice, and SUVmax was delineated at the tumor site of the two probes to compare their retention ability at the tumor site. Prove the ability of $^{124}$I-WPMNs to target PD-L1 in vivo through PET/MRI studies. ***Results:*** The radiochemical purity of $^{124}$I-WPMNs is more than 95%. And the uptake value of $^{124}$I-WPMNs in A549$^{PD-L1}$ cell was 1.49 ± 0.08 at 2h, which can be blocked by WL12 (0.39±0.03, $P<0.0001$). $^{124}$I-WPMNs showed higher affinity to PDL1 (Kd = 18.5 nM) than

$^{68}$Ga-NOTA-WL12 (Kd = 24.0 nM). And the micro-PET/CT imaging demonstrated specific uptake and high signal-to-noise ratio in a A549$^{PD-L1}$ xenograft mouse model with tumor-to-muscle ratio of 27.31±7.03 at 2 h and increased or remained for more than 72h, which significantly higher than $^{68}$Ga-NOTA-WL12 in tumor uptake with 6.08±0.62 at 2 h. And the retention ability of $^{124}$I-WPMNs makes it possible to conduct PET/MRI imaging for a long time and flexibly adjust the imaging with different purposes. ***Conclusion:*** A clear advance between $^{124}$I-WPMNs and $^{68}$Ga-NOTA-WL12 was observed for PDL1 targeting PET imaging after nanoparticle modification, supporting the application of $^{124}$I-WPMNs PET as a companion diagnostic tool for optimizing treatments that target PDL1.

## EP-0048

### Preclinical evaluation of novel PSMA-targeting ligands labelled with gallium-68

***Z. Novy***[1], *K. Hajduova*[1], *M. Petrik*[1], *K. Bendova*[1], *M. Benesova*[2], *M. Hajduch*[1];
[1]*Faculty of Medicine and Dentistry, Olomouc, CZECH REPUBLIC,* [2]*German Cancer Research Center, Heidelberg, GERMANY.*

***Aim/Introduction:*** The prostate-specific membrane antigen (PSMA) is well-known target in prostate cancer and is investigated for last 20 years. PSMA research led to clinically approved drugs like PSMA-11 or PSMA-617. Despite these great successes, research in the field is still ongoing in order to even improve target affinity or pharmacokinetics of PSMA ligands (inhibitors). In this study, we have focused in preclinical testing of three novel PSMA inhibitors. Compounds P15 and P16 possesses different binding motif compared to PSMA-617, meanwhile compound P19 is based on PSMA-617. ***Materials and Methods:*** Methods included basic stability test in PBS (0-2h), stability in human plasma (0-2h), determination of log D and evaluation of plasma protein binding for three tested compounds and for PSMA-617 as golden standard. The labelled ligands were tested in vitro to reveal their binding to LNCaP cells as well as their internalization into these cells. The ex vivo biodistribution studies were performed in LNCaP-tumor bearing mice (1, 2 h p.i.). Finally, tumor mice were injected with studied compounds and PET/CT imaging was done 1 h p.i. ***Results:*** All studied compounds reveal high stability both in PBS and in human plasma with minor decrease in radiochemical purity after 2 h. Log D values were determined to be -3 for all studied compounds. The plasma protein binding of PSMA-617 and P19 was in level of 50-60%, nevertheless P15 and P16 displayed much lower values (10-40%). Ex vivo biodistribution study showed the highest accumulation of the tracer in kidneys in case of PSMA-617, meanwhile the three tested ligands had much lower kidney uptake, but the tumor uptake was lower as well. Tumor uptake of P19 was 3,52% ID/g, compared to 5,25 %ID/g for PSMA-617. All tested compounds were able to image tumor using PET/CT. P19 showed best tumor contrast from tested compounds, but PSMA-617 had even higher contrast of tumor. Advantage of tested compounds was very low signal in kidneys compared to PSMA-617. ***Conclusion:*** In vivo experiments resulted in very favorable characteristics of all tested compounds comparable to PSMA-617. Ex vivo biodistribution revealed most remarkable difference in kidney uptake of tested, which was very low compared to PSMA-617. Nevertheless the tumor uptake was decreased as well. P19 was the only compound vere tumor/blood ratios were comparable to PSMA-617. PET/CT showed favorable tumor contrast only for P19 and PSMA-617.

## EP-0049

### Design of novel small molecules targeting Fibroblast activating protein and preclinical exploration of 47Sc labeling

***Y. Xia***;
*Second Affiliated Hospital of Chengdu Medical College (China National Nuclear Corporation 416 Hospital, Chengdu, CHINA.*

***Aim/Introduction:*** Fibroblast activating protein, (FAP) is highly expressed in fibroblasts in the mesenchymal stroma of most malignancies. In this study, we used computer-aided drug design (CADD) to design and simulate several novel FAPI small molecule drugs and to evaluate the physical and therapeutic properties of the beta-emitter ($^{47}$Sc). ***Materials and Methods:*** A library of molecules was designed using CADD and screened for high affinity small molecules by combining different chelators, FAPI groups and albumin binding modules. The labeling conditions were refined using $^{68}$Ga and $^{47}$Sc to determine the LogP values, in vivo and in vitro metabolic stability, cellular uptake and specific binding of the labeled products. The products were further used for SPECT/CT imaging and therapeutic experiments in the U87MG model mouse and the MCF-7 model was used as a negative control. ***Results:*** We screened three high affinity small molecules (XY201, XY202, XY203). We selected the one with the best simulation results for the follow-up study and showed that it was well labelled with $^{68}$Ga and $^{47}$Sc (90°C, 15 min, pH ≈ 4) with >90% labelling and >99% radiochemical purity. SPECT/CT imaging and biodistribution studies showed high tumour accumulation, mainly 24 h after injection. Its excretion was mainly in the liver and intestine. More significant tumour suppression was found in the experimental group relative to the saline group in treatment trials. ***Conclusion:*** Using CADD as a technical premise, we have screened novel FAPI small molecule drugs that demonstrate excellent targeting and affinity. $^{47}$Sc labeling shows good therapeutic potential.

## EP-0050

### Lead Optimisation Strategy for the Development Of New Grpr Radioantagonists

***P. Paraïso***[1], *C. van Deurzen*[2], *Y. Seimbille*[1,3];
[1]*Department of Radiology and Nuclear Medicine, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, NETHERLANDS,* [2]*Department of Pathology, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, NETHERLANDS,* [3]*Life Sciences Division, TRIUMF, Vancouver, BC, CANADA.*

***Aim/Introduction:*** To improve the in vivo biodistribution and metabolic stability of the current gastrin-releasing peptide receptor (GRPR)-targeted radioligands, we investigated the substitution of amino acids within the sequence of the GRPR antagonists RM2 (DOTA-Pip$^5$-D-Phe$^6$-Gln$^7$-Trp$^8$-Ala$^9$-Val$^{10}$-Gly$^{11}$-His$^{12}$-Sta$^{13}$-Leu$^{14}$-$NH_2$) and NeoBOMB1 (DOTA-Pip$^5$-D-Phe$^6$-Gln$^7$-Trp$^8$-Ala$^9$-Val$^{10}$-Gly$^{11}$-His$^{12}$-NH-CH[$CH_2$-CH($CH_3$)$_2$]$_2$) by unnatural amino acids. A library of 40 analogs was designed, synthesized and evaluated by competitive binding assay. The results of this study led to the identification of nine novel candidates for diagnosis and therapy of GRPR-positive breast tumors based on their $IC_{50}$, $logD_{7.4}$, cell uptake and stability. ***Materials and Methods:*** All NeoBOMB1/RM2-based compounds were synthesized by standard Fmoc-based solid-phase peptide synthesis (SPPS). Labeling with $^{111}$In was carried out at 95 °C for 20 min in a solution containing ascorbic/gentisic acids (50 mM), sodium acetate (2.5 M) and L-methionine (50 mM). Affinity ($IC_{50}$) to GRPR was determined using T-47D cells. In addition, cell uptake

and internalization (37 °C, 60 min), lipophilicity (expressed as n-octanol/PBS partition coefficient: $logD_{7.4}$), and in vitro metabolic stability in murine serum (up to 24 h at 37 °C) have been carried out to confirm the potential of our lead candidates. ***Results:*** Similar to the synthesis of the parent compounds (NeoBOMB1 and RM2), the new GRPR-targeted derivatives were accessible by SPPS and liquid phase coupling. All compounds were obtained in 33-56% yield after HPLC purification. The GRPR affinity ($IC_{50}$) of the new compounds varied from 0.97 to 1428 nM compared to 1.24 nM and 1.04 nM for RM2 and NeoBOMB1, respectively. The best nine compounds were selected for further examination (pADA-RM2 2: 1.14 nM, D-Cpa$^{6}$-RM2 6: 1.41 nM, D-Tyr$^{6}$-RM2 7: 1.55 nM, D-1-Nal$^{6}$-RM2 8: 1.30 nM, D-2-Nal$^{6}$-RM2 9: 1.19 nM, D-Igl6-RM2 10: 1.33 nM, Cba$^{14}$-RM2 11: 0.97 nM, Thi$^{14}$-RM2 14: 1.89 nM, Igl$^{14}$-RM2 16: 1.47 nM). High radiochemical purity (RCP) was obtained for all nine radioligands (94 - 99%). Candidates 7, 8, 14 and 16 showed a slightly better stability compared to RM2 (> 16% vs. 12% for [$^{111}$In] In-RM2 at 24 h). ***Conclusion:*** 40 new GRPR-targeted ligands were successfully synthesized and characterized by LC-MS. Based on the cell binding assay data, nine compounds were selected for further in vitro evaluation ($logD_{7.4}$, stability). Compounds 7, 8, 14 and 16 are the most promising due to a better stability in mouse serum at 24 h. These compounds will be further evaluated to identify a lead candidate for in vivo studies in tumor bearing mice.

## EP-0051

### Normal organs uptake values in F 18- FDG PET/CT in relation to serum blood glucose

***R. Mostafa***[1], *H. Askar*[2], *M. Helbawi*[2], *H. Mahmoud*[2]; *[1]Nuclear Medicine Unit, Department of Radiation Oncology and Nuclear Medicine, South Egypt Cancer Institute, Assiut University, Assiut, EGYPT, [2]Department of Clinical Oncology and Nuclear Medicine, Faculty of Medicine, Assiut University, Assiut, Assiut, EGYPT.*

***Aim/Introduction:*** PET/CT using F 18-FDG is widely used in oncology(1). The FDG molecule acts like glucose and accumulates at a rate proportional to glycolysis(2). The most commonly used method for quantification is the standardized uptake value (SUV). Several factors affect its measurement, including uptake period, injected dose, body mass index, and blood glucose(3). SUVmax values of healthy organs are considered as references in the evaluation of patients with different tumors. Aim: To analyze the SUVmax values of normal organs and assess their association with different factors. ***Materials and Methods:*** The Institutional Review Board approved this retrospective study which included 593 patients (276 males, 317 females; age 47 ± 20 years old; body mass index 28.31 ± 8.30). All patients underwent F 18-FDG PET/CT scans using a standardized imaging protocol. Blood glucose was measured immediately before injection. Diabetic status, BMI, uptake period and injected dose were extracted from patients records. Fixed regions of interest were drawn at cerebral hemispheres, lung, blood pool activity, liver, spleen, pancreas and muscle to extract SUVmax. Any organs with infiltration were excluded from this analysis. The study populations were divided into 2 groups depending on fasting blood glucose with a cut off value 160 mg/dl. Patients with a blood glucose less than 160 mg/dl were considered as control group. By dividing the difference in the mean SUVmax for the group with glucose ≥160 mg/dl by the mean SUVmax in the control group, effect size was calculated using pooled SDs. Multivariate linear regression analysis was used to assess the impact of important factors affecting uptake in normal organs. ***Results:*** 535 patients had fasting blood glucose level less than 160 mg/dl while 58 had blood glucose ≥ 160. Only two organs (brain and muscle) showed significant correlation with serum blood glucose. After adjustment of age, sex, body mass index, injected dose, and serum blood glucose; the brain shows significant inverse correlation with fasting blood glucose while the muscle demonstrated significant positive correlation. Age, sex, body mass index, and injected dose showed statistically significant positive correlation with uptake at different organs. ***Conclusion:*** The brain and muscle were the only two organs demonstrating a statistically significant relationship to glycemic status after adjustment for confounding potential values. ***References:*** 1. Gallamini A, Zwarthoed C, Borra A. Positron Emission Tomography (PET) in Oncology. 2014;1821-89. 2. Sarji SA. Physiological uptake in FDG PET simulating disease. 2006; 3. Fletcher JW. NIH Public Access. 2011;31(6):496-505.

## EP-0052

### Synthesis and preliminary assessment of 68Ga/177Lu-TATE-EB-01 for the theranostic in neuroendocrine tumor

***X. Wen***[1], *P. Xu*[2], *J. Liu*[1], *J. Zhang*[3], *Z. Guo*[1], *X. Chen*[3]; *[1]State Key Laboratory of Molecular Vaccinology and Molecular Diagnostics & Center for Molecular Imaging and Translational Medicine, School of Public Health, Xiamen University, Xiamen, CHINA, [2]Institute of Clinical Pharmacy & Pharmacology, Jining First People's Hospital, Jining Medical University, Jining, CHINA, [3]Department of Diagnostic Radiology, Yong Loo Lin School of Medicine and Faculty of Engineering, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** Somatostatin receptor (SSTR) is overexpressed in neuroendocrine tumors, TATE as an analogue of somatostatin, which could bind to SSTR with high affinity. This study aims to optimize TATE ligands through Evans blue modification to maximize the tumor uptake values and improve the therapy effect of neuroendocrine tumors. ***Materials and Methods:*** TATE-EB-01 was synthesized based on SSTR-targeting ligand (DOTA-TATE) and radiolabeled with $^{68}$Ga and $^{177}$Lu for radiotracer imaging and radioligand therapy. Cellular uptake assays were performed to identify the receptor binding affinity and SSTR targeting specificity. PET imaging of $^{68}$Ga-TATE-EB-01 and $^{68}$Ga-EB-TATE was performed to compare the tumor uptake and pharmacokinetics of the two radiotracers. In addition, SPECT/CT imaging and biodistribution studies of $^{177}$Lu-TATE-EB-01 and $^{177}$Lu-EB-TATE were conducted to explore the potential of theranostic in neuroendocrine tumors. ***Results:*** $^{68}$Ga/$^{177}$Lu-TATE-EB-01 had high SSTR binding affinity and targeting specificity in vitro and in vivo. PET imaging of $^{68}$Ga-TATE-EB-01 in AR42J tumor model indicated that obviously improved tumor uptake and tumor/normal tissue ratios compared to $^{68}$Ga-EB-TATE. SPECT/CT imaging and biodistribution studies showed that $^{177}$Lu-TATE-EB-01 had higher tumor absolute uptake, as well as longer tumor retention time than $^{177}$Lu-EB-TATE and $^{177}$Lu-DOTA-TATE in AR42J tumor model, which demonstrated the enormous therapeutic potential of $^{177}$Lu-TATE-EB-01 in neuroendocrine tumors. ***Conclusion:*** In this study, we successfully synthesized TATE-EB-01 and radiolabeled with $^{68}$Ga and $^{177}$Lu. High binding affinity and SSTR targeting specificity was verified, moreover, significantly ameliorative tumor absolute uptake and retention time was observed, that makes $^{177}$Lu-TATE-EB-01 has the potential to improve the therapy effect of neuroendocrine tumors with lower dosages and less cycles.

## EP-0053

**[18F]FDG-PET/CT and MRI to assess treatment response to anti-PD1 in an orthotopic mouse renal cancer model.**

***O. Bejuy***, *H. Poinot, D. Colin, A. Pommier, V. Garibotto;*
*University Of Geneva, Geneva, SWITZERLAND.*

***Aim/Introduction:*** Novel cancer treatments are required to improve the outcome of patients not responsive to current immunotherapies. Endogenous steroids have strong immunomodulatory functions but their role in resistance to immunotherapy in cancer is poorly understood. As a preliminary study, we evaluated the potential of multimodal Positron Emission Tomography (PET) / Computed tomography (CT) and Magnetic Resonance Imaging (MRI) in early quantification of anti-PD1 efficacy in an orthotopic mouse renal cancer model. ***Materials and Methods:*** 6-week-old balb/c female mice were orthotopically injected in the right kidney with Renca cells. Briefly, incisions of 0.5 to 0.7 cm were made into the skin of mice right flank without opening the peritoneum. Kidneys were localized and $10^5$ Renca cells were slowly injected with a Hamilton syringe. The incisions were closed with surgical glue and animals were carefully monitored for 3 days. 200 µg/mouse of anti-PD-1 antibodies treatment was administrated intraperitoneally starting from day 7 after tumor cell injection followed by further administrations every 2 and 3 days, up to 35 days. Tumor growth was monitored by MRI (FSE T2 FatSat) and tumor metabolism was assessed by [$^{18}$F]FDG-PET/CT imaging, once a week at 2 and 3 weeks after beginning of anti-PD1 treatment. ***Results:*** MRI showed tumor growth over time and [$^{18}$F]FDG-PET imaging showed tumor activity evolution over time. CT imaging provided sufficient anatomical data to localize kidneys and to allow coregistering of PET data. $SUV_{max}$ were quantified as the most relevant marker of tumor development by [$^{18}$F]FDG-PET/CT. During a one-week period, tumor volumes assessed by MRI showed a trend for increase. $SUV_{max}$ assessed by [$^{18}$F]FDG remained stable. However, only [$^{18}$F]FDG-PET revealed the onset of the response modulation to anti-PD1 treatment after three weeks, although not significant. Additionally, [$^{18}$F]FDG-PET metabolic volumes increased over time. ***Conclusion:*** Both MRI and [$^{18}$F]FDG-PET modalities bring insights in the evaluation of the therapeutic effect of anti-PD1, with [$^{18}$F]FDG-PET possibly more sensitive to the onset of the effect of anti-PD1. Further investigations on PET quantification methods, as well as animal survival correlation studies will be conducted to fully evaluate the potential of early [$^{18}$F]FDG-PET compared to MRI for anti-PD1 treatment response assessment.

**FAP-targeted cancer theranostics**

***W. Wei***;
*Shanghai Jiao Tong University, Shanghai, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein (FAP) is the most popular target in nuclear medicine imaging and cancer theranostics. Several big pharmas are developing state-of-the-art small molecule and peptide-based FAP-targeting molecular imaging and radiotherapy agents. We engineered three FAP-targeted peptide agents for molecular imaging and therapy of FAP-overexpressing tumors. There are several small molecule moieties (FAP-04 and FAP-46 etc) used for developing FAP-targeted theranostics agents. FAP-2286 is a very promising peptide under active investigation. However, the circulation time of FAP-2286 is short, resulting in rapid clearance via kidneys (associated with low tumor uptake and high kidney accumulation). For taking care of the existing drawbacks, we engineered three derivatives of FAP-2286 named as CD1, CD2, and CD3. ***Materials and Methods:*** CD1, CD2, and CD3 were synthesized using solid-phase peptide systhesis. The binding affinities of the three peptides to human and murine FAP proteins were meaused using SRP. Following this, the peptides were labeled with 68Ga and 177Lu for PET imaging and radioligand therapy, respectively. The theranostic value of the novel agents were evaluated in multiple tumor models expressing FAP. ***Results:*** All the three reported peptides bind to human and murine FAP with single digit nM affinity. After radiolabeling, CD1 has lower kidney uptake and CD2/CD3 have significantly prolonged circulation, increased tumor uptake and decreased kidney accumulation. Following thorough in vivo and in vitro studies, we found that [68Ga]Ga-DOTA-CD1 is well suited for PET imaging of FAP dynamics, [177Lu]Lu-DOTA-CD2 and [177Lu]Lu-DOTA-CD3 have impressive therapeutic effects in FAP-overexpressing tumor models. Therefore, [68Ga]Ga-DOTA-CD1/[177Lu]Lu-DOTA-CD2 and [177Lu]Lu-DOTA-CD3 are well characterized theranostic pairs. ***Conclusion:*** We developed three novel agents for . While [68Ga]Ga-DOTA-CD1 is ready for same-day PET imaging of FAP dynamics, [177Lu]Lu-DOTA-CD2 and [177Lu]Lu-DOTA-CD3 are promising radioligand therapy agents for treating FAP-overexpressing tumors. ***References:*** 1. **Development ofINER-PP-F11N as the Radionuclide Theragnostics Agent against Cholecystokinin B Receptor-overexpressed Tumors**

***M. Chang***, *C. CHEN, P. CHIANG, C. PENG;*
*Institute of Nuclear Energy Research, Taipei, TAIWAN.*

***Aim/Introduction:*** We aimed to evaluate an albumin affinity structure-containing radiopharmaceutical agents INER-PP-F11N-1 and INER-PP-F11N-2 for diagnostic/therapeutic the CCK2R-overexpressed cancers ***Materials and Methods:*** We developed the radionuclide labeled In-111/Lu-177-INER-PP-F11N radiopharmaceuticals in comparison with the current PP-F11N to investigate the radiochemical purity, SPECT/CT imaging, bio-distribution, and therapeutic responses in CCK2R-expressing tumor xenograft mice. ***Results:*** The radiochemical purity of In-111/Lu-177-INER-PP-F11N radiopharmaceuticals reached more than 90% after 144 hours of labeling. Both INER-PP-F11N increased cellular uptake and internalization 27% and 11% in compared with PP-F11N, respectively. In-vivo SPECT-CT imaging confirmed INER-PP-F11N could accumulate in the tumor site of mice in 24 hours after receiving those two radiopharmaceutical agents. Bio-distribution analysis revealed a significantly greater tumor uptake and reduced accumulation of INER-PP-F11N in kidney in compared with PP-F11N. Furthermore, INER-PP-F11N could significantly inhibit growth of the CCK2R-overexpressing tumors in mice. ***Conclusion:*** The INER-PP-F11N radiopharmaceuticals was superior in comparing with the current PP-F11N as a theragnostic agent. Our study suggested INER-PP-F11N could be an innovative radiopharmaceutical agent for CCK2R-overexpress-

ing cancer patients. ***References:*** 1. Targeting of a CCK(2) receptor splice variant with (111)In-labelled cholecystokinin-8 (CCK8) and (111)In-labelled minigastrin. ## EP-0056

### Local Infusion of 177Lu-Labeled Gold Nanoparticles Combined with anti-PD1 Checkpoint Immunotherapy Prolongs Survival of C57BL/6 Mice Bearing Orthotopic GL261 Murine Gliomas

***C. Georgiou***[1], *Z. Cai*[1], *J. T. Rutka*[2], *M. Winnik*[1], *R. M. Reilly*[1];
[1]*University of Toronto, Toronto, ON, CANADA,* [2]*The Hospital for Sick Children, Toronto, ON, CANADA.*

***Aim/Introduction:*** Glioblastoma (GBM) is the most common and aggressive primary adult brain tumour with a poor median survival. Standard-of-care treatment does not prevent the invasive growth that leads to recurrence Previous published research showed that local infusion of $^{177}$Lu-labelled gold nanoparticles as a monotherapy was impressively effective and non-toxic in controlling glioblastoma growth in an orthotopic mouse model[1]. Further improvement in therapeutic efficacy could be achieved by combining treatment modalities. We hypothesize that local infusion of $^{177}$Lu-labelled gold nanoparticles by convection enhanced delivery will be synergistic when combined with anti-PD1 checkpoint immunotherapy in controlling an orthotopic murine model of GBM. ***Materials and Methods:*** AuNP (18 nm) were labeled by conjugation to a metal chelating polymer (MCP) with 8 pendant DOTA and 4 lipoic acid groups [PEG-pGlu(DOTA)$_8$-LA$_4$] complexed to $^{177}$Lu. Murine GBM tumours were established by stereotaxic inoculation of GL261 cells into the right frontal lobe of C57BL6 mice. Mice were treated 10d after inoculation with either saline, anti-PD1 antibody (3×200 µg), non-radioactive AuNP, $^{177}$Lu-AuNP (0.8±0.1 MBq), or combination $^{177}$Lu-AuNP/anti-PD1 antibody (n=7-10). Median survival was estimated by Kaplan-Meier analysis. Novel Object Recognition (NOR) and Object-Location Task (OLT) were used to evaluate treatment effects on cognition 21d after inoculation. Flow cytometry was used to profile immune cell infiltration in the brain 21d post-inoculation of mice receiving the listed treatments. ***Results:*** Median survival of saline, non-radioactive AuNP, anti-PD1, $^{177}$Lu-AuNP, $^{177}$Lu-AuNP/anti-PD1 treated mice were estimated to be 24.5, 26, 32, 29, and 33d respectively with 30% of anti-PD1 treated and 43% of combination treated mice surviving long-term. NOR test and OLT revealed no differences in cognitive performance between treatment groups. Compared to saline, all treatments significantly reduced the population of CD4$^+$ T-Helper Cells (CD45$^+$,CD3$^+$,CD4$^+$,CD8$^-$) and increased the population of CD8+ Cytotoxic T-Cells (CD45$^+$,CD3$^+$,CD4$^-$,CD8$^+$). ***Conclusion:*** The novel combination of anti-PD1 checkpoint immunotherapy and local infusion of $^{177}$Lu-AuNP may show synergism when used to treat orthotopic murine GBM. None of the treatments impacted cognition, indicating that the radiation dose or the checkpoint immunotherapy was safe. Analysis of infiltrating lymphocytes indicated that $^{177}$Lu-AuNP/anti-PD1 combination therapy was able to modulate the immune profile of the tumours. These results may merit further advancement of the $^{177}$Lu-AuNP towards human trials in combination with anti-PD1 checkpoint immunotherapy. ***References:*** Georgiou, C.J., et al., Treatment of Orthotopic U251 Human Glioblastoma Multiforme Tumors in NRG Mice by Convection-Enhanced Delivery of Gold Nanoparticles Labeled with the beta-Particle-Emitting Radionuclide, (177)Lu. ## EP-0057

### Compositedegradablepolymer microspheresloaded with 177Lufor Transarterial Radioembolization therapy of Rat hepatocellular carcinoma

***L. Xiao***, *H. Cai, L. Li;*
*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** We developed a new biodegradable polymer microsphere that can simultaneously load $^{177}$Lu and MgO (Magnesium oxide) nanoparticle (relieve tumor hypoxia). Chitosan microsphere (CS) was regarded as skeleton structure for surface modification through polydopamine (PDA) to chelate $^{177}$Lu and load MgO ($^{177}$Lu-PDA-CS-MgO). Then, we explored TARE therapeutic efficacy and biosafety of $^{177}$Lu-PDA-CS-MgO on rat HCC. ***Materials and Methods:*** 1. Microspheres preparation: CS was prepared by emulsion crosslinking method. MgO nanoparticles were loaded at PDA-CS to develop PDA-CS-MgO. Catechol group in PDA-CS was used for chelating $^{177}$Lu. 2. TARE treatment efficacy evaluation in HCC rats: The HCC rats were divided into four groups: $^{177}$Lu-PDA-CS-MgO group, $^{177}$Lu-PDA-CS group, PDA-CS group and sham operation group. TARE was performed by laparotomy and then drug was injected through hepatic artery. SPECT/CT was performed to monitor in vivo stability of $^{177}$Lu-PDA-CS-MgO and $^{177}$Lu-PDA-CS. MRI scan was performed to evaluate tumor growth and gross specimens were monitored after administration. The survival duration of each rat was monitored. HE analysis, TUNEL analysis, immunohistochemical analysis, and WB (western blot) analysis were conducted on tumor tissues of each group 5 weeks after surgery. ***Results:*** CS and PDA-CS-MgO was successfully developed. The labeling rate of $^{177}$Lu-PDA-CS-MgO was 87.1 ± 0.5% and loading dose was 1.11 ± 0.005 mCi/g. When $^{177}$Lu-PDA-CS-MgO was placed in FBS and PBS for 11 days, radiochemical purity decreased slowly. After 216 h at FBS, radiochemical purity was 85.15 ± 0.91% , and that of PBS was 88.65 ± 0.20%. After 8 weeks of drug induction, 82 rat HCC models were successfully induced, with a success rate of 86.3% (82/95). SPECT/CT imaging after TARE operation showed that $^{177}$Lu-PDA-CS-MgO was mainly distributed in the liver until 56 days post-injection. MRI scan and gross specimens indicated $^{177}$Lu-PDA-CS-MgO could significantly inhibit tumor growth and spread compared with other treatment groups. HE staining and TUNEL analysis showed more tumor necrosis and apoptotic cells in $^{177}$Lu-PDA-CS-MgO group. The HCC rats in this group had longer overall survival. Immunohistochemical analysis and WB results showed that $^{177}$Lu-PDA-CS-MgO could reduce the expression of hypoxia inducible factor-1α (HIF-1α), CD31 and Ki-67. ***Conclusion:*** In this study, $^{177}$Lu-PDA-CS-MgO was developed successfully, with high labeling rate, good degradability, blood compatibility, and good in vivo and in vitro stability. $^{177}$Lu-PDA-CS-MgO can effectively inhibit tumor growth and spread, relieve hypoxia, prolong survival time in HCC rats through TARE treatment.

## EP-0058

### Nucleic acid nanospheres for PET imaging and antioxidant therapy of hepatic ischemia-reperfusion injury

***H. Wang***, *X. Lan, D. Jiang;*
*Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

***Aim/Introduction:*** Organ ischemia with inadequate oxygen supply followed by reperfusion can lead to complex inflammatory responses and oxidative stress. Liver is highly dependent on

oxygen supply and susceptible to hypoxic or anoxic conditions. Hepatic ischemia-reperfusion injury (IRI) includes the restriction and reoxygenation of blood supply to activate an immune response that may lead to cellular damage and organ dysfunction. This process is not only a pathophysiological process, but also a complex systemic process affecting multiple tissues and organs. Numerous studies have shown that oxidative stress plays a key role in IRI, and scavenging reactive oxygen species (ROS) through antioxidant supplementation can reduce oxidative stress and the ensuing organ damage. Herein, we asked whether DNA nanospheres delivered to the liver can react with ROS in the liver and alleviate the clinical symptoms of IRI. ***Materials and Methods:*** In this study, we successfully synthesized nucleic acid nanospheres (NANS) as a DNA nanoparticle with desirable ROS scavenging capacity, it can target and accumulate in the liver for antioxidant treatment of IRI. Approximately 100 μL (0.1 mCi) of $^{68}$Ga-NANS or $^{64}$Cu-NANS was administered intravenously to mice (n = 3) to monitor the biodistribution of NANS in vivo. PET/CT imaging was performed at three time points of 0.5, 1 and 2 h after injection of $^{68}$Ga-NANS. $^{64}$Cu-NANS in animals was imaged longitudinally at 0.5, 12, 24, and 48 h after injection. Tracer uptake in percentage of injected dose per gram of tissue (%ID/g) and time-activity curves were charted accordingly. At the final time point after PET/CT scanning, all mice were euthanized and dissected to collect major organs/tissues for biodistribution measurement and analysis. ***Results:*** After injection, NANS is mainly absorbed by mononuclear phagocyte system (MPS) and concentrated in Kupffer cells. NANS can effectively remove intracellular and extracellular ROS, inhibited the activation of Kupffer cells and macrophages, preventing them from releasing proinflammatory cytokines, subsequently minimizing the adhension, recruitment, and infiltration of neutrophils, and eventually inhibiting the continued inflammatory process, superoxide dismutase (SOD) levels were restored and maintain aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels in IRI mice in a relatively normal range, thereby alleviating the liver injury caused by IRI. ***Conclusion:*** NANS is mainly distributed in the liver after injection into the body, showing specific advantages in the treatment of hepatic IRI, and the increased ROS in the liver caused by IRI is consumed by NANS, which can significantly alleviate liver injury.

## EP-0059

### Continuous enzymatic hypoxia relief with NIR-II moderate photothermal assistance for enhanced Yttrium-90 microspheres oncotherapy

***J. Li***, *X. Su;*
*The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, CHINA.*

***Aim/Introduction:*** Radiopharmaceutical-based tumor theranostic is the representative modality in precise medicine. In situ tumor oxygenation via catalase-mimicking nanomaterials has been an attractive strategy to improve the therapeutic index of radionuclides internal radiotherapy (RIT). However, the fleeting hypoxia relief activated by the instable catalase or biodegradable nanoenzymes failed to match the days-scale therapeutic period of RIT, such as Yttrium-90 ($^{90}$Y) microspheres oncotherapy. ***Materials and Methods:*** A persistent RIT-enhancing method based on the NIR-II-responsive Pd-based nanoplatforms with facet-dependent catalase-like activity is proposed. Specifically, rationally designed Pd@Au nanosheets (Pd@Au NSs) enable steadily enzyme catalysis of endogenous $H_2O_2$ for $O_2$ generation to address the hypoxia-induced RIT resistance, the incompletely surface-coated Au layer can red-shift the absorption of Pd NSs to near-infrared-II (NIR-II) biowindow. With the combination of NIR-II moderate photothermal treatment, the catalase-mimicking activity of Pd@Au NSs and tumor blood perfusion are simultaneously boosted, which help building a feasible therapeutic tumor microenvironment and the inhibition of DNA damage repair for the enhanced $^{90}$Y microspheres therapy. ***Results:*** The facet-dependent catalase-like activity of Pd@Au NSs with polyethylene glycol modification can efficiently accumulate in tumor by enhanced penetration and retention (EPR) effect after intravenous injection, and enable the persistently efficient hypoxia relief, which fits the days-scale therapeutic period of $^{90}$Y-microshperes oncotherapy. Under the guidance of NIR-II photoacoustic imaging (PAI), the moderate NIR-II photothermal treatment was operated to further improve the enzyme activity of Pd@Au NSs and inhibit the repair of ionizing radiation-mediated DNA damage. Benefiting from this two-pronged tactic radiosensitization effect, $^{90}$Y-microshperes combined with Pd@Au NSs and low power density NIR-II laser irradiation enabled efficient ablation of 4T1 subcutaneous tumors (cure rate = 80%), while the single $^{90}$Y-microshperes with the same radioactivity dose could only slightly suppress tumor growth (cure rate = 0%) compared with saline-injected group. Hematoxylin-eosin and TUNEL staining analysis of treated tumors further demonstrated the enhanced therapeutic effect and good biocompatibility of this combined therapy. ***Conclusion:*** This work innovated a RIT sensitization strategy to strengthen the performance of clinically approved RIT formulations, pushing forward the incorporation of catalytic nanomedicine and nuclear medicine to improve the clinical benefits of RIT.

## EP-0060

### Prostate-specific membrane antigen-targeted endogenous radiotherapy of triple-negative breast cancer

***A. Heesch***[1], *J. Maurer*[2,3], *A. Florea*[1], *A. Morgenroth*[1], *F. M. Mottaghy*[1,4];
[1]*Department of Nuclear Medicine, University Hospital RWTH Aachen, Aachen, GERMANY,* [2]*Department of Obstetrics and Gynecology, University Hospital RWTH Aachen, Aachen, GERMANY,* [3]*Center for Integrated Oncology (CIO), Aachen, Bonn, Cologne, Düsseldorf (ABCD), GERMANY,* [4]*Department of Radiology and Nuclear Medicine, Maastricht University Medical Center (MUMC+), Maastricht, NETHERLANDS.*

***Aim/Introduction:*** Triple-negative breast cancer (TNBC) has a very aggressive nature and affects especially young women. Current treatments include chemotherapy, radiation, and surgery, however more specialized approaches are limited. Our previous in vitro data demonstrate prostate-specific membrane antigen (PSMA) expression on TNBC associated endothelial cells. Thus we aim to develop a treatment with PSMA as a vascular target for endogenous radiotherapy with [$^{177}$Lu]Lu-PSMA in a TNBC xenografted mouse model. The efficacy of one high dose versus four low doses of [$^{177}$Lu]Lu-PSMA is analyzed concerning tumour growth inhibition. ***Materials and Methods:*** [$^{177}$Lu]Lu-PSMA was successfully synthesized by a routine procedure. Quality control was done with radio-HPLC. MDA-MB-231 cells were used for orthotopic tumour implantation in immunocompromised mice. For therapy, the animals were intravenously injected with [$^{177}$Lu]Lu-PSMA (1x for single dose or 4x for fractionated treatment) or NaCl (control). Tumour growth was monitored weekly via 2-[$^{18}$F]FDG microPET/CT. Ex vivo analyses included immune-, H&E, and TUNEL staining. ***Results:*** We observed significant smaller tumour

volumes in both therapy groups compared to the control group 30 days after therapy start. Tumour growth inhibition rates were 38% (1x [$^{177}$Lu]Lu-PSMA) and 30% (4x [$^{177}$Lu]Lu-PSMA). Immunolabeling with α-PSMA and α-CD31 antibodies revealed co-localization on tumour-associated vasculature. H&E staining of organ sections showed no morphological abnormalities. TUNEL staining revealed a higher amount of apoptotic cells in the tumour compared to the control. ***Conclusion:*** Treatment of TNBC xenografted mice with [$^{177}$Lu]Lu-PSMA successfully and significantly (single dose: $p<0.001$; fractionated dose: $p=0.02$) inhibited tumour growth. Importantly, no off-target damage to other organs was observed. More ex vivo analyses like microautoradiography and hypoxia stainings will be done and the SUV values from the PET scans will be quantified. Future studies could include a combination of [$^{177}$Lu]Lu-PSMA radiotherapy and cytostatics to improve treatment efficacy. ***References:*** (1) Heesch et al. Cells 2023, 12(4):551

## EP-0061

### Impact of injection velocity during transarterial radioembolization, an in vitro analysis

***T. Snoeijink***[1], *J. L. van der Hoek*[2], *H. Mirgolbabaee*[2], *E. Groot Jebbink*[2], *J. F. W. Nijsen*[1];
[1]*Radboud University Medical Centre, Nijmegen, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS.*

***Aim/Introduction:*** Transarterial radioembolization (TARE) is an established treatment method for patients with primary and secondary liver malignancies. During this treatment, radioactive microspheres are injected into the arterial vasculature of the liver via a microcatheter. Microspheres are transported through the arterial vasculature until they lodge predominantly in and around tumorous tissue. However, it is seen in clinical practice that the microsphere distribution towards tumorous tissue differs per procedure, medical practitioner and patient. The aim of the current study was to investigate the influence of injection velocity on the microsphere mixture in the blood and distribution in the blood vessels during TARE. ***Materials and Methods:*** A symmetrical right hepatic artery phantom was developed which bifurcates three times into eight outlets. A blood-mimicking fluid (BMF) was pumped through the phantom composed of water, glycerol and urea, with respective weight percentages of 55.8%, 34.2% and 10%, yielding a density of 1.1 g/ml and viscosity of 3.5 cP. To create a physiological representative blood flow waveform, a programmable piston pump (SuperPump, ViVitro labs) was used. Microsphere injections were performed with non-irradiated holmium loaded poly(L-lactic acid) microspheres (Quirem Medical B.V.) in a pulsed manner (0.2 ml per push, 24 ml/min), using a Progreat 2.7F microcatheter (Terumo). The injection solution consisted of blue dyed 0.9% saline solution with a microsphere concentration of 15 mg/ml. To monitor the microsphere stream at the catheter tip, videos were taken with a high speed camera with 500 frames/s (Fastcam SA2, Photron) during injection. BMF and microspheres were collected at each outlet. Dye concentrations were measured using a spectrophotometer (Tecan Infinite 200 PRO, Tecan Trading AG) and microspheres were extracted and weighed for comparison. ***Results:*** The first preliminary results show that the flow profile of microspheres is influenced by the injection velocity. With currently used injection velocities (24 ml/min), streamlined outflow patterns were observed at the catheter tip, implying a laminar flow. ***Conclusion:*** In TARE it is assumed that microspheres will follow the blood flow, which is favourable is case of a non-targeted injection. However, in this in vitro set-up streamlined outflow patterns were observed, having an impact on the behaviour of the microspheres in the blood and thus the microsphere distribution. Therefore, exact influence of injection velocity on the mixing and distribution should be investigated quantitatively in both phantom models and patients.

## EP-0062

### Sn-117m Homogeneous Colloid is a Disease-Modifying Device in the Treatment of Osteoarthritis

***C. Doerr***[1], *A. Bendele*[2], *J. Simon*[3], *N. Stevenson*[4], *G. Gonzales*[1];
[1]*Serene, LLC, The Woodlands, TX, UNITED STATES OF AMERICA,* [2]*Inotiv, Boulder, CO, UNITED STATES OF AMERICA,* [3]*Isotherapeutics Group, LLC, Angleton, TX, UNITED STATES OF AMERICA,* [4]*Exubrion Therapeutics, Buford, GA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Radionuclides have been used to treat human rheumatoid (RA) and osteoarthritis (OA) for decades outside of the United States. The procedure, radiosynoviorthesis (RSO), is the intra-articular injection of an isotope, either as a non-homogeneous microparticle (Er-169 and Y-90) or a colloid (Re-186), that is engulfed by synovial macrophages. This results in thickening of the synovium and sclerosis and fibrosis resulting in decreased joint pain. Sn-117m, used in the manufacture of a homogeneous Sn-117m colloid (HTC) for RSO procedures, is generated in nuclear reactors via 117Sn(n,n'γ)117mSn. Although radionuclide drug injections for RSO are approved in Europe, in the US the HTC device is available only for the treatment of canine elbow OA. Our aim was to investigate whether the HTC demonstrated an OA disease modifying effect, and we report here the data from cGMP/GLP rodent trials which suggest the existence of that effect. ***Materials and Methods:*** Adult rats (n=109) were studied using the surgical meniscal tear OA model. The trial consisted of rats divided into 5 arms including 2 control arms, 1 safety arm, and 2 treatment arms using RSO dosages of 2μCi (low dose) and 10μCi (high dose) HTC. Rats were sacrificed at 1, 4, 6 and 10 weeks. Sacrificed study knees received histopathology analysis. Sn-117m was produced in the BR2 nuclear reactor followed by manufacturing of HTC. ***Results:*** Generally, animals treated with 2 or 10 μCi had lesion severity that was slightly to significantly reduced compared to non-injected OA controls. Based on substantial cartilage degeneration widths with support from other cartilage degeneration parameters (scores, depth ratios, osteophyte measures), there is evidence of beneficial effects of treatment at week 1, and trends toward at 4 and 6 weeks on some parameters. ***Conclusion:*** To our knowledge, this is the first time that a medical device has provided evidence of an OA disease modifying effect. Our rat data translates to and provides validation for the Phase 1 human clinical trial of OA and RA therapy that is authorized to begin in Canada. Although OA contributors include obesity, malalignment, acute and repetitive joint injuries, generalized disease, heredity, and muscle weakness, OA ultimately progresses to include a rheumatologic component which also is well known to respond to RSO treatments. We anticipate that HTC will produce a disease modifying effect in the planned human OA/RA trials, similar to that seen in the rat trials.

## EP-0063

### Therapeutic potential of a Claudin 18.2 targeted alpha therapeutic [225Ac]-FPI-2474 in a pre-clinical gastric cancer tumor model

***S. Almasi***, *T. Kostelnik, V. Subramony, N. Robinson, W. Turnbull, B. L. Thériault, C. P. Leamon, J. Valliant;*
*Fusion pharmaceuticals, Hamilton, ON, CANADA.*

***Aim/Introduction:*** Claudin 18.2 (CLDN18.2) is a tight junction protein which in healthy individuals is strictly expressed in differentiated epithelial cells of the gastric mucosa. Its high

expression has been reported on the epithelial surface of several malignant tumors such as gastric, colon, breast, and liver cancers. Its tumor-specific expression pattern points to an attractive molecular oncology target, and many therapies targeting Claudin 18.2 are currently in clinical development. To date, there is no approved targeted therapy for CLDN18.2 expressing tumors. Herein we describe the development of a Claudin 18.2 targeted alpha therapeutic (TAT), [$^{225}$Ac]-FPI-2474, in a pre-clinical mouse xenograft model of gastric cancer. ***Materials and Methods:*** [$^{225}$Ac]-FPI-2474 is a radioimmunoconjugate consisting of an anti-Claudin 18.2 monoclonal antibody conjugated to a proprietary DOTAGA-based chelate (FPI-2472) and radiolabeled with actinium-225 [$^{225}$Ac]. [$^{177}$Lu]-FPI-2473 is the Lutetium-based radiolabeled analogue. The biodistribution and therapeutic efficacy of these radioimmunoconjugates were evaluated in a gastric cancer model. MNK45 cells were engineered to stably overexpress Claudin 18.2 via lentiviral transduction (MKN45-CLDN18.2). Cell surface receptor expression was confirmed via flow cytometry, and receptor numbers quantified via radioligand binding assay. These MKN45-CLDN18.2 cells were used to generate subcutaneous tumor xenografts in athymic nude mice for in vivo evaluation. For biodistribution studies, approximately 185 MBq/kg of [$^{177}$Lu]-FPI-2473 was injected intravenously via the lateral tail vein, and organ radioactivity was quantified ex vivo at timepoints between 4 h and 168 h using a gamma counter by calculating the percentage of injected dose per gram of tissue (%ID/g). For therapeutic studies, a single intravenous dose of [$^{225}$Ac]-FPI-2474 was administered over a dose range of 92.5 to 555 kBq/kg. Tumor size and body weight were monitored for at least 30 days. Tumor volumes (V; in mm$^3$) were calculated as V = 0.5 x L (length) x W$^2$ (width). ***Results:*** A stable MKN45-CLDN18.2 overexpressing cell line was successfully generated, expressing on average 150,000 receptors/cell. Biodistribution studies of [$^{177}$Lu]-FPI-2473 showed robust average tumor uptake peaking at approximately 30%ID/g at 96 h post-injection, while minimal uptake (≤10%ID/g) was observed in normal organs at all time points tested. Therapeutic evaluation of [$^{225}$Ac]-FPI-2474 is currently underway. ***Conclusion:*** [$^{177}$Lu]-FPI-2473 demonstrated high tumor uptake along with minimal normal tissue uptake, suggesting a tumor specific accumulation of [$^{177}$Lu]-FPI-2473 in Claudin 18.2 expressing xenografts. Therapeutic evaluation of [$^{225}$Ac]-FPI-2474 has been initiated to ascertain whether the level of tumor uptake of the anti-Claudin 18.2 radioimmunoconjugate will translate into preclinical therapeutic efficacy.

## EP-0064

### Development and evaluation of fluorescent SSTR2-antagonists for intraoperative image-guided surgery of NETs

***M. Handula***[1], *S. Beekman*[1], *Y. Seimbille*[1,2];
[1]*Erasmus MC, Rotterdam, NETHERLANDS,*
[2]*TRIUMF, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Neuroendocrine tumors (NETs) are considered as a rare type of cancer with an incidence rate of 1-5 per 100,000 people affected yearly in Europe. Although advanced metastatic NET patients are treated with chemotherapy and peptide receptor radionuclide therapy (PRRT), surgery remains the main treatment for local neuroendocrine tumors. Considering that the somatostatin receptor subtype 2 (SSTR2) represents an optimal target for PET imaging and radionuclide therapy of NETs, it could also be exploited to design fluorescent probes that will help surgeons to visualize neoplasms and delineate surgical margins. The antagonist DOTA-JR11 showed higher tumor uptake and better biodistribution profile than the agonist DOTA-TATE during (pre)clinical evaluation. Therefore, we developed fluorescent probes based on JR11 for intraoperative image-guided surgery of NETs to reduce positive surgical margins and disease recurrence. ***Materials and Methods:*** Four fluorescent JR11 analogs were synthesized by solid-phase peptide synthesis (SPPS). The fluorescent dye, cyanine 5.5 (Cy5.5), was coupled either directly or via a 6-aminohexanoic acid, $PEG_3$ or $PEG_6$ linker at the N-terminal position of the peptide scaffold to obtain efSOMA-01, efSOMA-02, efSOMA-03 and efSOMA-04, respectively. Competitive binding assay in U2OS.SSTR2 cells was carried out to determine the affinity of the compounds to the receptor. Cell uptake assay was performed in U2OS.SSTR2 and SSTR2-negative (PC3-PIP) cells to demonstrate uptake specificity. ***Results:*** efSOMA-01-04 were obtained in 20.5, 4.4, 7.6 and 7.3% chemical yield, respectively. The four analogs were obtained in very high chemical purity (> 95%). Competitive binding assay showed that the binding affinity of the fluorescent efSOMA-01, efSOMA-02, efSOMA-03 and efSOMA-04 to SSTR2 was 4.7 to 16.3-fold lower than the binding affinity of the parent peptide DOTA-JR11 ($IC_{50}$ values of 84.7, 58.1, 27.3 and 24.5 nM, respectively, vs. 5.2 nM for DOTA-JR11). The preliminary cell uptake assay revealed high uptake in SSTR2-overexpressing cells for all analogs, whereas no fluorescence was observed in the SSTR2-negative cells, confirming the specificity of our fluorescent JR11 analogs to the receptor. ***Conclusion:*** The four fluorescent JR11 analogs were successfully synthesized and characterized by LC/MS. They all exhibited good binding affinity to SSTR2 and showed high and specific cell uptake. In vivo studies in tumor-bearing mice are underway to confirm the applicability of our probes to fluorescence-guided surgery of NETs.

## EP-0065

### Preclinical studies for optimal implementation of GRPR radiotracers in clinical studies

***T. S.T. Damiana***[1], *P. Paraïso*[1], *C. de Ridder*[2], *D. Stuurman*[1], *L. van den Brink*[1], *Y. Seimbille*[1], *S. U. Dalm*[1];
[1]*Department of Radiology & Nuclear Medicine, Erasmus Medical Center, Rotterdam, NETHERLANDS,* [2]*Department of Experimental Urology, Erasmus Medical Center, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Gastrin-releasing peptide receptor (GRPR) radiotracers have successfully been studied in preclinical and/or clinical studies for imaging and treatment of breast cancer (BC), prostate cancer (PCa), and gastrointestinal stromal tumors (GIST). However, there is no clear comparison of the GRPR radiotracers available, hampering accurate selection of the most optimal radiotracer. Moreover, as GRPR expression and radiosensitivity are prerequisites for the success of GRPR-mediated interventions, it is crucial to know how these factors are affected by standard-of-care treatments for correct positioning of GRPR radiotracers in disease management. Accordingly, we performed a head-to-head comparison of the two most applied GRPR radiotracers, RM2 and NeoB, and studied the effect of standard-of-care treatments on GRPR expression and radiosensitivity of cancer cells. ***Materials and Methods:*** We compared binding of [$^{111}$In]In-NeoB and [$^{111}$In]In-RM2 to PCa, BC and GIST tissues. Tissues were incubated with 1nM [$^{111}$In]In-NeoB and [$^{111}$In]In-RM2+/-1μM Tyr$^4$-BBN for 1h, and analyzed using the BeaQuant. Moreover, depending on the cell line, we studied the influence of doxorubicin, docetaxel, tamoxifen and letrozole on GRPR expression and radiosensitivity of the human PCa and BC cell line PC-3 and T47D, respectively. Cells were pre-treated at the

IC50 value of the treatments, subsequently incubated with 1nM [$^{111}$In]In-NeoB+/- 1µM Tyr$^4$-BBN to determine radiopharmaceutical uptake. Additionally, GRPR mRNA levels were measured using RT-qPCR. Results are expressed relative to vehicle-treated cells set at 100%. To determine radiosensitivity, pretreated cells were exposed to 0-14 Gy external beam radiation therapy (EBRT), and cell density was determined after five days using an SRB assay. ***Results:*** The autoradiography studies revealed higher binding of [$^{111}$In]In-NeoB to all investigated tissues. Docetaxel decreased radiotracer uptake to 52.5±3.4%, GRPR mRNA expression to 44.7±14.5% and radiosensitivity of PC-3 cells. Regarding T47D cells, doxorubicin-pretreated cells showed an increase in GRPR mRNA expression to 242.4±53.4% and radiotracer uptake to 125.2±6.3%, and cells were less sensitive to EBRT. Tamoxifen pre-treated cells reduced radiotracer uptake to 73.8±1.8%, and both tamoxifen and and letrozole pretreatment did not influence the radiosensitivity of T47D cells. ***Conclusion:*** We demonstrated that [$^{111}$In]In-NeoB is superior to [$^{111}$In]In-RM2 in binding to human PCa, BC and GIST tissue. Furthermore, we showed that prior treatment may alter essential factors for the success of GRPR radiotracer treatment and should be considered when GRPR-mediated interventions are positioned in the clinic. In-vitro and in-vivo studies further unravelling the effects of chemotherapies and hormone therapies on GRPR expression, radiosensitivity and GRPR-targeted radionuclide therapy are ongoing.

## EP-0066

### Restoration of impaired portal glucose sensing by targeted manipulation of GLP-1r density in a translational model of insulin resistance

***C. Malbert***[1], *R. Allouche*[2], *M. Horowitz*[3], *K. L. Jones*[3];
[1]*INRAE - Aniscan, Saint-Gilles, FRANCE,* [2]*Paltech, Paris, FRANCE,* [3]*Adelaide Medical School, The University of Adelaide, Adelaide, AUSTRALIA.*

***Aim/Introduction:*** The portal glucose sensor informs the brain of changes in glucose inflow via vagal afferents that are dependent on the glucagon-like peptide-1 (GLP-1) receptor (GLP-1r). We have shown that GLP-1r expression within the portal vein is markedly reduced in a translational model of insulin resistance (IR), associated with altered glucose signaling to the brain (1). We now investigated the potential for restoring reduced portal GLP-1r expression in IR animals using a targeted infusion of bioactive molecules, which have been demonstrated to increase GLP-1r expression in vitro. ***Materials and Methods:*** Five groups, each of five miniature Yucatan minipigs, aged three years, were used. One group was maintained lean and insulin sensitive, while the remaining four were made IR by a high fat-high sucrose diet for 4 months. The precise portal location of the low-density GLP-1r area (compared to lean animals) was initially defined using PET/CT imaging after the administration of 68Ga-DO3A- exendin-4 and a catheter, exiting in the portal connective tissue, was then fixed at this location during 3D guided laparoscopy based on PET/CT results. This catheter was used to infuse continuously either saline, dihydrotestosterone (DHT, 10 µg/kg/24H), metformin (MET, 2 mg/kg/24H), or exenatide (EX, 0.01 µg/kg/24H), i.e., molecules known to increase GLP-1r density in vitro. After 2 months continuous infusion, PET/CT imaging was repeated in all animals using the same GLP-1r radioligand. Vt/Vs coded images, were obtained from PET/CT concurrently with monitoring of the arterial input function extracted from an arteriovenous shunt and radioHPLC of the authentic ligand in the plasma. Duodenal and pancreatic Vt/Vs were also computed as references of GLP-1r expression organs. ***Results:*** In IR animals, there was a marked reduction in GLP-1r density at the portal vein ($p<0.05$), but not in the pancreas or duodenum (see table). Treatment with DHT increased GLP-1r density at the portal vein substantially to be comparable to that in lean animals. The other treatments had no effect on portal GLP-1r density. Furthermore, no treatment affected the GLP-1r density in the pancreas or duodenum. ***Conclusion:*** Localized administration of DHT normalises portal GLP-1r density in IR animals, without affecting GLP-1r density in other organs. Accordingly, it is possible to restore impaired glucose sensing in IR animals. The implications for optimal management of insulin resistance /type 2 diabetes now require evaluation in humans. ***References:*** (1) Malbert et al, Diabetes, 021 Jan;70(1):99-110. doi: 10.2337/db20-0361

## EP-0067

### Long-term characterization of a radiolabeled hydrogel after intrastriatal injection in rats to improve post-stroke brain repair

***N. Hugues***[1], *C. Pin-Barre*[2], *O. Nachar*[1], *V. Nail*[1], *L. Balasse*[1], *B. Guillet*[1], *T. Trimaille*[3], *J. Laurin*[4], *P. Garrigue*[1];
[1]*Centre Européen de Recherche en Imagerie Médicale (CERIMED), Marseille, FRANCE,* [2]*Syncrosome, Marseille, FRANCE,* [3]*Institut de Chimie Radicalaire (ICR), Marseille, FRANCE,* [4]*Insitut de Neurobiologie de la Méditerranée (INMED), Marseille, FRANCE.*

***Aim/Introduction:*** Ischemic stroke frequently leads to functional impairments by mainly affecting the striatum area. Given that few molecules are able to reach the affected cells, it remains crucial to define a suitable method for delivering promising drugs. Injectable and biodegradable hydrogels appear as an encouraging strategy to target the lesion area, avoiding repetitive administrations by precisely and progressively releasing a drug. To do so, this hydrogel was based on an amphiphilic PNIPA-Am-b-PLA-b-PEG-b-PLA-b- PNIPAAm pentablock. Hence, we aimed to characterize the degradation and biodistribution of this hydrogel following intrastriatal injection in healthy rats. Hydrogel toxicity was evaluated in hippocampal neuronal cell cultures. Then, blood-brain barrier permeability, brain glucose metabolism, microglia activation as well as dopamine transporters concentration were investigated over a 6-month period using both SPECT/CT and PET/CT in vivo imaging. ***Materials and Methods:*** Hippocampal neurons for cell culture were obtained from Sprague-Dawley rats (E18). NODAGA-functionalized hydrogel (6µl) was added to hippocampal neuronal cells at 4 days in vitro. For in vivo measurements, 9 female Sprague Dawley rats were assigned to two conditions following unilateral intrastriatal injection of 1) gallium-67 alone ($^{67}$Ga-NODA-GA) and 2) gallium-67 radiolabeled, NODAGA-functionalized hydrogel. SPECT/CT acquisitions were realized over 72h after injection to follow gallium-67 spreading. Blood brain barrier permeability ($^{99m}$Tc-DTPA SPECT/CT; day 2, 8 and 16), brain glucose metabolism ($^{18}$F- FDG PET/CT; day 2, 8, 16 and 6-month), microglia activation ($^{18}$F-DPA-714 PET/CT; 6-month) as well as dopamine transporters concentration ($^{123}$I-ioflupan SPECT/CT; 6-month) were investigated. Image treatment and volumes of interest were drawn according to a rat brain atlas. Immunohistochemical measurements of microglia activation and neuronal survival were ex vivo assessed after 6 months. ***Results:*** There was no significant difference between control and hydrogel conditions in vitro. The injection of the radiolabeled hydrogel enabled a prolonged residence time of the gallium-67 SPECT signal at the site of injection, with a slower and more progressive spreading (at 1h:***P=0.001; 18h:*P=0.028; 24h:P=0.729). Both the blood-brain barrier permeability and brain glucose metabolism

were not significantly modified following hydrogel injections. Finally, neither the microglial activation nor the dopamine transporter concentrations were affected by the hydrogel at 6 months. Immunohistochemistry confirmed the imaging results. ***Conclusion:*** This study used molecular imaging to characterize the hydrogel properties at both early and later time points after intrastriatal injection in healthy rats. The use of this hydrogel thus seems suitable to assess the local effects of a loaded drug, in a rodent model of stroke.

## EP-0068

### miRNAs as Early Biomarkers of GEPNET Disease Progression. Evaluation of Feasibility and Preliminary Results

***F. SCALORBI***, *M. Gariboldi, L. Roz, G. Centonze, F. Facchinetti, G. Calareso, E. Garanzini, V. Lagano, G. Argiroffi, S. Pusceddu, M. Maccauro, E. Seregni, M. Milione;*
*Istituto Nazionale Tumori Milano, MILAN, ITALY.*

***Aim/Introduction:*** Primary aim: to evaluate feasibility of miRNA expression in GEPNET (gastro-entero-pancreatic neuroendocrine tumours) paraffin samples (FFPE). Secondary aim: to early predict disease progression after RLT (radio ligand therapy) by miRNA expression. ***Materials and Methods:*** Tissue samples from G1-G2 well differentiated GEPNETs treated with RTL (177Lu-DOTATATE, 4 administrations, 7.4 GBq each) from April 2019 to December 2021 were included. FFPE collected before RLT, with at least 50% cellularity and no protein/solvent contamination were selected. Two contrast enhancement CT/MRI scans per patient were collected, performed within 3 months before and 3 months after RLT, to assess the response to treatment (progression (PD) versus non-progression), applying RECIST1.1 criteria. The expression of 13 miRNAs was quantified by qRT-PCR, after housekeeping normalisation, comparing progressive and non-progressive groups. One biological and 2 technical replicates were performed (Standard Deviation < 0,5). Delta Delta CT (DDCT) formula was applied to quantify miRNA expression. Univariate and multivariate analysis were performed to determine the power of clinical features (gender, age, Ki67 grading, primary tumor, metastatic disease) and miRNA expression to predict the disease progression. Stata v16 was applied. ***Results:*** Forty-eight FFPE samples (33/58 (68.7%) midgut, 15/58 (31.3%) foregut; 15/58 (52.1%) metastasis; whole population mean Ki67: 4.8%, SD 6.0, range 0.2-20; mean cellularity 80.3%, SD 14.1, range 50-99;) were selected. Thirty-three (68.7%) patients were females and the mean age of whole population was 56.4 years (range 33-75). No significant contaminations were observed. Results from the technical replicates were comparable for 9 out of 13 miRNAs. Eight (16.7%) cases showed progression after RLT. miRNA-21 expression and Ki67 grading were the only two significant predictive variables of PD. In details, low miRNA-21 expression has a protective role (Coefficient -0.22, 95%CI [-0.43; -0.009], p: 0.042) meanwhile high Ki67 grading (continuous values) has a negative prognostic role in terms of PD (Coefficient 1.01, 95%CI [0.30; 1.73], p: 0.010). ***Conclusion:*** Evaluation of miRNA expression is a feasible procedure in GEPNET FFPE, with good reproducibility. MiRNA-21 is a strong independent early predictor of disease progression that should be validated by clinical trials to more accurately stratify GEPNET aggressiveness and, therefore, predict the response to target therapies.

## EP-0069

### Implementation of a human brain tumour model in large animals, to translate holmium-166 microbrachytherapy towards the clinic.

***N. Klaassen***[1], *M. Boswinkel*[1], *N. C. Morsink*[2], *S. A. van Nimwegen*[2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Utrecht University, Department of Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** Glioblastoma is an inherently aggressive tumour and the most lethal primary brain tumour in adults. Standard-of-care include surgery, radiotherapy and chemotherapy. Despite these therapy options patients often get a recurrence after a few months, with limited treatment options consequently. To improve patient survival, advances in therapy are needed. An innovative form of brachytherapy, microbrachytherapy, may lead to better treatment. Holmium-166 ($^{166}$Ho) is a good candidate for microbrachytherapy due to its characteristics, which allow for MRI/CT/SPECT imaging and therapy (β-irradiation). $^{166}$Ho-microspheres have been injected subcutaneously in mice in vivo. However, the relatively deep penetration of $^{166}$Ho β-radiation and the absence of sulci in mice, make the brain of small animals unsuitable for translational purposes. Therefore, a tumour model in a large animal with a brain anatomically comparable to human brains is needed. The aim of this study was to setup a tumour model in a pig brain to ultimately test microbrachytherapy. ***Materials and Methods:*** Immune supressed Landrace pigs (n=8) were injected with 30-70x$10^6$ human glioblastoma cells (U87, 50 µL) in both frontal lobes. Injection positions were confirmed using X-ray. To monitor tumour growth, animals were imaged on days 0, 7, 14, 21 and 28 post-implantation using MRI. Animal health was monitored closely and the degree of immune suppression was determined by immune suppressive drugs levels in the blood. After the last imaging session the animals were euthanised, subsequently, the brain tissue was imaged ex vivo on CT and MRI. After fixation, histology (H&E, S100, GFAP, SOX10 and Vimentin) was performed to characterize the tumour and surrounding tissue. ***Results:*** During the experiment, animals showed only minor side effects. MR imaging showed cell growth in all pig brains over time (diameter of 5 to 15 mm). The amount of tumour cells injected was optimized to 70 million cells per injection, injecting the cells very slowly into the brain and leaving the syringe for 1 min before removal. Cell growth was also seen with macroscopic and histological evaluation. Histological analysis showed the presence of tumour cells, but in several animals also a considerable amount of immune cells. In these animals levels of immune suppressive drugs in the blood turned out to be lower than anticipated. ***Conclusion:*** Implementing a human tumour model in pigs is feasible and looks promising, but the model needs further optimization to become a reliable and translatable tumour model for treatment validation.

## EP-0070

### Targeted Alpha Therapy Using Terbium-149 with Somatostatin Analogues: Comparison of [149Tb]Tb-DOTA-LM3 and [149Tb]Tb-DOTATATE

***S. D. Busslinger***[1], *A. K. Mapanao*[1], *C. Favaretto*[1,2], *P. V. Grundler*[1], *U. Köster*[3], *K. Johnston*[4], *R. Schibli*[1,5], *N. P. van der Meulen*[1], *C. Müller*[1,5];
[1]*Paul Scherrer Institut, Villigen-PSI, SWITZERLAND,* [2]*University Hospital Basel, Basel, SWITZERLAND,* [3]*Institut Laue-Langevin, Grenoble, FRANCE,* [4]*ISOLDE/CERN, Geneva, SWITZERLAND,* [5]*ETH Zurich, Zurich, SWITZERLAND.*

***Aim/Introduction:*** Terbium-149 is regarded as a particularly attractive radionuclide for targeted α-therapy. It is characterized by favorable physical decay properties ($T_{1/2}$: 4.1 h, $E_\alpha$: 3.97 MeV, I:

16.7%) and the absence of α-emitting daughter nuclides [1-2]. The presence of a positron emission branch ($E_{\beta+ mean}$: 720 keV, I: 7.11%) can be exploited for PET imaging [3-5]. Stable complexation of terbium-149 by a DOTA chelator allows combination with established tumor-targeting agents. The goal of this project was to investigate terbium-149 in combination with the cell-internalizing somatostatin receptor agonist (DOTATATE) and the membrane-localizing antagonist (DOTA-LM3) for direct comparison of the therapeutic efficacy of the resultant radiopeptides. ***Materials and Methods:*** Terbium-149 was produced at ISOLDE/CERN using spallation reactions and online mass separation followed by radiochemical separation at the Paul Scherrer Institute, as previously reported [4]. [$^{149}$Tb]Tb-DOTATATE and [$^{149}$Tb]Tb-DOTA-LM3 were used to determine somatostatin receptor-positive AR42J tumor cell viability in vitro after exposure to the respective radiopeptides. In vivo, the therapeutic efficacy of the radiopeptides was directly compared in mice (n=4) bearing AR42J xenografts (initial tumor size: ⊠200 mm$^3$). The distribution profile of the radiopeptides was assessed using PET/CT imaging 2 h after injection of the mice. ***Results:*** [$^{149}$Tb]Tb-DOTATATE and [$^{149}$Tb]Tb-DOTA-LM3 were produced at molar activities up to 20 MBq/nmol with radiochemical purities >99%. A dose-dependent effect on the AR42J cell viability was observed for both radiopeptides. [$^{149}$Tb]Tb-DOTA-LM3 ($EC_{50}$ = 0.5 kBq/mL) was somewhat more potent than [$^{149}$Tb]Tb-DOTATATE ($EC_{50}$ = 1.2 kBq/mL). PET images showed high accumulation of both radiopeptides in AR42J tumor xenografts. After application of 5 MBq [$^{149}$Tb]Tb-DOTATATE or 5 MBq [$^{149}$Tb]Tb-DOTA-LM3, tumor growth was delayed, resulting in significantly prolonged median survival times of mice in the treated groups (16.5 days and 19 days, respectively) in comparison to that of untreated control mice (8 days). For both radiopeptides, a second injection of 5 MBq on the consecutive day resulted in further delay in tumor growth. ***Conclusion:*** The data of these studies demonstrated the promising potential of $^{149}$Tb-based somatostatin analogues for targeted α-therapy. Only minor differences were observed between the agonist and antagonist, which indicates that the subcellular localization of the radiopeptides was not decisive to effectively treat the AR42J tumors in this study. ***References:*** [1]Beyer et al. Radiochim Acta 2002, 90:247. [2]Browne and Tuli Nucl. Data Sheets 2009, 110:507 [3]Müller et al. EJNMMI Radiopharm Chem 2016, 1:5. [4]Umbricht et al. Sci Rep 2019, 9:17800. [5]Singh and Chen Nucl. ## EP-0071

### Radiation dosimetric and biodistribution comparison of the PSMA agonists 177Lu-PSMA I&T, 99mTc-Hynic PSMA and 99Tc-PSMA I&T to the 177Lu-RM2 antagonist

***G. Limouris***[1,2], *M. Paphiti*[3], *A. Zafeirakis*[2];
[1]*Nuclear Medicine, Medical School, National and Kapodistrian University of Athens, Athens, GREECE,* [2]*Nucl Med Dept, Army Share Fund Hospital of Athens, Athens, GREECE,* [3]*Cyclotron Section, Pharmazac SA, Athens, GREECE.*

***Aim/Introduction:*** Prostate cancer cells, besides PSMA, similarly over-express gastrin-releasing peptide receptor (GRPr), consisting a novel potent promising target, fulfilling the TheraGnostic concept. GRPr-antagonist RM2 with a high affinity of 3.0 to 4.7 nM, has been achieved to be labeled with beta-emitting radio-metals, as $^{177}LuCl_3$, for therapeutic purposes. We aimed to compare the absorbed doses of tumor lesions and critical organs of the agonists $^{177}$Lu-PSMA I&T, $^{99m}$Tc-Hynic PSMA, and $^{99}$Tc-PSMA I&T, used in our Institution and compare them to the absorbed doses of the antagonist $^{177}$Lu-RM2. ***Materials and Methods:*** In a tiny cohort of 9 patients (median age 73 years) suffering from hormone-resistant prostate cancer (mCRPC), candidates for n.c.a. $^{177}$Lu-PSMA therapy (recently for first time implemented in our Institution), pre-therapeutic whole-body PSMA scans were performed to detect and confirm the degree of PSMA expression, using $^{177}$Lu-PSMA I&T in 5, in a diagnostic activity of 444 MBq, called by us "LuteScan", $^{99m}$Tc-Hynic PSMA in 2 and $^{99m}$Tc-PSMA I&T in another 2 patients, in an activity of 740 MBq respectively. For dosimetry, patients underwent whole-body planar as well SPECT tomo-scintigraphy of head-neck, 4, 24 and 48h along with blood sampling, 0.5, 1, 2, 4 and 24 h p.i. Dosimetry was performed according to OLINDA/EXM 1.1 program. Individual organ masses were extracted from CT. Absorbed dose to bone marrow was calculated based on serial whole-body images and blood sampling according to the EANM guidelines. ***Results:*** The absorbed doses outcome of the three studied PSMA agonists compared to those of the antagonist RM2 showed increased uptake in tumor lesions, kidneys, lacrimal and parotid glands and not in the pancreas, observed in RM2, seen within the first p.i. 4 hrs, first-in-human reported by Kurth et al. For the latter, mean absorbed organ doses were 1.08 ± 0.44 Gy/GBq in the pancreas, 0.35 ± 0.14 Gy/GBq in the kidneys, 0.05 ± 0.02 Gy/GBq in the liver, 0.10 ± 0.06 Gy/GBq in the spleen, and 0.02 ± 0.01 Gy/GBq for the red bone marrow. The mean dose for tumor lesions was 6.20 ± 3.00 Gy/GBq. ***Conclusion:*** According to the correlative dosimetric results, the introduction and implementation of GRPr antagonist $^{177}$Lu-RM2 seems to promisingly enhance the targeted radiotherapy in hormone-resistant prostate cancer patients, particularly in cases where PSMA is not overexpressed. The critical organ receiving the highest absorbed dose was the pancreas in contradistinction to the PSMA treatments performed with PSMA agonists.

### WAY100635 and altanserin differentially modulate nigrostriatal and mesolimbic D2 receptor binding

***S. Nikolaus***[1], *H. J. Wittsack*[1], *M. Beu*[1], *C. Antke*[1], *B. Fazari*[2], *H. Hautzel*[3], *E. Mamlins*[1], *H. Müller*[1], *G. Antoch*[1], *F. L. Giesel*[1];
[1]*University Hospital Düsseldorf, Düsseldorf, GERMANY,* [2]*Heinrich-Heine University, Düsseldorf, GERMANY,* [3]*University Hospital Essen, Düsseldorf, GERMANY.*

***Aim/Introduction:*** WAY100635 and altanserin (ALT) act as 5-HT1A receptor (R) agonist and 5-HT2AR antagonist, respectively. In the present study, we compared the effect of acute treatment with WAY100635 and ALT on the regional D2R binding in the rat brain. ***Materials and Methods:*** In 33 male Wistar rats, D2R binding was measured after intraperitoneal injection of WAY100635 (0.4 mg/kg), ALT (10 mg/kg) and vehicle (1 ml/kg 0.9% NaCl and 0.5 ml/kg dimethylsulfoxide, respectively). Iodine-123-IBZM (30 ± 4 MBq iv) was injected 30 and 45 min, respectively, post-challenge. Imaging data were acquired at 75 and 90 min, respectively post-challenge with the TierSPECT. For the acquisition of morphological data, rats were scanned with a dedicated small animal MRI (MRS3000

Pre-clinical MRT, 3.0 T, MR Solutions, Guildford, UK). D2R imaging data were evaluated with PMOD (version 3.5, PMOD Technologies Ltd., Zürich, Switzerland). Based on the implemented Paxinos rat brain atlas, the following regions of interest (with a diameter ≥ FWHM of the TierSPECT) were defined on SPECT-MRI overlays: nucleus accumbens (NAC), caudateputamen (CP), substantia nigra/ventral tegmental area (SN/VTA), thalamus (THAL), frontal cortex (FC), motor cortex (MC), and parietal cortex (PC), dorsal hippocampus (dHIPP) and ventral hippocampus (vHIPP), for which the presence of D2R has been confirmed (1). ***Results:*** WAY-100635 reduced D2R binding in CP (p=0.047), THAL (p=0.047), vHIPP (p=0.013), FC (p=0.015) and PC (p=0.050) relative to vehicle, whereas ALT induced an increase of D2R binding in the vHIPP (p=0.030). ***Conclusion:*** The regional reductions of D2R binding after WAY100635 reflect increases of synaptic dopamine (DA) concentrations in the nigrostriatal and mesolimbic system. Contrarily, the increase of D2R binding after ALT indicates a reduction of DA, which, however, was confined to vHIPP. From this may be concluded that DA function is modulated differentially by 5-HT1AR and 5-HT2R in the individual regions of the nigrostriatal and mesolimbic system. ***References:*** (1) Bouthenet et al., Neuroscience. 1987;20:117-55.

## EP-0073

### 5-HT1A and 5-HT2A receptor agonists and antagonists modulate behavior and regional DAT binding in the rat brain

***S. Nikolaus***, *M. Beu;*
*University Hospital Düsseldorf, Düsseldorf, GERMANY.*

***Aim/Introduction:*** The present study assessed the effects of the 5-HT1A receptor (R) and 5-HT2AR agonists 8-OH-DPAT and D-iodoamphetamine (DOI) and of the 5-HT1AR and 5-HT2AR antagonists WAY100635 and altanserin (ALT) on motor/exploratory behaviors and dopamine transporter (DAT) binding in the rat. ***Materials and Methods:*** The rats of the first batch (n=108) received i.p. injections of either 8-OH-DPAT (3 mg/kg), DOI (0.5 mg/kg), WAY100635 (0.4 mg/kg), altanserin (10 mg/kg) or vehicle (VEH; 1 ml/kg 0.9% NaCl and 0.5 ml/kg dimethylsulfoxide, respectively) and were placed immediately post-challenge into an open field for a 30-min assessment of motor/exploratory behaviors (duration of ambulation, rearing, sitting and explorative head-shoulder motility). The rats of the second batch (n=58) received the same treatments, but were injected 123I-FP-CIT (9±3 MBq) 30 min post-challenge into the tail vein. Specific binding of 123I-FP-CIT to the DAT was determined by subtracting unspecific binding in the cerebellar reference region from radioligand concentrations obtained 150 min post-challenge in cingulate (CING), caudateputamen (CP) and nucleus accumbens (NAC). Motor/exploratory behaviors were evaluated with Ethovision XT. ***Results:*** After 8-OH-DPAT, ambulation and head-shoulder motility were increased, while rearing and sitting were decreased relative to VEH. 8-OH-DPAT increased ambulation and head-shoulder motility, but decreased sitting relative to DOI, WAY100635 and ALT. After ALT, ambulation, rearing and head-shoulder motility were decreased, while sitting was increased relative to VEH. ALT decreased ambulation relative to DOI and explorative head-shoulder motility relative to DOI and 8-OH-DPAT. DOI decreased rearing, and WAY100635 decreased head-shoulder motility relative to VEH. WAY100635 increased rearing relative to DOI, ALT and 8-OH-DPAT. In the CING, DOI increased DAT binding relative to VEH, ALT and 8-OH-DPAT. In the CP, 8-OH-DPAT increased DAT binding relative to VEH. In the NAC, 8-OH-DPAT decreased DAT binding relative to VEH, DOI and WAY100635. Moreover, ALT decreased DAT binding relative to DOI and WAY100635. ***Conclusion:*** The 5-HT1AR agonist elevated horizontal motor activity and exploratory head-shoulder motility and reduced passive immobility relative to the other 5-HTergic compounds, while the 5-HT1AR antagonist reduced exploratory vertical motor activity relative to the other 5-HTergic compounds. Findings imply that the 5-HT1AR plays a predominant role in motor activation and inhibition as well as in the triggering of explorative behaviors. It may be inferred that the mediation of motor/exploratory behaviors is associated with 5-HTergic action on DA neurons in CING, CP and NAC.

## EP-0074

### Somatostatin receptor imaging in mice with different positive rate of SSTR2

***Q. Xie***, *X. Meng, Z. Yang, J. Yu;*
*Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** The imaging with $^{68}$Ga-DOTA-TATE, $^{68}$Ga-DOTA-JR11 and Al$^{18}$F-NOTA-JR11 was performed to analyze the difference, and to analyze the correlation between parameters of image and pathology. ***Materials and Methods:*** The tumor bearing mouse with difference positive rate of SSTR2 was established with HEK293-SSTR2 and HEK293 cells, and the imaging was performed at the same tumor bearing mice with $^{68}$Ga-DOTA-TATE, $^{68}$Ga-DOTA-JR11 and Al$^{18}$F-NOTA-JR11 at 20, 60 and 120min. The parameters of image were obtained, including the maximum standard uptake value (SUVmax), the mean standard uptake value (SUVmean), standard deviation of SUVmean, tumor volume and coefficient of variation (CoV). Immunohistochemistry of tumor was carried out after imaging to obtain positive rate of SSTR2 and receptor expressing tumor volume (RETV). The statistics analysis was carried out to analyze the difference of three imaging and the correlation between the relative parameter of imaging and immunohistochemistry. ***Results:*** The SUVmax of Al$^{18}$F-NOTA-JR11 at 20min and 60min were higher than that of $^{68}$Ga-DOTA-TATE (p=0.001, 0.004) and $^{68}$Ga-DOTA-JR11 (p=0.033, 0.019), no significant difference was found in other groups (P>0.05). There was a significant positive correlation between positive rate and SUVmean of tumor with $^{68}$Ga-DOTA-TATE, $^{68}$Ga-DOTA-JR11 and Al$^{18}$F-NOTA-JR11 (P<0.05). And a significant positive correlation was also observed between RETV and SUVmean in all groups (P<0.05). But a significant negative correlation between positive rate and CoV was only found at the group of $^{68}$Ga-DOTA-TATE at 60min and 120min (P=0.048 and 0.026). ***Conclusion:*** The uptake of tumor for Al$^{18}$F-NOTA-JR11 within an hour is significantly higher than that of $^{68}$Ga-DOTA-TATE and $^{68}$Ga-DOTA-JR11. The correlation analysis shows that the higher SUVmean of three tracers means the higher positive rate and the higher RETV. However, only does the lower CoV of $^{68}$Ga-DOTA-TATE mean the higher positive rate.

## EP-0075

### Assessment of macrophage inflammatory activity on visceral adipose tissue in high-fat diet-induced obese mice by 18F-FDG PET/CT

***K. Pahk***, *H. Kwon, S. Kim;*
*Korea University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Obesity induced inflamed visceral adipose tissue (VAT) secretes pro-inflammatory cytokines thereby promoting systemic inflammation and insulin resistance which further exacerbate obesity-related cardiovascular disease (CVD). Macrophages are the key players in the development of obesity-associated VAT inflammation. Extensive clinical studies

have reported that $^{18}$F-fluorodeoxyglucose positron emission tomography/computed tomography ($^{18}$F-FDG PET/CT) can be used to evaluate the macrophage inflammatory activity on VAT in human beings. However, due to difficulty in human VAT biopsy, pathologic correlations were lacking and there was a few study on preclinical animal models. Here, we investigated whether $^{18}$F-FDG PET/CT could reflect the macrophage inflammatory activity on VAT in high-fat diet-induced obese mice. ***Materials and Methods:*** Obese animal models were induced by a high-fat diet (60% fat) for 20 weeks using the male C57BL/6 mice. Insulin tolerance test was performed to evaluate the status of insulin resistance and C-reactive protein (CRP) was measured to assess the status of systemic inflammation. All animals underwent $^{18}$F-FDG PET/CT before sacrifice. Macrophage inflammatory activity was evaluated using the maximum standardized uptake value (SUVmax). Flow cytometry-, histological-, and molecular analyses were performed on harvested VAT. ***Results:*** All obese animals showed insulin resistance which resembled the human metabolic syndrome, a key pathophysiological process that contributes to increase CVD risk. VAT SUVmax was increased in obese mice and significantly correlated with the levels of CRP. Furthermore, VAT from obese mice showed increased macrophage infiltration, compared to normal mice. ***Conclusion:*** $^{18}$F-FDG PET/CT could visualize and evaluate the macrophage inflammatory activity on obesity-driven inflamed VAT in obese mice model. Our preclinical study strongly supports the clinical application of $^{18}$F-FDG PET/CT in the assessment of VAT inflammation to patients who are vulnerable to CVD.

## EP-0076

### IPCEF1 serves as a novel biomarker and correlates with immune infiltration in PTC

***X. Jia***, *R. Gao, J. zhang, H. Xu, Y. Yang, A. Yang;*
*The first hospital of Xi'an jiaotong university, Xi'an, CHINA.*

***Aim/Introduction:*** RAIR-DTC is the main reason for poor prognosis of differentiated thyroid cancer. It is widely accepted that dedifferentiation of thyroid cancer cells and loss of the ability of the iodine uptake are the primary cause. Due to the fact that this cohort of patient is generally only discovered after multiple failed iodine treatments, late-line treatment of the disease is difficult to achieve ideal results. IPCEF1 (Interaction protein for cytohesin exchange factors 1), a scaffold protein that binds to cytohesin2, has been found to be closely related to the radioiodine therapy response in DTC. However, its biological function in tumors is not clear. Its relationship with the dedifferentiation of thyroid cancer cells is also worth further exploration. ***Materials and Methods:*** The differential expression of IPCEF1 was detected in papillary thyroid carcinoma (PTC) and normal tissue using The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO) databases (from the GSE3678 dataset). The relationship between IPCEF1 and tumor-infiltrating lymphocytes in the tumor microenvironment was identified using the Tumor Immune Estimation Resource (TIMER) datasets. Additionally, the biological function of IPCEF1 in PTC was evaluated using flow cytometry analysis, wound healing assays, Cell Counting Kit-8 assays, and transwell assays in vitro. The relationship between NIS and IPCEF1 was determined using clinical samples and cell lines of PTC. The diagnostic value was analyzed using receiver operating characteristic curve analysis, and the independent prognostic value of IPCEF1 was verified using Cox regression analysis in PTC patients from the TCGA cohort. ***Results:*** IPCEF1 expression were drastically downregulated and correlated with PTC grade, stage, and nodal metastasis, whereas in neighboring non-tumor thyroid tissue it was upregulated. IPCEF1 is not only involved with immune infiltration (negatively associated with dendritic cell, CD4+ central memory T cells, CD4+ effective memory T cells, Gamma delta T cell, NK cells and immunoinhibitors), but also increases apoptosis, decreases proliferation, inhibits migratory and invasive capabilities. IPCEF1 was positively associated with thyroid differentiation score and NIS expression in PTC patients in TCGA datasets. Overexpressed IPCEF1 could enhance NIS expression in vitro. Furthermore, it has the potential to provide remarkable diagnostic value in PTC (AUC = 0.966, CI = 0.952-0.980). Cox regression analysis verified IPCEF1 as an independent prognostic factor (P=0.011, HR 0.420, CI 95%: 0.215-0.815). ***Conclusion:*** IPCEF1 is a promising biomarker and may play a significant role in PTC progression, immune infiltration and differentiation.

## EP-0077

### Pilot study: non-invasive imaging of CD8+ T-cell infiltration during the development of type 1 diabetes in non-obese diabetic mice

***S. Tokgöz***[1], *C. Frielink*[1], *P. J. Wierstra*[1], *I. M. Hagemans*[2], *M. Verdoes*[2], *S. Heskamp*[1], *M. Gotthardt*[1], *M. Boss*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of Tumor Immunology, Radboud University Medical Center, Nijmegen, NETHERLANDS.*

***Aim/Introduction:*** Type 1 diabetes (T1D) is a chronic autoimmune disease caused by immune-mediated destruction of insulin producing beta cells. Beta cell destruction is preceded by immune cell infiltration inducing inflammation of the pancreatic islets, the so-called insulitis. Although several studies suggest a potential role of autoreactive T-cells in the pathophysiology of T1D, the exact course of the T-cell infiltration during disease development is still unknown. Therefore, we have developed a non-invasive in vivo imaging technique to monitor CD8+ T-cells during the course of T1D using $^{111}$In-labeled anti-CD8 SPECT/CT. The aim of this pilot study was to determine the feasibility of SPECT/CT imaging to monitor CD8+ T-cell infiltration during early immune cell infiltration, insulitis and new-onset diabetes phases of T1D in non-obese diabetic (NOD) mice. ***Materials and Methods:*** Fifteen female NOD mice aged 6, 13 and 18 weeks (n=5/group), representing early immune cell infiltration, insulitis and new-onset diabetes phases respectively, were used in this study. Mice were injected intravenously with [$^{111}$In]In-anti-CD8 (12.5 MBq; 8.5 µg). Three days after injection, in vivo SPECT/CT imaging was performed followed by ex vivo SPECT/CT imaging of the pancreas, ex vivo biodistribution, autoradiography, histology and immunohistochemistry (IHC) to stain for CD8+ T-cells. ***Results:*** Our results showed tracer uptake in the pancreas during the development of T1D with no significant differences in pancreatic uptake between the early immune cell infiltration (6-week-old NOD mice) and insulitis (13-week-old NOD mice) phases of T1D (1.4±0.68 vs 1.1±0.55 %ID/g, p=0.99). This was in line with IHC showing similar CD8+ T-cell infiltration in these two groups. In one mouse with new-onset T1D, we noticed lower pancreatic tracer uptake (0.34 %ID/g), which correlated well with low pancreatic CD8+ T-cell infiltration observed using IHC. In addition, we observed a clear correlation between pancreatic tracer uptake on autoradiography and CD8+ T-cell staining on IHC. ***Conclusion:*** This imaging technique allows to non-invasively follow CD8+ T-cell infiltration in the pancreas during the development of T1D. More research is required to increase our knowledge about the immunological

processes involved in the pathophysiology of T1D, which can be used to design clinical studies and thereby to possibly permit targeted therapies in T1D. This imaging technique has the potential to represent a valuable tool to monitor responses of targeted therapies. Since this imaging technique is already available in the clinics, it offers great opportunities for future clinical studies.

## EP-0078

### 68Ga-siderophores for Klebsiella pneumoniae detection by positron emission tomography

***K. Bendová***[1], *M. Zappeová*[1], *P. Mlynárčik*[2], *Z. Nový*[1], *M. Popper*[1], *M. Hajdúch*[1];
[1]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacký University, Olomouc, CZECH REPUBLIC,* [2]*Department of Microbiology, Faculty of Medicine and Dentistry, Palacký University, Olomouc, CZECH REPUBLIC.*

***Aim/Introduction:*** Klebsiella pneumoniae (KP) is a bacterial pathogen that becomes increasingly more dangerous due to its growing antimicrobial resistance. Rapid and accurate diagnosis is essential to prevent the spread of this pathogen, especially in hospital setting, and to provide adequate treatment to infected patients. Here we present the use of radiolabelled siderophores, chelators produced by microorganisms, in a novel approach to diagnosis of KP infection. By replacing the iron in siderophores with radioactive gallium-68, siderophores can be detected by positron emission tomography, thereby localizing the pathogen. Based on previous testing of in vitro characteristics, we have selected several siderophores that have suitable properties and are therefore applicable candidates for in vivo imaging. ***Materials and Methods:*** Various siderophores were radiolabelled with gallium-68 and the radiochemical purity of resulting complexes was tested on radio-iTLC. In vitro uptake of radiolabelled siderophores was compared in various KP strains cultivated in different media. In vivo PET/CT imaging was performed in healthy mice and in mouse model of muscle infection with KP. Additional imaging in different animal models of KP infection was initiated. ***Results:*** All siderophores were labelled with high radiochemical purity (>95 %). Uptake in KP cultures varied depending on the KP strain and siderophore. In general, we observed very high uptake in KP cultures cultured in minimal medium in contrast to cultures cultured in rich medium. In vivo, we observed mainly renal excretion and low activity in blood 90 min p.i. in most siderophores. In addition, some of the selected siderophores showed activity in liver and intestine. In muscle infection model, we observed signal at the site of infection that varied in intensity depending on the siderophore used. ***Conclusion:*** We were able to successfully radiolabel various siderophores with high radiochemical purity and demonstrated that the resulting complexes have high in vitro uptake in KP if proper media is used. In vivo the siderophores showed accumulation at the site of infection in muscle infection model. These preliminary results indicate that siderophores might be used to diagnose KP infection, yet further testing in different infectious models is necessary and is currently being conducted. ***References:*** Acknowledgement: Funded by National Institute of virology and bacteriology (Programme EXCELES, ID Project No. LX22NPO5103) - Funded by the European Union - Next Generation EU and the Internal Grant Agency of Palacky University (project IGA_LF_2023_006)

## EP-0079

### Renal-clearable gambogic acid nanoparticles for PET imaging-guided acute kidney injury treatment

***N. Liu****, X. Su;*
*PET Center, Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

***Aim/Introduction:*** Acute kidney injury (AKI) is a common clinical syndrome lacking effective pharmacotherapy. Gambogic acid (GA) as an active ingredient of herbal medicines, exhibits antioxidant and anti-inflammatory effects that benefit for the treatment of AKI , but its poor aqueous solubility limits effective renal delivery. ***Materials and Methods:*** Water-soluble GA nanoparticles (GA-NPs) were prepared by PEGylating with NH2-PEG5000-NOTA. First, we characterized the physicochemical properties of GA-NPs to confirm the ultrasmall size and stability. Next, we tested its protective effects against oxidative stress damage in vitro. We further imaged the health- and AKI-mice using Al18F-labeled GA-NPs to evaluate their renal-targeting properties. Finally, the in vivo reno-protective effects and biosafety of GA-NPs were assessed by blood tests and histology analysis. ***Results:*** We had successfully constructed ultrasmall GA-NPs with preferential renal uptake for AKI theranostics. The in vitro assays confirmed that GA-NPs could protect HK-2 cells against oxidative stress damage. Besides, PET imaging of Al18F-labeled GA-NPs allowed visualization of enhanced renal uptake in murine AKI models. Importantly, the biocompatible GA-NPs efficiently ameliorated renal damage in two murine AKI models via its antioxidative, antiapoptotic, and anti-inflammatory activities. ***Conclusion:*** This work indicates that GA-NPs can be a promising therapeutic candidate for the management of AKI. ***References:*** (1) Pickkers, P.; Darmon, M.; Hoste, E.; Joannidis, M.; Legrand, M.; Ostermann, M.; Prowle, J. ### A longitudinal PET study of an open blast induced TBI model in NHP (Cynomolgus macaques) by [11C]PBR28 and [18F]FlumazenilA longitudinal PET study of an open blast induced TBI model in NHP (Cynomolgus macaques) by [11C]PBR28 and [18F]Flumazenil

***P. Padmanabhan***[1], *K. K. Ghosh*[1], *C. Yang*[2], *Z. Wang*[1], *K. Ng*[3], *B. Ogden*[4], *J. Lu*[3], *C. Halldin*[1], *B. Gulyás*[1];
[1]*LKC School of Medicine, NTU, Singapore, SINGAPORE,* [2]*Singapore General Hospital, Singapore, SINGAPORE,* [3]*DSO National Laboratories, Singapore, SINGAPORE,* [4]*SingHealth Experimental Medicine Centre, Singapore, SINGAPORE.*

***Aim/Introduction:*** Traumatic brain injury (TBI) causes pervasive disability caused by impairment of consciousness and psychological disruption, which can significantly affect life quality. Extreme shifts of blastwaves cause substantial cellular disruption

in biological systems. To decrease the impact of the blast wave, it is essential to employ appropriate experimental methods. The present study includes the outcome of TBI in non-human primates (NHPs) brain due to an open blast explosion, followed by the examination of changes of neuroinflammation and neuronal density in a longitudinal manner by using PET radioligands [$^{11}$C] PBR28 which quantify the neuroinflamation and [$^{18}$F]flumazenil, measures the loss of GABAgeric neurons due to TBI consecutively. ***Materials and Methods:*** A total of six Cynomolgus macaques with ages ranging from 8-10 years were used for this evaluation. Before the radiotracers were injected by intravenously, the animals were fasted overnight and then anesthetized. The PET imaging was performed using a LFER 150 PET/CT scanner (Mediso, Hungary) at SingHealth Experimental Medicine Centre. The injected radioactivity was 74.00 to 90.00 MBq, and the maximum injected volume is capped at 5 ml for both the radiotracers. The Molar radioactivity for [$^{11}$C]PBR28 was 105.00 ± 24.00 GBq/umol and for [$^{18}$F]Flumazenil 740.00 ± 250.00 GBq/umol. All PET-CT images were analysed using PMOD. After automatic registration with CT scans, PET images were manually co-registered with the Macaca fascicularis MRI atlas. Pre-blast baseline scan. Scanning occurred 3 days, 2 weeks, and 8-9 months after the explosion ***Results:*** The longitudinal monitoring of whole-brain and regional uptake of [11C]PBR28 revealed an association between uptake and microglial activity and neuroinflammation. At 3- and 14-days post-injury, a decrease in uptake was observed. The mean regional update of [11C]PBR28, segmented by distinct brain regions, exhibited a comparable uptake pattern, with reduced uptake observed at 3 days and 2 weeks post-blast and a marked increase at 8 months. The findings indicate a delayed inflammatory response after a blast, as evidenced by the heightened uptake observed 8 months post-blast. The gradual increase in [18F]Flumazenil uptake showed an increase in receptor density between 3 days and 2 weeks after injury. At the 8-month time, the [18F]Flumazenil binding activity showed a decreasing trend in receptor density, suggesting a potential decrease in neuronal activity. ***Conclusion:*** Despite the limited availability of PET datasets, the findings of this study show the possibility of longitudinally quantifying molecular changes through PET imaging utilising [11C] PBR28 and [18F] flumazenil in a TBI NHPs model

## EP-0081

### GPT-MI: An automated GPT-based pipeline to meta-analyse the field of molecular imaging

***P. Jané***[1], *X. Xu*[2], *V. Taelman*[2], *E. Jané*[3], *K. Gariani*[1], *R. Dumont*[2], *M. Gómez*[4], *M. Walter*[2];
[1]*Hôpitaux Universitaires de Genève, Geneva, SWITZERLAND,*
[2]*University of Lucerne, Lucerne, SWITZERLAND,*
[3]*Universidad Politécnica de Madrid, Madrid, SPAIN,*
[4]*Hospital Universitario Ramón y Cajal, Madrid, SPAIN.*

***Aim/Introduction:*** The advent of general-purpose large language models like GPT4 will revolutionize informed clinical decision-making by introducing new, fast and simple approaches to analyse big data in medicine, and allowing meta-analyses of entire clinical fields. Herein, we present an automated GPT-based approach to meta-analyse the entire field of molecular imaging. ***Materials and Methods:*** We downloaded the complete Medline dataset (courtesy of the National Library of Medicine, USA), and developed a deep learning-based hybrid human-AI pipeline with a series of different ad-hoc artificial intelligence tools and manual revision to create a database of radiopharmaceutical-gene associations as a reference standard. Then, we created a natural text query template for GPT4 to obtain the genes that need to be expressed in a cell for it to have an uptake of defined radiopharmaceuticals. We measured the precision of the GPT4 model by comparing the returned associations to our gold standard database. ***Results:*** The ad-hoc artificial intelligence tools and manual revision produced a dataset of 9'285 radiopharmaceutical-gene associations targeting 1'173 genes and their bibliographical records. We then iterated over a subset of 100 radiotracers in the gold standard dataset adapting the GPT4 template query. No fine-tuning of the model was applied to obtain these results. Overall, the GPT4 model showed a precision of 88.29%, a recall of 93.26% and an F1 Score 90.71%. When the model returned an incorrect answer, up to three correction chances were given by pointing out the mistake. Thirteen corrections were allowed to the model, producing three more true positives, and increasing the performance of the model to a precision of 88.65%, a recall of 96.63% and an F1 Score 92.47%. The whole of the false positives were initially due to errors in the abbreviation and acronym disambiguation step. In three cases the feedback of the complete chemical name helped the model identify the radiotracer and associated genes correctly. A significant amount of the false negatives was linked to molecules that were named according to their patent registration numbers. ***Conclusion:*** To the best of our knowledge, we present for the first time an automated GPT-based approach to meta-analyse the entire field of molecular imaging. This global approach will serve as a first-in-class project to automatize meta-analyses of entire clinical fields, and will allow integrating molecular imaging with other global approaches, such as genomics, proteomics and metabolomics.

## EP-0082

### Pilot PET study of molecular processes disturbing the electrode nerve interface in a guinea pig model of cochlear implantation

***P. Deutsch***[1,2], *M. Mamach*[3,2], *J. Schweiger*[4,2], *J. Bankstahl*[1], *F. M. Bengel*[1], *T. Lenarz*[4,2], *V. Scheper*[4,2], *G. Berding*[1,2];
[1]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY,* [2]*Cluster of Excellence Hearing4all, German Research Foundation, GERMANY,* [3]*Department of Radiation Protection and Medical Physics, Hannover Medical School, Hannover, GERMANY,* [4]*Department of Otolaryngology, Hannover Medical School, Hannover, GERMANY.*

***Aim/Introduction:*** There is a variety of different reasons for poor speech understanding after cochlear implantation. One type of reasons arises from disturbances of the electrode nerve interface due to molecular processes like inflammation in the cochlear caused by damaging the tissue through the insertion of the electrode or the development of fibrosis around the electrode itself. To evaluate such processes, we used PET imaging with F-18-FDG (fluorodeoxyglucose) and Ga-68-FAPI (fibroblast activation protein inhibitor) in a guinea pig model of unilateral cochlear implantation. ***Materials and Methods:*** In total 26 ears were scanned using a Siemens Inveon PET/CT, either with FDG (16) or FAPI (10) in n= 11 animals. Scans with FDG took place early after insertion of a cochlea implant (CI): $CI_{early}$ after 7, 14 and 21 days (n = 1 animal) and late: $CI_{late}$ after 1 year (n = 3) as well as in not implanted (NI) animals (n = 2). FAPI scans took place 1 year after insertion (n = 3) and in additional 2 NI animals (n = 2). A volume of interest (VOI) defined over the cochlea in the CT image was used to extract standardized uptake values (SUV) in the corresponding region from the PET image. SUV values were compared between groups using unpaired t-Tests. ***Results:*** The

sizes of the VOIs (in voxels) were virtually equal for all groups (FDG: NI: 2288±311, CI: 2110±241; FAPI: NI: 2342±236, CI: 2450±433). SUV values were normally distributed (Shapiro-Wilk-Test, p>0.05) in all groups. Analyses showed a significantly higher mean FDG SUV after implantation in all CI (early and late) compared to NI ($CI_{all}$: 878±120 vs. NI: 650±90; p=0.0035) and in CI early after insertion compared to NI ($CI_{early}$: 864±28 vs. NI: 650±90; p<0.001), but no significant difference when comparing $CI_{early}$ and $CI_{late}$ as well as $CI_{late}$ and NI. The mean FAPI SUV for CI differed significantly from NI, with a higher activity late after implantation ($CI_{late}$: 656±24 vs. NI: 535±121; p=0.0393). ***Conclusion:*** The presented preliminary data suggest that early inflammatory processes and late fibroblastic activity in the cochlear after CI insertion can be measured using PET biomarkers. This pilot study is encouraging for the future use of PET after CI implantation in preclinical studies e.g. assessing new therapeutic options with locally applied anti-inflammatory drugs or its final translation into patient studies.

## EP-0083

### Evaluating the Relevance of Non-invasive Measurement of Protein Synthesis by Gallium-68-DOTA-puromycin PET/MRI for Imaging of Mycobacterial Infection - a Preclinical Report

***J. Kleynhans***[1,2], *S. Eigner*[3], *M. M. Sathekge*[4,2], *T. Ebenhan*[2,4]; *[1]Radiopharmaceutical Research, Catholic University of Leuven, Leuven, BELGIUM, [2]Nuclear Medicine Research Infrastructure NPC, Pretoria, SOUTH AFRICA, [3]Nuclear Physics Institute, Academy of Science of the Czech Republic, Rez near Prague, CZECH REPUBLIC, [4]Nuclear Medicine and Steve Biko Academic Hospital, University of Pretoria, Pretoria, SOUTH AFRICA.*

***Aim/Introduction:*** Puromycin is a relevant scaffold for the development of a radiopharmaceutical that will allow the quantification of protein synthesis non-invasively through nuclear based imaging techniques. A significant clinical application of radiolabeled puromycin depends on the visualization of mycobacterial protein synthesis for future clinical investigations of tuberculous lesions. To date, no systematic characterization of a puromycin-based radiopharmaceuticals as potential in vivo infection imaging agents has been reported. Therefore, this study will address selectivity, sensitivity, and accuracy of [$^{68}$Ga]Ga-DOTA-puromycin-micro-positron emission tomography combined with magnetic resonance imaging (microPET/MRI) imaging to determine the role and value of this technique to detect mycobacterial infection in vivo. ***Materials and Methods:*** The radiopharmaceutical was produced by a previously published procedure (1). Sensitivity of [$^{68}$Ga]Ga-DOTA-Puromycin microPET/MRI imaging was determined using SCID mice inoculated with of 1.5 x 105 units of Mycobacterium bovis (M. Bovis). Infected mice alternatively received follow-up microPET/MRI imaging ([$^{18}$F]FDG and [$^{68}$Ga]Ga-DOTA-Puromycin) after a 12-week monitoring period. Tracer selectivity was tested using animals bearing sterile inflammation or S. aureus (reference bacteria). Imaging results were correlated to outcome from tissue immunohistochemistry for accuracy consideration. ***Results:*** MicroPET/MRI was capable of visualizing a widespread infection originating from the subdermal infection inoculum induced in the armpit. This tracer accumulation 60 min post injection resulted in good signal-to noise-ratios (2.8 ± 0.5); however acute infected lungs areas showed diffuse uptake only (ratio 0.95 - 1.49). Tracer sensitivity for chronic pulmonary infection was deemed low (range 0.07 - 0.29). Expected tracer uptake (NUV) was seen in spleen (0.33), liver (0.98), and myocardium (0.78). [68Ga]Ga-DOTA-puromycin demonstrated selectivity for infection over inflammation (ratio >2.5), however, it accumulated in both M.bovis and S.aureus, i.e., the procedure was non-selective towards imaging mycobacteria species, only. The NUVs versus infected tissue histopathology revealed a positive Spearman rank order analysis (rho = 0.735; p = 0.0012; S = 180, N=16) confirming an accurate [68Ga]Ga-DOTA-Puromycin signal to reflect protein synthesis in viable mycobacteria ***Conclusion:*** The relevance of [$^{68}$Ga]Ga-DOTA-puromycin-microPET/MRI for imaging of mycobacterial infection sites is presented. The results indicate that [68Ga]Ga-DOTA-puromycin has the potential to become a viable tool for the noninvasive visualization of elevated protein synthesis in infectious lesions. Tracer sensitivity may be further improved by changes to radioisotopes, radiolabeling procedures and a more tailored preclinical setting. ***References:*** (1) Eigner S, et. al. Recent Results Cancer Res., 194:269-283. (2013)

### Performance of 68Ga-FAPI PET/CT in evaluation of Erdheim-Chester disease: compared with 18F-FDG PET/CT

***J. Ma****;*
*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Erdheim-Chester disease (ECD) involves multiple organs and has diverse manifestation, which causes difficulty to distinguish lesions caused by ECD from disguisers. Variable degrees of fibrosis is present in ECD. Therefore, we conducted a prospective cohort study to explore the ability of $^{68}$Ga-FAPI PET/CT to detect lesion in ECD patients. ***Materials and Methods:*** 14 patients diagnosed with ECD confirmed by histology were included in this study. For every patient, $^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT were conducted within 1 week. The positive rate and SUVmax of lesions in the involved organs were compared between the examinations. ***Results:*** The most commonly involved organs were bones (100%), heart (57.1%), lung (57.1%), intracranial infiltration (50%), kidney (42.9%), peritoneum or omentum (35.7%) and cutaneous infiltration (35.7%). $^{68}$Ga-FAPI PET/CT detected 64 of 67 lesions in 14 patients whereas $^{18}$F-FDG PET/CT detected 51 of 67 lesions (p=0.004). The SUVmax on $^{68}$Ga-FAPI PET/CT was significantly higher than SUVmax on $^{18}$F-FDG PET/CT for heart (4.9±2.4v.s. 2.8±1.2, p=0.050), lung or pleura (6.8±4.9v.s. 3.1±1.3, p=0.025), perioneum or omentum (5.7±3.6v.s. 2.8±1.7, p=0.032) and kidney or perinephric infiltration (4.9±1.2v.s. 2.9±1.1, p=0.009). ***Conclusion:*** The detectivity of $^{68}$Ga-FAPI PET/CT is superior to $^{18}$F-FDG PET/CT. Besides, $^{68}$Ga-FAPI PET/CT has a better image contrast and higher SUVmax for lesions in multiple organs including heart, lung, perioneum and kidney. $^{68}$Ga-FAPI PET/CT is a promising tool to assess pathologic features and disease extent in ECD patients.

## EP-0085

### Effects of Aromatase inhibitors on bone mineral density and trabecular bone score in patients with breast cancer

***V. Dabbagh***[1], *F. Homaee Shandiz*[2], *A. Taghizadeh Kermani*[3], *F. Nesari Javan*[1];
[1]*Nuclear Medicine Research Center, Ghaem Hospital, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Ghaem Hospital, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [3]*Omid Hospital, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** One of the most important treatments in breast cancer is aromatase inhibitors (AI), which reduce bone density and increase the possibility of bone fractures. Therefore, to identify people who are at risk of fracture, bone mineral density (BMD) should be measured by bone mineral densitometry (DXA) (Dual-energy X-ray absorptiometry). In recent years, another criteria namely the trabecular bone score (TBS) has been introduced as a software to assess the bone quality of patients, which leads to changes in DXA reports and can be used to improve the assessment of bone density in patients before and after any provisional treatment. ***Materials and Methods:*** Patients with proven pathology of breast cancer, who at the discretion of the oncologist had indication for the use of aromatase inhibitors, were referred for bone mineral density before treatment. Base TBS and Bone mineral density (BMD) were registered by DXA method for the patient. After 6 months from the start of treatment, the patient's bone mineral density was repeated. BMD and TBS before and 6 months after treatment was compared. ***Results:*** A total of 50 patients ( mean age of 56.33±10.67) with breast cancer were included in the study. We found that there was a significant difference between BMD in the lumbar area well as in total hip area, but no significant difference was found in TBS. Also, by comparing the 10-year risk of major osteoporosis and hip fracture (FRAX) before and after starting the drug and adjusting it to the TBS, we concluded that there is no statistically significant difference between before and after treatment.***Conclusion:*** Based on this study, bone density in the lumbar and total hip area is significantly reduced in patients treated with AIs. S it seems to be increased the risk of fracture. However, according to this study, TBS and FRAX, due to the lack of significant differences, do not help further treatment of these patients to prevent the risk of possible fractures. However duration of the 6 months for this conclusion may be a short time.

## EP-0086

### Bone SPECT-CT in the study of facet arthropathy

***B. Martins****, A. Duarte, M. Correia, A. Figueiredo, S. Matos, N. Canto, D. Calado, C. Loewenthal;
Hospital da Luz, Lisboa, PORTUGAL.*

***Aim/Introduction:*** Facet pain, despite being clinically recognized for decades, remains a diagnostic challenge, mainly because Revel's clinical criteria, used to select patients for therapy with infiltrations, showed a rather low sensitivity [1]. For this reason, imaging studies are essential. However, even the gold standard modality, MRI, may not be conclusive [1]. SPECT-CT can add value in the diagnostic process, detecting foci of increased osteoblastic activity, with high sensitivity and specificity [1]. Since the implementation of the SPECT-CT technique in our institution, the number of exam requests with this indication has been growing, mainly referenced by neurosurgery. In this sense, this study aims to review the series of patients already studied, analyzing the usefulness of SPECT-CT in the evaluation of facet arthropathy. ***Materials and Methods:*** The clinical records of patients referred for bone SPECT-CT due to suspected facet pain in the period between June 2020 and March 2023 were reviewed. The final sample included 169 patients, 57 men and 113 women, with a mean age of 51 years (age range 21-82). The respective SPECT-CT scans of these patients were reviewed, which were evaluated by two nuclear medicine physicians. ***Results:*** Of the 169 patients studied, 77 showed increased osteoblastic activity in at least one joint facet (45.6% of the sample). Forty-seven patients (27.8%) did not show any significant change in radiopharmaceutical uptake in the joint facets. The remaining patients (45/169) had pathological alterations other than facet arthropathy (mainly disc disease, osteophytosis and sacroiliitis). A total of 104 hypermetabolic joint facets were documented, the majority of them in the lumbar segment (n=91, 30 at the L4/L5 level and 33 at the L5/S1 level), 2 in the dorsal and 11 in the cervical segment. 100% inter-observer agreement was documented in the identification of hypermetabolic joint facets. ***Conclusion:*** The prevalence of hypermetabolic joint facets in this series overlaps with other recently published series (45.6% vs 48% in [1]), located mainly at the level of L4/L5 (28.8%) and L5/S1 (31.7%). Since the evidence of metabolic activity on SPECT-CT is predictive of treatment response, this imaging modality may contribute to reducing the number of unnecessary interventions [1]. ***References:*** [1] Perez-Roman RJ et al. Use of Single-Photon Emission Computed Tomography Imaging for Hypermetabolic Facet Identification in Diagnosis of Cervical and Axial Back Pain. World Neurosurg. 2020 May; 137:e487-e492.

## EP-0087

### Usefulness of bone scan in the management of Paget's disease

***N. Ben Fekih***[1], *W. El Ajmi*[2], *S. Cherif*[3], *A. Sellem*[2], *H. Hammami*[2];
[1]*faculty of medicine monastir, Tunis, TUNISIA,* [2]*Military Hospital of Tunis, Tunis, TUNISIA,* [3]*faculty of medicine Tunis, Tunis, TUNISIA.*

***Aim/Introduction:*** Paget's Disease is a metabolic bone disorder that is the second most common after osteoporosis. It is primarily characterized by increased osteoclastic bone resorption and subsequent disorganized bone remodeling of poor quality. This condition affects approximately 2% of adults aged over 55 years. Bone scintigraphy with diphosphonates is a valuable tool that can be used to evaluate the osteoblastic activity associated with Paget's Disease. Through this work, we elucidate the interest of bone scintigraphy in the management of Paget's disease. ***Materials and Methods:*** This is a six-year retrospective descriptive study, from January 2017 to December 2022, including 45 patients referred for an assessment of Paget's disease. All patients underwent planar whole-body skeletal imaging using a Siemens Symbia S dual-head gamma camera, 2-3 hours after injection of a weight-adjusted activity from 370 to 740 MBq of $^{99m}$Tc-hydroxymethylene diphosphonate ***Results:*** The study population consisted of 28 men (62,2%) and 17 women (37,8%), with a sex ratio of 1,64. The median age was 64 years [range: 41-80 years]. 9,1% were aged 50 years or younger. The examination was requested for a topographic assessment in 68.9% of cases. The disease was monostotic in 35.6% of cases and polyostotic in 53.3% of cases, at a mean of 3 affected bones with a maximum of 13 bones. The most commonly affected ones were the pelvis (27%), femur (17%), dorsal spine (14%), lumbar spine (15%), and skull (12%). Bone scan was required as a therapeutic evaluation assessment in 13.3% of cases (6 patients) and showed a partial

decrease of tracer uptake sometimes even restitution ad integrum. In 17.8% of cases (8 patients), bone scan was demanded to confirm a suspicious lesion on radiological examination. It did not show typical lesions of Paget's disease in 37.5% of cases and confirmed the suspicion in 62.5% of cases. ***Conclusion:*** The metabolic exploration of the whole skeleton using bone scan with diphosphonates is particularly valuable in the diagnostic and topographic assessment of active Paget's disease. Additionally, the decrease in osteoblastic activity is a reliable indicator for therapeutic monitoring. Normal bone uptake may be explained by quiescent Paget's disease.

## EP-0088

### Is there any added value of a DXA scan of the distal forearm to lumbar and hip DXA values in predicting osteoporotic bone fractures?

***M. ROMERA***[1], *Á. Bronte*[1], *V. Betech-Antar*[1], *F. Mínguez*[1], *J. Rosales*[1], *S. Menéndez-Sánchez*[1], *J. Bastidas*[1], *E. Guillén*[2], *L. Sancho*[2], *L. García-Belaustegui*[2], *J. Arbizu*[1], *M. García Velloso*[1], *F. Pareja*[1], *M. Rodríguez*[1];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,*
[2]*Clínica Universidad de Navarra, Madrid, SPAIN.*

***Aim/Introduction:*** To determine whether the distal forearm dual-energy X-ray absorptiometry (DXA) values allow a more accurate prediction of the probability of osteoporotic bone fracture than lumbar and hip DXA values and lumbar trabecular bone score (TBS) measures, in postmenopausal women and men >50 years. Secondarily, to determine the change that forearm values had in the final diagnosis. ***Materials and Methods:*** Patients studied between 10/2016 and 04/2023 with DXA that included distal forearm measurements were analyzed. Lumbar, hip and forearm T-Score DXA and TBS values, non-traumatic osteoporotic fractures suffered prior and after treatment, risk factors for fractures, prior diagnoses and demographic and analytic data, were gathered from medical records. Correlation between variables was studied by Pearson coefficient. To identify independent predictors for bone fractures, a logistic regression model was used. ***Results:*** Eighty-five patients were retrospectively studied. Clinical and demographic characteristics are shown in Table 1. Mean follow-up time from the DXA was 56.5 (±22.7) months. According to WHO criteria, in basal DXA, 44.7% of patients were diagnosed with osteoporosis, 48.2% osteopenia and 7.1% normal BMD. In 36/85 patients (42.4%), forearm values changed the final diagnosis (9/36 from normal to osteopenia and 27/36 from osteopenia to osteoporosis). Using TBS software, TB was classified as degraded (22.4%), partially degraded (42.4%) and normal (35.3%). Seventeen patients (20%) suffered an osteoporotic fracture after the basal densitometry. A positive correlation between forearm and lumbar T-score values and the occurrence of bone fracture was found. Patients with fractures had lower T-scores in lumbar (-2.4±1.1; p=0.005) and forearm (-2.4±1; p=0.001) than in patients who did not (-1.4±1.3; p=0.005 for lumbar and -1.2±1.3; p=0.001 for forearm). No correlation between clinical factors and bone fractures was found. Similarly, no association between TBS and fracture events was identified, except for patients with Diabetes Mellitus (p<0.001). Furthermore, and interestingly, no patients with normal baseline DXA presented osteoporotic fractures during the follow-up. On multivariate regression analysis, only baseline forearm T-score <-1.3 (OR=5.0 [95%CI:1.3-19.7, p=0.02)] significantly predicted osteoporotic bone fractures during the follow-up. ***Conclusion:*** In postmenopausal women and men >50 years, basal distal forearm T-score values were significantly lower in patients with bone breakage than in patients without fractures. A T-score value of <1.3 was a significant predictor for the risk of bone fractures. Moreover, forearm values worsen the final DXA diagnosis in 42.4% of patients. Therefore, DXA of the distal forearm provides benefit in predicting bone fractures over central DXA measurements.

## EP-0089

### Optimization of SPECT/CT reconstruction parameters for intrapancreatic accessory spleen imaging

***D. Sfiligoj Planjsek****, S. Rep, A. Cuderman, J. Jamsek, L. Lezaic;*
*UMC Ljubljana, Ljubljana, SLOVENIA.*

***Aim/Introduction:*** Intrapancreatic accessory spleen (IPAS) is a rare benign finding (representing 11-17% of all accessory spleens), that can be difficult to diagnose, especially when a pancreatic neuroendocrine tumour is suspected (1). Selective spleen scintigraphy (SSS) using Technetium-99m [$^{99m}$Tc]-labelled denatured erythrocytes is the preferred method for imaging accessory spleens (AS) (2), with IPAS best visualised by SPECT/CT. However, small IPAS located near the spleen can be difficult to detect due to poor sharpness and contrast in reconstructed SPECT images. Our research aimed to optimise SPECT reconstruction parameters in order to improve contrast and sharpness in SSS SPECT/CT imaging of IPAS. ***Materials and Methods:*** To evaluate the effect of different Gaussian filter FWHM (soft tissue) settings (10 mm, 8 mm, 6 mm, 4 mm and 2 mm) on contrast and sharpness, we iteratively reconstructed SPECT images with 8 iterations and 4 subsets. These parameters were used to analyse NEMA body phantoms and SPECT/CT images in a selected group of patients who had undergone SSS at our department of nuclear medicine within the last 5 years. ***Results:*** Lower values of the Gaussian filter FWHM resulted in increased contrast and sharpness of lesions, but also increased background graininess and noise. The contrast of the spheres in the NEMA body phantom was increased by narrowing FWHM from 10 mm to 8 mm, to 6 mm, to 4 mm and to 2 mm. With each narrowing of the FWHM, the contrast increased by approximately 12% for smaller (≤ 13 mm) spheres and by approximately 5% for larger (≥ 17 mm) spheres ($p < 0.05$). Likewise, in the patient group, IPAS were better defined in SPECT images at lower values of Gaussian filter FWHM. The increased noise did not affect image interpretation because the exact location of IPAS was known due to concomitant low-dose CT. The image contrast obtained using different FWHM filters was comparable to results obtained with the NEMA body phantom. ***Conclusion:*** In our opinion 2 mm of the Gaussian filter FWHM in SSS SPECT/CT images provide better contrast and sharpness especially in small IPAS positioned in close proximity to spleen. ***References:*** 1. ## EP-0090

### Identifying immunotherapy progressors by 18F-FLT PET/CT in solid tumours: a pilot study

***P. Aravind***[1], *M. Lythgoe*[1], *J. Evans*[2], *L. Tookman*[2], *W. E. Park*[2], *N. Sarwar*[2], *A. Sita-Lumsden*[3], *D. J. Pinato*[2], *T. D. Barwick*[1,2], *E. O. Aboagye*[1], *R. Sharma*[1,2];
[1]*Imperial College London, London, UNITED KINGDOM,*
[2]*Imperial College Hospital NHS TRUST, London, UNITED KINGDOM,* [3]*Guys and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM.*

***Aim/Introduction:*** Immunotherapy (IO) confers a survival benefit in advanced cancers. Response to IO is not adequately assessed by RECIST 1.1 due to pseudo progression and iRECIST still relies on changes in tumour size. The primary objective of this pilot study was to assess the feasibility of ($^{18}$F)FLT PET/CT as a marker of response to IO (modified PERCIST) and to determine PET parameters that correlate with imaging response (RECIST 1.1 and iRECIST) and progression free survival(PFS). ***Materials and Methods:*** Patients with metastatic cancer scheduled to receive IO for advanced disease underwent ($^{18}$F)FLT PET/CT at baseline and 12 weeks after initiating IO. All sites of disease avid above background and >10mm were outlined on PET. SUV parameters ($SUV_{mean}$, $SUV_{max}$, proliferative tumour volume (PTV), total lesion proliferation (TLP: calculated as the product of SUVmean and PTV) were calculated. (18F)FLT PET response(PERCIST, modified PERCIST: max5 lesions, unto 2 per organ, Total lesion PERCIST: all lesions outline) were compared to RECIST 1.1 and iRECIST at follow up scan at 12 weeks. PFS was calculated from baseline scan to progression. ***Results:*** Sixteen patients had evaluable PET scans. The tumour types were hepatocellular (8), non small cell lung cancer(1), Ovarian cancer (2), Renal cancer(1), endometrial cancer(1), oesophageal squamous cell cancer(3). Median age was 68yr (42-80), median cycles of IO received was 8(2-19) and the most common toxicity was fatigue. (38%, n=6) followed by liver toxicity(31%, n=5). Disease control rate after IO therapy was 74% on RECIST 1.1 response (PR: n=4, SD: n=8, PD: n=4) and 81% on iRECIST (PR: n=4, SD: n=8, immune unconfirmed PD: n=1, immune confirmed PD: n=3). For PET, 88% (14/16) were responders (PMD, SMD) on modified PERCIST and 94% (15/16) on PERCIST. Changes in tumour ($^{18}$F)FLT PET uptake were moderately correlated with changes in RECIST 1.1 measurements ($\Delta SUV_{max}$ p=0.049, rho -0.499, $\Delta SUV_{mean}$ p=0.009, rho-0.633). Progression was characterised by increases in ΔPTV and ΔTLP of 230 and 431, respectively (p=0.021, p=0.008) compared to non progression (-32 and -38). Median PFS was 9.3m (2m vs 10m in PD vs non-PD based on RECIST or modified PERCIST (log rank p=0.003) compared to 3.4m vs 10m based on iRECIST (p=0.005). ***Conclusion:*** Progressors on immunotherapy show increases in ΔPTV and ΔTLP at 12 weeks. ($^{18}$F)FLT PET/CT is a promising to detect futile immunotherapy.

### Unraveling the Relationship Between Glioma Tumor Residuals from Incongruent 18F-FET PET/MR Imaging and Tumor Proliferation Utilizing Multiparametric MRI Radiomics Analysis

***X. Li***[1,2], *Y. Cheng*[3], *X. Han*[1], *H. Yang*[1], *B. Cui*[1,2], *J. Li*[1,2], *G. Xu*[3], *Q. Lin*[3], *X. Xiao*[3], *J. Tang*[3], *J. Lu*[1,2];
[1]*Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA,* [2]*Beijing Key Laboratory of Magnetic Resonance Imaging and Brain Informatics, Capital Medical University, Beijing, CHINA,* [3]*Department of Neurosurgery, Xuanwu Hospital, Capital Medical University, Beijing, CHINA.*

***Aim/Introduction:*** The study aimed to using multiparametric magnetic resonance imaging radiomics to predict glioma tumor residuals ($TR_{FET\ over\ MR}$) derived from incongruent O-(2-$^{18}$F-fluoroethyl)-L-tyrosine ($^{18}$F-FET) positron emission tomography/magnetic resonance (PET/MR) imaging. ***Materials and Methods:*** A total of 110 patients with gliomas who underwent preoperative hybrid $^{18}$F-FET PET/MR scanning were retrospectively analyzed. The biological tumor volume (BTV) was semi-automatically segmented based on a threshold of tumor background ratio (TBR) > 1.6 on $^{18}$F-FET PET images. The $TR_{FET\ over\ MR}$ was identified by the discrepancy-PET that the extent of resection (EOR) based on MRI subtracted the BTV. The expressions of molecular markers related to proliferation, including epidermal growth factor receptor (EGFR) and Ki-67, were identified by immunohistochemistry.The MRI parameters and radiomics features based on anatomical MRI, diffusion-weighted imaging, and arterial spin labeling imaging were extracted based on EOR. Subsequently, the least absolute shrinkage and selection operator (LASSO) were used to construct the radiomics score (Rad-score). Comparison of clinical features and Rad-score between $TR_{FET\ over\ MR}$ and non $TR_{FET\ over\ MR}$ groups was tested by the Mann-Whitney U test. The correlation network analysis of all features was analyzed by the Spearman's correlation tests. The methods for evaluating the accuracy of machine learning models established by logistic regression consisted of the receiver operating characteristic curve, the calibration curve, and decision curve analysis. ***Results:*** The Rad-score of the patients with the $TR_{FET\ over\ MR}$ was significantly higher than those with the non $TR_{FET\ over\ MR}$ ($p < 0.001$). The Rad-score was significantly correlated with the discrepancy-PET ($r = 0.72$, $p < 0.001$), Ki-67 level ($r = 0.76$, $p < 0.001$), and EGFR of gliomas ($r = 0.75$, $p < 0.001$), respectively. And the discrepancy-PET was also moderately correlated with the EGFR ($r = 0.64$, $p < 0.001$) and Ki-67 level ($r = 0.67$, $p < 0.001$). Moreover, there was a difference of the correlation network analysis between the $TR_{PET\ over\ MR}$ group and non $TR_{FET\ over\ MR}$ group. The nomogram combing Rad-score and clinical features had the greatest performance in predicting $TR_{FET\ over\ MR}$ (AUC = 0.90/0.87, training/testing) compared to single clinical features or Rad-score. ***Conclusion:*** Multiparametric MRI radiomics could help explain the proliferation of gliomas leading to intra-tumor heterogeneity and $TR_{FET\ over\ MR.}$ The nomogram based on MRI radiomics would predict tumor residuals caused by the absence of $^{18}$F-PET PET examination and adjust EOR to improve prognosis of gliomas.

## EP-0092

### [18F]FDG-PET Radiomics Improves Outcome Prognostication in Patients With Primary CNS Lymphoma

***S. Chen***[1], *O. Yildirim*[2], *A. Mauguen*[2], *C. Grommes*[2], *H. Schöder*[2], *M. E. Mayerhoefer*[2], *S. Krebs*[2];
[1]*Weill Cornell Medical College, New York, NY, UNITED STATES OF AMERICA,* [2]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Current clinical and imaging tools remain suboptimal for outcome prognostication in primary CNS lymphoma (PCNSL). This study evaluated the prognostic utility of standard metabolic parameters and radiomic features extracted from baseline [$^{18}$F]FDG-PET/CT in patients with newly diagnosed PCNSL and combined with clinical parameters. ***Materials and Methods:*** Ninety patients with newly diagnosed PCNSL and clearly FDG-avid lesions on [$^{18}$F]FDG-PET/CT of the brain before receiving standard therapy with high dose methotrexate with/without consolidation treatment (radiotherapy or chemotherapy) and with/without rituximab were included in this retrospective study. Manual segmentation of up to five [$^{18}$F]FDG-avid lesions per

patient was performed, and standardized uptake values ($SUV_{max}$), metabolic tumor volumes (MTV), total lesion glycolysis (TLG), and 158 radiomic features were extracted. ComBat harmonization of imaging features was performed to correct for potential systematic differences between PET/CT scanners, and gradient boosting was used for feature selection. Clinical and PET-based features and their combinations were tested for overall survival (OS) prognostication. ***Results:*** In 90 patients with measurable disease on PET, 195 lesions were identified, including 156 deep brain lesions. The OS was 80% at 2 years. In a multivariable analysis, age at diagnosis, KPS and treatment with rituximab were prognostic for OS. Standard metabolic parameters ($SUV_{max,}$ MTV, and TLG) and the sum thereof were not associated with outcome. Five radiomic features (three derived from the histogram, one from the co-occurrence matrix, and one from the run-length matrix) were selected from gradient boosting. Five-fold cross-validation was performed for the radiomics, the clinical, and a composite model. For 2-year OS status prediction, areas under the receiver operating characteristic curve (ROC AUC) were 0.580 for the radiomics model, 0.763 for the clinical model, and 0.863 for the composite model. ***Conclusion:*** In PCNSL, radiomic features, but not standard metabolic parameters, are prognostic of OS, and may improve clinical prognostic models.

**Somatostatin Receptor-Directed Theranostics in Paragangliomas of the Head and Neck**

***S. Serfling***[1], *Y. Zhi*[2], *E. Gerhard-Hartmann*[3], *A. Weich*[4], *T. Higuchi*[5], *S. Hackenberg*[6], *R. Hagen*[2], *H. Remde*[7], *A. Scherzad*[1], *M. Fassnacht*[8], *R. A. Werner*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Department of Otorhinolaryngology, Plastic, Aesthetic and Reconstructive Head and Neck Surgery, University Hospital Würzburg, Würzburg, GERMANY,* [3]*Institute of Pathology and Comprehensive Cancer Center Mainfranken, Würzburg, GERMANY,* [4]*ENETS Center of Excellence, University Hospital Würzburg, Würzburg, GERMANY,* [5]*University Hospital Würzburg, Würzburg, GERMANY,* [6]*RWTH Aachen University, Aachen, GERMANY,* [7]*Internal Medicine II, Gastroenterology, University Hospital Würzburg, Würzburg, GERMANY,* [8]*8 Internal Medicine I, Endocrinology, University Hospital Würzburg, Würzburg, GERMANY.*

***Aim/Introduction:*** Given their neuroendocrine origin, paragangliomas of the head and neck (HNPGL) can be imaged with somatostatin receptor (SSTR)-directed PET/CT. We aimed to determine whether the in-vivo PET signal can differentiate between varying HNPGL subtypes. In addition, we also report on feasibility of peptide receptor radionuclide therapy (PRRT) in this patient population. ***Materials and Methods:*** 14 patients with HNPGL received pretherapeutic SSTR-PET/CTs using [$^{68}$Ga] Ga-DOTATOC. Six (42.9%) patients had paraganglioma jugulare (PGL-J), five (35.7%) were diagnosed with paraganglioma caroticum (PGL-C) and the remaining three patients (21.4%) had a PGL-C with pathogenic SDHx germline variants (PGL-C-SDH). We performed visual and quantitative assessment of the primary on SSTR-PET, including maximum standardized uptake values ($SUV_{max}$) and target-to-background-ratio (TBR). Quantitative values were then compared between subgroups of patients affected with different HNPGL entities. Patients eligible for PRRT were also identified. ***Results:*** On a visual assessment, all primary HNPGL could be readily identified on SSTR-PET/CT. Quantification of HNPGL then provided substantially elevated $SUV_{max}$ in PGL-J (101.7±58.5) when compared to PGL-C-SDH (13.4±5.6, P<0.05), but not when compared to PGL-C (66.7±27.3, P=0.4; PGL-C vs PGL-C-SDH, P=0.2). TBR of PGL-J (202.9±82.2), however, then further differentiated between PGL-C (95.7±45.4, P<0.05) and PGL-C-SDH (20.4±12.2, P<0.01; PGL-C vs PGL-C-SDH, P=0.3). Moreover, whole-body read-out revealed an M1 status in 2/3 (66.7%) PGL-C-SDH patients, with a single SSTR-expressing skeletal lesion in one subject and bipulmonary lesions in the other patient. The latter individual received 2 cycles of PRRT (cumulative activity, 14.7 GBq [$^{177}$Lu] Lu-DOTATOC). No acute or long-term side effects (including haemato- or nephrotoxicity) were recorded and 5 months after PRRT, mixed response was achieved. ***Conclusion:*** In patients with HNPGL, SSTR-PET identifies widespread metastatic disease and provides substantially elevated TBR, indicative for excellent image contrast. PET-based quantification can also differentiate between varying HNPGL subtypes. In a theranostic setting, PRRT might be feasible, which may achieve outcome benefits without relevant side effects.

### EP-0094

**Prediction of Nodal Metastasis by FDG PET/CT in Untreated Laryngeal Carcinoma; Comparison to MRI**

***A. Al ibraheem****, A. S. Abdlkadir, H. KHCC Group, D. Al-adhami;
King Hussein Cancer Center, Amman, JORDAN.*

***Aim/Introduction:*** Squamous cell carcinomas account for over 95% of laryngeal tumors, necessitating accurate staging for optimal treatment and outcome. While conventional imaging, such as magnetic resonance imaging (MRI), has been used to detect primary tumors and regional nodal metastases, it lacks the ability to differentiate between metastatic and non-metastatic cervical lymph nodes. FDG PET/CT is being used to characterize metastases at local, regional, and distant levels. This study aims to determine the diagnostic accuracy of PET/CT and neck MRI in laryngeal carcinoma patients, with a focus on the prognostic value of PET/CT for survival outcomes. ***Materials and Methods:*** Data from a tertiary referral cancer center were collected and analyzed retrospectively. A cohort of patients diagnosed with laryngeal cancer between December 2014 and January 2021 was investigated. Among this group of patients, only 68 of them had undergone post-imaging neck dissection with biopsy-proven laryngeal malignancy. Sensitivity, specificity, and overall accuracy were calculated for each diagnostic test, along with 95% confidence intervals. McNemar test was used to compare data obtained separately from FDG PET/CT and neck MRI. The Kaplan-Meier method was used to plot survival curves for progression-free survival (PFS) and overall survival (OS). The log-rank test was used to assess survival differences between subgroups. ROC curve analysis was employed to determine optimal cutoff values for each continuous variable (e.g., Semiquantitative PET parameters). The Cox proportional hazards regression model was used in both univariate and multivariate analyses to assess the relationship between survival, clinicopathological factors, and several Semiquantitative PET parameters. A significant threshold of $p < 0.05$ was established. SPSS 26.0 for Windows (SPSS, Inc., Chicago, IL) was used for all analyses. ***Results:*** The sensitivity and specificity

of PET/CT, and MRI were evaluated. PET/CT had 93.8% sensitivity, 58.3% specificity, and 75% ac-curacy for nodal metastasis, while MRI had 68.8%, 61.1%, and 64.7%, respectively. At a median follow-up of 51 months, 23 patients developed disease progression, and 17 patients died. Univariate survival analysis revealed all utilized PET parameters as significant prognostic factors for OS, and PFS (p value < 0.03 each). On multivariate analysis, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) predicted better PFS (p value < 0.05 each). ***Conclusion:*** PET/CT improves the accuracy of nodal staging in laryngeal carcinoma over neck MRI and adds to the prognostication of survival outcomes through the use of several PET metrics.

## EP-0095

### Diagnostic utility of Semiquantitative parameters on FDG PET/CT for lymph node metastases in patients with laryngeal Squamous Carcinoma

***A. Al ibraheem****, A. Abdlkadir, D. Al-Adhami, King Hussein Cancer Center Head and neck cancer Group, H. KHCC Group;*
*King Hussein Cancer Center, Amman, JORDAN.*

***Aim/Introduction:*** Accurate staging in laryngeal squamous carcinoma is essential for selecting the most effective treatment and achieving the best outcome. FDG PET/CT is being used to characterize metastases at locoregional, and distant levels. PET/CT can be used to assess metabolic activity in cervical lymph nodes. Hypermetabolic lymph nodes carry a high potential for metastatic processes. Therefore, it can provide concrete evidence in determining metastatic lymph nodes. Lymph nodes (LN) semiquantitative PET parameters had previously shown promising results in providing prognostic background for disease progression of respiratory tumors. This study aims to examine semiquantitative PET metrics for laryngeal cancer to determine the diagnostic value ***Materials and Methods:*** Patients diagnosed with laryngeal Squamous cell carcinoma between December 2014 and January 2021 were retrospectively enrolled. These patients had previous baseline FDG PET/CT for initial disease assessment. The PET images were reviewed visually and semi-quantitively using several metabolic PET parameters. Biopsy results were examined to determine nodal disease status and reach definitive staging results. To measure the metabolic parameters of LNs, maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), total lesion glycolysis (TLG) were examined. The diagnosis of each retrieved LN was confirmed based on histopathological examination of surgical tissue specimens. Receiver operating characteristics (ROC) curves with area under the curve (AUC) calculations and multivariate analysis by logistic regression were performed. A significant threshold of $p < 0.05$ was established. ***Results:*** Seventy-two Patients with 144 clinically diagnosed positive lymph nodes were enrolled. Of the 144 LNs, only 106 LNS were pathologically proven as positive (73.7%). The SUVmax, MTV, and TLG of LN metastasis were significantly higher than those of benign nodes. In the ROC analysis, the AUC value of LN MTV [AUC, 0.88; 95% confidence interval (CI), 0.82-0.93] was higher than that of LN TLG (AUC, 0.72; 95% CI, 0.64-0.79) or LN SUVmax (AUC, 0.69; 95% CI, 0.61-0.77). Using the optimal Cutoff value of 1.2 for LN MTV, the sensitivity, specificity, were 87.7, and 86.8%, respectively. Multivariate analysis with logistic regression showed that LN MTV was an independent predictor for LN metastasis (odds ratio, 5.19; 95% CI, 2.8-9.712; $P < 0.01$). ***Conclusion:*** Our findings suggest that LN MTV on FDG PET/CT is a useful predictor for LN metastasis in patients with laryngeal squamous carcinoma. This PET-derived metric might provide solid functional imaging evidence for future studies to pursue.

## EP-0096

### Role of F-18-FDG PET/CT in staging and assessment of treatment response to neoadjuvant chemotherapy in patients with extra-ocular retinoblastoma (EORB) - a single centre initial experience

***S. G Ravindra****, S. Garg, A. Khurana, J. Pathak, N. Lomi, R. Seth, R. Kumar, C. S. Bal;*
*All India Institute of Medical Sciences, New Delhi, INDIA.*

***Aim/Introduction:*** The most common intra-ocular malignancy of childhood is retinoblastoma. Extra-ocular dissemination, albeit rare, is the most important cause of poor prognosis and death in these children, particularly in the developing countries. The most common sites of metastasis include central nervous system, bone and lymph nodes. The systemic work-up for suspected metastatic disease includes brain and orbital MRI with or without contrast, lumbar puncture for cerebrospinal fluid cytology, bone marrow aspiration/biopsy and bone scintigraphy. Detection of distant metastasis, is important, not only to prognosticate the patient, but also to determine the appropriate dose and schedule of the chemotherapeutic regime. ***Materials and Methods:*** A total of 20 patients with a diagnosis of EORB were enrolled prospectively in this study. F-18-FDG PET/CT scan was performed at baseline, prior to initiation of chemotherapy and after 3 cycles of neoadjuvant chemotherapy. ***Results:*** A total of 20 patients of extra-ocular retinoblastoma were evaluated in the study. 14 patients had unilateral eye disease while 6 patients had bilateral eye disease. 9 patients had clinical evidence of extra-ocular extension in the form of marked proptosis. SUVmax of involved eye in patients with clinical evidence of extra-ocular extension in the form of marked proptosis was greater than 2.5 as compared to patients with only radiological evidence of extra-ocular extension. 5 patients showed evidence of bone marrow metastasis - 1 detected by bone marrow studies alone, 1 patient positive on MRI, PET/CT and bone marrow studies, 1 patient positive on PET/CT and bone marrow studies and negative on MRI, 2 patients positive only on PET/CT and negative on MRI and bone marrow studies. The reason for false negativity on bone marrow studies in these patients may be due to limited sites of bone marrow involvement. A total of 7 patients had pre-auricular lymph node metastases, of which 5 were detected only on PET/CT and not on MRI. Follow-up scan after 3 cycles of neo-adjuvant chemotherapy was done in 14 patients, who showed partial metabolic response with significant reduction in metabolic activity at sites of lymph node and distant metastases if present initially. ***Conclusion:*** F-18-FDG PET/CT may aid in identifying lymph node and distant metastases in patients with advanced extra-ocular retinoblastoma and help in accurate staging of disease and further treatment. However, more studies are required in this regard.

## EP-0097

### The impact of the COVID 19 pandemic on nasopharyngeal carcinoma extent at FDG PET/MR staging:the NPCOVIPET study

***Y. Xu****;*
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To evaluate the impact of coronavirus disease 2019 (COVID-19) pandemic ondiseaseextentinnasopharyngealcarcinoma(NPC)patients using18 fuorodeoxyglucose (FDG) positron emission tomography (PET)/magnetic resonance imaging (MRI) staging as surrogate measure. ***Materials and Methods:*** Retrospective observational study including biopsy-proven, newly diagnosed NPC patients using whole-body FDG PET/MR

staging in two selected intervals: May 1, 2017 to January 31, 2020 (Group A), and February 1, 2020 to June 30, 2021 (Group B). Data regarding primary tumour, regional lymph nodal (N) status and number of involved regional lymph nodal stations, and presence and number of distant metastases (M) were collected. ***Results:*** Three hundred ninety patients were included (201 in Group A vs 189 in Group B, respectively). The median intervals to PET/MR from the initial symptom ingroup A and group B were 2.5 (0.1-60.4) and 3.4 (0.2-56.3) months, respectively (p>0.05). The median intervals to treatment from the initial symptom in group A and group B were 2.8 (0.2-60.5) and 3.6 (0.3-56.3) months, respectively (p>0.05). No significant difference was observed in terms of T classification, N classification,overall stage, N stations and M stations between the two groups (p>0.05). For the the involved neck node levels, more patients had developed level Vc metastasis in the group B (p=0.044). ***Conclusion:*** For NPC, staging by PET/MR and therapy were not significantly delayed after quarantine restrictions initiated. Although the overall stage was not affected, more NPC patients had developed level Vc metastasis in the era of COVID-19.

## EP-0098

### Use of 18F-FDG PET/MR as an initial staging procedure for nasopharyngeal carcinoma

***Y. Xu***;
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** The purpose of this study was to determine the clinical value and cost-effectiveness of PET/MR as an initial staging procedure for nasopharyngeal carcinoma (NPC) compared with the conventional work-up (CWU). ***Materials and Methods:*** From May 2018 to March 2021, 1020 consecutive patients with biopsy-proven, newly diagnosed NPC in our center were enrolled in this study. Among them, 343 patients underwent PET/MR before treatment and the remaining 677 patients only underwent CWU. For PET/MR and CWU, charges were used as issued in 2021 by the Medical Insurance Administration Bureau of Zhejiang, China. Incremental costeffectiveness ratio (ICER) measured cost of using PET/MR per percent of patients who avoided a false-positive (FP). ***Results:*** For the whole group, the de novo metastatic disease rate was 5.2% (53/1020). A total of 187 patients with FP results were observed. More patients with FP results were observed in the CWU group (25.6% vs. 4.1%, p<0.001). The mean interval from pathological diagnosis to initiation of treatment was 13.1 days in the CWU group versus 7.9 days in the PET/MR group (p< 0.001). Mean cost per patient was $417 for CWU and $1585 for PET/MR. The ICER was $54 for each percent of patients who avoided a FP. ***Conclusion:*** Compared with CWU, PET/MR reduced FP risk and decreased workup of incidental findings, allowing for earlier treatment start. PET/MR may be cost-effective in initial staging procedure for NPC.

## EP-0099

### A diagnostic model of nasopharyngeal carcinoma based on PET/MRI radiomics and semi-quantitative parameters

***J. Liang***;
杭州通用医学影像诊断中心, 杭州, *CHINA.*

***Aim/Introduction:*** The staging of nasopharyngeal carcinoma (NPC) is of great value in treatment and prognosis. We explored whether a positron emission tomography/ magnetic resonance imaging (PET/MRI) based comprehensive model of radiomics features and semiquantitative parameters was useful for clinical evaluation of NPC staging. ***Materials and Methods:*** A total of 200 NPC patients diagnosed with non-keratinized undifferentiated carcinoma were divided into early-stage group (I-II) and advanced-stage group (III-IV) and divided into the training set (n = 70) and the testing set (n = 30). Radiomics features (n = 382 × 2) of the primary site of NPC were extracted from MRI and PET images, respectively. Three major semiquantitative parameters of primary sites including maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) in all NPC patients were measured. After feature selection, three diagnostic models including the radiomics model, the meta-bolic parameter model, and the combined model were established using logistic regression model. Finally, internal validation was performed, and a nomogram for NPC comprehensive diagnosis has been made. ***Results:*** The radiomics model and metabolic parameter model showed an area under the curve (AUC) of 0.85 and 0.82 in the testing set, respectively. The combined model based on radiomics and semiquantitative parameters showed an AUC of 0.93 in the testing set, with the best performance among the three models. ***Conclusion:*** The combined model based on PET/MRI radiomics and semiquantitative parameters is of great value in the evaluation of clinical stage (early-stage group and advanced-stage group) of NPC.

## EP-0100

### Detection of metastatic lymph nodes with multiparametric PET/MR in head and neck imaging

***A. Harteveld***, *E. H. M. Kemper, N. D. Sijtsema, P. A. Wielopolski, D. H. J. Poot, M. Segbers, F. A. Verburg;*
*Erasmus MC, Rotterdam, NETHERLANDS.*

***Aim/Introduction:*** Detection of lymph node involvement has a significant negative impact on the treatment outcome for patients with head and neck squamous-cell carcinomas (SCC). Metastatic lymph nodes can be detected with high sensitivity by [18F]FDG-PET. However, false-positive metastatic lymph nodes occur relatively often. Additional information of lymph nodes which are suspected for metastasis based on the [18F]FDG-PET to improve specificity would be highly desirable. The use of physiological magnetic resonance imaging (MRI) sequences may provide this missing information. Physiological MRI sequences uses techniques that allow for the measurement of physiological processes within a tissue. Therefore, the aim of this study was to determine the added predictive value of quantitative physiological MRI in combination with [18F]FDG-PET for the detection of malignant lymph nodes in head and neck PET/MR. ***Materials and Methods:*** Between September and December 2022 25 patients with (suspected) SCC were included scheduled for a diagnostic PET/MR (Signa PET/MR, GE Healthcare), including dedicated [18F]FDG-PET and structural MR imaging of the head and neck region according to the standard clinical protocol. Physiological diffusion-weighted imaging intravoxel incoherent motion (DWI-IVIM) and dynamic contrast-enhanced (DCE) MRI sequences were acquired additionally to obtain diffusion and perfusion related quantitative parameters, respectively. Image registration was performed to align all images obtained in each patient. A region-of-interest was manually delineated in each identified lymph node to obtain quantitative parameters of DWI-IVIM (D, D*), DCE-MRI ($K_{trans}$, $K_{ep}$, $V_p$) and [18F]FDG-PET (SUV). Lymph node scoring was performed based on the standard PET/MR images. Pathology was obtained in a subset of lymph nodes as part of the standard clinical workup. ***Results:*** In total 10 subjects were used for analysis including 41 identified lymph nodes. Pathology

was obtained in 13 lymph nodes, three were malignant and ten non-malignant. Significant differences were found between the malignant and non-malignant lymph nodes for quantitative parameters of D, D*, $K_{trans}$, $K_{ep}$ and SUV. Based on the standard PET/MR image findings, 6/10 of the non-malignant lymph nodes were scored as suspect. ***Conclusion:*** Based on these preliminary results the physiological MRI showed multiple quantitative parameters correlating to malignancy. Moreover, the relatively high number of non-malignant lymph nodes scored as suspect based on the standard PET/MR images emphasizes the potential specificity improvement additional physiological MRI may provide for head and neck PET/MR imaging. To determine this potential synergistic added value combined with [18F]FDG-PET logistic regression analysis will be performed on the entire dataset.

## EP-0101

### Clinical Value of [18F]FDG PET-CT In the Study of Head and Neck Carcinoma of Unknown Origin.

***V. Carrero-Vásquez***, *L. Rodríguez-Bel, C. Martinez-Ramos, P. Notta, L. Gracia-Sánchez, I. Sanchez-Rodriguez, A. Palomar-Muñoz, M. Cortés-Romera;*
*Nuclear Medicine Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** Head and neck carcinoma of unknown origin (CUO) is defined as the presence of cervical adenopathies with anatomopathological (AP) confirmation of squamous cell carcinoma metastasis without evidence of primary lesion after standard diagnostic study, including physical examination and computed tomography. Our study aimed to investigate the diagnostic performance of [18F]-FDG PET-CT in identifying the primary lesion in CUO. ***Materials and Methods:*** Retrospective analysis of 20 consecutive patients (July-2018 to July-2022), 62.5 years (37-85); 12 men. 3 patients were excluded (2: diagnosis of lymphoma, 1: anaplastic carcinoma). All 17 studies included underwent full-body PET-CT and dedicated head-neck scans. Visual analysis of the primary suspect was performed through a qualitative evaluation (grouped as positive, negative or doubtful) and quantitatively with the standardized uptake value (SUVmax). The probable location of malignancy suggested by the PET-CT was confirmed by AP, additional examinations and follow-up. ***Results:*** 9 Studies were grouped as positive, with a SUVmax mean of 6.6(2-11.5); 6 had AP confirmation; in 3 patients, AP of the primary was not performed. The most frequent location was the oropharynx(4/6), most of which were HPV-related (p16+). 4 studies were grouped as doubtful: 3 had tonsillar metabolic asymmetry, with AP analysis negative or not confirmed in the follow-up; in 1 case, the supraglottic larynx was suggested to be the primary site but was located at the base of the tongue. Finally, the remaining 4 studies were grouped as negatives: in 2 patients, the primary site was not detected at follow-up; in 1 case, the post-surgical evaluation located it in the left tonsil-base of the tongue (tumour focus: 1.4mm); and in 1 case AP was not performed due to extensive lymph node and distant dissemination. Sensitivity specificity PPV and NPV were 87.5%, 50%, 77% and 66%, respectively, with an accuracy rate of 75%. Of the 17 patients included, 4 had metastatic spread at diagnosis. ***Conclusion:*** In our population, [18F]-FDG PET-CT proved to be an effective technique with high sensitivity in detecting the primary tumour in patients with CUO, also serving as a biopsy guide and remote disease detection, consistent with the published data. All of this has a clinical impact by contributing substantially to patient care, through an improvement in staging, with the consequent selection of the most appropriate treatment for each case.

## EP-0102

### Pretreatment PET-derived GLCM & TLG model predicts therapy outcome in patients with Head & Neck S.C.C.

***M. Elahmadawy***[1], *A. Ashraf*[1], *H. Moustafa*[2], *M. Kotb*[1];
[1]*Nuclear Medicine Unit, National Cancer Institute (NCI) , Cairo University, Cairo, EGYPT,* [2]*Nuclear Medicine Unit, Kasr Al-Ainy (NEMROCK Center), Cairo University, Cairo, EGYPT.*

***Aim/Introduction:*** to assess the prognostic value of pretreatment PET-derived parameters in Head & Neck Squamous Cell Carcinoma (S.C.C). ***Materials and Methods:*** 55 adult patients with Head & Neck S.C.C. were enrolled. Semiquantitative pretherapy PET derived volumetric (SUV max & mean, TLG & MTV) and radiomics analyses (using LIFEx v7.2.0) were performed. Follow-up data were retrieved. ***Results:*** 67.3% were males and 32.7% were females with median age 57 years. 63.6% of the patients received concomitant chemo- and radio-therapies. On last follow-up 74.5% of them showed favorable response and 25.5% were non-responders. The mean value for the primary tumors SUVmax was 14.8 +/-6.3, the metabolic tumor volume (MTV) mean value was 15.4 +/-16 and the total lesion glycolysis (TLG) mean value was 153.1 +/-188.4. There were statistically significant higher MTV values reported among those who died on follow-up compared to those survived till last follow-up with mean value 26.2 +/- 24.9 compared to 13 +/- 12.5 respectively (P-value 0.045). ROC marked a cutoff value for MTV (>10.8) that was able to predict survival with AUC 0.704, sensitivity 80% and specificity 68.9% (P-value 0.048). ROC successfully marked cutoff points that predict survival for morphological_approximate volume (>10083.9), with AUC 0.736, sensitivity 90%, specificity 53.3% (P-value 0.007), morphological_integrated intensity (>97954.1), with AUC 0.702, sensitivity 80% and specificity 66.7% (P-value 0.046), intensity-based_total lesion glycolysis (>101.2), with AUC 0.762, sensitivity 90% and specificity 66.7% (P-value 0.001), GLCM_difference variance (< 81.022) ,with AUC 0.704 , sensitivity 70%, specificity 75.6% (P-value 0.014). NGTDM_coarseness (< 0.0074), with AUC 0.707, sensitivity 60%, specificity 82.2% (P-value 0.035). The synergistic performance of such significant parameters was tested to create the most accurate stable prediction model. Hence Multivariate logistic regression analysis to detect independent predictors of mortality was performed. The combination of TLG and GLCM_difference variance provided the most accurate prediction for mortality with with Sensitivity=70%, Specificity=91.1%, PPV=63.6%, NPV=93.2%, and Overall accuracy=87.3% (P-value <0.001). ***Conclusion:*** Pretreatment PET-derived radiomics, in patients with Head and Neck S.C.C., were able to predict therapy outcome with a prediction model for survival was successfully generated. ***References:*** C Nioche, F Orlhac, S Boughdad, S Reuzé, J Goya-Outi, C Robert, C Pellot-Barakat, M Soussan, F Frouin, and I Buvat. LIFEx: a freeware for radiomic feature calculation in multimodality imaging to accelerate advances in the characterization of tumor heterogeneity. Cancer Research 2018; 78(16):4786-4789

## EP-0103

### Application value of 18F-FDG PET/MRI in scanning for cephalic and cervical lymph node metastasis of nasopharyngeal carcinoma

***J. Liang***;
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To study the value of integrated PET/MRI scanning in the detection of cephalic and cervical lymph node metastasis in patients with nasopharyngeal carcinoma. ***Materials and Methods:*** PET/MRI imaging data of 120 patients

with pathologically confirmed nasopharyngeal carcinoma in our hospital from June 2017 to January 2023 were retrospectively analyzed. The characteristics of PET image, MRI image and PET/MRI image for lymph node detection were analyzed, and the differences of cervical lymph node metastasis diagnosis among each group were compared. ***Results:*** A total of 120 patients were found to have lesions, including 305 positive lesions and 145 negative lesions in MRI group, with sensitivity of 81.9% and specificity of 84.0%. There were 298 positive and 152 negative lesions in PET group, with sensitivity of 92.8% and specificity of 89.1%. PET/MRI group found 281 positive lesions, 169 negative lesions, sensitivity 98.5%, specificity 97.9%. ***Conclusion:*** PET/MRI scan has important application value in the diagnosis of cephalic and cervical lymph node metastasis of nasopharyngeal carcinoma, not only in the detection of lymph nodes, but also in the diagnosis of benign and malignant.

## EP-0104

### Application value of 18F-FDG PET/MRI in monitoring the staging and treatment effectiveness of nasopharyngeal carcinoma

***J. Liang***;
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** This study was to evatuate the clinical application of $^{18}$F-FDG PET/MRI to the staging, restaging, and treatment effectiveness of nasopharygeal carcinoma(NPC). ***Materials and Methods:*** The $^{18}$F-FDG PET/MRI whole-body scanning data of 198 patients with NPC in our center from August 2017 to December 2022 were retrospectively analyzed. According to clinical data, pathological results and clinical follow-up results, The accuracy, specificity, sensitivity, positive predictive value and negative predictive value of $^{18}$F-FDG PET/MRI and traditional imaging(including CT and MRI) were calculated. The results are compared and analyzed. ***Results:*** The total accuracy, sensitivity, specificity, positive predictive value and negative predictive value of $^{18}$F-FDG PET/MRI in the diagnosis of NPC were 98.2%, 100.0%, 91.6%, 94.1% and 100.0%, respectively. Those of CT and MRI were 70.4%, 80.5%, 73.1%, 84.9% and 69.2%, respectively. The results of $^{18}$F-FDG PET/MRI diagnosis changed the treatment plans of 8 patients with the staging and 28 patients with restaging, and affected the formulation of treatment plans of 4 patients with the staging and 12 patients with restaging. In the therapeutic effect monitoring group, a total of 45 cases were guided to modify the treatment plan. $^{18}$F-FDG PET/MRI detected 8 secondary primary tumors, 4 of which were lung cancer, 1 laryngeal cancer, and 3 colon cancer. ***Conclusion:*** $^{18}$F-FDG PET/MRI is better than CT and MRI in N and M staging and efficacy monitoring of nasopharyngeal carcinoma.

## EP-0105

### Deciphering Organ-Specific Interactions in Cancer-Associated Cachexia in Head and Neck Squamous Cell Carcinoma Using FDG PET/CT Imaging

***J. Yu***[1], *D. Ferrara*[2], *S. Gutschmayer*[2], *M. Moreira Pires*[2], *L. Shiyam Sundar*[2], *C. Spielvogel*[1], *D. Haberl*[1], *T. Beyer*[2], *M. Hacker*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA.*

***Aim/Introduction:*** Cancer-associated cachexia (CAC) is a complex syndrome characterized by unintentional weight loss, muscle wasting, and systemic inflammation. The specific patterns of organ involvement in CAC remain unclear. This study investigates the organ-specific involvement patterns in CAC among head and neck squamous cell carcinoma (HNSCC) patients. ***Materials and Methods:*** We conducted a retrospective analysis of 139 HNSCC patients, stratified by the BMI-adjusted Weight Loss Grading System (WLGS), utilizing FDG PET/CT imaging and state-of-the-art automatic segmentation software (MOOSE)[1]. Patients were classified into two cohorts based on their WLGS: WLGS0-2 (N=73, 60M/13F, mean age 58.5 years, overall survival 62 months) and WLGS3-4 (N=66, 57M/9F, mean age 56.95 years, overall survival 59 months). FDG whole-body PET/CT scans were processed using a data-centric artificial intelligence approach for automatic segmentation, and standardized uptake values (SUV) were calculated for seven distinct organ labels to assess the organ-specific involvement patterns in CAC. ***Results:*** In patients with severe cachexia (WLGS3-4), skeletal muscle (SKM) glucose uptake correlated positively with the spleen, kidneys, and liver (R=0.51, 0.31, and 0.55). Conversely, in patients with milder cachexia (WLGS0-2), SKM only correlated with the gastrointestinal tract. Our findings reveal distinct patterns of organ involvement depending on cachexia severity. Although gluconeogenesis may explain the correlation with kidney and liver, the spleen association suggests an upregulated immune response within the inflammatory setting of CAC. ***Conclusion:*** The observed organ-specific involvement patterns in CAC, particularly the association with the spleen, highlight the complex inter-organ connections in this multifactorial disease. Investigating these connections may provide insights into new treatment strategies and options for CAC patients. This preliminary finding serves as a seeding point for more in-depth analyses to elucidate the role of the immune response and explore the potential benefits of targeting specific organ systems to improve outcomes in patients with cancer-associated cachexia. ***References:*** Sundar, L. K. S., Yu, J., et al. (2022). Fully-automated, semantic segmentation of whole-body 18F-FDG PET/CT images based on data-centric artificial intelligence. ### Comparison of 1 day protocol and 2 day protocol of lymphoscintigraphy by subareolar injection in the detection of sentinel lymph nodes in breast cancer patients.

***J. Seok***;
*Chung-Ang University, College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Lymphoscintigraphy and sentinel node biopsy were used for the detection of axillary lymph node metastasis in breast cancer patients. We compared the results of subareolar injections on the day of surgery (1 day protocol) with injections the day before surgery (2 day protocol). ***Materials and Methods:*** This study included 1,612 breast cancer patients who underwent surgery between 2001 and 2023. For the 1 day protocol 0.8 ml of Tc-99m Tin-Colloid (37MBq) was injected in 1,200 patients in the subareolar region on the morning of the surgery. For the 2 day

protocol 0.8 ml of Tc-99m Tin-Colloid (185MBq) was injected in 412 patients on the afternoon before surgery. Lymphoscintigraphy was performed in the supine position and sentinel node identification was performed by hand-held gamma probe during surgery. ***Results:*** Among 1,200 patients with the 1 day protocol, 1,168 cases (97.3%) were identified by sentinel node lymphoscintigraphy, and 1,173 cases (97.8%) were identified by gamma probe. Among the 412 patients, in the 2 day protocol, 389 cases (94.4%) had the sentinel node identified by lymphoscintigraphy, and 379 cases (92.0%) had the sentinel node identified by the gamma probe. There was no significant difference in the identification rate of the sentinel node between the 1 day and 2 day protocol by lymphoscintigraphy and the gamma probe. ***Conclusion:*** The results of the identification of the sentinel node according to 1 day or 2 day protocols showed no significant differences. Because the 2 day protocol allows for an adequate amount of time to perform the lymphoscintigraphy, it is a more useful protocol for the identification of sentinel nodes in patients with breast cancer. ***References:*** Seok JW, Kim IJ, Heo YJ, Yang YJ, Choi YS, Kim BG, Park SJ. Comparison of subareolar injection lymphoscintigraphy with the 1-day and the 2-day protocols for the detection of sentinel lymph nodes in patients with breast cancer. ### The comparative study of the validation for Tc-99m Tin-colloid and Tc-99m Phytate in sentinel node detection in breast cancer patients.

***J. Seok****;*
*Chung-Ang University, College of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Lymphoscintigraphy and sentinel node biopsy has become a standard method for detection of axillary lymph node metastasis in breast cancer patients, but the standard radiopharmaceutical was not prepared. About detection of axillary lymph node metastasis by lymphoscintigraphy and sentinel node biopsy in breast cancer patient, we compared the results of Tc-99m Tin-colloid and Tc-99m Phytate by subareolar injection. ***Materials and Methods:*** This study included 1,612 breast cancer patients who were performed operation during 2001-2023. Four hundred twelve patients were injected 0.8 ml of Tc-99m Tin-colloid (37-185 MBq) by subareolar injection. One thousand two hundred patients were injected 0.8 ml of Tc-99m Phytate (37-185 MBq). Lymphoscintigraphy was performed in supine position and sentinel node localization was performed by hand-held gamma probe in operation. ***Results:*** Among 412 patients by Tc-99m Tin-colloid, 374 cases (90.8%) were localized the sentinel node by lymphoscintigraphy and 367 cases (89.1%) were localized by gamma probe. Among 1,200 patients by Tc-99m Phytate, 1,183 cases (98.6%) were localized by lymphoscintigraphy and 1,185 cases (98.8%) were localized by gamma probe. The detection rate by lymphoscintigraphy and gamma probe was superior for Tc-99m Phytate compared to that for Tc-99m Tin-colloid, with a statistically significant difference. ($p<0.05$, $p<0.05$) ***Conclusion:*** Tc-99m Phytate is a better choice for localization of sentinel node than Tc-99m Tin-colloid in breast cancer patients. ***References:*** Seok JW, Choi YS, Chong S, Kwon GY, Chung YJ, Kim BG, Park SJ. Sentinel lymph node identification with radiopharmaceuticals in patients with breast cancer: a comparison of 99mTc-tin colloid and 99mTc-phytate efficiency. ### Prediction of HER2 expression status in breast cancer based on 18F-FDG PET-CT radiomics

***D. Han***[1,2]*, X. Duan*[1]*, N. Yu*[2]*;*
*[1]the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, CHINA, [2]Affiliated Hospital of Shaanxi University of Chinese Medicine, Xianyang, CHINA.*

***Aim/Introduction:*** To evaluate the value of $^{18}$F-FDG PET/CT radiomics in judging the expression status of human epidermal growth factor receptor 2 (HER2) in breast cancer. ***Materials and Methods:*** 100 patients with breast cancer were retrospectively collected, including 72 HER2 negative patients and 28 positive patients. The differences of PET/CT parameters between groups were compared, including the maximum standard uptake value (SUVmax), the average standard uptake value (SUVmean), the standard deviation (SD) of SUVmax and the metabolic tumor volume. After the PET images was standardized, the PET/CT physician manually segmented the region of interest (ROI) and radiomics features were calculated. The Radiomics risk score (RRS) was obtained by linear weighting of the dimensional-reduced radiomics features and coefficients. ROC curves were drawn and area under the curves (AUC) was calculated to evaluate the efficacy of indicators with statistically significant differences in determining HER2 status in breast cancer patients. Bootstrap 1000 repeated sampling was used for internal validation, and the corrected AUC was calculated. The corrected AUC was compared by Delong test. The net benefit of patients was evaluated by decision curve analysis. ***Results:*** SUVmax, SUVmean and SD in HER2 positive group were significantly higher than those in HER2 negative group (all $P < 0.05$). A total of 704 radiomics features were obtained. After screening, 10 non-zero coefficient features were finally obtained for calculating RRS. RRS in HER2 (+) group was greater than that in HER2 (-) group, and the difference was statistically significant ($P<0.001$). The AUC of HER2 status in patients with breast cancer judged by RRS [0.79 (95%CI: 0.70-0.86)] was greater than SUVmax, SUVmean and SD, and the difference was statistically significant (all $P<0.05$). The diagnostic sensitivity was 78.57% and the specificity was 77.78%. The results of decision curve analysis show that RRS can make the net benefit of patients higher within a larger probability threshold range. ***Conclusion:*** $^{18}$F-FDG PET/CT RRS achieves medium diagnostic performance in evaluating HER2 status of breast cancer. ***References:*** CHEN Y, WANG Z, YIN G, et al. Prediction of HER2 expression in breast cancer by combining PET/CT radiomic analysis and machine learning[J]. Ann Nucl Med, 2022,36(2):172-182.

## EP-0109

### Detection of internal mammary lymph node chain infiltration in breast cancer patients by 18F-FDG-PET/MRI. Impact on patient management

***M. Kauak Kuschel****, J. García Garzón, A. Compte, E. Valls, P. Bassa, M. Minoves, E. Llinares, L. Mont, E. Riera, M. Blanch Labrador;*
*CETIR ASCIRES, Barcelona, SPAIN.*

***Aim/Introduction:*** In patients recently diagnosed with breast cancer, infiltration of the internal mammary node (IMN) chain bears a poor prognostic with impact on patient therapy. Diagnostic imaging plays a role to increase its detection rate. We aimed: 1) To assess detection rate of IMN infiltration in patients diagnosed with breast cancer, for whom 18F-FDG-PET/MRI is indicated for staging purposes 2) To assess therapy impact of IMN infiltration depending on TNM staging by 18F-FDG-PET/MRI. ***Materials and Methods:*** Prospective study including 41 women (31-89 years) with breast cancer referred for staging assessment (stage ≥IIB)

by integrated 18F-FDG-PET/MRI study in 2022. The study was dual-phase: 1) Selective prone breast PET/MRI imaging (3D-T1, T2-CUBE, DWI, 3D-VIBRANT-Gadolinium). 2) Supine whole-body PET/MRI study (T1-LAVA, T2 FAT, DWI, STIR). TNM staging was reached by consensus. Detection of an afferent vessel (AV) to IMN was assessed by Cadstream software on selective breast MRI. IMN infiltration was then correlated with patient's age, AV-IMN, T-staging, quadrant localisation, detection of axillary and distant infiltration. Multidisciplinary committee then assessed changes in therapy after TNM staging of patients with IMN involvement detected by 18F-FDG-PET/MRI. ***Results:*** The detection rate of IMN infiltration on 18F-FDG-PET/MRI was 34% (14/41), with 8 patients younger than 55 years. Node size ranged 7-20 mm. The SUVmax ranged 1.5-16.4. In all 14 patients (100%) with IMN infiltration, AV-IMN was shown, with no AV-axillary in 6 (43.9%). Among the 27 patients with no IMN infiltration, in 13 (48.1%) only AV-axillary was detected, while in the remaining 14 (51.9%) AV-axillary and AV-IMN were both shown. Regarding T staging, 57% (8/14) of cases were multicentric and 42% (6/14) were focal, in inner quadrants in 4/6 patients (66.7%). Regarding NM staging, 1/14 patient (7.1%) showed IMN infiltration only, 9/14 (64.3%) showed both axillary and IMN infiltration, while distant metastases were present in 4/14 patients (28.6%). Committee decided to carry out radiotherapy over IMN in 10/14 patients (71.4%) due to IMN only and axillary & IMN infiltration, and systemic therapy in 4/14 patients (28.6%) due to metastases. ***Conclusion:*** Detection rate of IMN infiltration by 18F-FDG-PET/MRI in staging of our breast cancer patients was 34%. Factors associated with IMN infiltration were age, multicentric tumours and when focally detected, located on the inner quadrants, AV- IMN positive, as well as IMN staging. Accurate IMN detection allowed for individualisation of therapy, thus indicating the need for thoracic radiotherapy in 71.4% of patients with IMN.

## EP-0110

### A pilot study of the use of positron emission tomography to evaluate early oestrogen receptor changes in patients with advanced and/or relapsed breast cancer administered endocrine therapy and CDK4/6 inhibitor combination therapy

***I. Kuji***[1], *K. Matsuura*[2], *A. Osaki*[2], *T. Yamane*[1], *H. Ishiguro*[2], *T. Saeki*[2];
[1]*Department of Nuclear Medicine, Saitama Medical University International Medical Center, Hidaka, Saitama, JAPAN,*
[2]*Department of Breast Oncology, Saitama Medical University International Medical Center, Hidaka, Saitama, JAPAN.*

***Aim/Introduction:*** We performed F-18-fluoroestradiol (FES) positron emission tomography (PET)/computed tomography to observe oestrogen receptor changes in patients with advanced and/or relapsed breast cancer positive for oestrogen receptors before and after endocrine therapy and CDK4/6 inhibitor combination therapy. The efficacy of CDK4/6 inhibitor therapy for each lesion was evaluated based on changes in F-18-fluorodeoxyglucose (FDG) accumulation. ***Materials and Methods:*** Eight patients with postoperative breast cancer recurrence pathologically confirmed as oestrogen receptor-positive before pretreatment were enrolled in this study. FDG and FES PET were performed before the initiation of CDK4/6 inhibitor treatment and 2 to 3 months after treatment initiation. The FDG maximum standard uptake value (SUVmax), FDG peak standard uptake value (SUVpeak), and FES in the evaluable lesions were measured. Blood tests were performed to obtain the levels of white blood cells, red blood cells, hemoglobin, platelets, alkaline phosphatase, lactate dehydrogenase, creatinine, and estradiol. Eighteen lesions were evaluated. ***Results:*** We compared the values of the positive therapy response (RP) group (lesions with a decrease in the FDG SUVpeak >=30% after treatment) and the negative therapy response (RN) group (lesions with a decrease in the FDG SUVpeak <30%). The FES SUV was significantly different in both groups before (RPpre and RNpre) and after (RPpost and RNpost) treatment (RPpre vs. RNpre: 6.11±4.78 vs. 2.32±1.15, P=0.017; RPpost vs. RNpost: 1.65±0.49 vs. 2.42±1.21; p=0.049). The FES value was high before treatment and low after treatment. A decrease trend like FES changes was observed for the FDG SUV (RPpre vs. RNpre: 7.83±3.34 vs. 5.27±2.67, P=0.045; RPpost vs. RNpost: 1.97±0.91 vs. 4.60±1.81, p<0.001). When analysed using the receiver-operating characteristic (ROC) curve, the FES value before treatment was significant (area under the ROC curve=0.79; p=0.038). Setting the FES SUV threshold to 2.84 before treatment resulted in sensitivity of 0.84, specificity of 0.90, positive predictive value of 0.61, negative predictive value of 0.97, and accuracy of 0.89. It was again confirmed that FES accumulation and FDG accumulation decreased in the RPpost group. ***Conclusion:*** Oestrogen receptor expression was higher before treatment. Oestrogen receptor withdrawal was higher in the RP group than in the RN group after CDK4/6 inhibitor treatment. To predict the therapeutic effect of CDK4/6 inhibitor treatment, it is important to re-evaluate oestrogen receptor expression in individual tumor lesions. Different treatments could be administered for lesions with low oestrogen receptor expression even if that expression is positive at the time of initial treatment.

## EP-0111

### Is subcutaneous/cutaneous uptake on [18F] FDG PET/CT a prognostic marker for breast cancer patients undergoing surgery?

***Y. Kitano***[1], *K. Miyake*[2], *T. Nobashi*[1], *T. Ishimori*[3], *R. Nakamoto*[1], *S. Koyasu*[1], *M. Kataoka*[1], *K. Kawaguchi*[4], *Y. Takeuchi*[5], *M. Toi*[6], *Y. Nakamoto*[1];
[1]*Diagnostic Imaging and Nuclear Medicine, Kyoto University Hospital, Kyoto, JAPAN,* [2]*Department of Advanced Imaging in Medical Magnetic Resonance, Kyoto University Hospital, Kyoto, JAPAN,* [3]*Diagnostic Radiology, Medical Research Institute Kitano Hospital, PIIF Tazuke Kofukai, Osaka, JAPAN,* [4]*Department of Breast Surgery, Graduate School of Medicine, Kyoto University, Kyoto, JAPAN,* [5]*Clinical Bio Resource Center, Kyoto University Hospital, Kyoto, JAPAN,* [6]*Breast Surgery, Tokyo Metropolitan Cancer and Infectious Disease Center, Komagome Hospital, Tokyo, JAPAN.*

***Aim/Introduction:*** To investigate the prognostic value of subcutaneous/cutaneous uptake (SCU) on pretreatment whole-body [18F] FDG PET/CT in patients with breast cancer treated with surgery. ***Materials and Methods:*** A retrospective study was performed of 171 women with M0 unilateral invasive breast cancer who underwent whole-body [18F] FDG PET/CT and were treated with surgery with or without neoadjuvant therapy (NAT) at our institution from January 2012 to March 2021. SCU was defined as abnormal FDG uptake extending along the skin apart from the tumor. The subareolar SUV ratio (sSUVr) - subareolar SUVmax of the affected side divided by the unaffected side - was used as a quantitative measure. The association of progression-free survival (PFS) and disease-specific survival (DSS) with the following 9 factors was evaluated using the log-rank test and univariate and multivariate Cox-regression analysis: age (≥60 vs. <60), visual SCU (positive vs. negative), sSUVr (>1.3 vs. ≤1.3), tumor SUVmax (>10 vs. ≤10), cT stage (T3 vs. T1-2), cN stage (N1-3 vs. N0),

histological type (ILC or others vs. IC(NST)), histological grade (G3 vs. G1-2), and subtype (triple negative vs. non-triple negative). ***Results:*** Of 171 women (median age, 56 years; range, 23-85 years), SCU was present in 27 (15.8%). After a median follow-up period of 4.4 years (range, 0.3-11.0 years), 18 (10.5%) developed recurrence and 8 (4.7%) died. The log-rank test showed that visual SCU, sSUVr, and cN stage effectively stratified patients by PFS and DSS. Univariate Cox-regression analysis showed that visual SCU-positive (PFS, hazard ratio [HR] 3.29, 95% confidence interval [CI] 1.23-8.76, p = 0.02; DSS, HR 9.89, 95% CI 2.36-41.49, p <0.01) and sSUVr >1.3 (PFS, HR 3.90, 95% CI 1.53-9.91, p <0.01; DSS, HR 9.32, 95% CI 1.87-46.39, p <0.01), and cN stage 1-3 (PFS, HR 4.45, 95% CI 1.58-12.51, p <0.01; DSS, HR 5.06, 95% CI 1.02-25.11, p = 0.05). Multivariable survival analysis revealed that sSUVr >1.3 was an independent significant prognostic factor for PFS and DSS (PFS, HR 2.75, 95% CI 1.06-7.11, p <0.01; DSS, HR 6.96, 95% CI 1.36-35.59, p <0.01). ***Conclusion:*** The sSUVr was an independent prognostic factor for recurrence and death after surgery. This study suggests that SCU is a potentially useful prognostic biomarker in patients with breast cancer treated with surgery.

## EP-0112

### [18F]FDG-PET/MRI in Breast Cancer

***G. Argalia***[1], *F. M. Fringuelli*[1], *G. Biscontini*[1], *A. Palucci*[1], *C. Romagnolo*[1], *C. Cottignoli*[1], *P. Ercolani*[2], *B. F. Simonetti*[2], *S. Borgoforte Gradassi*[2], *L. Burroni*[1];
[1]*Nuclear Medicine, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY,*
[2]*Radiology, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY.*

***Aim/Introduction:*** Breast cancer is the most common malignancy and has the second highest cancer-related morbidity, in women worldwide. [18F]FDG-PET/CT has been introduced for breast cancer staging, distant-metastasis detection, prognostic prediction and evaluation of the pathological response to treatment. Contrast-enhanced-MRI, nowadays, is considered the most sensitive technique for breast cancer screening, locoregional staging and treatment monitoring. Therefore, hybrid [18F]FDG-PET/MRI exam, through which it is possible to acquire both metabolic data and high-contrast morphological images in a single exam, may be useful in the management of these patients. ***Materials and Methods:*** We enrolled all consecutive patients with breast cancer who underwent [18F]FDG-PET/MRI at our department from September 2022 to March 2023. The scans were performed with a hybrid PET/MRI tomograph permitting simultaneous acquisition of whole body PET and 3 Tesla-MRI images. MRI-contrast-agent was injected. The examination was completed with a PET/MRI bed of the breast with the patient prone and dedicated RM coils. [18F]FDG-PET/MRI was performed at different stages of the disease: staging, restaging post neoadjuvant CHT, restaging in suspected recurrence (radiological/biochemical) and follow-up. Agreement between FDG-enhancing findings and MRI contrast-enhancing findings was evaluated. ***Results:*** Overall, 17 female patients were included (9 right breast, 7 left breast, 1 bilateral neoplasm; mean age 54.4 years; range 34-83 years). 3 staging, 7 restaging post neoadjuvant CHT, 6 restaging in suspected recurrence (5 radiological and 1 biochemical) and 1 follow-up. [18F]FDG-PET/MRI and contrast-agent-MRI were concordant in the majority of cases (15/17 patients). In 2/17 cases the results were discordant: a small skin lesion and 3 axillary lymph nodes (both suspicious for recurrence) were revealed by contrast-agent-MRI, without radiotracer uptake at [18F]FDG-PET/MRI. This to underscore the importance of performing a hybrid [18F]FDG-PET/MRI examination with a synchronous MRI with contrast medium, to completely stage and restage patients with breast cancer, allowing to evaluate the metabolism of some doubtful MRI findings (without motion artifacts) and to highlight no-FDG-avid findings but still worthy of further investigation/monitoring. ***Conclusion:*** The importance of [18F]FDG-PET/CT and contrast-enhanced-MRI is already known from the literature. Based on our preliminary results, [18F]FDG-PET/MRI with contrast-agent-MRI, as a hybrid exam, results to be even more accurate in the management of breast cancer patients especially in terms of spatial resolution and metabolic activity.

## EP-0113

### Automated Lesion Detection for 18F-Fluoroestradiol PET/CT Images Demonstrates Lesion Heterogeneity in Patients with ER+ Metastatic Breast

***M. Battle***[1], *K. Wangerin*[2], *R. Miller*[1], *S. S. Houshmandi*[3], *D. T. Huff*[3], *A. J. Weisman*[3], *T. G. Perk*[3], *G. A. Ulaner*[4];
[1]*GE HealthCare, Little Chalfont, UNITED KINGDOM,*
[2]*GE HealthCare, Marlborough, MA, UNITED STATES OF AMERICA,* [3]*AIQ Solutions, Madison, WI, UNITED STATES OF AMERICA,* [4]*Hoag Family Cancer Institute, Long Beach, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Tumoral heterogeneity within individual cancer patients is increasingly recognized as a cause of therapy failure. Heterogeneity may be spatial (phenotypically diverse tumors across different disease sites) or temporal (tumour phenotype changes over time). $^{18}$Ffluoroestradiol injection ([$^{18}$F]FES, CERIANNA) is a PET radiotracer which detects estrogen receptor (ER) available for estrogen binding. As heterogeneity of ER expression influences response to endocrine therapy, [$^{18}$F]FES PET can inform better treatment decisions. Utilizing an automated tool could aid lesion detection and further our understanding of image heterogeneity. ***Materials and Methods:*** Manual contouring, performed on 52 paired images from ER-positive breast cancer patients (37 [$^{18}$F]FES & CT, 15 [$^{18}$F]FES & FDG), was used for lesion identification and model training. Concordance analysis on reader-identified lesions was performed on a subset of cases for more in-depth analysis: [$^{18}$F]FES with [$^{18}$F]FDG (n=12), CT (n=12), or both (n=1), selected as a representation of the larger data set. Images were evaluated for overall lesion identification. A previously developed AI model[1] was expanded to detect and segment [$^{18}$F]FES -positive lesions. Model performance was assessed through lesion sensitivity and false positive rate compared to reader results. ***Results:*** For subjects with [$^{18}$F]FES and CT images, 2 cases showed 100% concordance. Six cases identified a proportion of lesions with CT but not [$^{18}$F]FES, and 3 cases included a mix of lesions identified with [$^{18}$F]FES only, CT only, or both modalities. Two cases identified lesions with [$^{18}$F]FES alone or with both [$^{18}$F]FES and CT. For subjects with [$^{18}$F]FES and [$^{18}$F]FDG images, 1 case showed 100% concordance. One case identified lesions only with [$^{18}$F]FDG. Three cases had a proportion of lesions identified with [$^{18}$F]FES and [$^{18}$F]FDG or [$^{18}$F]FDG only. Five cases included a mix of lesions identified with [$^{18}$F]FES only, [$^{18}$F]FDG only, or both modalities. One case reported 100% lesions identified only with [$^{18}$F]FES, and 2 cases identified lesions with [$^{18}$F]FES only or [$^{18}$F]FES and [$^{18}$F]FDG. Overall model performance gave a median sensitivity of 62%, with a median false positive rate of 0. ***Conclusion:*** Lesion heterogeneity was demonstrated between modalities ([$^{18}$F]FES vs CT and [$^{18}$F]FES vs [$^{18}$F]FDG), offering a useful insight into tumour composition. Understanding heterogeneity

in a subject could help inform patient management. Our model, although trained on a limited data set, performed well. With further training on a larger dataset, the model has the potential to support [$^{18}$F]FES readers to quickly identify lesions for evaluation. ***References:*** Weisman et. al. JNM 63:3215, 2022

## EP-0114

### Potential role of 18F-FDG PET/CT in the initial staging of breast cancer.

***R. Sanchez Sanchez***[1], *A. González Jimenez*[2], *T. Aroui Luquin*[1], *A. Piñero Donis*[1], *J. Villa Palacios*[1];
[1]*Hospital Virgen de las Nieves, Granada, SPAIN,*
[2]*Hospital Universitario de Jaén, Granada, SPAIN.*

***Aim/Introduction:*** Multiple studies have evaluated the usefulness of PET/CT in the initial staging of breast cancer, demonstrating an important clinical impact with a change in therapeutic management in a high percentage of these patients when compared with conventional imaging methods. However, its role in routine clinical practice is controversial and its use is still considered optional for the main guidelines. The aim of our work is to assess the usefulness of PET/CT in this context. ***Materials and Methods:*** The results of PET/CT in patients recently diagnosed with breast cancer (2021-2022) have been analyzed visually and semiquantitatively by calculating the SUVmax. Positive findings were confirmed by specific imaging procedures. ***Results:*** We prospectively evaluated 166p, mean age 59.8a ± 12.08 (SD), ductal carcinoma (81%), grade II (54%) and luminal subtype (76%). The primary tumor was detected by PET/CT in all cases, the mean SUVmax of the primary lesion was 20.7. At diagnosis, 58p (35%) presented axillary lymph node involvement by PET/CT. Lymph node involvement was detected by axillary ultrasound in 79% (46/58). In addition, in the 46p that lymph node involvement was detected by both tests, PET/CT increased the number of lymph node lesions, thus modifying the stage (N1→N2 at 13p, N1→N3 at 1p, N2→N3 at 4p).Unsuspected distant metastases were diagnosed by PET/CT in 12p (7%), ten of them had axillary lymph node involvement (17%). Distant metastasis sites: bone (n=7), liver (n=1), lung (n=1) and lymph nodes (n=3). The variables significantly associated with a higher probability of axillary or distant metastases on PET/CT were: high histological grade (2-3) (p=0.03), high Ki67 levels (p=0.002) and higher SUVmax of the primary lesion. (p=0.02). ***Conclusion:*** Our results suggest a potential utility of PET/CT in the initial staging of patients with breast cancer, particularly in those patients with metastatic axillary lymph node involvement for the detection of unsuspected distant metastases.

## EP-0115

### Standardized Uptake Values of Breast Cancer in Sub-millimetre 18F-FDG-PET/CT: Direct Correlation with Histopathology

***L. Maris***[1,2], *M. Göker*[3], *K. De Man*[4], *B. Van den Broeck*[4], *R. Van Holen*[2], *V. Keereman*[1,2], *K. Van de Vijver*[5,6], *C. Vanhove*[1,7];
[1]*Department of Electronics and Information Systems, Ghent University, Ghent, BELGIUM,* [2]*XEOS Medical, Ghent, BELGIUM,* [3]*Department of Gynaecology, Ghent University Hospital, Ghent, BELGIUM,* [4]*Department of Medical Imaging, Nuclear Medicine, Ghent University Hospital, Ghent, BELGIUM,* [5]*Department of Pathology, Ghent University Hospital, Ghent, BELGIUM,* [6]*Department of Diagnostic Sciences and Cancer Research Institute Ghent (CRIG), Ghent University, Ghent, BELGIUM,* [7]*INFINITY Lab, Ghent University, Ghent, BELGIUM.*

***Aim/Introduction:*** The current role of PET in breast cancer (BCa) detection is limited as sensitivity depends on the lesion's size and histology. It is especially difficult to detect ductal carcinoma in situ (DCIS) and invasive lobular carcinoma (ILC), which generally show lower uptake than invasive carcinoma of no special type (NST). However, as the spatial resolution of PET scanners constantly evolves, visualization of BCa will improve in the future. Therefore, it is of great importance to improve our understanding of the distribution of radiotracers in different types of breast tissue at a previously unseen resolution. Earlier, we developed a strategy to co-register ex vivo high-resolution PET/CT images of resected cancer specimens with the corresponding histopathology. Here we present the first results of applying this technique to breast cancer specimens. ***Materials and Methods:*** We imaged BCa specimens of 9 patients who underwent breast-conserving surgery after preoperative injection with 0.8MBq/kg $^{18}$F-FDG. Specimens included 8 NSTs (combined with DCIS), and 1 ILC. After resection, the specimens were sliced into ±2mm-thick lamellas. In total, 17 NST and 2 ILC lamellas were imaged using a PET/CT specimen scanner with sub-millimetre resolution. Afterwards, the tissue was further processed to obtain one H&E-stained section of every lamella. Whole-slide images (WSIs) were captured using a section scanner. To align PET/CT images and WSIs, we developed a deformable co-registration algorithm to compensate for tissue deformation. An experienced pathologist annotated the WSIs to distinguish tumour and healthy tissue, to evaluate intratumoral standardized uptake values (SUVs). ***Results:*** By acquiring PET/CT images of breast lamellas, tissue deformation was minimized and the correlation with histopathology was immediately visible. Mathematical co-registration further optimised image alignment. After transferring the histopathology annotations to the co-registered PET/CT images, the following mean tumour SUVs were found across all patients: 2.43±2.50, 1.50±1.58, and 2.70 for NST, DCIS, and ILC respectively. The SUVs for hyperplastic, inflammatory, and healthy tissue were found to be 0.55±0.41, 1.88±2.01, and 0.27±0.22 respectively. ***Conclusion:*** We collected a unique dataset of sub-millimetre $^{18}$F-FDG-PET/CT images of BCa specimens, that were co-registered with annotated histopathology images. While the dataset is currently still limited, it already provides insights in breast SUVs at a sub-millimetre resolution. The preliminary results give an indication that NST and ILC generally show high SUVs compared to the background in sub-millimetre PET, while for DCIS a lower uptake is found. As expected for $^{18}$F-FDG, notable uptake is detected in inflamed tissue.

## EP-0116

### The Role Of F-18 FDG PET/CT In The Prediction of Residual Cancer Burden After Neoadjuvant Chemotherapy In Locally Advanced Breast Cancer

***E. KAYA***[1], *O. VURAL TOPUZ*[1], *B. E. AKKAS*[1], *M. KAYA*[1], *T. SOYLEMEZ AKKURT*[2], *E. ACAR*[1];
[1]*University of Health Sciences, Başakşehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, Turkey., Istanbul, TÜRKIYE,* [2]*University of Health Sciences, Başakşehir Cam and Sakura City Hospital, Department of Pathology, Istanbul, Turkey., Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Presence of residual disease after neoadjuvant chemotherapy (NAC) in locally advanced breast cancer (LABC) can be measured by the pathological Residual Cancer Burden score (RCB)(1).RCB scoring system is an independent prognostic factor in survival of LABC patients. The aim of our study was to determine the value of F-18 fluorodeoxyglucose (FDG) positron

emission tomography/computed tomography (PET/CT) studies in predicting RCB scores. ***Materials and Methods:*** Patients with LABC who underwent staging (PET1) and post-NAC (PET2) PET/CT studies and subsequently operated were evaluated retrospectively. Patients were grouped according to their molecular subtypes as luminal, non-luminal HER2 positive (+) and triple negative (TN) . SUV and SUL values of breast lesions (L) and their ratio to liver SUV and SUL values (Li) were recorded (L/Li). The patients were divided into 2 groups as RCB 0-1 and RCB 2-3 according to the RCB scores in their postoperative pathology. ***Results:*** The mean age of the patients was 48.2±11,4 (27-82). 34 patients (39.1%) were luminal, 38 (43.7%) were non-luminal HER2+, and 15 (17.2%) were TN. Metabolic parameters obtained from the primary tumor in PET1 were significantly different between the groups and they were higher in the TN group (p<0.01)In PET2 scan; SUL L/Li in the TN group were significantly lower than other subtypes (0.68 vs 1.1 and 1.2, p<0.01). In postoperative pathologies, RCB scores was 0-1 in 30 patients (34.5%) and 2-3 in 57 patients (65.5%). When RCB scores were compared between the luminal and HER2 groups, no significant difference was observed, while the RCB 0-1 ratio was significantly higher in the TN group (p<0.01).While metabolic parameters in PET1 did not differ significantly between RCB groups, in PET 2, SULL and SUL L/Li differed significantly between RCB 0-1 and RCB 2-3 groups (0.6±0.1 vs 1.4 ±1.1, p<0.001). In receiver operating characteristic (ROC) analysis, PET2 SUL L/Li were found to be the highest predictor of RCB 0-1 group (AUC:0.93, 0.86-1, 95% CI). When cut-off value was determined as 0.82, the sensitivity and specificity of SULL/Li in predicting RCB 0-1 group were calculated as 88% and 80%,respectively. ***Conclusion:*** SUL L/Li and SUV L/Li obtained from post-NAC PET/CT in LABC provide a non-invasive prediction of postoperative RCB in the preoperative period. Regarding the prognostic value of RCB for LABC patients, we consider that the prediction of RCB score on preoperative PET/CT will contribute to patient management. ***References:*** 1.Yau C, et al.Lancet Oncol. 2022;23(1):149-160.

## EP-0117

### Therapeutic impact of [18F]FDG PET/CT for initial staging in patients with clinical stage I and IIA, HER2-positive and triple negative breast cancer

***C. François***[1], *A. Mailliez*[2], *S. Chrétien*[2], *L. Ceugnart*[3], *A. Oudoux*[1], *O. Cougnenc*[4], *A. Olivier*[1];
[1]*Department of Nuclear Medicine, Centre Oscar Lambret, Lille, FRANCE,* [2]*Department of Medical Oncology, Centre Oscar Lambret, Lille, FRANCE,* [3]*Department of Radiology, Centre Oscar Lambret, Lille, FRANCE,* [4]*Department of Clinical Pharmacy, Centre Oscar Lambret, Lille, FRANCE.*

***Aim/Introduction:*** Breast cancer is a heterogeneous disease with varying treatment and prognosis according to subtype. Aggressive features like HER2+ or triple-negative increase the risk of metastases. Accurate staging is crucial for patient management. While [$^{18}$F]FDG-PET/CT (FDG-PET/CT) is consensual for clinical stage ≥IIB, there is lack of data regarding its actual benefit for clinical stage I or IIA HER2+ and triple-negative breast cancer patients (TNBC). These stages encompass heterogeneous population with different tumor sizes and possible axillary involvement, necessitating further study to determine which patients would benefit most from FDG-PET/CT. We propose a single-institution, retrospective study evaluating the impact of FDG-PET/CT on patient management and staging for female patients with clinical stage I or IIA HER2+ and TNBC. ***Materials and Methods:*** All patients who underwent FDG-PET/CT staging before any treatment were included. Patients with symptoms or conventional imaging suggestive of metastatic dissemination, or with prior malignancies were excluded. The initial stage was determined from mammography, ultrasound, MRI, and clinical examination. Staging and therapeutic impact based on FDG-PET/CT findings were collected, including intra- (modification of dose/site/strategy in a type of management previously indicated) and inter-modality (modification of planned treatment strategy) changes. ***Results:*** The impact of FDG-PET/CT on management and staging was evaluated in 287 female patients with clinical stage I or IIA, HER2+ or TNBC. Results showed therapeutic impact for 18% of patients (n=52), with 2.4% (n=7) undergoing an inter-modality change with omission of planned surgery. Intra-modality changes were observed for 16% of patients (n=45). The impact on patient management was higher for stage IIA patients (20%, 47/237) than stage I patients (10%, 5/50). Among patients with stage IIA disease, changes in management were more important for T2N0 patients (22%, 44/205) than T1N1 patients (9%, 3/32). While not statistically significant, this trend suggests potential usefulness of FDG-PET/CT for T2N0 patients. ***Conclusion:*** FDG-PET/CT is recommended for breast cancer patients with stage IIB or higher. However, FDG-PET/CT is often planned for patients with stage I and IIA before neoadjuvant chemotherapy, especially for those with HER2+ or TNBC. Our results support recent French National recommendations ; considering high therapeutic implications, our study suggests potential usefulness of FDG-PET/CT for patients with stage IIA, HER2-positive or TNBC with tumor size greater than 2 cm (T2N0). However, there is not enough evidence to corroborate the routine use of FDG-PET/CT for patients with stage I or IIA and tumors smaller than 2 cm (T1N1 and T1N0).

## EP-0118

### The Role of Primary Tumor PET/MR Quantitative Values in Predicting Pathological Complete Response after Neoadjuvant Treatment in Breast Cancer

***Y. Ünlüer Ates****, U. Aydos, E. Balcı, L. Atay;*
*Gazi University Medicine Faculty, Nuclear Medicine, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Pathologic complete response (pCR) is a criterion for neoadjuvant therapy (NAT) success and a marker of recurrence. This study aimed to evaluate the role of primary tumor quantitative parameters obtained from 18F-FDG PET/MRI in breast cancer (BC) patients in the prediction of pCR. ***Materials and Methods:*** Female patients diagnosed with BC who underwent PET/MRI for staging and treatment response evaluation, and underwent surgical resection at the end of the treatment (EOT) were retrospectively reviewed. During the NAT period, 22 patients with interim PET/MRI (interim evaluation group, mean age: 48.8±13 years) and 34 patients with end-of-the-treatment PET/MRI (EOT evaluation group, mean age: 51.5±11.3 years) were included in the study. SUVmax, SULpeak, MTV, TLG, ADCmin, SUVmax/ADCmin values of the primary tumors were obtained from the initial, interim, and end-of treatment PET/MRI. The percentages of change of quantitative parameters according to the initial staging values were also calculated in both evaluation groups. The C4.5 algorithm was used to classify quantitative variables. The implementation of this algorithm was carried out with J48() in the Rweka package in the R software. The role of quantitative parameters in predicting pCR was evaluated by using decision tree models created as a result of classifications. ***Results:*** Ten patients (45.5%) in the interim evaluation group and 13 patients (38.2%) in the EOT evaluation group had pCR. In the model created for the interim evaluation group, patients were classified using TLG_1

(cutoff value: ≤27.6 pCR +) in the first layer and the percentage change of ADCmin (cutoff value: ≤106.4% pCR - and >106.4% pCR +) in the second layer. In the model created for the EOT evaluation group, patients were classified using triple layer with the values of SUVmax/ADCmin_2 (cutoff value: >1.86 pCR -), ADCmin_2 (cutoff value: >1.55 pCR +) and SUVmax_2 (cutoff value: ≤1.51 pCR + and >1.51 pCR -). According to the confusion matrices obtained for the two groups, the model classified 20 patients correctly (accuracy:90.9%, sensitivity:100%, specificity:86%) in the interim evaluation group, while in the EOT evaluation group, the model classified 33 patients correctly (accuracy:97.1%, sensitivity:93%, specificity:100%). ***Conclusion:*** In BC patients who received NAT, the staging TLG value and ADCmin change level in the interim evaluation group, and the EOT SUVmax/ADCmin, ADCmin, and SUVmax values in the EOT group were found as predictive factors for pCR. Assessment of tumor metabolism and cellularity together may be beneficial in the early detection of treatment response.

## EP-0119

### Can Tumor Heterogeneity in TNBC Obtained With FDG PET/CT Predict Survival? a Novel Method: Heterogenity index3

***G. B. Babacan***[1], *M. Öner Tamam*[1], *S. Saraçoğlu*[1], *M. N. Acar*[1], *M. C. Şahin*[1], *G. Kulduk*[2], *H. Özçevik*[3];
[1]*University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,*
[2]*University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Department of Pathology, Istanbul, TÜRKIYE,*
[3]*University of Health Sciences, Hamidiye Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** This study aimed to investigate the potential prognostic significance of tumor heterogeneity in triple-negative breast cancer(TNBC) and compare different heterogeneity methods(the new method with $HI_3$). ***Materials and Methods:*** Data of the patients with histopathologically diagnosed as TNBC were analyzed. Patients in the $T_1$ stage, according to the 8th of TNM classification, were excluded from the study. Images of 80 patients who underwent pre-treatment $^{18}$F-FDG PET/CT between January 2016 and June 2022 were evaluated. Semi-quantitative PET parameters (SUVmax, SUVmean, SUVmin, SUVpeak, MTV, TLG) were determined semi-automatically by using the auto contour tool with three-dimensional visual correction. Heterogeneity index ($HI_1$, $HI_2$, and $HI_3$) parameters were calculated as SUVmax minus SUVmin divided by SUVmean at a 30% threshold ($HI_1$), the slope of the linear regression line of the MTV with 30-40-50%($MTV_{30\text{-}40\text{-}50}$) thresholds ($HI_2$), and slope of the percentages at $MTV_{30\text{-}40\text{-}50}$ ($HI_3$). ***Results:*** Median age was 46.5 (range 29-88), and 18 patients (23%) died during the follow-up period. The median follow-up duration was 24(8-75) months. The PET parameters SUVmax-min-mean, SUVpeak, $HI_1$, and $HI_3$ were positively correlated with the tumor diameter (All $p<0.05$). The $HI_2$ was strongly correlated with tumor diameter and TLG ($p<0.001$, $r=0.906$; $p<0.001$, $r=0.817$). Among all variables, a statistically significant relationship was found between Age, T stage, M stage, $HI_1$, $HI_2$, $HI_3$, and survival (p=0.042, p=0.007, p<0.001, p=0.028, p=0.045, p=0.014 respectively). The predictive performances of $HI_{1\text{-}2\text{-}3}$ were measured using the area under the ROC curve, cut-off values were measured by using the Youden-index, and Odds Ratio for the cut-off values were determined by Cox regression analysis (AUC= 0.663, 0.656, 0.681; cut-off values=1.371, 1.325, 2.85; OR=2.687, 5.013 respectively). HIs were also found predictive for metastatic disease status in the initial $^{18}$F-FDG PET/CT; all the HI values were statistically significantly higher in the $M_1$ group compared to the $M_0$ group (p=0.028, p=0.045, p=0.014). ***Conclusion:*** According to our results, HI variables can predict metastatic status and OS, unlike the conventional PET parameters like SUVmax-peak-mean, MTV, and TLG in this cohort group of TNBC patients. $HI_2$ was found strongly associated with tumor diameter and TLG meaning the results of this method may vary in the different datasets. Therefore we offered a new method in $HI_3$. Instead of using the MTV value itself, calculating the linear regression slope with the percentage-based measurement method may produce more standardized and size-independent values. Based on our results, this method had slightly better accuracy in predicting survival status.

## EP-0120

### The Role Of 68ga Dotatate Pet/Ct In Breast Cancer Imaging; A Prospective Study Compared With 18f Fdg Pet/Ct

***C. Sezgin***, *T. Coşkun, Y. Parlak, G. Mutevelizade, E. Sayıt, G. Gümüşer;*
*Celal Bayar University, Manisa, TÜRKIYE.*

***Aim/Introduction:*** Currently, F-18 FDG PET/CT is routinely used for breast cancer staging and treatment response assessment. Most breast cancers express Estrogen Receptor (ER) and Progesterone Receptor (PR) and this subtype shows lower activity on FDG imaging. Case reports are showing 68Ga DOTATATE uptake in non-neuroendocrine tumors such as breast cancer. There are also histochemical studies showing that SSTR is a potential radiopharmaceutical target for ER+/PR+ breast cancer. In this study, we aimed to compare the uptake pattern of breast cancer lesions and HR status with 68Ga DOTATATE and 18F FDG uptake in lesions. ***Materials and Methods:*** Sixteen female patients (mean age 53±11 years) with breast cancer underwent 18F FDG and 68Ga DOTATATE PET/CT imaging at one week intervals. Images were evaluated visually and semiquantitatively. The data obtained were analyzed with SPSS 15. program ***Results:*** In 13 of 16 patients, the tumor subtype was invasive ductal carcinoma, 1 patient had lobular carcinoma, 1 patient had invasive ductal carcinoma associated with lobular carcinoma, and 1 patient had ductal carcinoma in situ. In 14 of 16 patients, the breast lesion showed activity uptake on both DOTA and FDG . In 1 patient, activity uptake was observed on FDG but not on DOTA; the subtype of breast carcinoma observed in this patient was invasive ductal carcinoma; ER and PR were negative. No significant FDG and DOTA uptake was observed in the ER+/PR+ breast lesion in the lobular carcinoma subtype. There was no statistically significant difference between the SUVmax of breast lesions in FDG and DOTA ($p>0.05$), similarly, there was no statistically significant difference between the SUVmax of the axilla ($p>0.05$) . There was no statistically significant difference between ER and PR receptor status and FDG and DOTA uptake ($p>0.05$). In 6 of 7 patients with axillary lymph node metastases, both FDG and DOTA uptake were observed, while only FDG positivity was observed in 1 patient. In 4 patients with bone metastases, bone lesions showed FDG and DOTA uptake . ***Conclusion:*** 68Ga DOTATATE PET/CT showed similar results to 18F FDG PET/CT in breast cancer imaging. Although no significant correlation was observed between HR status and both FDG and DOTA SUVmaxes in our study, further studies are needed in this area. In addition, studies with a larger number of patients suggest that 177Lu DOTATATE treatment may be considered in the treatment of metastatic breast cancer.

## EP-0121

### FAPI-04 uptake in healthy breast glandular tissue

***Y. Zhang***, *M. Su;*
*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Fibroblast activation protein inhibitor (FAPI) is sensitive on breast cancer staging.[1] However, its clinical utility may be limited by the high physiological FAPI uptake in normal breast tissue that can obscure primary tumors. The characteristics of breast physiological uptake on FAPI PET have been rarely reported yet.[2] The aim of this study was to elucidate the characteristics of physiological $^{68}$Ga-FAPI-04 uptake in normal breast. ***Materials and Methods:*** A total of 138 consecutive women with $^{68}$Ga-FAPI-04 PET between February 2022 and February 2023 were reviewed retrospectively. Maximum standardized uptake value ($SUV_{max}$), density and thickness of breast gland, as well as $SUV_{max}$ of nipple, were measured. Univariate and multivariate regression analyses were used to identify factors related to the breast and nipple SUVs. ***Results:*** Twenty-four premenopausal (25.3%), 62 menopausal (65.3%) and 9 post-operative (after bilateral adnexectomy, 9.4%) women (median age, 55 years [IQR, 43-67 years]) with 98 examinations were included. All had a diffuse, symmetrical uptake in breast gland. There was no difference in FAPI uptake between bilateral breasts (P = 0.179) with a median inter-breast percentage difference (PD) of 12.1%. The median intra-breast PDs were between 52.1% to 56.7%. Breast SUVs fluctuated with the expected estrogen level throughout the menstrual cycle. Patients in menstrual status with expected high estrogen level (late follicular, ovulatory and mid luteal phases) had higher breast SUVs (median, 3.16) than those with expected moderate (early follicular, early luteal and late luteal phases; median, 1.57; P < 0.001) or low level (menopause and post-operation; median, 0.97; P < 0.001). Menstrual status was an independent predictors of breast SUV ($r^2$ = 0.673, P < 0.001). All the patients had a focal, symmetrical uptake in nipples with a median inter-nipple PD of 17.4%. Nipple SUV did not correlate with menstrual status (P = 0.871). ***Conclusion:*** Physiological breast FAPI uptake levels are related to menstrual status. Premenopausal patients with breast lesions should be examined $^{68}$Ga-FAPI-04 PET during the perimenstrual period (five days before and during menstruation). ***References:*** 1. Ding F, Huang C, Liang C, et al. $^{68}$Ga-FAPI-04 vs. 18F-FDG in a longitudinal preclinical PET imaging of metastatic breast cancer. Eur J Nucl Med Mol Imaging. 2021;49:290-300. 2. Dendl K, Koerber SA, Finck R, et al. $^{68}$Ga-FAPI-PET/CT in patients with various gynecological malignancies. Eur J Nucl Med Mol Imaging. 2021;48:4089-4100.

## EP-0122

### Role of semi quantitative 18F-FDG PET/CT parameters in prediction of the hormone status and progression free survival of advanced stage breast carcinoma patients

***S. Sarswat***, *A. Singhal, K. J. Das;*
*AIIMS DELHI, Delhi, INDIA.*

***Aim/Introduction:*** Role of semi-quantitative $^{18}$F-FDG PET/CT parameters is coming up in prediction of histopathological features and survival. This study aimed to assess correlation of these parameters with hormone status of tumor and their role in prediction of progression free survival(PFS) of patients with invasive ductal breast carcinoma. ***Materials and Methods:*** Fifty patients who had undergone histopathological examination and had proven primary breast cancer with locally advanced/distant metastatic disease, were included in this ambispective study. All patients underwent $^{18}$F-FDG PET/CT. Primary and metastatic lesions were evaluated and standardized uptake values-SUVmax, SUVmean, Tumor to background ratio (TBR), Metabolic tumor volume (MTV) and Total lesion glycolysis(TLG) were calculated. ROC analysis was done to determine cutoff of parameters to predict PFS. Kaplan Meier survival analysis & Cox proportion hazard test were performed. T test and Kruskall-Wallis tests were used to assess correlation between abovementioned PET/CT parameters and clinicopathological characteristics of patients. With data available on clinical and radiological follow up, progression free survival period was determined. ***Results:*** Among fifty (median age: 45 years) with histologically proven primary invasive ductal carcinoma breast, n= 22 had luminal type B, n=16 had luminal type A and n=12 had triple negative type carcinoma, 32 patients had de novo metastatic disease and rest had locally advanced breast cancer. SUVmax of primary lesion was 11.29. SUVmean for primary was 7.35+ 2.7, lymph node metastasis (n=50) 6.41+ 1.4, liver metastasis (n=22) 6.1+ 1.6, skeletal metastasis (n=11) 4.2+ 1.1 and for brain metastasis was (n=3 patients) 6.7+ 1.7. TBR was 2.41+ 0.67 for primary, 2.26+ 0.7 lymph nodes, 1.38+ 0.2 liver, 2.68+ 0.3 skeletal metastasis, 1.13 + 0.2 brain metastasis. average value of TLG was 285mL. The median PFS was 18 months. Cox regression analysis MTV cutoff to predict poor PFS was 31$cm^3$, Pvalue 0.017. AUC 0.66, Pvalue 0.022. Cutoff point of TLG was 186mL, Pvalue 0.01; with AUC 0.81, sensitivity 78% and specificity 83%. There was a moderate correlation of both MTV (r=0.6) and TLG (r=0.7) with PFS on linear regression analysis. Higher semi-quantitative parameter values (above cutoff) were associated with luminal type B or triple negative type histopathology and lower with luminal type A carcinoma. ***Conclusion:*** $^{18}$F-FDG PET/CT is useful in predicting histopathology and PFS of patients with invasive ductal carcinoma breast. Further studies are required to validate this on a larger scale.

## EP-0123

### The Detection Value of 18F-FDG PET/MR for Breast Cancer Liver Metastasis

***X. Chenjie***;
*Hangzhou Universal Medical Imaging Diagnostic Center, hangzhou, CHINA.*

***Aim/Introduction:*** To explore the value of 18F-FDG PET/MR systemic imaging in detecting liver metastasis of breast cancer. ***Materials and Methods:*** The PET/MR and PET/CT imaging of 78 cases of liver metastasis were analyzed retrospectively. On the same day, whole body 18F-FDG PET/CT imaging and PET/MR imaging were performed, taking pathological and clinical diagnosis as the gold standard to compare the differences in the lesions. ***Results:*** 78 patients with liver cancer, a total of 106 intrahepatic metastasis lesions, PET/MR detected all lesions, and PET/CT detected 69 lesions, with significant statistical differences (P<0.01). Among them, 25 lesions were PET-MR positive, while PET-CT was negative; and 19 other lesions were negative for both equipment PET intake. Compared with PET/CT, PET/MR changed the diagnostic results of 28 (35.9%) patients. ***Conclusion:*** The detection rate of PET/MR for breast cancer liver metastasis is significantly better than that of PET/CT.

## EP-0124

### Dose Reduction for 89Zr ImmunoPET Imaging Using LAFOV PET/CT: An Analysis Based on Count-Reduced Images

***P. Mohr***, *J. van Sluis, L. Providência, A. A. Lammertsma, A. H. Brouwers, C. Tsoumpas;*
*University Medical Center Groningen, Groningen, NETHERLANDS.*

***Aim/Introduction:*** $^{89}$Zr immunoPET is a valuable technique for characterising tumour lesions and supporting monoclonal antibody drug development. The long half-life of $^{89}$Zr ($T_{1/2}$=78.4 h) matches the slow kinetics of monoclonal antibodies, but also leads to a relatively high radiation dose. Given the low count rates, $^{89}$Zr immunoPET may benefit from the improved signal-to-noise ratio of long axial field-of-view (LAFOV) PET

systems, especially when including coincidences between all detector rings, without limiting the acceptance angle. The aim of this study was to investigate possibilities in dose reduction with full 3D reconstructions compared to the limited acceptance angle currently used. ***Materials and Methods:*** Patients with metastatic breast cancer were scanned for 30 minutes, 4 days after injection of 37 MBq [$^{89}$Zr]trastuzumab on a 106 cm LAFOV PET/CT acquiring data with a maximum ring difference (MRD) of 322. Image reconstructions were performed for dose reduction factors ranging from 2 to 10 by using each list-mode entry with a probability corresponding to the dose reduction factor. Two independent noise realisations were generated for each dose reduction factor. Images were reconstructed offline using E7Tools VR20 (Siemens Healthineers) with 3.3x3.3x1.65 mm$^3$ voxels and a 5 mm Gaussian filter for both an MRD of 85 (available on current systems) and an MRD of 322. Tumours were segmented semi-automatically using a 50% isocontour of $SUV_{peak}$. To indicate noise levels, the liver coefficient of variation (COV) was derived with a d=3 cm sphere. Bland-Altman analysis was used to compare repeatability coefficients (RCs) (1.96SD%) of lesion $SUV_{max}$ and $SUV_{peak}$ from the two noise realisations. ***Results:*** Initial results (n=8 patients) showed for a reduction factor of 2 an average liver COV of 6.5%(MRD322) compared with 8.4%(MRD85) with RCs (n=18 lesions) of 8.4%(MRD322) and 13.0%(MRD85) for $SUV_{max}$ and 5.4%(MRD322) and 7.8%(MRD85) for $SUV_{peak}$. For a reduction factor of 4 liver COV was 8.7%(MRD322) compared with 11.8%(MRD85) and RCs were 16.8%(MRD322) and 23.3%(MRD85) for $SUV_{max}$ and 7.4%(MRD322) and 11.0%(MRD85) for $SUV_{peak}$. Further reduction resulted in larger COV and poor repeatability coefficients: even for MRD322, liver COV was up to 14% and RCs were up to approximately 21% for $SUV_{max}$ and 12% for $SUV_{peak}$. ***Conclusion:*** MRD322 reconstructed images lead to lower liver COV and to superior $SUV_{max}$ and $SUV_{peak}$ repeatability than MRD85. Full 3D LAFOV PET/CT makes dose reduction $^{89}$Zr immunoPET by a factor of 4 feasible, if the regions of interest are not at the edges of the FOV.

## EP-0125

### Prone FDG PET/CT in breast cancer restaging (Response to treatment evaluation)

***M. Agolti***, *L. Solari;*
*Centro de Medicina Nuclear Clinica Modelo, Parana, ARGENTINA.*

***Aim/Introduction:*** Supine [18F]Fluorodeoxyglucose (FDG) positron emission technology/computed tomography (PET/CT) is a commonly used modality for the restaging of breast cancer (BC). Superior sensitivity and specificity of prone FDG PET/CT image acquisition in comparison to its supine equivalent has been described in the initial staging of BC, probably due to it allows a better separation of deep breast structures from the chest wall and better relaxation of the pectoral muscles. Our aim is to determine if there is a change in restaging/response to treatment evaluation in both positions, regards local relapse, intramammary, internal mammary and axial lymph nodes. ***Materials and Methods:*** In this retrospective analysis we included 127 female patients treated with surgery and radiotherapy (when indicated), we performed conventional supine FDG PET CT images and after 1 hour we performed prone thorax images with an styrofoam device we have designed. We excluded 3 patients for involuntary movements. We compare the number of increased uptake breast lesions, the differences in Standard Uptake Value (SUV), the number of axilary lymph nodes, their SUV, the intrammammary and internal mammary lymph nodes when seen. ***Results:*** We found 54 increased uptake images in breast in prono position and 47 in supine position, we assumed as relapse, according to biopsy and follow up. One case had a seroma and adjacent to it a solid increased uptake image seen only in prono acquisition .Regards the SUV in Prono acquisition the medium SUV was 3,52 and in supine images the medium SUV was 3,27 with statistical significance (less than 0,05, in this case p=0,01) according to Wilcoxon Test. Regarding Axilary nodes we found 34 in supine position and 36 in prono. We found only three intramammary lymph nodes one of them that was less than1 cm size was not seen in supine images and one internal mammary lymph node in one patient with clear increased uptake in prone (SUV Max 2,5) regards to supine acquisition (SUV Max1,8 ) which allowed better visualization. ***Conclusion:*** Prono images in treated breast cancer showed relapse in 7 patients that weren't seen in conventional images , showing a change in stratification in 12,9 % of the cases. Regards lymph nodes metastasis we found no significative change in axillary nodes ; regards intramammary and internal mammary lymph nodes, it showed increased sensibility (change staging in 50%), although the number of patients (4) may not be significative.

## EP-0126

### Comparison of whole-body PET/CT and dedicated breast PET with F-18 Fluoroestradiol for breast cancer detection in patients with newly diagnosed ER-positive breast cancer

***K. Miyake***[1], *M. Takada*[2], *Y. Shimizu*[1], *S. Yuge*[1], *Y. Kitano*[1], *T. Ishimori*[3], *M. Kataoka*[1], *M. Kawashima*[2], *K. Kawaguchi*[2], *T. Oishi*[1], *K. Itagaki*[2], *Y. Yamada*[2], *Y. Takeuchi*[2], *M. Toi*[4], *Y. Nakamoto*[1];
[1]*Kyoto University Graduate School of Medicine, Kyoto, JAPAN,* [2]*Kyoto University Hospital, Kyoto, JAPAN,* [3]*Kitano Hospital, Osaka, JAPAN,* [4]*Komagome Hospital, Tokyo, JAPAN.*

***Aim/Introduction:*** To compare the diagnostic performance of F-18 Fluoroestradiol (FES) dedicated breast PET (dbPET) with that of whole-body PET/CT in patients with newly diagnosed oestrogen-receptor (ER)-positive breast cancer. ***Materials and Methods:*** A total 27 women (age 39-80 years, median 58 years) with newly diagnosed ER-positive breast cancer who consented to an IRB-approved prospective FES PET study and underwent both whole-body PET/CT and dbPET in the absence of SERM/SERD between March 2021 and April 2023 were analyzed. Approximately 1 hour after the intravenous injection of FES, whole-body PET/CT with a PMT-based detector was obtained with a patient in the supine position (3 min/bed), and subsequently, dbPET with a ring-shaped detector was performed for each breast in the prone position (10 min/breast). After inconclusive lesions were excluded, a total of 55 lesions, including 27 index ER-positive cancers (IDC n=21, ILC n=2, mucinous carcinoma n=1, DCIS n=3) and 28 additional lesions (malignancy n=21 vs. benign and ER-negative double primary n=7), in 49 breasts were assessed. Diagnostic performance was compared between PET/CT and dbPET using McNemar`s test and Fisher's exact test. ***Results:*** On a per-breast basis, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 89.7%, 100%, 100% and 87.0% for PET/CT and 93.1%, 95.0%, 96.4% and 90.5% for dbPET (no significant differences for all). On a per-lesion basis, sensitivity for index ER-positive tumours was 92.6% (25/27) with PET/CT and 96.3% (26/27) with dbPET (p=0.074). The sensitivity for additional malignancy was significantly greater with dbPET (81.0%, 17/21) than with PET/CT (38.1%, 8/21, p=0.016). While there were no false positives on PET/CT, dbPET showed false-positive uptake in two pathologically-proven benign lesions. PPV for additional lesions was 100% (8/8) with PET/CT and 89.5% (17/19) with dbPET (p=1.000). ***Conclusion:*** dbPET using FES was significantly superior to conventional whole-body PET/CT in detecting additional breast lesions in newly diagnosed ER-positive breast cancer patients and may be useful for preoperative surgical planning. However, we identified a few false negatives and false positives on dbPET, and further improvement in image quality and image interpretation is desired.

## EP-0127

### 18F-FDG PET/CT for monitoring treatment response in bone-dominant metastatic breast cancer patients.

***P. Portilla Merino***, *C. Escabias del Pozo, Y. Abadi Sedraoui, E. López Llobet, L. Giraldo Gonzalez, S. Rizkallal Monzon, D. Monachello Araujo, C. Lancha Hernandéz, S. Rodado Marina, M. Coronado Poggio, J. Cordero García, L. Domínguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.*

***Aim/Introduction:*** Breast cancer (BC) presents a long life expectancy and up to 70% of patients develop bone metastasic disease (BMD) at some point within the disease periode. An appropriate follow-up would allow modification and early withdrawal of ineffective or toxic treatment. ***Materials and Methods:*** We conducted a retrospective study between July 2018 to February 2023, we reviewed 158 patients (p) with BC, among them, we identify 25 p BMD, who underwent a total of 93 PET/CT. BMD are confirmed by biopsy or conventional imaging (both at initial staging and distant relapse during follow-up). We also collected morphological data on the lesions. The criteria for response evaluation by PET/CT was visual assessment, and the reports suggested: complete/partial response, stable disease and progressive disease. We categorized treatments as local or systemic, including a third category mixing both. The mean follow-up time was 51±39 months. ***Results:*** BMD was confirmed by biopsy (59%) compared to conventional imaging (41%). The average interval between PET-CT scans performed for each p was 18 months.The BMD group at initial diagnosis (n=9, age at diagnosis= 54 ± 10 years), the primary breast tumour was invasive ductal carcinoma (CDI) (67%) and invase lobular carcinoma (CLI) (33%). The lesions were mainly lytic (45%), followed by sclerotic lesions (33%). The PET/CT modified the treatment in 100%p, adding local treatment (RT or surgery) in 5p due to oligometastatic disease. During follow-up, 3p progressed (33%), the progression-free survival (PFS) was 68±73 months and one p died. In the recurrence group (n=16, mean age at diagnosis of BC: 52±11 years and BMD: 58±11 years), the primary breast tumor was CDI (81%) and CLI (19%). The lesions were predominantly lytic (75%), followed by mixed lesions (25%). All of the patients with progressive disease by PET/CT, the treatment was modified. During follow-up 8p (50%) progressed, the PFS was 44±32 months, and one p died. ***Conclusion:*** In our study, we found less progression and PFS in the group with de novo BMD. PET/CT is an effective tool for monitoring treatment in BMD, improving clinical-therapeutic decisions related to patients survival factors. ***References:*** Naghavi-Behzad, M., Vogsen, M., Vester, R.M. et al. Response monitoring in metastatic breast cancer: a comparison of survival times between FDG-PET/CT and CE-CT. Br J Cancer 126, 1271-1279 (2022). https://doi.org/10.1038/s41416-021-01654-w

## EP-0128

### Metabolic Parameters of FDG PET/CT to Predict Disease Progression in Breast Cancer Type

***J. Park***[1], *J. Choi*[1], *Z. Kim*[1], *C. Lim*[1], *J. Yoon*[2], *C. Lim*[3], *S. Park*[3], *J. Moon*[1], *S. Seo*[4], *S. Woo*[5], *J. Choi*[6];
[1]*Soonchunhyang University Bucheon Hospital, Bucehon, KOREA, REPUBLIC OF,* [2]*Ajou University Medical Center, Suwon, KOREA, REPUBLIC OF,* [3]*Soonchunhyang University Seoul Hospital, Seoul, KOREA, REPUBLIC OF,* [4]*Pai Chai University, Daejeon, KOREA, REPUBLIC OF,* [5]*Korea Institutes of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [6]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Breast cancer is one of the metabolic tumors, thus we investigated whether metabolic parameters of FDG PET/CT, such as liver uptake, muscle uptake, psoas muscle volume, and psoas muscle index (PI) at L3, as well as histopathologic results, clinical and serologic metabolic profile (including neutrophil-lymphocyte ratio, total cholesterol, vitamin D level, blood glucose level, BMI and fatty liver change) with age could predict disease progression (PD) in breast cancer patients who underwent curative surgery during a 5-year follow-up period (between 2012 and 2017). ***Materials and Methods:*** A total of 176 patients with breast cancer were finally included in the analysis and exclusion criteria; 26 hepatic dysfunctions, 6 hepatic cysts, 1 portal vein thrombosis, 6 other major diseases, and 7 less than 6 mo of follow-up intervals). ***Results:*** There were the luminal type of breast cancer (N=112, 51.5 ±10.1 y.o.) and non-luminal type (N=64, 54.3±11.24 y.o.) (p=0.094): HER2 (N=22, 59.9±9.2 y.o.), triple-negative (N=22, 51.6±10.4 y.o), and luminalHER2 (N=20, 51.2±12.3 y.o.) (p=0.006), respectively. We analyzed progression-free survival (PFS), and OS using the Cox proportion hazards model with the stage of breast cancer, lymphatic invasion (LI), perineural invasion (PNI), liver-to-muscle uptake ratio at L3 (LMR), psoas muscle volume, density, psoas muscle index (PI) at L3, tumor SUVmax and total lesion glycolysis. Univariable analyses showed stage, lymphatic invasion, LMR at L3, and PI were associated with PFS. Metabolic indices which were obtained by repeatedly drawn ROIs with 2 mo. intervals showed good agreement of LMR and PI at L3 (0.74 and 0.61, respectively). The multivariable Cox hazard model, in which combined with age, stage, and PI, showed a higher predicted probability for the luminal type [C-index (SE) of 0.86 (0.05)] compared to the model with age and stage [0.74(0.06), respectively]. Meanwhile, the model that combined age, stage, and LMR for the non-luminal type showed a higher predicted probability [0.86[0.05)] than the model with age and stage [0.74 (0.07), respectively]. ***Conclusion:*** In predicting PD of patients with breast cancer who underwent curative surgery, LMR could be more effective in predicting PD in non-luminal types of breast cancer, while PI may be more suitable for the luminal type of breast cancer among the clinical and metabolic parameters using FDG PET/CT. ***References:*** Prognostic impact of skeletal muscle volume derived from cross-section computed tomography images in breast cancer. ## EP-0129

### Comparative Analysis of Immunohistochemistry Markers for Breast Carcinoma (ER, PR And HER 2 NEU) With Respect to Bone Metastasis

***N. Kumar Gupta***, *V. K Dhingra, S. Jha, A. S.;*
*AIIMS Rishikesh, Rishikesh, INDIA.*

***Aim/Introduction:*** To analyze the relationship between immunohistochemistry (IHC) markers [Estrogen Receptor(ER), Progesterone Receptor (PR) and Human Epidermal Growth Factor Receptor 2 (HER2NEU)] in biopsy proven breast carcinoma patients with respect to the bone metastasis detected in 99mTc-MDP bone scintigraphy. ***Materials and Methods:*** Among the patients referred for 99m Tc-MDP bone scintigraphy to the Department of Nuclear Medicine at AIIMS, Rishikesh from 2020 to 2022, 107 biopsy proven breast carcinoma female patients with their IHC status known were analyzed retrospectively. All patients underwent 99mTc-MDP bone scintigraphy using 20mCi of 99mTc-MDP and images were then evaluated by an experienced Nuclear Medicine Physician. Patients were categorized into different IHC status groups as shown in Table 1. A comparison was made between

various IHC status groups with respect to the bone metastasis detected on the 99m-Tc MDP bone scintigraphy. ***Results:*** The mean age of the patients was 49.1 ±10.8 years. Out of the 107 female patients, 34 (31.8%) patients had skeletal metastasis and 73 (68.2%) patients had no evidence of skeletal metastasis. The most common IHC markers status combination was double positive(ER+, PR+ and Her2neu-) accounting for 37/107 patients (34.6%). In this study, 26/107 patients (24.3 %) had triple negative breast carcinoma(ER-, PR- and Her2neu-) and all of these patients had no evidence of active skeletal metastasis present.***Conclusion:*** From this study, it was concluded that skeletal metastasis was not observed in the triple negative breast carcinoma(ER-, PR- and Her2neu-) patients. Hence, the probability of skeletal metastasis is minimal in the triple negative breast carcinoma patients. This study demonstrates that the metastatic patterns in breast cancer strongly correlate with various breast cancer subtypes, mainly designated by ER, PR, and HER2. Hormone receptor-positive tumors show a predilection for bones as the first site of relapse compared to hormone-receptor-negative tumors which have a proclivity to develop as visceral metastases. ***References:*** Pareek A, Singh OP, Yogi V, Ghori HU, Tiwari V, Redhu P. Bone metastases incidence and its correlation with hormonal and human epidermal growth factor receptor 2 neu receptors in breast cancer. Journal of Cancer Research and Therapeutics. 2019 Jul 1;15(5):971-5.

## EP-0130

### Depth of response using total tumor volume with [18F]-Fluorodeoxyglucose PET/CT for monitoring therapy response to Cyclin Dependent 4/6 Kinase Inhibitors

***O. Garcia-Perez****, P. Cabrera Galeana, I. Soldevilla Gallardo, E. Bargallo, D. Gutierrez-Cruz, A. Franco-Ardila;*
*Instituto Nacional de Cancerologia, Mexico city, MEXICO.*

***Aim/Introduction:*** The most common type of breast cancer is ER positive, PR negative, and HER2 negative. A significant proportion of these patients will progress to incurable metastatic disease. CDK4/6 inhibitors as treatment have become in last years an excellent option for these patients. However, response evaluation could be a challenge due to the absence of target lesions. Currently, metrics generated with PET are capable tools for generating objective analysis for this evaluation. In recent years the estimation of the depth response has gained popularity as a predictor of overdrive. However, its estimation has only been performed with conventional imaging modalities. ***Materials and Methods:*** We retrospectively analyzed changes un values of total lesion glycolysis, total tumor volume, target lesion dimensions (RECIST 1.1), and target lesion s SUVmax (PERCIST-5) after CDK4/6 inhibitor therapy in ER-positive, PR-negative, and HER2-negative immunohistochemical profile patients with metastatic breast cancer and first-line treatment failure and compared depth of response using these molecular and anatomical metrics. ***Results:*** 15 female patients with metastatic disease were included with a median age of 54 years (range 34-71), the median baseline of TTV was 231 ml +/- 67 ml TLG 1563 mean/ml +/- 567 ml, SUVmean 5.6, SUVmax 7.1 and target lesion of 32.1 mm +/- 5.2 mm, and post-therapy TTV was 15 ml +/- 3.1 ml TLG 45 mean/ml +/- 8.1 ml, SUVmean 1.5 +/- 0.6, SUVmax 2.5 +/- 1.1 and target lesion of 25.8 mm +/- 6.8 mm. The depth of response estimated using TTV was significantly higher with a median of 89% +/- 7.1%, compared to TLG, RECIST 1.1 and PERCIST-5 with 51%, 37% and 41.6% respectively. In one case stable disease was observed (-18%), while the response rate evaluated by tumor metabolic volume was of 95%. Bone disease occurred in 100% (n=15) liver 30 % (n=3), lung 26.6% (n=4), breast 53.5 % (n=8), lymph nodes 66% n=10 . The analysis between the different response modalities showed statistical significance, especially between the VMT and the RECIST 1.1 criteria. (p=0.05) ***Conclusion:*** Metabolic information obtained with [18F]-Fluorodeoxyglucose PET/CT, especially the total tumor volume is highly efficient for estimating the depth of response in a more objective way and can avoid the information loss due to rigid criteria used in RECIST 1.1 and might provide more powerful and informative metric to understand the intensity of the response.

## EP-0131

### Does Body Mass Index correlate with risk of recurrence in patients with breast cancer undergoing [$^{18}$F]FDG PET/CT ?

***N. Quartuccio****, S. Ialuna, S. Pulizzi, D. D'Oppido, M. Antoni, A. M. Moreci;*
*Nuclear Medicine Unit, A.O.O.R. Villa Sofia Cervello, Palermo, ITALY.*

***Aim/Introduction:*** To investigate whether breast cancer patients with high body mass index (BMI) have increased risk of recurrence and higher glucose uptake in recurrent lesions compared to women with normal weight. ***Materials and Methods:*** The hospital database was searched to retrieve women with an histologically proven diagnosis of breast cancer, who had undergone an [$^{18}$F]FDG PET/CT scan before neoadjuvant chemotherapy and curative-intent surgery. At the baseline [$^{18}$F]FDG PET/CT scan, BMI was calculated using the following formula: weight in Kg/(height in m)$^2$. A median follow-up of 5 years after the baseline PET/CT scan was done by means of serial [$^{18}$F]FDG PET/CT scans, which were reviewed to identify recurrence in the breast (T_rec), lymph nodes (N_rec) or distant locations (M_rec); furthermore, SUVmax was measured in the sites of recurrence. A chi-square test was used to investigate any difference in the frequency of any recurrence, T_rec, N_rec, and M_rec between overweight women (BMI≥25 kg/m$^2$) compared to women with a BMI<25 kg/m$^2$ ($p<0.05$). SUVmax, measured in the sites of recurrences, was compared between the two groups using a t-test ($p<0.05$). ***Results:*** A total of 142 women (84 overweight and 58 with normal weight) were retrieved (BMI: 26.84±5.59, range: 17-44 kg/m2; age: 63.21±11.02, range: 35-86 years). There were 48 recurrence at the follow-up. The chi-square test demonstrated and increased frequency of recurrence in overweight women compared to women with a BMI<25 kg/m$^2$ (35 vs. 13; p=0.025). A significantly higher frequency of recurrence in the breast was found in overweight women (15 vs. 2; p=0.018). The SUVmax of the T_rec was significantly higher in overweight woman (4.74±2.90) compared to women with a BMI<25 kg/m$^2$ (1.85 ± 0.63; p=0.09). Only a trend for higher frequency in overweight women was found for N_rec (p=0.12) and M_rec (p=0.15) compared to women with a BMI<25 kg/m$^2$. ***Conclusion:*** BMI seems to correlate with an increased rate of recurrence, especially in the breast, and a higher glucose uptake in patients with recurrent breast cancer.

**PERCIST and Beyond : revisiting 18FDG PET/CT response patterns to ICPIs for non-small cell lung cancer considering atypical response, and their long-term prognostic value.**

***M. Masse***[1], *D. Chardin*[1,2], *P. Tricarico*[1], *N. Martin*[1], *J. Darcourt*[1], *J. Otto*[1], *O. Humbert*[1,2];
[1]*Centre Antoine Lacassagne, Nice, FRANCE,* [2]*TIRO-UMR E 4320, UCA/CEA, Nice, FRANCE.*

***Aim/Introduction:*** Our study aimed to assess the long-term prognosis of PERCIST criteria in the context of immunotherapy and to investigate the prognostic significance of atypical response patterns, namely pseudo-progression (PsPD) and dissociated response (DR). ***Materials and Methods:*** We analyzed data of 109 patients from two prospective trials involving patients with metastatic non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICPIs). Each patient underwent $^{18}$FDG PET/CT at baseline, and after 7 weeks ($PET_{interim}1$) and 3 months ($PET_{interim}2$) of treatment. Tumor response was assessed using PERCIST criteria and expanded upon them by including two new atypical response profiles: PsPD, defined by a PERCIST response or stability on $PET_{interim}2$ after initial progression and DR, characterized by the concomitance of both responding and non-responding lesions in the same exam. Long-term prognosis of each pattern was compared through overall survival (OS) and progression free survival (PFS) confirmed by a multi-disciplinary tumor board. ***Results:*** Median OS was 21 months [range 1-66] and median PFS was 8 months [range 1-60]. Using PERCIST criteria on $PET_{interim}1$, 39.5% of patients had a complete/partial metabolic response or stable disease, while 60.5% had progressive metabolic disease (PMD) (median OS : NA vs 15 months, median PFS : NA vs 5 months, $p < 0.001$). The prognosis of these four PERCIST subgroups was significantly different ($p < 0.001$). Among patients with PMD on $PET_{interim}1$ (N=66), nearly half of them had an atypical response pattern on $PET_{interim}2$: 23% subsequently showed a complete, partial, or stable metabolic response, indicated retrospectively an initial PsPD and 18.5% showed a DR. Only 58.5% showed a second homogeneous progression. There was no statistically significant difference in OS and PFS between patients with PsPD and those with DR (27 vs 29.5 months, $p = 1$; 17 vs 12 months, $p = 0.2$, respectively). Patients with PsPD or DR on $PET_{interim}2$ had significantly better median OS and PFS than those with PMD (29 vs 9 months, $p < 0.02$; 16 vs 2 months, $p < 0.001$, respectively), but worse than those who achieved a metabolic complete/partial response ($p < 0.001$). ***Conclusion:*** $^{18}$FDG PET/CT is an effective tool for early prognostic stratification of NSCLC patients treated with ICPIs. By introducing new criteria that consider atypical response patterns to ICPIs (DR and PsPD) after initial metabolic progression, three distinct prognostic subgroups can be identified, allowing to refine the prognostic stratification of the usual PERCIST criteria.

### EP-0133

**Comparison of Diagnostic Performance Between 68Ga-FAPI-04 and 18F-FDG PET/CT in Patients with Non-Small Cell Lung Cancer**

***C. Li***[1], *Y. Tian*[1], *Z. Xiao*[1], *J. Chen*[1], *L. Li*[1], *N. Lu*[1], *H. Li*[1], *J. Zhong*[1], *D. Zeng*[1], *B. Wen*[1], *Q. Chen*[2], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Pathology, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

***Aim/Introduction:*** This study aimed to investigate and compare the diagnostic performance between $^{68}$Ga-FAPI-04 and $^{18}$F-FDG PET/CT, and to evaluate the correlation between $^{68}$Ga-FAPI-04 uptake and fibroblast activation protein (FAP) expression level in the tumour stroma in non-small cell lung cancer (NSCLC). ***Materials and Methods:*** Patients with suspected or needle biopsy confirmed NSCLC who underwent both $^{68}$Ga-FAPI-04 and $^{18}$F-FDG PET/CT within one week for initial stage were retrospectively analyzed in this study, which was from a prospective parent study. Histopathological findings were as reference standard. The diagnostic efficiency of $^{68}$Ga-FAPI-04 and $^{18}$F-FDG were calculated and compared. The maximum standardized uptake value (SUVmax), mean SUV (SUVmean) of lesions were measured and recorded. The tissue sections from primary tumour were tested by hematoxylin-eosin (H&E) and FAP immunohistochemistry (IHC) staining. Spearman's correlation coefficient was used for assessing the correlation between $^{68}$Ga-FAPI-04 uptake and tumour FAP expression level. ***Results:*** A total of 48 patients (34 men, age range of 44-80 years) with NSCLC confirmed by surgery or needle biopsy were finally included in this study. In lesion-based analysis, the diagnostic sensitivities were 95.83% (46/48) and 91.67% (44/48) on $^{68}$Ga-FAPI-04 and $^{18}$F-FDG PET/CT, respectively, for the detection of primary tumour ($p = 0.500$). There was no significant difference in the primary tumour uptake on $^{68}$Ga-FAPI-04 and $^{18}$F-FDG (median SUVmax: 13.40 vs. 11.84, $p = 0.486$; median SUVmean: 7.68 vs. 6.82, $p = 0.361$). For the detection of regional lymph node involvement, in patient-based analysis, $^{68}$Ga-FAPI-04 showed the same sensitivity of 100% (15/15) with $^{18}$F-FDG, but higher specificity (76.92% vs. 38.46%, $p = 0.063$). In lesion-based analysis, $^{68}$Ga-FAPI-04 revealed much higher sensitivity (94.64% vs. 77.38%, $p < 0.001$) and specificity (95.85% vs. 80.83%, $p < 0.001$) than that of $^{18}$F-FDG for the detection of regional lymph node involvement. Twenty-three patients' tissue specimens (18 surgery and 5 biopsy) from primary tumour were available for FAP IHC staining. The SUVmax and SUVmean were positively correlated with tumour FAP expression level ($r = 0.582$ and 0.562, $p = 0.004$ and 0.005, respectively). ***Conclusion:*** Our study demonstrated $^{68}$Ga-FAPI-04 had superior diagnostic efficiency compared with $^{18}$F-FDG in NSCLC, especially in identifying regional lymph node metastasis. $^{68}$Ga-FAPI-04 uptake extent has a close association with FAP expression level in the tumour stroma of NSCLC.

### EP-0134

**First-in-human PET imaging of KRAS p.G12C mutation status in NSCLC and CRC patients using 18F-AMG510**

***J. Ye***, *X. Li, M. Zhang, W. Yang, F. Kang, J. Wang;*
*Xijing Hospital, Xi'an, CHINA.*

***Aim/Introduction:*** Kirsten rat sarcoma (KRAS) mutation would consecutively activate downstream oncoprotein pathway, thereby promoting tumor growth and survival. It is considered a key predictor of the efficacy of EGFR-targeted therapy in lung cancer, colorectal cancer and other tumors, and is included in guidelines such as NCCN. Therefore, accurate detection of

KRAS mutations is a significant clinical need for precision cancer diagnosis and treatment. In this study, we sought to develop a PET tracer based on newly FDA-approved KRASG12C targeted drug AMG510 (Sotorasib), and to investigate its translational potential for noninvasive screening of KRASG12C mutation in NSCLC and CRC patients. ***Materials and Methods:*** 18F-AMG510 was synthesized based on AMG510 through modifying the quinazolinone structure with polyethylene glycol chain. The binding affinity of 18F-AMG510 was assessed by molecular docking, and further verified by cell uptake (H358: KRASG12C mutation; A549: non-KRASG12C mutation) study and micro-PET/CT imaging study on tumor bearing mice. Five healthy volunteers were enrolled for investigating the safety, biodistribution and dosimetry of 18F-AMG510. Subsequently, 14 NSCLC or CRC patients with or without KRASG12C mutation underwent 18F-AMG510 and 18F-FDG PET/CT imaging. SUVmax of tumor uptake of 18F-AMG510 was quantified and compared between patients with KRASG12C mutation and non-KRASG12C mutation. ***Results:*** 18F-AMG510 was successfully prepared with high radiochemical yield and high radiochemical purity. Molecular docking assay revealed F-AMG510 bind with KRASG12C protein. 18F-AMG510 uptake in H358 was significantly higher than A549, and decreased by pretreatment with AMG510 (H358 vs. A549: 3.22 ± 0.28% vs. 2.50 ± 0.25%, $p < 0.05$, block: 2.06 ± 0.13%, $p < 0.01$). Similar results were observed in tumor bearing mice PET imaging study (H358 vs. A549: 3.93 ± 0.24 vs.2.47 ± 0.26 % ID/g, $p<0.01$; block: 2.89 ± 0.29% ID/g, $p < 0.05$). 18F-AMG510 was safe in human, and it was primarily excreted by gallbladder and intestine. The effective absorbed dose was comparable to that of 18F-FDG. The accumulation of 18F-AMG510 at KRASG12C mutated tumors was significantly higher than non- KRASG12C mutation tumors (SUVmax: 3.73 ± 0.58 vs. 2.39 ± 0.22, $p < 0.01$) in NSCLC and CRC patients. ***Conclusion:*** 18F-AMG510 is a safe and promising PET tracer for clinically non-invasive imaging of KRASG12C mutation status in NSCLC and CRC patients. This study provided a new method for accurate non-invasive screening of tumor KRASG12C mutation, be valuable in achieving precise cancer diagnosis and treatment, and provide a reference for clinical translation studies of other KRASG12C probes.

## EP-0135

### Qualitative Analysis of Pericardial Metastasis in Oncologic F-18 FDG PET/CT

***H. Lee****;*
*Dongnam Institute of Radiological and Medical Sciences, Busan, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Accurate diagnosis of the pericardial metastasis on the positron emission tomography/computed tomography with F-18 fludeoxyglucose (F-18 FDG PET/CT) in oncologic patients is challenging both in initial staging work-up on and follow-up. The aim of this study was to assess the qualitative analysis of pericardial metastasis on the F-18 FDG PET/CT in oncologic patients. ***Materials and Methods:*** Between Jan 2012 and Dec 2022, we reviewed 22,508 consecutive F-18 FDG PET/CT studies done for an oncologic indication at our institution. 43 oncologic patients (range, 37-88 y; mean age, 63.6±12.5 y), who demonstrated pericardial metastasis on F-18 FDG PET/CT enrolled in this study. A qualitative analysis was performed on the images. All pericardial metastases were scored for their extent and intensity using a 3-point scale (1 = low, 2 = moderate, 3 = high). Diffuse pericardial thickening with diffuse FDG uptake was considered as low-grade. Diffuse pericardial thickening with several hypermetabolic nodules was considered as moderate-grade. Intense hypermetabolic pericardial thickening was considered as high-grade. A final diagnosis of the pericardial metastasis was based on pericardial fluid cytology or clinical and imaging follow-up. ***Results:*** Among 43 oncologic patients with pericardial metastasis on F-18 FDG PET/CT, the most frequent primary tumor was lung cancer (21/43, 48.8%), followed by breast cancer (6/43, 14.0%), gastric cancer (5/43, 11.6%), thymic carcinoma (3/43, 7.0%), head and neck cancer (2/43, 4.7%), and six other malignancies (esophageal cancer, adenoid cystic carcinoma, pancreatic cancer, malignant B-cell lymphoma, malignant mesothelioma, and metastasis of unknown origin). Of 43 patients, the number of patients with pericardial metastasis which was diagnosed in initial staging work-up and follow-up was 14 and 29 patients, respectively. On qualitative analysis, the number of patients low-grade, moderate-grade and high-grade was 18 (41.9%), 13 (30.2%) and 12 (27.9%), respectively. In 12 patients with high-grade, the number of patients (6) who were diagnosed in initial staging was equal to that of patients (6) who in follow-up. However, in 18 patients with low-grade, the number of patients (5) who were diagnosed in initial staging was lower than that of patients (13) who in follow-up. ***Conclusion:*** In oncologic patients with F-18 FDG PET/CT, the most frequent primary tumor with pericardial metastasis was lung cancer. Patients with high-grade pericardial metastasis were observed on initial staging work-up equal to on follow-up F-18 FDG PET/CT. ***References:*** Douroukas. "Detection of metastatic involvement of the pericardium on F-18 FDG-PET/CT imaging." Clinical Nuclear Medicine 34.1 (2009): 40-41.

## EP-0136

### Comparison of FDG PET/CT and PET/MR Imaging for Primary Staging of Newly Diagnosed Lung Cancer

***E. Erbil****, U. Aydos, Ü. Akdemir, N. Karabacak, L. Atay;*
*Gazi University Faculty of Medicine, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study was to compare the diagnostic performances of FDG PET/CT and PET/MR imaging in TNM staging of newly diagnosed lung cancer patients. ***Materials and Methods:*** The images of 76 patients (59 males, 17 females, mean age: 64.1±8.5 years) diagnosed with lung cancer who underwent PET/CT and PET/MRI after a single radiopharmaceutical injection (mean activity: 214.6±55 MBq) for primary staging between 2015 and 2021 were retrospectively evaluated. The diagnostic performances of the two modalities were compared using the eighth edition of the TNM staging system of the IASLC. The imaging findings for T and N staging were compared with the histopathological results in 18 patients who underwent surgical resection after primary staging. Histological findings, follow-up imaging, and clinical management of the patients were used as reference standard in cases that did not undergo surgical resection. The diagnostic performances of two imaging methods were evaluated by using McNemars' chi-square test. Semiquantitative measurements were compared by using the Wilcoxon signed-rank test. ***Results:*** The mean time after injection was 87.7±34.8 minutes for PET/CT and 125.7±46.9 minutes for PET/MR. While PET/CT imaging was performed firstly in 60 of the patients, PET/MR imaging was performed firstly in 16 patients. Concordance between the two imaging modalities in terms of T, N, M stages and overall TNM stage was found to be 96.1%, 90.8%, 89.5%, and 90.8%, respectively. According to the histopathological results, PET/CT and PET/MR accurately determined the T stage in all patients, while the N stage was correctly detected in 58.8% of the patients. While the agreement of the reference TNM stage and

PET/CT was 81.6%, the agreement of PET/MR was 86.8%. While there was no significant difference between the two imaging modalities in T and N staging (p>0.05, each), the difference between two methods in M staging was significant (p= 0.046). The mean number of distant metastases detected in PET/MR was significantly higher than PET/CT (6.5 vs 3.2, p<0.001). There were no significant differences between the primary tumor sizes measured in the two imaging modalities (p=0.15). While SUVmax, SUVpeak and TLG values of the lesions were significantly higher in PET/MR images, MTV values were significantly higher in PET/CT images (p<0.05). ***Conclusion:*** FDG PET/CT and PET/MR have similar diagnostic performances in primary T and N staging of newly diagnosed lung cancer patients. In the M staging, the diagnostic performance of PET/MR imaging was found to be superior to PET/CT.

## EP-0137

### Added diagnostic sensitivity of MTV and TLG in the assessment of left adrenal gland metastasis in lung cancer with [18F]FDG PET/CT

***H. Hautzel***[1], *F. Özkan*[2], *C. Laschinsky*[1], *D. Kersting*[1], *M. Opitz*[3], *D. Theegarten*[4], *K. Darwiche*[2], *K. Herrmann*[1];
[1]*Department of Nuclear Medicine, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [2]*Department of Pneumology, Section of Interventional Pneumology, Ruhrlandklinik Essen, Universitätsmedizin Essen, Essen, GERMANY,* [3]*Institute of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [4]*Institute of Pathology, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY.*

***Aim/Introduction:*** Adrenal metastases account for about 20% of distant metastases in lung cancer. Therefore, it is of high relevance to correctly identify an adrenal involvement during whole body [$^{18}$F]FDG PET/CT staging. However, while highly sensitive specificity is apparently impaired with a false positive rate of 28% [1]. Endoscopic trans-esophageal/gastral ultrasound (EUS-B) in direct succession to endobronchial ultrasound for obtaining biopsies and hilar/mediastinal N-staging emerged as another staging tool for the left adrenal gland (LAG). By EUS-B not only the anatomical LAG configuration might be explored but also LAG biopsies can be drawn. Using EUS-B LAG results plus follow-up as reference this study aimed to test if the metabolic tumor volume (MTV) and/or the total lesion glycolysis (TLG) of the LAG might overcome the shortcoming of [$^{18}$F]FDG PET/CT in specificity and outperform the SUVmax estimation. ***Materials and Methods:*** 253 patients with suspected/verified lung cancer undergoing initial staging with both [$^{18}$F]FDG PET/CT and EUS-B were included. Using syngo.via (Siemens Healthineers, Germany) the following PET parameters were collected: SUVmax of the primary, SUVmax of LAG (SUVmaxLAG), LAG MTV and LAG TLG. Standard of reference was either EUS-B derived LAG histology or unremarkable ultrasound appearance of LAG in EUS-B plus follow-up with abdominal CT of at least 3 months. ROC analyses including area under the curve (AUC) were calculated. From these analyses cut-off values were derived for optimal sensitivities and specificities. ***Results:*** The AUC for SUVmax of the primary was highly limited with 0.543 while the AUCs of SUVmaxLAG and MTV LAG were almost the same with 0.870 and 0.873. AUC of TLG LAG was highest with 0.883. The ROC analyses translated into the following cut-off values, sensitivities and specificities: SUVmax of the primary cut-off 11.0, sensitivity 31.6%, specificity 77.3%; SUVmaxLAG cut-off 4.7, sensitivity 84.2%, specificity 75.0%; MTV LAG cut-off 2.0 ml, sensitivity 89.1%, specificity 73.2%; TLG LAG cut-off 6.6, sensitivity 89.2%, specificity 74.2%. ***Conclusion:*** The SUVmax of the primary lung tumor proved inappropriate to predict a LAG metastasis. In comparison to SUVmaxLAG MTV LAG and TLG LAG increased the sensitivity to about 90% while specificity remained almost unchanged at about 75% adding no further increase to [18F]FDG PET/CT LAG staging specificity. However, since estimation is straightforward and fast especially TLG might be implemented in clinical reading of [18F]FDG PET/CT for LAG metastasis detection in lung cancer, in particular if EUS-B is lacking. ***References:*** [1] Lang et al., World J Surg 2015;39:1902-1908

## EP-0138

### Value of 18F-FDGPET/CT in the Differential Diagnosis of Tuberculous Pulmonary Cavity and Lung Cancer Cavity

***M. Zhao***[1,2], *L. Ma*[1];
[1]*Shandong Cancer Hospital of China, Ji Nan, CHINA,* [2]*Department of Nuclear Medicine, Zibo Central Hospital, Shandong Province, Zibo City, CHINA.*

***Aim/Introduction:*** To analyze the $^{18}$F-fluorodeoxyglucose (FDG) PET/CT imaging features of lung squamous cell carcinoma cavity, lung adenocarcinoma cavity and pulmonary tuberculosis cavity, and to evaluate its value in the differential diagnosis. ***Materials and Methods:*** The $^{18}$F-FDG PET/CT features of 104 patients including 38 patients with lung squamous cell carcinoma cavity, 36 patients with lung adenocarcinoma cavity and 30 patients with pulmonary tuberculosis cavity were retrospectively analyzed. The differences of lesion maximum diameter, cavity wall thickness maximum diameter, cavity maximum diameter, $SUV_{max}$, $SUV_{avg}$, $SUV_{peak}$, TLG and MTV values among the three groups were analyzed, and correlation analysis and ROC curve analysis were performed. ***Results:*** The $^{18}$F-FDG PET/CT manifestations of pulmonary tuberculosis cavity were multiple, diverse and different activities with calcification and proliferation, and the positive rate was significantly higher than that of pulmonary squamous cell carcinoma cavity and pulmonary adenocarcinoma cavity. The $SUV_{max}$ values of the three groups were 16.2 ± 7.8, 10.4 ± 5.5, 4.2 ± 1.8 ($P < 0.05$), the maximum lesion diameters were 6.0 ± 2.7, 3.8 ± 1.6, 3.4 ± 1.7 ($P < 0.05$), the maximum diameter of cavity wall thickness were 2.4 ± 1.7, 1.4 ± 0.8, 1.3 ± 0.8 ($P < 0.05$), the maximum cavity diameters were 3.0 ± 2.0, 2.0 ± 1.3, 2.0 ± 1.5 ($P < 0.05$). The $SUV_{max}$ in the group of lung squamous cell carcinoma cavity was significantly higher than that of the pulmonary tuberculosis cavity ($P < 0.05$) , there were also statistical differences in lesion maximum diameter, cavity wall thickness maximum diameter, cavity maximum diameter, $SUV_{avg}$, $SUV_{peak}$, TLG and MTV between the two kinds of cavities ($P < 0.05$). The $SUV_{max}$ of pulmonary adenocarcinoma cavity was significantly larger than that of the pulmonary tuberculosis cavity ($P < 0.05$) , the differences of $SUV_{avg}$ and $SUV_{peak}$ between the two groups were also statistically significant ($P < 0.05$) , however, the differences showed no statistical significace in lesion maximum diameter, cavity wall thickness maximum diameter, cavity maximum diameter ($P > 0.05$) ; The $SUV_{max}$ of lung squamous cell carcinoma cavity was also significantly higher than that of the pulmonary adenocarcinoma cavity ($P < 0.05$) . ***Conclusion:*** Comprehensive analysis of $^{18}$F-FDG PET/CT metabolic characteristics, anatomical details and quantitative indexes of lung cavities including adjacent lung tissues is of important value in differentiating lung cavities with squamous cell carcinoma, lung adenocarcinoma and pulmonary tuberculosis.

## EP-0139

### Contribution of 18F-FDG PET-CT in initial staging of non-small cell lung cancers

***H. Noamen***[1,2], *H. Charfi*[2], *I. Jardak*[1], *R. Sfar*[2], *I. Touil*[2], *K. Chatti*[2], *K. Chtourou*[1], *F. Guermazi*[1];
[1]*University hospital of Habib Bourguiba, Sfax, TUNISIA,*
[2]*University of Monastir, Monastir, TUNISIA.*

***Aim/Introduction:*** The prognosis and choice of treatment of non-small cell lung cancers (NSCLC) depend on the TNM and stage classifications.The aim of our study is to confront the results of $^{18}$F-FDG PET-CT with the data of the initial conventional imaging extension evaluation of NSCLC. ***Materials and Methods:*** Single-centre retrospective analytical transversal study performed over a period of 25 months including 75 patients referred for NSCLC extension evaluation. All patients underwent CT with enhanced contrast and then $^{18}$F-FDG PET-CT. We compared the findings in TNM staging of conventional imaging (CT, bone scintigraphy), $^{18}$F-FDG PET-CT, and histological data and studied the impact of the staging change in the management of these patients. ***Results:*** In (N)-staging: $^{18}$F-FDG PET-CT resulted in upstaging 46% patients.The comparison of the data from PET-CT and CT to the histological findings in the evaluation of lymph node involvement showed that PET-CT reduced the number of CT false-negative cases. In (M)-staging: $^{18}$F-FDG PET-CT revealed metastases in 30% of patients classified as non-metastatic by the conventional imaging, including bone, adrenal, and liver locations not detected by CT scan, as well as metastases in atypical sites poorly identified by morphological imaging. Overall, the stage of the disease was changed in 52% of the cases. The upstaging by $^{18}$F-FDG PET-CT was mainly in locally advanced stages (IIIA and IIIB) and in patients classified as IIB. $^{18}$F-FDG PET-CT allowed a more accurate clinical staging avoiding futile mediastinoscopy and unnecessary thoracotomy. In the 35 patients who were upstaged by PET-CT, the number of operable patients decreased, and multimodal treatment was proposed in 31 patients. The downstaging of 4 patients allowed half of them to be treated surgically. ***Conclusion:*** $^{18}$F-FDG PET-CT, through its more accurate staging of the disease, allows the initial therapeutic strategy of NSCLC to be optimized, particularly for patients classified as IIIA and IIIB by conventional imaging, thus avoids invasive and unnecessary treatments. ***References:*** Schmidt-Hansen M, Baldwin DR, Hasler E, Zamora J, Abraira V, Roquéi Figuls M. PET-CT for assessing mediastinal lymph node involvement in patients with suspected resectable non-small cell lung cancer. Cochrane Database Syst Rev. 2014;2014.

## EP-0140

### Prediction of mediastinal node involvement in non-small lung cancer by baseline 18 F-FDG PET/CT metabolic parameters

***H. Noamen***[1,2], *H. Charfi*[2], *I. Jardak*[1], *R. Sfar*[2], *I. Touil*[2], *K. Chatti*[2], *K. Chtourou*[1], *F. Guermazi*[1];
[1]*University hospital of Habib Bourguiba, Sfax, TUNISIA,*
[2]*University of Monastir, Monastir, TUNISIA.*

***Aim/Introduction:*** The aim of this study is to assess the predictive value of tumoral semi-quantitative parameters in nodal staging (N) in non-small cells lung cancer (NSCLC). ***Materials and Methods:*** Our study included 75 patients (67 M/8 F; median age 65, range 41-88) diagnosed with NSCLC who underwent pre-treatment $^{18}$F-FDG PET/. We assessed whether semi-quantitative metabolic PET parameters (SUVmax, MTV and TLG) varied with the nodal status (N). ***Results:*** The median values of tumoral MTV and TLG in the group of patients with mediastinal homolateral and/or contralateral node metastasis were higher compared to the group of patients without node involvement or with only homolateral hilar node disease (MTV: M=21, IQR=[7,9-70,7] vs M=19,7, IQR=[4,6-35]; TLG: M=76,5, IQR=[16-328] vs M=185,5, IQR=[40-499]) without a statistically significant difference (p >0,05). Also, the comparison between tumoral SUVmax values in both groups didn't show a significant difference (M=11, IQR= [5,4-15,6] vs M=11,7, IQR= [8-17,3] and p>0,05). ***Conclusion:*** Despite the lack of statistical significance, this analysis suggests that $^{18}$F-FDG volumetric parameters MTV and TLG would be better predictors of nodal extension than SUVmax. A further study enrolling a larger population would better demonstrate the predictive value of metabolic parameters in lymphatic node metastasis in NSCLC. ***References:*** Ouyang M li, Xia H wei, Xu M man, Lin J, Wang L li, Zheng X wu, et al. Prediction of occult lymph node metastasis using SUV, volumetric parameters and intratumoral heterogeneity of the primary tumor in T1-2N0M0 lung cancer patients staged by PET/CT. ### PET attenuation correction of chest FDG PET/MRI: Deep learning-based denoising and pseudo-CT generation using fast zero-TE MRI and unpaired PET/CT data

***M. Nogami***[1,2], *H. Matsuo*[3], *M. Nishio*[3], *M. Tachibana*[3], *J. Inukai-Inoue*[3], *F. Zeng*[3], *K. Kubo*[1], *T. Kurimoto*[4], *T. Murakami*[3,1];
[1]*Kobe University Hospital, Kobe, JAPAN,* [2]*University of Fukui, Fukui, JAPAN,* [3]*Kobe University Graduate School of Medicine, Kobe, JAPAN,* [4]*GE Healthcare, Hino, JAPAN.*

***Aim/Introduction:*** Zero echo-time (ZTE) is a suitable proton-density MRI for bone imaging and is used in PET/MRI for head attenuation correction (AC) of bone components. The field of view (FOV) needs to be expanded to use ZTE for chest AC, resulting in increasing the imaging time. Fast ZTE with small FOV can be used for training data of deep learning-based PET/MRI AC of the chest by expanding the data, doubling the FOV, and using deep learning to reduce noise. This study aimed to explore the feasibility of deep learning to reduce noise in fast ZTE with double FOV and to generate a pseudo-CT (pCT) for PET/MRI AC. ***Materials and Methods:*** The data of 250 patients who underwent chest FDG PET/MRI with central-frequency-adjusted ZTE were retrospectively analysed. The ZTEs, acquired in one minute with a small FOV (36 cm), were expanded and reconstructed in a FOV of 72 cm, followed by noise reduction using deep learning. Unpaired training data included bias-corrected ZTE and CT components of PET/CT. They were used for training unsupervised generative adversarial networks with a modality-independent neighbourhood descriptor (U-GAT-IT/MIND) model. Also, 20 cases with paired ZTE PET/MRI and PET/CT were used to validate the model for standardised uptake values (SUV) after AC. The mean SUV (SUVmean) of bone and liver in the chest region was measured by segmenting bone on pCT and placing a fixed region of interest in the liver, respectively. An MRI-based AC map with bone ($MRAC_{ZTE}$) was created by merging the segmented bone map onto a conventional two-point Dixon-based AC map ($MRAC_{Dixon}$) and was applied to PET reconstruction on the offline workstation. Bland-Altman plots were used to compare SUVmeans between $MRAC_{Dixon}$, $MRAC_{ZTE}$, and CT-based AC (CTAC). Wilcoxon's signed rank test was used to compare SUVmeans between AC maps. ***Results:*** Mean differences in bone SUVmeans by $MRAC_{ZTE}$ and CTAC were significantly smaller than by $MRAC_{Dixon}$ and CTAC ($p<0.05$). Bone and liver SUVmeans were significantly

larger by $MRAC_{ZTE}$ than by $MRAC_{Dixon}$ (p<0.001). The spine and liver SUVmeans were significantly larger by $MRAC_{ZTE}$ than by $MRAC_{Dixon}$. ***Conclusion:*** Deep learning-based denoising and pseudo-CT generation using fast zero-TE MRI and unpaired PET/CT data were feasible. AC maps with bone components from pCT yield smaller differences in bone SUVs with CT-based AC than $MRAC_{Dixon}$ and larger SUVs in the bone and liver than $MRAC_{Dixon}$. ***References:*** 1. arXiv:1907.10830. 2. Med Image Anal. 2012 Oct;16(7):1423-35.

## EP-0142

### Prediction of 131I Uptake in Lung Metastases of Differentiated Thyroid Cancer UsingDeep Learning before Radioiodine Therapy: a Pilot Study

***H. Song***;
*Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

***Aim/Introduction:*** Radioiodine therapy forms the core treatment of differentiated thyroid cancer (DTC) with lung metastases unless radioactive iodine ($^{131}$I) accumulation capacity is lost. Computed tomography (CT) scans can accurately detect lung metastases of DTC. Deep learning (DL) algorithms have made substantial strides in image recognition tasks and are gaining extensive attention. We attempted to develop a deep convolutional neural network (DCNN) model for the prediction of the $^{131}$I uptake in lung metastases of DTC before radioiodine therapy. ***Materials and Methods:*** In this population-based cohort study, a training data set of chest CT images in DTC patients with lung metastases from our hospital (20175 imaging studies from Jan 2017 to Jan 2021, 261 patients) were collected retrospectively. According to the post-therapeutic $^{131}$I whole-body scan ($^{131}$I-WBS), pulmonary metastases were classified as $^{131}$I-avid (positive $^{131}$I uptake, $n_1$=140) and non-$^{131}$I-avid (negative $^{131}$I uptake, $n_2$=121). The anatomical structure-aware pulmonary nodule detection via parallel multi-task region-of-interest (RoI) Head was proposed. We built a predictive model from the outputs using the transfer learning techniques of a residual convolutional neural network (ResNeSt50 4s2x40d). The model's diagnostic performance was validated in an internal validation set (4530 imaging studies from Feb 2021 to Jun 2022, 59 patients). We further compared the prediction accuracy of our method with the two classic classification model architectures, Inception_V3 and ResNet50. ***Results:*** In the training and internal validation set, the accuracy of our deep learning model was 71.0%( 95% CI: 70.9%-71.0%) and 62.4% (62.1%-62.6%), respectively, both higher than that of Perception_V3 and ResNet50. ResNeSt50 4s2x40d model has a good area under curve (AUC) both in the training (AUC=0.77) and internal (AUC=0.72) test sets. ***Conclusion:*** The DL model demonstrated a good performance for predicting the $^{131}$I uptake in lung metastases of DTC before radioiodine therapy and may play a potential role in better screening patients who can benefit from $^{131}$I therapy. Further improvement is necessary before clinical utilization.

## EP-0143

### The value of 18F-FDG PET/CT radiologic features and radiomics features predicting the bronchogenic carcinomas with ALK rearrangement fused gene

***Y. Xu***;
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** With aim to assess whether radiologic feature and radiomics features are predictive of anapalstic lymphoma kinase(ALK) rearrangement in bronchogenic carcinomas, and to compare the differences between the two prediction models. ***Materials and Methods:*** ALK rearrangement was screened in 530 patients with pathologic proved lung cancer.Of those 48 patients detected with positive ALK fused gene were enrolled. Analyze the relationship between the positive rate of ALK and the clinical, pathological and imaging features. For radiomics features, we used AK software to extract the most relevant imageomics features for tumor classification, and randomly divided the images into training set (70%) and test set (30%). The maximum correlation and minimum redundancy (mRMR) and minimum absolute shrinkage and selection operator (LASSO) methods were used to select features from 2800 features extracted from CT and PET, and finally 12 best features were retained. ***Results:*** The prevalence of ALK positivity in bronchogenic carcinoma was 48 case,including 27 female and 21 male (p>0.05).The mean ages were 53.71±10.98 yrs and 59.94±9.75 yrs(,p<0.01).The number of non-cigarette smokers was more than that of smokers(p<0.05). There also were difference between two groups in lobuated shape and solid components within lesion(p<0.01). The mean SUVmax were 4.23±2.31 and 3.81±2.51,in positive and negative group resptectively.The area under the ROC curve of the predictive model was 0.644(95%CI:0.540-0.747). when SUVmax=3.45 was used as threshold,positive rate in ≥3.45 was much higher than less than <3.45 in diameter group(p<0.05).when multivariate factors such as age less than 50yrs, no-smoker, lobulated shape solid components and SUVmax≥3.45 in lesions used as predictive factors of ALK rearrangement, the area under the ROC curve of the predictive model was 0.809(95%CI:0.744-0.875),with sensitivity of 62.8%,and specifity of 77.6%,respectively.The established PET/CT imaging features have good prediction efficiency for the recognition of bronchogenic carcinomas with ALK rearrangement fused gene. In the radiomics prediction model, the AUC of the training group and the validation group were 0.948 (95% CI: 0.792-0.991).The results of the two prediction models have significant statistical differences(p<0.05). ***Conclusion:*** ALK fused gene showed more frequently in pulmonary adenocarcinoma,less also may detected in squamous cell and small cell lung cance. In the traditional prediction model: younger, non-cigarette, with lobulated shape, contain solid components and higher SUV value as predictor factor of ALK fused gene. Compared with the traditional prediction model combining radiologic features and clinical features, the prediction model based on radiomics has higher prediction value.

## EP-0144

### The value of PET/MRI radiomics features in predicting synchronous brain metastases in non-small cell lung cancer

***J. Liang***;
杭州通用医学影像诊断中心, 杭州, *CHINA.*

***Aim/Introduction:*** To investigate the value of CT-based radiomics features in predicting syn-chronous brain metastases from non-small cell lung cancer (NSCLC). ***Materials and Methods:*** The clinical and imaging data of 120 patients with pathologically confirmed NSCLC in our hospital from June 2017 to June 2022 were retrospectively analyzed. According to the PET/MRI imaging features, the patients were divided into 48 patients with brain metastasis group and 72 patients without brain metastasis group. All patients were divided into the training set (84 cases) and the verification set (36 cases) in a ratio of 7:3. ITK-SNAP software was used to manually delineate the ROI of the lesions layer by layer on PET images and T2WI images respectively, and the volume ROI of the lesions was obtained by three-dimensional fusion,

and then imported into AK software to extract the texture features of each lesion. The features of PET images, T2WI images and multi-sequences ( PET + T2WI) were selected by minimum redundancy maximum correlation ( mRMR) and minimum absolutevalue convergence and selection operator ( L.ASSO) to predict brain metastasis, the radiomics model was established by logistic regression analysis , and the radiomics score ( rad-score) of each case was calculated. Through logistic regression analysis, the variables with statistically significant differences between groups in clinical and imaging data were established into a conventional model, and combined with the most effective radiomics model to establish a synthetic diagnostic model, and then nomography was drawn for evaluation the predicive rate of the model. ***Results:*** The area under curve (AUC) of PET, T2WI and combined sequences radiomics model in the training group and verification group were 0.89 and 0.86, 0.79 and 0.75, 0.91 and 0.93 respectively, and combined sequence model had the highest predictive efficiency. The AUC of the conventional model and synthetic diagnostic model in training group and validation group were 0.71 and 0.79, 0.92 and 0.95. The synthetic diagnostic model was relatively effective in predicting synchronous brain metastasis in NSCIC patients , which was significantly better than the conventional model (P=0.001), and the multi-sequences rad-score is an independent factor (OR=2.5, P<0.001). ***Conclusion:*** The prediction efficiency of all radiomics model were higher than conventional models, and the synthetic diagnostic model was significantly better than the conventional model. The radiomics is expected to become a new biological indicator to help clinically predict the risk of synchronous brain metastases.

## EP-0145

### The Application of Three-dimensional Ventilation/Perfusion single photon emission tomography/computed tomography in Asthma and COPD

***H. Xie***, *L. Li;*
*West China Hospital of Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** To investigate the role of ventilation/perfusion single photon emission tomography/computed tomography (V/P SPECT/CT) quantitative parameters in evaluating COPD and asthma disease severity and airway obstructivity-grade. Establish a new parameter to optimize the identification of the most affected lung lobe and to explore the value of V/P SPECT/CT in quantifying regional lung function to guide localised treatments of asthma and COPD in the future. ***Materials and Methods:*** Fifty-three subjects, including patients with COPD or asthma, and healthy controls, who underwent V/P SPECT/CT and pulmonary function tests (PFTs) were included. Preserved lung ventilation function (PLVF), preserved lung perfusion function (PLPF), airway obstructivity-grade (OG) and volume perfusion ratio (VPR) were evaluated using V/P SPECT/CT. VPR was established by combining relative lung volume from low dose CT and relative perfusion from perfusion SPECT. In addition, the difference of V/P SPECT/CT-related parameters were compared. ***Results:*** The airway OG, PLVF and PLPF differed significantly among the severe-very severe COPD and mild-moderate asthma patients (P<0.05). And the PLPF was statistically significant among the disease severity groups in asthma and COPD (P<0.05). The airway OG, PLVF and PLPF in asthma and COPD differed significantly from the control group (P<0.05). A reference range of VPR for each lung lobe in the normal population was established. In normal subjects, VPR in the right upper lobe 1.09±0.31; VPR in the middle lobe 1.15±0.43; VPR in the right lower lobe 0.91±0.22; VPR in the total right lung 0.98±0.06; VPR in the left upper lobe 1.14±0.24; VPR in the left lower lobe 0.99±0.31; VPR in the total left lung 1.02±0.07. A high VPR implies a large volume of lung lobes with correspondingly low perfusion; these lobes impede the function of the respiratory pump and are not related to the actual perfusion contribution. In the opposite case, a low VPR means that this lobe is compressed but retains perfusion function. ***Conclusion:*** Quantitative assessment of ventilation and perfusion abnormalities and the degree of pulmonary functional loss by V/P SPECT/CT shows promise as an objective measure to assess severity of disease and lung function to guide localized treatments. There are differences among the disease severity groups in asthma and COPD in SPECT/CT parameters, which may enhance, to some extent, the understanding of complex physiological mechanisms in asthma and COPD. VPR allows identifying possible target structures with much higher sensitivity than PFTs or CT alone.

***Aim/Introduction:*** In patients with somatostatin receptor 2 (SSTR2)-expressing small cell lung cancer (SCLC), SSTR2-antagonist PET imaging using satoreotide trizoxetan (SSO-120, previously OPS-202) bears the potential for accurate tumor detection and screening for SSTR2-antagonist radionuclide therapy. Here, we evaluate tumor uptake and detection rates by $^{68}$Ga-SSO-120 PET versus $^{18}$F-FDG PET in the initial staging of patients with SCLC. ***Materials and Methods:*** We retrospectively included patients who underwent additional $^{68}$Ga-SSO-120 PET/CT in the initial staging of SCLC. PET-positive lesions were reported in 7 anatomical regions according to the 8$^{th}$-edition TNM classification for lung cancer (primary tumor, thoracic lymph nodes, and distant metastases including pleural, contralateral pulmonary, liver, bone, other) by two nuclear medicine physicians. If gold-standard $^{18}$F-FDG PET/CT was available within 2 weeks prior/post $^{68}$Ga-SSO-120 PET/CT and if morphologic differences in CT were absent, a comparative analysis was performed. Consensus TNM from clinical tumor board (using CT, EBUS-TBNA, PET, brain MRI) served as reference standard. ***Results:*** We included 37 patients (18 female/19 male), 13 with limited and 24 with extensive disease according to VALG classification. Mean administered activity was 140 MBq and mean uptake time was 62 min. SSO-120 positive tumor was detected in all patients (100%) and in 110 of a total of 259 evaluated regions (42.5%). Thirty-three patients (89.3 %) showed average SSO-120 tumoral uptake higher than in liver tissue (region-based mean $TLR_{peak}$>1) and 17 patients (45.9%) demonstrated intense

uptake (region-based mean $SUV_{max}$≥10). All 28 patients for whom $^{18}$F-FDG PET was available had SSO-120- and FDG-positive tumor. SSO-120 versus FDG-positive thoracic lymph node metastases were detected in 25 versus 26 patients (89.3% versus 92.9%) and distant metastases in 19 versus 17 patients (67.9% versus 60.7%). In detail, $^{68}$Ga-SSO-120 PET detected additional uptake in contralateral lymph nodes (N3 versus N2), cervical lymph nodes, and liver metastases in one patient each and in brain lesions in 2 patients. $^{18}$F-FDG PET detected additional uptake in thoracic lymph nodes in 4 patients (3 N3 versus N2, 1 N3 versus N0) and in pancreas in one patient. Region-based detection rates were 97.6% for $^{68}$Ga-SSO-120 versus 95.3% for $^{18}$F-FDG PET. Lesion-based monotonical correlation between SSO-120 and FDG uptake was low (Spearman's rho 0.44 for $SUV_{max}$). ***Conclusion:*** $^{68}$Ga-SSO-120 PET demonstrated intense tumoral uptake in nearly every second patient and offers comparable detection rates to the gold standard $^{18}$F-FDG PET. Ongoing investigation aims to characterize subgroups for identification of candidates for SSTR2-directed radionuclide therapy.

## EP-0147

### Ongoing Trial on the Role of the Promising Oncological PET/CT Tracer [68Ga]Ga-FAPI-46 for Staging Suspected/Confirmed Lung Cancer: Preliminary Results on Patients who Underwent Radical Surgery

***E. Fortunati***[1], *L. Zanoni*[2], *G. Cuzzani*[1], *C. Nanni*[2], *F. Lodi*[2], *F. Antonacci*[3], *P. Solli*[3], *F. Giunchi*[4], *A. Degiovanni*[4], *M. Ferrari*[5], *F. Natali*[5], *T. Galasso*[5], *G. Bandelli*[5], *P. Candoli*[5], *A. D'Errico*[4], *S. Fanti*[1,2]; [1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Division of Thoracic Surgery, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Pathology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Interventional Pulmunology Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** To evaluate the diagnostic performance of [68Ga]Ga-FAPI-46 PET/CT in staging suspected/confirmed lung cancer (LC) patients. ***Materials and Methods:*** A prospective monocentric ongoing study (CE, AIFA approved, started April2022) is enrolling patients with suspected/confirmed LC to perform a PET/CT with the investigational tracer [68Ga]Ga-FAPI-46(FAPI), in addition to conventional-staging-flow-chart scheduled by ThoracicSurgery/InterventionalPulmonologyDepartments [within 3 (±1) weeks from standard [18F]F-FDG PET/CT (FDG)]. No changes in patient's management derive from FAPI (Thoracic physician and patient blinded to FAPI results). In pts undergoing radical surgery, histopathology represents the StandardOfTruth. Biopsy and 1-year standard follow-up are used either for patients or anatomical regions not surgically treated. For the current preliminary purpose, only patients who underwent surgery (available pathological results before March23), were included. PET/CT findings were visually defined as positive/negative for T and N, classified according to TNM-Staging_AJCC8thEdition. On a T- and N-based analysis, for both tracers: agreement to pTN,AUC,accuracy-Acc.,sensitivity-Sens.,specificity-Spec.,positive/negative-predictive-value(PPV,NPV) were evaluated; semiquantitative-parameters [SUVmax, SUVmean, SUVmax/SUVmean_ratio and Target-to-background-ratios-TBRs, calculated as TargetLesionSUVmax divided by either SUVmax or mean of healthy-backgrounds (lung/mediastinal-blood-pool,MBP/liver)] were calculated on 60min scans and ROC_AUCs applied. ***Results:*** 23 patients (among 40 to date enrolled) were included (median age:69y; M:F=16:7). Histopathology excluded malignancy in 2/23 cases (1 Actinomyces abscess, 1 fibrocalcified-necrotic lung nodule) and demonstrated: adenocarcinoma in 16, squamous-cell-carcinoma in 5; 4 pT1b, 1 pT1c, 1 pT2, 6 pT2a, 3 pT2B, 6 pT3; 1pNx, 13/23(57%) pN0 whereas 9/23(39%) LNmetastases-LNM (pN1:8/9, pN2:1/9); 100% R0; 11 PL1; 13 LV1. Median(mean±SD, range) were: n°removed LN overall=408, per patient=17(19±12, 2-53); n°LNM overall=40/408(10%) and per patient=0(2±4,0-19); dimension(max, in mm) T=25(31±18,7-68); days between FDG-FAPI 7(10±9,1-30) and between FAPI-surgery=41(46±32, 13-154). On visual analysis (FAPI vs FDG): T:TP.19vs14;FP.1vs1;TN.1vs1;FN.2vs7;AUC.0.702vs0.583;Acc.87%vs65%;Sens.90%vs67%;Spec.50%vs50%;NPV.33%vs12%;PPV.95%vs93%.N:TP.6vs7;FP.1vs3;TN.13vs11;FN.3vs2;AUC.0.798vs0.782;Acc.83%vs78%;Sens.67%vs78%;Spec.93%vs79%;NPV.81%vs85%;PPV.86%vs70%. FAPI and FDG-PET/CT equally correctly staged TN in 7/23(30%) patients. Among the discordant staging cases (16/23, 70%), PET/CT was visually classified as either in favour of FAPI in 9 (5 T; 3 N; 1TandN) or in favour of FDG in 2 (1T, 1N) or equally inferior to pathology in 5 cases (3/5 for T). ROC-AUCs of semiquantitative parameters for T evaluation were respectively (FAPI vs FDG): SUVmax.0.738vs0.595;SUVmean.0.738vs0.595;-SUVmax/SUVmean0.631vs0.786;TBRs. Varied, depending on background, between 0.619 and 0,750 (TBR_Liver_Max) vs between 0.571 and 0.667. ***Conclusion:*** Preliminary results, limited to the surgically-treated cohort, report good performance of [68Ga]Ga-FAPI-46-PET/CT for staging suspected/confirmed LC, overall slightly higher than standard tracer [18F]F-FDG, in particular when using Visual interpretation or e.g TBR_Liver_max. Enrolment and further analyses (whole population, conventional follow-up; lesion-, volume- and immunohistochemical-based analyses; collateral findings) are ongoing.

## EP-0148

### Can [18F] FDG PET/CT parameters Predict Pathological Response in Locally Advanced NSCLC? Findinds from NADIM Study

***R. Jimeno Pernett***[1], *J. Mucientes Rasilla*[1], *J. Gonzalez Larriba*[2], *A. Martinez Martí*[3], *E. Nadal*[4], *N. Viñolas*[5], *J. Bosch Barrera*[6], *A. Insa Mallá*[7], *J. Casal Rubio*[8], *M. Cobo Dols*[9], *R. Bernabe Caro*[10], *M. Mitjavila Casanovas*[1], *V. Calvo de Juan*[1], *M. Provencio Pulla*[1]; [1]*Hospital Universitario Puerta De Hierro, Madrid, SPAIN,* [2]*Hospital Univeristario Clínico San Carlos, Madrid, SPAIN,* [3]*Hospital Universitario Vall d'Hebrón, Barcelona, SPAIN,* [4]*ICO Hospitalet, Barcelona, SPAIN,* [5]*Hospital Clínic Barcelona, Barcelona, SPAIN,* [6]*Instituto Catalán de Oncología Médica de Girona, Barcelona, SPAIN,* [7]*Hospital Clínico Universitario de Valencia, Valencia, SPAIN,* [8]*Hospital Álvaro Cunqueiro, Vigo, SPAIN,* [9]*Hospital Carlos Haya, Málaga, SPAIN,* [10]*Hospital Virgen del Rocío, Sevilla, SPAIN.*

***Aim/Introduction:*** Neoadjuvant chemo-immunotherapy in lung cancer is emerging as the treatment of choice, especially in locally advanced stages, offering high resectability rates, increased progression-free survival, and high rates of pathological complete response. There is little information on the correlation between imaging and pathological response. This aspect is crucial when planning surgery. OBJECTIVEEstablish the relationship between metabolic and pathological response, based on tumor volume parameters, MTV, TLG and SUVmax, in [$^{18}$F]FDG PET/CT. ***Materials and Methods:*** Analysis based on the NADIM study: Patients with locally advanced resectable non-small cell lung cancer (NSCLC) were included. Forty-two patients who received chemotherapy or chemo-immunotherapy prior to radical surgery, and who had initial and post-neoadjuvant [$^{18}$F]FDG PET/CTwere included. The percentage reduction of the semiquantitative parameters before and after neoadjuvant therapy and the residual metabolic

volume in post-neoadjuvant [18F]FDG PET/CT of the lung tumor and the hilar and mediastinal lymph nodes were calculated and compared with the pathological response (complete, major, and incomplete). Statistical analysis was performed using Kruskal-Wallis, Mann-Whitney U, and area under the curve (AUC) to determine the association of the described variables. ***Results:*** The percentage reduction of the quantification parameters and the residual metabolic volume of the lung tumor and the hilar lymph nodes showed statistically significant differences. In the residual metabolic volume, TLG of the lung tumor was better associated with all three classes of pathological response (Kruskal-Wallis, probability: 0.0421), and to differentiate between complete and incomplete response (Mann-Whitney U, p: 0.008239), with an AUC/ROC: 0.7454. In the hilar lymph nodes, TLG was best associated with all three classes of response (Kruskal-Wallis, probability: 0.0189) and to differentiate between complete and incomplete response (Mann-Whitney U, p: 0.00347), with an AUC/ROC: 0.7454. In the percentage reduction of the lung tumor, TLG was best associated with the pathological response (Kruskal-Wallis, probability: 0.0324; Mann-Whitney U p:0.00347; AUC/ROC: 0.7387). In the hilar lymph nodes, MTV was best associated with the response (Kruskal-Wallis, probability: 0.0338; Mann-Whitney U p: 0.01511; AUC/ROC: 0.8034). No significant differences were found in the mediastinum among the types of pathological response. ***Conclusion:*** The percentage reduction of [18F]FDG PET/CT parameters in the lung tumor and hilar region, before and after neoadjuvant chemotherapy or chemo-immunotherapy in patients with locally advanced NSCLC, is able to predict the pathological response. Mediastinal metabolic. ***References:*** Neoadjuvant chemotherapy and nivolumab in resectable non-small cell lung cancer (NADIM): an open-label, multicentre, single-arm, phase 2 trial. ## EP-0149

### Relationship between [18]FDG myocardial uptake and subsequent evolution towards cachexia and outcome in lung cancer patients. Assessment from the retrospective LuCaPET database.

***E. Abenavoli***[1], *A. Grosso*[2], *T. Beyer*[3], *S. Duke*[4], *D. Ferrara*[3], *A. Frille*[5], *S. Gruenert*[6], *M. Hacker*[6], *S. Hesse*[5], *L. Hofmann*[7], *S. Holm*[4], *O. Sabri*[7], *L. Sundar*[3], *J. Yu*[3], *R. Sciagrà*[1];
[1]*Department of Nuclear Medicine, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY,* [2]*Department of Pneumology, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY,* [3]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [4]*University of Copenhagen, Copenhagen, DENMARK,* [5]*University Hospital of Leipzig, Leipgz, GERMANY,* [6]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [7]*University Hospital of Leipzig, Leipgz, AUSTRIA.*

***Aim/Introduction:*** Cachexia is a severe complication of lung cancer with significant prognostic implications. The purpose of the LuCaPET project (ERAPERMED2021-324) is to identify the metabolic connections that pave the way for cachexia to allow earlier therapeutic interventions. Aside from tumour characteristic aberrations of [18F]FDG uptake patterns, myocardial uptake of [18F]FDG is observed in a significant proportion of lung cancer patients. The study assessed a relationship of myocardial [18F]FDG uptake at initial PET/CT imaging and subsequent evolution towards cachexia and overall survival. ***Materials and Methods:*** 189 lung cancer patients who underwent [18F]FDG PET/CT imaging for staging were included. The presence of myocardial uptake was visually evaluated on anonymized attenuation-corrected images, taking care to avoid interference from blood pool activity. The trained observer was blinded to the clinical evolution. The cachexia diagnosis was based on the Fearon criteria [1] that were evaluated approximately six months after staging PET and first line treatment. Moreover, patient outcome was monitored, and cancer-related deaths registered. The time of the latest control or the death date was used as follow-up conclusion. The relationships between myocardial [18F]FDG uptake, cachexia diagnosis and death were analysed using the Fisher exact test. The cachexia-free survival and the overall survival curves of patients with versus without myocardial [18F]FDG uptake were compared using the Kaplan-Meier log rank test. ***Results:*** At initial PET, visible myocardial [18F]FDG uptake was registered in 72 patients. Cachexia was diagnosed in 73 subjects. During the follow-up (17 ± 4 months) 54 patients had died. There was a clear connection between cachexia and patient outcome ($p < 0.0001$). However, a significant relationship between [18F]FDG uptake and cachexia and between [18F]FDG uptake and death was observed as well ($p < 0.03$ and $p < 0.02$, respectively). Most interestingly, the Kaplan-Meier curves showed a significant difference both for cachexia-free status and for overall survival in the patients with versus those without myocardial [18F]FDG uptake: $p < 0.02$ and $p < 0.01$). ***Conclusion:*** Based on these preliminary results, the role of metabolic conditions at staging, such as in this analysis myocardial [18F]FDG uptake, for the evolution towards cachexia and even for patient outcome, can be significant and their early detection could be useful for timely therapeutic and nutritional interventions aimed at preventing cachexia and at improving prognosis. ***References:*** Fearon K, et al. Definition and classification of cancer cachexia: an international consensus. Lancet Oncol. 2011;12:489-95.

### Diagnostic and prognostic value of TOF-18F-FDG PET/CT in patients with malignant pancreatic tumors

***S. Stanzel****, T. Nazerani-Zemann, R. M. Aigner;*
*Division of Nuclear Medicine, Graz, AUSTRIA.*

***Aim/Introduction:*** The aim of this study was to evaluate whether the application of time-of-flight (TOF) in 18F-FDG PET/CT can improve the accuracy in diagnosing malignant pancreatic lesions. Furthermore, we assessed the impact of TOF on image quality and its prognostic value compared to standard PET/CT reconstruction. ***Materials and Methods:*** Eighty-six patients with a histologically proven malignant pancreatic carcinoma were included in this retrospective study and underwent a dual phase (DP) 18F-FDG PET/CT with imaging 30 and 90 min. p.i. A total of 86 pancreatic lesions were assessed by one board-certified nuclear medicine physician and a third-year resident. SUVmax, tumor volume (V), and the RI (retention index) of pancreatic lesions were compared between TOF and standard. Image quality regarding pancreatic lesion demarcation was rated according to a 6-point Likert-type scale. The median follow up was 17.2 mo. The correlation of PET-derived image features and the presence of metastases at the time of PET/CT with overall survival (OS) was assessed. ***Results:***

With TOF, 80/86 tumors were PET-positive compared to 76/86 tumors without TOF resulting in an improvement of 4.7% (4/86). With TOF, V was significantly lower than without TOF (standard, 20.4 $cm^3$ vs. TOF, 16.3 $cm^3$; P < 0.001). In TOF reconstructed images SUVmax was significantly increased (standard, 9.6; TOF, 10.4; P < 0.001), whereas RI was significantly decreased (standard, 42.5% vs. TOF, 38.3%; P = 0.024). Lesion demarcation of pancreatic lesions was excellent (standard, 2.7; TOF, 1.2; P < 0.001) in reconstructed TOF images. The RI without TOF (P = 0.041; cutoff = 38.2%), the V with TOF (P = 0.032; cutoff = 2.0 $cm^3$), and the presence of metastases at the time of PET/CT (P = 0.034) were strongly correlated to OS. ***Conclusion:*** TOF-PET/CT showed an improvement in the diagnosis of malignant tumors compared to imaging without TOF due to better lesion demarcation and improved image quality, which may be useful in treatment planning. In TOF-reconstructed images the lesion volume and the RI was significantly decreased due to better visualization of tumor necrosis and intratumoral heterogeneity. The RI without TOF, the V with TOF, and the presence of metastases at the time of PET/CT correlated significantly with OS. ***References:*** Hausmann D, Bittencourt LK, Attenberger U, et al. Diagnostic accuracy of 18F-choline PET/CT using time-of-flight reconstruction algorithm in prostate cancer patients with biochemical recurrence. Clin Nucl Med 2014;39:e197-e201.

## EP-0151

### Diagnostic and prognostic value of time-of-flight 18F-FDG PET/CT in staging of patients with pancreatic ductal adenocarcinoma using TrueX and Q.Clear reconstruction

***S. Stanzel***, *T. Nazerani-Zemann, R. M. Aigner;*
*Medical University of Graz, Department of Nuclear Medicine, Division of Nuclear Medicine, Graz, AUSTRIA.*

***Aim/Introduction:*** The aim of the present study was to evaluate the impact of time-of-flight (TOF) reconstruction in conjunction with TrueX (=point spread function (PSF)-based algorithm) or Q.Clear (=Bayesian penalised likelihood reconstruction algorithm) on image quality (IQ), lesion detection rate, metabolic tumor volume (MTV), and SUVmax in dual-phase (DP) $^{18}$F-FDG PET/CT in staging of patients with pancreatic ductal adenocarcinoma (PDAC). ***Materials and Methods:*** Seventy-two patients with a histologically proven PDAC were included in this retrospective study and underwent a dual phase (DP) $^{18}$F-FDG PET/CT with imaging 30 and 90 min. p.i. Fifty-five patients had TOF reconstruction in conjunction with TrueX and 17 patients with Q.Clear on two different PET/CT scanners. Standard PET/CT imaging was performed in accordance with the EANM guidelines. A total of 72 pancreatic lesions were assessed by one board-certified nuclear medicine physician and a third-year resident. SUVmax and metabolic tumor volume (MTV) of pancreatic and metastatic lesions were compared between TOF and standard. Lesion demarcation of pancreatic tumors and overall IQ were rated according to a 6-point Likert-type scale. Interrater agreement was assessed. ***Results:*** Forty-one additional lesions in 72 patients were detected using TOF alone (SUVmax, 5.2 [2.6]; MTV, 3.1 $cm^3$ [1.4]). Of these two were pancreatic primary tumors, and 34 metastases (pancreas, liver, lung, adrenal glands, lymph nodes), and 5 were benign. 30/34 metastatic lesions identified with TOF alone led to therapy change in 8 patients. Lesion demarcation of PDAC was excellent (standard, 2.7; TOF, 1.2; P < 0.001) and overall IQ was excellent in reconstructed TOF images (standard, 2.7; TOF, 1.1; P < 0.001). Interrater agreement was good forcombined ratings (1 + 2, 3 + 4, 5 + 6). SUVmax was significantly increased in TOF reconstructed images (standard, 10.3 [7.7].; TOF, 11.2 [7.7]; P < 0.001), whereas there was no significant difference in MTV (standard, 16.2 [29.4] $cm^3$ vs. TOF, 13.0 [12.4] $cm^3$; P = 0.691). ***Conclusion:*** The application of TOF in conjunction with TrueX or Q.Clear seems to be of additional value in detecting pancreatic and small metastatic lesions in patients with PDAC, which has an impact on treatment planning preventing metastatic patients from surgery. TOF with TrueX or Q.Clear impacts image quality and SUVmax presenting more clearly tumor necrosis and tumor heterogeneity compared to standard imaging.

## EP-0152

### Evaluation of Liver Lesions with Diffusion Weighted Imaging PET/MRI in Transarterial Radioembolization Treatment Patients

***A. Kibar***, *F. Aghazada, L. Uslu-Besli, O. E. Sahin, S. Asa, S. Sager, K. Sonmezoglu;*
*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Y90 microsphere transarterial radioembolization therapy (TARE) is a well-known treatment modality for malignant liver lesions, particularly hepatocellular cancer and colon cancer metastases. Pre and post-treatment FDG PET is a useful tool for treatment planning and determination of response. Our aim in this study is to determine the relationship between MRI ADC values of liver lesions before and after Y90 treatment using FDG PET/MRI images. ***Materials and Methods:*** Forty-five patients who were treated with TARE for malignant liver lesions, had FDG PET/MR imaging before and after treatment, and had target lesion/lesions (lesion showing FDG uptake more than healthy liver tissue before treatment) were included in the study. According to PERCIST, patients divided into two groups, responders (23/45) (complete response and partial response) and non-responders (22/45) (stable disease and progressive disease). A maximum of 3 target lesions were selected for each patient. SUXmax, SUVmean, SULpeak, ADCmin , ADCmean values were determined before and after treatment for the lesions. ***Results:*** Mean ADCmean values of responders before and after treatment were 1.15+0.437x10-3 (range: 0.100-2.050x10-3) and 1.519+0.429x10-3 (range: 0.100-2.050x10-3), respectively. Mean ADCmean values of non-responders before and after treatment were 1.258+0.400x10-3 (range: 0.170-1.850x10-3) and 1.367+0.342x10-3 (range: 0.313-1.940x10-3), respectively. . While the change in ADCmean was significant in responders according to the Wilcoxon test (p=0.004), it was not significant in non-responders (p=0.108). However, when we performed the Wilcoxon test on all patients regardless of their response status, we found that ADCmin and ADCmean values increased significantly after treatment (p=0.034, p=0.001, respectively). Changes in mean SUVmax and SUVmean were not associated with change in ADCmean; (r=-0.117, p=0.445, r=-0.149, p=0.328, respectively). ***Conclusion:*** Evaluation of treatment response for Y90 is a crucial part of patient management. The MRI component of PET/MRI provides important information about the response. In our study, we found that there was an increase in ADC values after Y90 treatment, and this increase was higher in those who responded to treatment. We evaluated that ADC values can be used as a parameter in evaluating response to treatment. However SUV and ADC changes were not correlated.

## EP-0153

### Comparison of Tc-99m Mebrofenin Scintigraphy with Other Parameters in Prediction of Patient Status in Y-90 Patients

***A. Kibar***, *S. Asa, F. Aghazada, N. Yeyin, M. Abuqbeitah, K. Sahin, C. Guneren, K. Saglam, B. Ince, S. Sager, K. Sonmezoglu;*
*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Y90 microsphere transarterial radioembolization therapy (TARE) is an evidence-based treatment modality for malignant liver lesions, particularly hepatocellular cancer and colon cancer metastases. Child Pugh score and ALBI score can be used in patient selection and evaluation of patient status before the procedure. In our study, we aimed to investigate the correlation of liver uptake values of patients who underwent Tc99m-mebrofenin scintigraphy before Y90 with other scores, its success in predicting prognosis after treatment, and its relationship with parameters in pre-treatment function evaluation. ***Materials and Methods:*** Dynamic and SPECT/CT imaging were performed in 21 patients who were scheduled for TARE treatment due to malignant liver lesions, after 6.63+1.59 mCi Tc99m-mebrofenin injection. Liver uptake values were calculated. Spearman correlation test were applied to show the relationship of these values with ALBI score, Child-Pugh score, total bilirubin, direct bilirubin, albumin, INR, ALT and AST. In addition, t-test was performed to determine the difference in uptake between those who died and those who did not. ***Results:*** Significant correlation was found between Liver uptake of mebrofenin and total bilirubin, direct bilirubin ($p<0.001$); ALBI score ($p<0.01$) and albumin ($p<0.05$). Although the mean uptake of the patients who died were higher than the uptake of the survivors, this result was not significant (dead patients' mean: 5.3%/min/m2, median: 3.3%/min/m2, standard deviation: 4.9; survivors' mean: 6.1%/min/m2, median : 4.5%/min/m2, standard deviation: 6.5; p: 0.747). Mebrofenin uptake value correlated with other parameters measured before Y90 treatment and was lower on average in patients who died, even though it was not statistically significant in predicting the prognosis before treatment. In addition by looking at the corresponding areas in the mebrofenin scintigraphy, it can be predicted how much of the functional capacity of the liver corresponds to the area where the MAA is given. In this way, benefits can be obtained in patients who have large tumors. While the volume occupied by the MAA was approximately 70% in 3 patients in our study, we found that the function was affected less than 70% in the corresponding areas in the mebrofenin scintigraphy. ***Conclusion:*** Scintigraphic evaluation of Tc99m-mebrofenin uptake appears to be a useful method in predicting liver function, due to its capability of showing segmental function of the liver it may also provide additional information in patients who are planned to be treated with Y90. Prospective studies with large patient groups are needed.

## EP-0154

### Dual-tracer PET/CT protocol with [18F]FDG and [68Ga]Ga-FAPI-46 outperforms single-tracer PET/CT with [18F]FDG in gastrointestinal and head and neck cancer, due to higher tumour to background ratio and larger gross and functional tumour volume.

***Aim/Introduction:*** Fibroblast activation protein (FAP) visualized by positron-emission-tomography (PET) using fibroblast activation protein inhibitor (FAPI) appears to be a promising target for cancer imaging, staging and therapy, providing added value and strength as a complement to [$^{18}$F]FDG in cancer imaging. We recently introduced a combined single session/dual-tracer protocol with [$^{18}$F]FDG and [$^{68}$Ga]Ga-fibroblast activation protein inhibitor (FAPI) for cancer imaging and staging. In the present study malignant tissue visualization, target to background uptake ratios (TBR) as well as gross tumour volume (GTV) and functional tumour volume (FTV) measurement were assessed with single-tracer [$^{18}$F]FDG PET/CT and with dual-tracer [$^{18}$F]FDG&[$^{68}$Ga]Ga-FAPI-46 PET/CT, respectively. ***Materials and Methods:*** 19 patients with head and neck and gastrointestinal cancers received an initial [$^{18}$F]FDG-PET/CT followed by a dual-tracer PET/CT after additional injection of [$^{68}$Ga]Ga-FAPI-46 within the same medical appointment (on average 13.9±12.3 minutes after injection of [$^{18}$F]FDG). Two readers visually compared detection rate of malignant tissue, TBR, GTV and FTV for tumour and metastatic tissue in [$^{18}$F]FDG PET/CT and [$^{18}$F]FDG&[$^{68}$Ga]Ga-FAPI-46 PET/CT. ***Results:*** Diagnostic performance of dual-tracer compared to single-tracer PET/CT was superior in six patients and equal in 13 patients. Mean TBR of tumours and metastasis in [$^{18}$F]FDG&[$^{68}$Ga]Ga-FAPI-46 PET/CTs were mostly higher compared to [$^{18}$F]FDG PET/CT using maximal count rates (CRmax). GTV and FTV were significantly larger, when measured on dual-tracer than on single-tracer PET/CT. ***Conclusion:*** Dual tracer PET/CT with [$^{18}$F]FDG and [$^{68}$Ga]Ga-FAPI-46 showed better visualization of malignant tissue due to a generally higher TBR, larger FTV and GTV compared to [$^{18}$F]FDG-PET/CT in gastrointestinal and head and neck cancer, suggesting that [$^{68}$Ga]Ga-FAPI-46 provides added value in pretherapeutical staging.

## EP-0155

### Surveillance 18F-FDG PET/CT in predicting the prognosis of esophageal cancer patients

***S. Chan***, *C. Tseng, S. Llu;*
*Hualien Tzu Chi Hospital, Hualien, TAIWAN.*

***Aim/Introduction:*** The prognostic value of performing surveillance PET/CT imaging after the conclusion of therapy in esophageal cancer is not well established. This study aimed to evaluate the predictive value of surveillance PET/CT in predicting the prognosis of esophageal cancer patients. ***Materials and Methods:*** This was a retrospective study of 202 biopsy-proven esophageal cancer patients at a single tertiary center. In total, we included 604 surveillance PET/CT scans done after the completion of treatment in this study. Median follow-up from the completion of therapy to surveillance PET scan was 23.15 months (range, 4-134.8 months). A survival benefit was measured using Kaplan-Meier plots with a Mantel-Cox log-rank test. A multivariate Cox regression model was provided with clinical covariates. ***Results:*** Of the 604 PET/CT scans, 234 had positive findings. Overall median survival from the time of the PET/ CT study was 32 months. The median survivals of PET-positive and PET-negative groups differed significantly (survival=12.4 and 55.5 months, respectively; $P < 0.0001$). The subgroup analysis demonstrated that the prognostic value of PET scans performed between 4 and 24 months after treatment ($P < 0.0001$) was more prominent than the scans after 24 months ($P = 0.0006$). However, the predictive value of surveillance PET scans was similar in early-stage patients (stage 1,2) and late-stage patients (stage 3,4). In a multivariate Cox regression model, factors associated with Overall Survival(OS) were PET/CT result ($P = 0.0012$) and chemoradiotherapy ($P=0.0024$).

***Conclusion:*** The result of surveillance 18F-FDG PET/CT is a prognostic marker of overall survival in esophageal cancer patients, regardless of the tumor stage. The predictive power of PET/CT is better in the scans between 4 and 24 months after treatment.

## EP-0156

### A dose optimization study using Visual Grading Regression in [68Ga]-FAPI-46 PET imaging of patients with pancreatic lesions

***T. Nilsson***[1], *P. Rasinski*[1,2], *S. af Burén*[1,2], *Ö. Smedby*[3], *A. Blomgren*[1], *M. Löhr*[2,4], *E. Sparrelid*[5], *T. Tran*[6,7], *R. Axelsson*[1,8], *M. Holstensson*[1,2]; *[1]Department of Medical Radiation Physics and Nuclear Medicine, Karolinska University Hospital, Huddinge, SWEDEN, [2]Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, SWEDEN, [3]Department of Biomedical Engineering and Health Systems, KTH Royal Institute of Technology, Stockholm, SWEDEN, [4]Department of Upper Gastrointestinal Diseases, Karolinska University Hospital, Huddinge, SWEDEN, [5]Division of Surgery and Oncology, Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, SWEDEN, [6]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, SWEDEN, [7]Department of Radiopharmacy, Karolinska University Hospital, Stockholm, SWEDEN, [8]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN.*

***Aim/Introduction:*** The administered activity to patients should be kept as low as reasonably achievable whilst simultaneously result in an image quality good enough to ensure a reliable diagnosis. The aim of this study is to evaluate the feasibility of reducing administered activity in $^{68}$Ga-FAPI-46 imaging while maintaining a satisfactory image quality, with a certainty that it will not affect the radiologist's ability to make a clinical diagnosis. ***Materials and Methods:*** A visual grading assessment was performed on images from ongoing $^{68}$Ga-FAPI-46 PET/CT studies (EudraCT 2020-002568-30; NCT05172310). Ten patients scheduled for surgery due to suspected stomach cancer or desmoplastic tumors of the pancreas were included. The patients were administered with 4.0 MBq/kg ±10% (mean 270 MBq, range 226-309 MBq). PET/CT-Imaging was performed from scull vertex to mid-thigh, 60 minutes post injection in step-and-shoot mode with list-mode enabled. The acquisition time was 4 minutes per bed position. PET-images were statistically truncated and reconstructed to represent images with an administered activity of 1, 2, 3 and 4 MBq/kg. Two radiologists performed a blinded grading of the images in Hermes (Hermes Medical Solutions AB, Stockholm, Sweden). Four image quality criteria were graded on a four-point Likert scale ranging from 1 = Completely certain that the criterion is not fulfilled to 4 = Completely certain that the criterion is fulfilled. Two criteria were defined to assess how discernible and distinct structures belonging to the thoracic cage and the heart were visualized. The other two criteria regarded the disruptive effect of noise and whether the overall image quality was good enough to make a clinical diagnosis. The gradings were analyzed with a mixed-effects ordinal logistic regression using the statistical software R. ***Results:*** Increased satisfaction of the image quality with an increase in activity was observed for all criteria. For the overall image quality, there was no significant difference between 3 MBq/kg and 4 MBq/kg images, whereas the 1 MBq/kg and 2 MBq/kg images were rated significantly ($p<0.05$) lower than the 4 MBq/kg images. For the other criteria, all images with shorter acquisition were rated significantly inferior to the 4 MBq/kg images. ***Conclusion:*** The administered activities can be reduced from 4 to 3 MBq/kg while maintaining satisfactory image quality. Reducing administered activities to 2 MBq/kg or lower is not recommended since it results in images with a low satisfaction level and a significant disruptive effect of noise on the evaluation.

## EP-0157

### The prognostic value of metabolic parameters and heterogeneity index of PET/CT in patients with advanced gastric adenocarcinoma

***Y. Tian***, *T. Zhao, W. Cai, Y. Dong, X. Ma, P. Ma, Q. Zhao; General Hospital of Ningxia Medical University, Yinchuan, CHINA.*

***Aim/Introduction:*** Gastric cancer is one of the most common malignant cancers of digestive system. So finding effective indicators for evaluating the patients' prognosis and curative effect is key to make the best treatment strategy and improve the quality of life. The present study aimed to assess the prognostic value of PET parameters combined with clinical characteristics in patients with advanced gastric adenocarcinoma (AGA). And the prognostic value of PET parameters alone was evaluated on patients with different treatment and different Ki67 levels. ***Materials and Methods:*** 71 patients with advanced gastric adenocarcinoma and without anti-gastric-cancer therapy were included in this retrospective study. Their metabolic parameters and heterogeneity index (HI) were collected and calculated. Furthermore, clinical prognostic indicators were collected. Variables were grouped by cut-off values of Receiver operating curve and the median. Kaplan-Meier method and COX regression analysis for progression-free survival (PFS) and overall survival (OS) were used for survival analysis and evaluate the prognosis. ***Results:*** Survival analysis showed that patients in low value group have longer median PFS and median OS than corresponding high-value group. For all patients with AGA before treatment, HI-2 was the independent risk factor of PFS, while total glycolysis (TLG) was common independent risk factor for both PFS and OS. For patients in different groups, HI-2 also was the independent risk factor for PFS in patients with Ki67<70%, chemotherapy or radiotherapy and combined therapy. While in patients with Ki67≥70% and surgery, it was Maximum standardized uptake value (SUVmax) that correlated with PFS and OS. For clinicopathological factors, CEA and N staging were related to the prognosis, but only N staging was a common independent risk factor for both PFS and OS. ***Conclusion:*** HI-2, TLG and CEA, N staging played main role in the prognosis of all patients with AGA. While in different groups with the simple analysis of PET parameters, HI-2 and SUVmax correlated with PFS and OS

## EP-0158

### Incremental value of 18F-FDG PET-CECT over conventional imaging in evaluation of Gall Bladder Carcinoma.

***P. Singh***, *T. Singhal, P. Kumar, G. Parida, R. Emerson, K. Bishnoi, A. Rehman, K. Kandula, K. Agrawal, S. Patro; AIIMS Bhubaneswar, Bhubaneswar, INDIA.*

***Aim/Introduction:*** Gallbladder carcinoma (GBCa) is one of the most common carcinomas of gastroenteric system with 5-year survival for localized, regional and distant disease being ~69, 28 & 3% respectively. Thus, making accurate staging of GBCa important. Commonly used imaging for evaluation of GBCa include ultrasonography (USG), contrast-enhanced computed-tomography (CECT), magnetic resonance imaging (MRI), and the latest addition to this armamentarium i.e., Fluo-

rine-18-fluorodeoxyglucose (18F-FDG) PET-CECT (1, 2). This study evaluated diagnostic utility of 18F-FDG PET-CECT over CECT in staging GBCa patients ***Materials and Methods:*** This was a retrospective study including patients with GBCa (initial staging, restaging and recurrence-detection) who underwent both anatomical imaging with CECT abdomen-pelvis with HRCT-thorax and 18F-FDG PET-CECT within 10 days of each-other. The difference in staging by both modalities was noted. True positive findings in case of disparities between the two modalities was considered based on follow-up or histopathological examination. ***Results:*** Fifty-seven patients (36-females) were included with median age 55 (range 35-74) years. Of these, 28 were post-cholecystectomy and 29 were treatment-naïve. In the post-cholecystectomy group, local-residual disease/recurrence was seen in 12 patients on 18F-FDG PET-CECT (11 true-positive and 1 false-positive) while CECT detected local disease only in 7 patients (6 true-positive and 1 false-positive). Thus, giving a sensitivity, specificity and diagnostic accuracy of 100%, 94.1% & 96.4% for 18F-FDG PET-CECT compared to 54.5%, 94.1% & 78.6% for CECT, respectively. In treatment-naïve group, PET-CECT increased T-stage in 4/29 (13.7%), T2-T3 in 3 patients and T3-T4 in 1 patient. For nodal-staging PET-CECT upstaged the disease in 10/57 (17.5%) patients, N0-N1 in 2 patients and N0-N2 in 8 patients. Major impact of FDG PET-CT was seen in metastatic disease detection where it upstaged 10/57 (17.5%) patients while additional metastatic lesions were identified in 21 (36.8%) patients compared to CECT alone. Based on FDG PET-CECT findings change in management was observed in 12 (21.1%) patients (table 1).

## EP-0159

### Prognostic value of negative FDG PET/CT in curatively treated colorectal carcinomas with rising CEA levels during surveillance

***A. Suresh***[1], *V. Rangarajan*[2], *N. Purandare*[2], *A. Agrawal*[2], *S. Shah*[2], *A. Puranik*[2], *A. Saklani*[2];
[1]*Tata Memorial Centre, Varanasi, INDIA,* [2]*Tata Memorial Centre, Mumbai, INDIA.*

***Aim/Introduction:*** The purpose of this study was to determine the prognostic usefulness of negative FDG PET/CT in curatively treated non-metastatic colorectal carcinomas with growing CEA levels during surveillance. ***Materials and Methods:*** Between 2013 and 2018, a retrospective audit of 194 colorectal cancer patients (Stage I-III) with rising CEA levels during surveillance and subsequent negative FDG PET/CT (index PET/CT) was performed. Electronic medical records (EMR) were tracked for an average of 45 months (until May 2020). The following variables were audited: lesion site, baseline CEA (ng/ml), treatment (surgery, chemotherapy, and radiotherapy), time interval for CEA level to reach nadir and subsequent rise in CEA warranting PET/CT, additional investigation within 12 months (PET/CT, CECT, MRI, and staging laparoscopy), treatment started on disease detection, and final follow-up. The further investigation was used to determine if the PET/CT true negative (TN) or false negative (FN) index was the gold standard. The prognostic value of FDG PET/CT was estimated in terms of disease-free survival (DFS) and overall survival (OS). ***Results:*** Within 12 months of the initial PET/CT, only 82 of 194 (46%) patients received further investigations. Using Kaplan Meier analysis, stage 3 disease (p-value 0.046), histology of signet ring cell and poorly differentiated adenocarcinoma (p-value 0.001) were found to be poor prognostic variables. A FN index PET/CT (18 of 82, 21.9% mortality) had a median DFS of 4.21 months. Those with TN index PET/CT (64 of 82) had just 4 confirmed recurrences, one of whom was alive at the conclusion of the research period. CEA levels at the time of the index PET/CT were observed to indicate poor outcome (hazard ratios of 1.01 for OS, p-value 0.001; 1.006 for DFS, p-value 0.004). The median CEA level for FN index PET/CT was 9.7 ng/ml, while for TN index PET/CT it was 6.3 ng/ml. ***Conclusion:*** In a subset of patients with poor survival, stage 3, greater tumour grade at diagnosis and higher CEA levels during post-curative surveillance may have a falsely negative PET/CT. A prospective study should be considered to determine which additional investigation might be useful for declaring an index PET/CT true negative or positive for prognosis, as well as to identify a CEA level cut-off that could predict the false negativity of an index PET/CT in order to initiate further management.

## EP-0160

### Comparison of 18F-FAPI-04 and 18F-FDG PET/CT in detecting the primary tumor and metastatic lesions in patients with initial pancreatic ductal adenocarcinoma

***L. Lin****, G. Wang, X. Su;*
*Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

***Aim/Introduction:*** Gallium-68($^{68}$Ga)-labeled fibroblast activation protein inhibitor (FAPI) PET/CT imaging has been widely used in the diagnosis of several malignant tumor. Compared with $^{68}$Ga, $^{18}$F has a great practical and economic advantage. There is very little data on the use of $^{18}$F-AlF-NOTA-FAPI-04 ($^{18}$F-FAPI-04) for detecting pancreatic ductal adenocarcinoma (PDAC). Herein, this prospective research aimed to evaluate performance of $^{18}$F-FAPI-04 in delineating the primary tumor and staging in initial pancreatic ductal adenocarcinoma, as well as to compare it with $^{18}$F-FDG PET/CT. ***Materials and Methods:*** Fifty-nine patients with histologically proven PDAC via fine need biopsy were enrolled in this study for staging. Each patient underwent both $^{18}$F-FAPI-04 and $^{18}$F-FDG PET/CT within 3-5 days. Lesion detectability and the tracer uptake of lesions were evaluated visually and semi-quantitatively by measuring maximum standardized uptake value of tumor ($SUV_{max}$). Normalized $SUV_{max}$ (the original $SUV_{max}$ of lesion divided by the $SUV_{max}$ of descending aorta). Histopathological findings or follow-up data such as laboratory examinations and radiographic scans were served as a standard of reference. ***Results:*** The fifty-nine enrolled patients (median age: 63 years; range: 58-70 years) included forty-one males and eighteen females. Of fifty-nine patients, twenty-one underwent Whipple surgery or pancreatoduodenectomy. For primary tumor detection, $^{18}$F-FAPI-04 PET/CT has a great advantage with 100% of positive rate compared to $^{18}$F-FDG PET/CT [37.3% (22/59)] due to higher both original $SUV_{max}$ (16.0 vs. 8.1, $p<0.0001$) and normalized $SUV_{max}$ (10.25 vs. 4.24, $p<0.0001$). For PDAC staging, $^{18}$F-FAPI-04 PET/CT was superior to $^{18}$F-FDG PET/CT in detecting more metastatic lesions, including portal vein tumor thrombus and metastatic lesions in lymph nodes, liver, peritoneum, and bone, particularly for lymph nodes, peritoneal and liver metastasis ($p<0.0001$, 0.0001 and $p= 0.028$, respectively), resulting in up-regulating TNM staging in seven patients compared with $^{18}$F-FDG PET/CT. Furthermore, univariate and multivariate analysis showed that the maximum diameter of primary tumor and lymph nodes metastasis were independent risk factors for PDAC staging by $^{18}$F-FAPI-04 PET/CT. ***Conclusion:*** $^{18}$F-FAPI-04 PET/CT outperformed $^{18}$F-FDG PET/CT in visualizing the primary tumor and metastatic lesions in initial PDAC and might be a promising imaging method for PDAC diagnosis and staging.

## EP-0161

### Comparison of Diagnostic Efficacy of 18FAl-NOTA-FAPI-04 and 18F-FDG PET/CT for recurrence and/ormetastasis in patients with gastric cancer

***K. Zheng***, *Y. Zhang, H. Ye, A. Xie;*
*Hunan Cancer Hospital (the Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University), Changsha, CHINA.*

***Aim/Introduction:*** This study aimed to compare the efficacy of $^{18}$FAl-NOTA-FAPI-04 PET/CT with that of $^{18}$F-FDG PET/CT for detecting tumor recurrence and/or metastases in gastric cancer. ***Materials and Methods:*** This single-center retrospective clinical study was performed at the Hunan Cancer Hospital between December 2020 and June 2022. The participants underwent both $^{18}$FAl-NOTA-FAPI-04 and $^{18}$F-FDG PET/CT within 14 days. Histopathologic examination, morphologic imaging, and/or follow-up imaging were used as a reference for the final diagnosis. The SUVmax and back-ground ratios (TBR) of the recurrence and metastases between $^{18}$F-FDG and $^{18}$FAl-NOTA-FAPI-04 PET/CT were compared using the paired-sample t test. The comparisons of sensitivity and specificity for the detection of gastric cancer between $^{18}$FAl-NOTA-FAPI-04 and $^{18}$F-FDG were performed with McNemar's test. ***Results:*** Forty-eight patients (27 males, aged 29 - 68 years) with gastric cancer after curative resection (27 with adenocarcinoma, 17 with signet ring cell carcinoma and 4 with mucinous adenocarcinoma) were included in the study. $^{18}$FAl-NOTA-FAPI-04 accumulation was significantly higher than that of $^{18}$F-FDG in cancer recurrence (SUVmax, 11.65 vs 3.48, P< 0.01; TBR, 12.93 vs 2.94,P< 0.01), lymph node metastases (SUVmax, 13.35 vs 2.75, P=0.001; TBR, 14.60 vs 2.00, P< 0.01), and distant metastases (SUVmax, 12.07 vs 2.98, P < 0.01; TBR, 13.66 vs 2.36, P < 0.01). Based on patients, $^{18}$FAl-NOTA-FAPI-04 PET/CT showed a higher sensitivity (97.4% vs 71.1%, p = 0.002) in suspected cancer recurrence and/or metastases compared to $^{18}$F-FDG PET/CT. ***Conclusion:*** Our findings indicate that $^{18}$FAl-NOTA-FAPI-04 PET/CT outperformed $^{18}$F-FDG PET/CT in the diagnosis in suspected recurrence and/or metastasis of gastric cancer.

## EP-0162

### Prognostic value of semiquantitative [18F]F-FDG PET/MRI parameters in patients with a newly diagnosed Pancreatic Adenocarcinoma

***G. Mango***[1], *P. Bartoletti*[2], *S. Serafini*[3], *R. Guastella*[4], *C. Berto*[5], *S. Da Pozzo*[6], *M. Sitara*[2], *G. Fichera*[7], *C. Giraudo*[2], *L. Evangelista*[2];
[1]*Nuclear Medicine, Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [2]*Nuclear Medicine Unit, Department of Medicine DIMED, University of Padua, Padua, ITALY,* [3]*General Surgery Padua University Hospital, Padua, ITALY,* [4]*Hepato-Pancreato-Biliary Surgery and Liver Transplantation Unit, Padua University Hospital, Padua, ITALY,* [5]*Radiology Unit, Department of Medicine DIMED, University of Padua, Padua, ITALY,* [6]*Radiology Unit, Azienda Ospedaliera di Padua, Padua, ITALY,* [7]*Pediatric Radiology Unit, Padua University Hospital, Padua, ITALY.*

***Aim/Introduction:*** To assess the prognostic value of semiquantitative [18F]F-FDG PET/MRI parameters in a cohort of patients with a newly diagnosed pancreatic adenocarcinoma ***Materials and Methods:*** From 2017 to 2022, [18F]F-FDG PET/MRI scans performed in patients with a newly diagnosed pancreatic adenocarcinoma were retrospectively collected. PET and MRI images were visually and semi-quantitatively analyzed. In particular, SUVmax, SUVmean, TLG and MTV of the primary tumor for PET images were calculated. The apparent diffusion coefficient (ADC) of the primary tumor was computed by using diffusion weighted sequences (DWI). Data about outcomes were recovered in terms of progression and overall survival (PFS and OS, respectively), by using the electronic chart. t-Student test, ROC curves and Kaplan-Meier analysis were used to test the correlation between PET/MR parameters and outcomes. ***Results:*** Data from 30 patients (median age: 70 years and male/female ratio: 22/8) were considered. Seventeen patients (57%) were treated with neoadjuvant chemotherapy, 2 (6%) were treated with neoadjuvant chemotherapy followed by surgery and 11 (37%) underwent primary surgical approach. After a median follow-up time of 29 (4-98) months, data from 28 (91%) patients were recovered. Fifteen (54%) had a progression of disease. Moreover, 12 (40%) died. Only SUVmean was significantly higher both in patients with a progressive disease and in those who died than their counterpart (4.3±1.9 vs. 3.1±1.1 and 4.4±1.9 vs. 3.2±1.2, respectively; p<0.05). At ROC analysis, the value of 3.38 for SUVmean was used as the best cut-off point (sensitivity: 75%, specificity: 75%). Indeed, at Kaplan-Meier analysis, patients with a SUVmean <3.38 in the primary tumor have a better prognosis than those with a SUVmean > 3.38 (chi-square: 5.6; log rank p<0.05). ***Conclusion:*** In pancreatic adenocarcinoma patients, our results suggest SUVmean of the primary tumor should be further investigated as a valuable prognostic factor in pancreatic ductal adenocarcinoma. ***References:*** - Diagnostics 2020; 10: 952;- Molecular Imaging and Biology 2021; 23, 456-466- Clinical Radiology 2020;75: 478.e1-478.e11- Clinical radiology 2022; 77: 436e442

## EP-0163

### Head-to-head comparison of 18F-FDG and 68Ga-DOTA-FAPI PET/CT for staging and therapeutic evaluation of esophageal cancer

***W. Hou***, *R. Tian;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Precise staging and therapeutic evaluation are essential for the management and preoperative evaluation of esophageal cancer. We aimed to compare the value of $^{68}$Ga-FAPI and $^{18}$F-FDG PET/CT for the detection of lesions and therapeutic evaluation of esophageal cancer. ***Materials and Methods:*** Thirty-seven patients with pathologically proven advanced esophageal cancer were enrolled from February 2022 to December 2022. $^{18}$F-FDG and $^{68}$Ga-FAPI PET/CT were obtained within 1 week for treatment evaluation and preoperative evaluation. Treatment strategies, SUVmax, TBR, and therapeutic evaluation were recorded. A paired Wilcoxon signed-rank test was used to compare differences between two scans. Sensitivity, specificity, PPV, NPV, and accuracy were also evaluated. ***Results:*** Among the enrolled patients, all primary lesions (100%) showed significant uptake in two scans. TBR (4.29-7.05, 5.93 vs. 14.66-23.49, 14.66, P<0.001), but not SUVmax (12.21-18.00, 15.19 vs. 13.83-19.58, 16.17, P=0.792), of FAPI was significantly higher than that of FDG in primary lesions. As for regional lymph nodes, FDG showed more lymph nodes than FAPI (0-1.5, 1 vs. 0-1,1, P=0.002). Finally, 19 (51.4%) patients underwent surgeries, and 10 patients achieved primary pathological complete response, among which 8 patients achieved pathological complete response. Compared with FDG, FAPI PET presented a higher sensitivity but a lower accuracy for residual primary tumor detection (88.89% vs. 66.67% and 56.67% vs. 38.89%, respectively). Additionally, FAPI PET showed higher sensitivity and accuracy than FDG PET (50.00% vs. 25.00% and 50.00% vs. 25.00%, respectively) for lymph node metastasis. ***Conclusion:*** Both FDG and FAPI can show the primary lesions of

esophageal cancer, but FDG can show more lymph nodes. As for therapeutic evaluation, FDG is superior to FAPI in residual primary tumor detection, but inferior to FAPI in evaluating lymph node metastasis.

## EP-0164

### Comparison of 3D Voxel-Based Yttrium-90 Dosimetry Quantification of using Y90 PET/CT Versus Y90 SPECT/CT

***N. Kokabi***[1,2], *M. Xing*[3], *D. Brandon*[2], *H. Dabbous*[2], *J. R. Galt*[4], *I. Sethi*[2], *S. Kappadath*[5], *A. Villalobos*[1], *D. M. Schuster*[2];
[1]*University of North Carolina School of Medicine, Chapel Hill, NC, UNITED STATES OF AMERICA,* [2]*Emory University School of Medicine, Atlanta, GA, UNITED STATES OF AMERICA,* [3]*University of North Carolina School of Public Health, Chapel Hill, NC, UNITED STATES OF AMERICA,* [4]*Emory University School of Medicine, Atalnta, GA, UNITED STATES OF AMERICA,* [5]*MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Post-Y90 dosimetry analysis has been used to ensure delivery of tumoricidal dose. However, there are fundamental differences in quantification of Y90 dose using positron emission tomography (PET)/computed tomography (CT) versus single-photon emission computed tomography (SPECT)/CT. The aim of this study was to further investigate these differences and identity potential correlations between these quantitative methods. ***Materials and Methods:*** In a prospective single-center clinical trial with the primary aim of evaluating the feasibility of scout activity for resin-based Y90 for treatment planning (NCT04172714) (1), patients with treatment naïve HCC were recruited. A secondary aim of the study was to evaluate dosimetry differences between Y90 PET/CT and Y90 SPECT/CT. All patients underwent both PET and SPECT after scout and therapeutic resin-based Y90. 3D voxel-based dosimetry for the targeted tumors and the perfused liver segment/lobe was performed with MIM Sureplan® (MIM Software, Cleveland, OH, USA) using cumulative scout and therapeutic activities. Paired t-tests were used compare matched dosimetry variables. Pearson linear correlations between corresponding parameters calculated by PET and SPECT were also performed. All statistical analyses were performed using SPSS v.28 (IBM, Armonk, NY, USA). ***Results:*** Overall, N=30 patients with 33 tumors were treated. Calculated mean tumor dose (TD) was significantly higher on PET compared to SPECT/CT (493 Gy vs. 366 Gy) p<0.001). Similarly, minimum TD (197 Gy vs. 179 Gy), maximum TD (966 Gy. 591 Gy), mean tumor dose to top 30% (TD-V30) (594 Gy vs. 408 Gy), and 70% (TD-V70) of tumor volume (405 Gy vs. 326 Gy) were significantly higher on PET/CT versus SPECT/CT (p-values<0.001). Moreover, there was a strong linear correlation between corresponding tumor dose variables on PET/CT and SPECT/CT (r coefficients>0.9; p-values<0.001). Conversely, mean non-tumoral liver dose (NTLD) was significantly higher on Y90 SPECT/CT vs. PET/CT (181 Gy vs. 103 Gy; p<0.001). Similarly, minimum, maximum, V-30 and V-70 NTLD were higher on SPECT versus PET, although only statistically significant for V-70 (p<0.001). There was also a strong linear correlation between mean NTLD on SPECT/CT vs. PET/ CT (r=0.9; p<0.001). ***Conclusion:*** PET/CT and SPECT/CT demonstrated significant differences in Y90 dose quantification. Specifically, tumor doses were observed to be higher on Y90 PET/CT than on Y90 SPECT/CT, while non-tumoral liver doses were observed to be lower on Y90 PET/CT than on Y90 SPECT/CT. Further investigation on post-Y90 PET/CT and SPECT/CT thresholds is warranted to ensure optimal treatment response. ***References:*** 1. Kokabi et al. JVIR. 2022.

## EP-0165

### 2-[18F]FDG PET/CT derived semi-quantitative parameters in predicting response to chemoradiation in oesophageal squamous cell carcinoma

***L. Lemos***[1], *I. Lopo*[1], *P. Lapa*[1,2], *G. Costa*[1,2];
[1]*Nuclear Medicine Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,* [2]*Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL.*

***Aim/Introduction:*** Oesophageal squamous cell carcinoma has been shown to display high response rates to chemoradiation therapy (CRT), which has become a mainstay of the management of locally advanced cancers. 2-[$^{18}$F]FDG is extensively used in staging and response assessment of this cancer. This study aims to assess if 2-[$^{18}$F]FDG PET/CT derived semi-quantitative parameters at initial staging can help predict response to CRT, improving patient stratification. ***Materials and Methods:*** We retrospectively reviewed 885 studies of patients with oesophageal cancer who underwent 2-[$^{18}$F]FDG PET/CT in our department between January/2013-March/2023. Of these studies, we selected those with histology-proven squamous cell carcinoma who underwent neoadjuvant or definitive chemoradiation therapy and whose staging and response assessment studies were done in the same PET/CT scanner. For each staging study, semi-automatic tumour volumes of interest (VOI) were defined using an SUV threshold of 2.5g/ml, and SUVmax, SUVmean, SUVpeak, metabolically active tumour volume (MTV) and total lesion glycolysis (TLG) were extracted. Response to CRT was defined as a decrease of 30% or greater of SUVmax in the known lesions and the appearance of no new lesions in the post-therapy scans. Demographical and histological data were also collected. ***Results:*** Fifty-six patients fulfilled inclusion criteria, 87.5% of which were male, with an average age of 63.8±9.53 (39-88) years. Median FDG-PET/CT derived metrics were as follows: SUVmax 15.26 (IQR 11.28-19.63); SUVpeak 11.24 (IQR 8.78-15.55); SUVmean 5.83 (IQR 4.85-6.68); MTV 29.48 cm$^3$ (IQR 17.56-46.12); TLG 155.83 (IQR 89.98-318.52). The mean time between the completion of CRT and the response assessment PET/CT was 46.7±15.97 (4-90) days. Eighty-two per cent responded to CRT, whereas 18% showed no response or displayed progressive disease. Only MTV showed statistically significant differences between responders and non-responders (Mann-Whitney U, p=0.049). MTV was also the only parameter differentiating responders from non-responders (AUC 0.700, p=0.049). An MTV cut-off value of 41.1 cm$^3$ was able to predict the absence of response with 80% sensitivity, 76% specificity and 95% negative predictive value. However, although response in the post-chemoradiation study was associated with a higher overall survival (p=0.036), no differences in survival were found for this MTV cut-off value (p=0.070). ***Conclusion:*** In this study, 2-[$^{18}$F]FDG PET/CT-derived MTV at initial staging accurately predicted the response to chemoradiation therapy in squamous cell carcinoma of the oesophagus.

## EP-0166

### Role of whole-body FDG PET/CT in the detection of peritoneal metastases in cases of gastroesophageal junction adenocarcinoma

***S. Thakur***, *N. Purandare, V. Rangarajan, A. Agrawal, S. Shah, A. Puranik, C. Pramesh, G. Karimundackal, K. Prabhash, S. Jinwani, D. Niyogi, R. Kumar;*
*Tata Memorial Hospital, Mumbai, INDIA.*

***Aim/Introduction:*** In this study, our aim was to evaluate the diagnostic role of 18-Flouride (18F) Flourodeoxyglucose (FDG) Positron Emission Tomography/Computed Tomography (PET/CT) for the detection of peritoneal metastases in cases of Sieverts III Gastroesophageal Junction Adenocarcinoma. To

study the relations of standardised uptake value (SUV), total lesional glycolysis (TLG), metabolic tumour volume (MTV), and FDG PET-positive nodal disease with the occurrence of peritoneal disease. And to assess the incremental value of FDG PET/CT over CT. ***Materials and Methods:*** This was a single institution, institutional review board (IRB) approved retrospective study with a study population of biopsy-proven Sieverts III gastroesophageal junction adenocarcinoma patients who were non-metastatic on initial work-up and who underwent diagnostic staging laparoscopy. There were a total of 86 cases with proven gastroesophageal junction adenocarcinomas who had undergone FDG PET CT for pretreatment initial staging. The peritoneal metastases detected on [18F]FDG-PET/CT were compared with the gold standard staging laparoscopy. Sensitivity, specificity, positive predictive value, and negative predictive value calculated using a 2x2 table were used to assess the diagnostic role of FDG PET/CT for the detection of peritoneal metastases. Logistic regression was used to identify factors related to the presence or absence of peritoneal metastases. ***Results:*** Sensitivity: 45%Specificity: 93.94%Positive Predictive value:69.23%Negative Predictive value: 84.93%Accuracy:82.56% Logistic regression showed that SUVmax Primary, TLG, MTV, and SUV Max nodes had no significant effect on the presence or absence of peritoneal metastases.Only one out of nine true positive cases showed isolated PET-positive findings, indicating no incremental benefit of PET/CT over CT. ***Conclusion:*** PET/CT has limited sensitivity but good specificity for the detection of peritoneal metastases in cases of adenocarcinoma of the gastroesophageal junction. The limited sensitivity and PPV make it a less appropriate tool for screening of peritoneal metastases and thus have a limited role in the detection of peritoneal metastases in initial staging. There is no incremental benefit of PET/CT over CT for the detection of peritoneal metastases. The metabolic parameters of PET/CT showed no relation to the occurrence of peritoneal disease.

## EP-0167

### 18F-AlF-NOTA-FAPI PET/CT in the evaluation of gastric, liver, and pancreatic cancer and comparison with 18F-FDG PET/CT

***w. xu***, *J. Cai, Y. Pang, L. Sun, H. Chen;*
*Department of Nuclear Medicine & Minnan PET Center, Xiamen Cancer Center, The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, China, xiamen, CHINA.*

***Aim/Introduction:*** Previous studies have reported the use of $^{68}$Ga-labeled FAPIs for imaging of various types of cancer, but reports of $^{18}$F-labeled FAPIs are limited. we aimed to investigate the diagnostic accuracy of $^{18}$F-AlF-NOTA-FAPI PET/CT in gastric, liver, and pancreatic cancer, and compared the results with those of $^{18}$F-FDG PET/CT. ***Materials and Methods:*** This study was approved by the Institutional Review Board and was registed at ClinicalTrials.gov (NCT05430841). Patients with confirmed gastric, liver, and pancreatic malignancies who underwent concurrent $^{18}$F-FDG and $^{18}$F-AlF-NOTA-FAPI PET/CT between July 2022 and January 2023 were retrospectively analyzed. The PET/CT findings were confirmed by histopathology or radiographic follow-up. $^{18}$F-FDG and $^{18}$F-AlF-NOTA-FAPI uptakes and tumor-to-background ratios were compared using the Wilcoxon signed-rank test. McNemar's test was used to compare the diagnostic accuracy between the two scans. ***Results:*** Our cohort consisted of 112 participants, including 49 patients with gastric cancer, 39 with liver cancer, and 24 with pancreatic cancer. $^{18}$F-AlF-NOTA-FAPI PET/CT with a dose of 151.7-222 MBq demonstrated satisfactory image quality and lesion detectability. Regarding the lesion-based diagnostic accuracy, $^{18}$F-AlF-NOTA-FAPI PET/CT showed higher sensitivity than $^{18}$F-FDG in detecting primary tumor (96% [66/69] vs. 78% [54/69]), local recurrence (92% [23/25] vs. 56% [14/25]), involved lymph nodes (61% [140/230] vs. 38% [88/230]), bone and visceral metastases (98% [350/358] vs. 47% [168/358]) (all $p < 0.05$). Compared with $^{18}$F-FDG, $^{18}$F-AlF-NOTA-FAPI PET/CT upstaged 17 patients' TNM staging among all treatment-naïve patients (17/69, 25%). ***Conclusion:*** $^{18}$F-AlF-NOTA-FAPI PET/CT is superior to $^{18}$F-FDG PET/CT for detecting primary tumors, local recurrence, lymph nodes, bone and visceral metastases in gastric, pancreatic, and liver cancers, with higher uptake in most primary and metastatic lesions.

## EP-0168

### Diagnostic Efficiency of F-18 Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography in Malignant Biliary Obstruction

***Z. Koç***[1], *P. Özcan*[1], *E. Reyhan*[2], *M. Yaldız*[3], *E. Üçbilek*[4];
[1]*Mersin University Hospital Nuclear Medicine Dpt., Mersin, TÜRKIYE,* [2]*Mersin University Hospital Surgical Oncology Dpt., Mersin, TÜRKIYE,* [3]*Mersin University Hospital Pathology Dpt., Mersin, TÜRKIYE,* [4]*Mersin University Hospital Gastroenterology Dpt., Mersin, TÜRKIYE.*

***Aim/Introduction:*** Malignant Biliary Obstruction is a diagnostic challenge as it leads the patients to a process that ends up with futile surgical procedure (1). The primary lesion might most of the times be so subtle that the morphological imaging methods cannot depict (2). Thus functional cross sectional imaging by means of F-18 FDG PET/CT has clear advantage of high lesion/nonlesion contrast. However there is limited number of studies in this field (3). The aim was to determine the role of F-18 FDG PET/CT in the diagnosis of Malignant Biliary Obstruction. ***Materials and Methods:*** 45 patients (25 M, 20 F; mean: 64 years) with suspicion of malignant biliary obstruction were included in the study. Retrospective evaluation of the patients F-18 FDG PET/CT images compared to surgery and pathology results were performed. The area under curve and ROC analysis was obtained as a result. ***Results:*** The mean primary tumor lesion size was 29,8 mm and the SUVmax level was 13,7. 31 patients that had additional metastatic site with mean SUVmax level of 11,0. Pathological diagnosis was obtained in 31 patients which are malignant in 29. Five of the patients died during the disease course. The cut off level that was obtained from the ROC curves was 7.5 for SUVmax but not significant (p=0.2636) (Graph 1) (Table 1). Although the sensitivity and specificity levels were not high the imaging resulted in the clear advantage of pointing out correct diagnostic sampling site. ***Conclusion:*** F-18 FDG PET/CT guided surgical resections/interventions and management revealed high rate of successful diagnostic procedures. These results are encouraging for the determination of Malignant Biliary Obstruction by means of F-18 FDG PET/CT. ***References:*** 1. ## EP-0169

### Caracterization of pancreatic lessions by PETMR and evaluation of the diagnostic efficacy of this technique correlated to anatomopathological findings

***C. A. Field Galán***, *L. Delgado Niño, I. Plaza de las Heras, R. de Teresa Herrera, P. Recarte Ortega, L. García Cañamaque; HM Hospitales Madrid, Madrid, SPAIN.*

***Aim/Introduction:*** Patient analysis with 18FFDG PETMR as an initial study of pancreatic lesions by comparing the findings of different image tests, morphologic and metabolic, correlating histological results of fine-needle (PAAF) puncturing of the lesion by means of echoendoscopy and/or anatomopathological analysis with SUV value. ***Materials and Methods:*** From 11-2014 until 12-2019 a retrospective analysis was carried out in 152 patients with pancreatic lesions, exclusión criteria patients with an initial study other than PET-MR and with metástasis. PETMR was required as an initial staging study for the presence of one or more pancreatic lesions detected in other diagnostic test. Studies were carried out in Siemens BiographmMR, FDG iv dose 296 +/- 37MBq. Fasting 4-6h, glucemia control levels <200mg/dl and resting 45min +/- 10 minutes prior acquisition.A localized pancreatic MR study was performed in all patients (sequences T2 sagittal, HD coronal and axial, diffusion, T1 axial, T1axial FS, T1 dynamic axial) and a complete whole body post-iv contrast study with simultaneous acquisition of 4 minute PET beds, sequences T2 HASTE and T1 VIBE. Imaging analysis was carried out jointly by a nuclear medicine specialist and a radiologist. The anatomopathological result (AP) was checked of both echo-endoscopy PAAF and the surgical piece of those patients who had undergone surgery. ***Results:*** PETMR study gave the following results and correlated the SUVmax of PET and MR findings with the presurgical hystology. Correlation SUVmax of the152 patients with presurgical histology was: 79 adenocarcinoma: media SUVmax: 6,6 (range 0-15,5)22 TNEp: media SUVmax:1,68 (0-8,39).26 TPMI media SUVmax 2,81(0-11,4). 9 atypia media SUVmax: 2,70 (0-13,5) 6cysts:media SUVmax: 0,48 (rango 0-3,8)2 cystoadenoma seroso: media SUVmax: 1,98 (0-3,96) 8 negative: media SUVmax: 1,60 (0-5,47) Results of the79 histologicaly confirmed adenocarcinomas 94% (74/79) MR suggestive of adenocarcinoma.84% (66/79) sugestive by PET(SUVmax).Of the NET 50% (11/22) sugestive by MR 59% (13/22) suggestive of G1NET by PET 100% concordancy with AP. 27% (6/22) NET G2/G3 by PET positive100% concordant with AP. 10% (2/22) not concordant with PET (highSUVmax): 2 NET low grade with avidity for FDG.2 serous cystadenomas confirmed by AP:1 suspiciousby PET and MR. 26 TMPI confirmedby AP. 42% (11/26) suggestiveby MR 54% (14/26) by PET. 6 pancreatic cysts confirmedby AP 67% (4/6) suggestive by MR.100% suggestive by PET .17 patients left were non conclusive. ***Conclusion:*** The use of PETMR increased diagnostic efficacy in caracterizing pancreatic lessions when correlating with anatomopathological findings.

## EP-0170

### Diagnostic Value of Integrated PET/MR in Postoperative Recurrence of Liver Cancer

***X. Chenjie***;
*Hangzhou Universal Medical Imaging Diagnostic Center, hangzhou, CHINA.*

***Aim/Introduction:*** Compare the diagnostic value of 18F-FDG PET/MR and PET/CT in postoperative recurrence of liver cancer. ***Materials and Methods:*** Retrospective analysis of 92 patients with suspected recurrence of liver cancer, systemic 18F-FDG PET/CT examination and upper abdominal PET/MRI scan were retrospectively analyzed. Taking pathological results and clinical diagnosis as the gold standard, the image quality of PET/CT and PET/MRI was compared. Diagnostic efficiency. ***Results:*** A total of 43 patients relapsed. The sensitivity, specificity and accuracy of PET/CT are 45.15%, 90.45% and 78.38% respectively; the sensitivity, specificity and accuracy of PET/MRI are 100%, 84.61% and 94.59% respectively, and the diagnostic accuracy is significantly higher than that of PET/CT (P). <0.05). There were 15 cases of CT and PET image misalignment in PET/CT, the fusion of PET/MR images was accurate, and there were significant statistical differences between the two sides (P<0.05). A total of 25 cases of liver cancer invaded the biliary tract, 16 cases had bile duct obstruction with obstructive jaundice, 10 cases of PET/CT showed signs of obstruction, and PET/MR could clearly show that there were significant statistical differences between the two sides. In 25 cases, lymph node metastasis occurred, both of which can be clearly displayed. 20 cases of vascular invasion occurred, of which 14 invaded the portal vein or lower vena cava, which can be clearly distinguished by both devices; another 12 cases invaded abdominal trunk, superior mesenteric artery, splenic blood vessels, superior mesenteric veins, etc. PET/MR clearly diagnosed 8 cases than PET/CT, with significant statistical differences (P<0 .05). In 15 cases of invasion of lung, bone, adrenal gland, brain and other organs, PET/MR was more clearly diagnosed than PET/CT, with significant statistical differences (P<0.05). ***Conclusion:*** The sensitivity, specificity and accuracy of PET/MRI in diagnosing recurrence after liver cancer are higher than PET/CT. The image ratio is more accurate, which can better judge biliary metastasis, lymph node metastasis, peripheral structure and other organ invasion.

## EP-0171

### Prospective Intra-individual comparison of 68Ga-FAPI and 18F-FDG PET/CT in the diagnosis and staging of gastric malignancies

***M. Jayanthi***, *S. BATCHU, A. Sekaran, G. VENKAT RAO, N. Duvvur; AIG Hospitals, Hyderabad, INDIA.*

***Aim/Introduction:*** Studies have shown a wide range of sensitivity and specificity for 18F-FDG PET/CT in gastric adenocarcinomas because of some limitations, including physiological uptake in the stomach wall, uptake due to gastritis, early gastric cancers, inherent low metabolic activity of certain histologic types like non-intestinal diffuse type, mucinous carcinoma, poorly differentiated and signet-ring cells carcinomas. In this study, we aimed to evaluate the diagnostic accuracy of 68Ga-FAPI PET/CT and 18F-FDG PET/CT in lesion based comparison for primary lesion, loco-regional disease and distant organ metastases of primary gastric adenocarcinomas ***Materials and Methods:*** We performed an intra-individual prospective comparison of 68Ga-FAPI and 18F-FDG PET/CT in 47 patients with suspected or proven gastric adenocarcinoma who presented for either diagnosis (n=9) or initial staging (n=38) of disease. Lesion detection and SUVmax were compared between the two radiotracers and are compared with the histopathologic results and/or follow up imaging, which was used as the reference standard ***Results:*** Total of 47 patients were analyzed of which 9 were referred for the purpose of diagnosis and 38 for the staging purpose. 68Ga-FAPI PET/CT showed higher SUVmax and higher sensitivity in detection / evaluation of primary tumors, particularly in early gastric malignancies. Also 68Ga-FAPI PET/CT has higher negative predictive value in the background of chronic gastritis or polypoidal disease. Absence of 68Ga-FAPI tracer uptake is consistent with absence of malignant cells in the

multiple repeated histopathology results.68Ga-FAPI PET/CT study detected lymph nodal disease, liver, peritoneal, lung and skeletal metastases with higher sensitivity and confidence intervals for the SUVmax values of two radiotracers in identifying these lesions showed that the difference is statistically significant. ***Conclusion:*** Compared with 18F-FDG PET/CT, 68Ga-FAPI PET/CT showed higher sensitivity in detection of primary lesions due to very low background uptake, absence of physiological or inflammatory uptake in the stomach. Also, 68Ga-FAPI PET/CT significantly outperformed 18F-FDG PET/CT in detection of loco-regional disease and distant organ metastases in lesion based comparison resulting in upstaging in 26% of patients

## EP-0172

### The value of 18F-FDG PET/MR radiomics features in predicting regenerative nodules (RN), dysplastic nodules (DN) and small hepatocellular carcinoma nodules (sHCC) in cirrhosis

***Y. Xu***;
*Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To explore the value of 18F-FDG PET/MR radiomics features in predicting regenerative nodules (RN), dysplastic nodules (DN) and small hepatocellular carcinoma (sHCC) in cirrhosis. ***Materials and Methods:*** The clinical data and PET/MR imaging data of 256 patients with liver cirrhosis were collected, including 88 cases of RN, 76 cases of DN and 92 cases of sHCC. Pathological and clinical diagnosis results serve as the gold standard for diagnosis. We used AK software to extract the most relevant imageomics features for tumor classification, and randomly divided the two groups of images into training set (70%) and test set (30%). The maximum correlation and minimum redundancy (mRMR) and minimum absolute shrinkage and selection operator (LASSO) methods were used to select features from 2200 features extracted from MR and PET, and finally eight best features were retained. Multivariate logistic regression analysis was performed using the radiomics features and clinical variables to establish the prediction model. The receiver operating characteristic (ROC) analysis is used to evaluate the prediction model. ***Results:*** The established PET/MR imaging features have good prediction efficiency for the recognition of RN, DN and sHCC, and there are significant differences. The AUC of the training group and the validation group were 0.898 (95% CI: 0.756-0.961), 0.872 (95% CI: 0.773 - 0.985) and 0.915 (95% CI: 0.788 - 0.979), respectively. ***Conclusion:*** The prediction model of PET/MR radiomics features can be used as an auxiliary method to predict regenerative nodules (RN), dysplastic nodules (DN) and small hepatocellular carcinoma nodules (sHCC) in cirrhosis. It can also provide objective basis for accurate clinical diagnosis and individualized treatment, and has important guiding significance for clinical treatment.

## EP-0173

### The Detection Value of 18F-FDG PET/MR for Small Hepatocellular Carcinoma

***X. Chenjie***;
*Hangzhou Universal Medical Imaging Diagnostic Center, hangzhou, CHINA.*

***Aim/Introduction:*** To explore the value of 18F-FDG PET/MR systemic imaging in the detection of small hepatocellular carcinoma and the formulation of treatment plans. ***Materials and Methods:*** Retrospective analysis of PET/MR and PET/CT imaging of 89 patients with small hepatocellular carcinoma before treatment. On the same day, whole body 18F-FDG PET/CT imaging and PET/MR imaging were performed. Taking pathological and clinical diagnosis as the gold standard, the differences in detection rates and treatment plans of small hepatocellular carcinoma were compared. ***Results:*** 89 patients with small liver cancer, a total of 98 small liver cancer lesions, PET/MR detected all lesions, 90 correct diagnosis, PET/CT detected 43 lesions, 31 correct diagnosis, with significant statistical differences (P<0.01). Among them, 20 lesions were PET-MR positive, while PET-CT was negative; another 36 lesions were negative for both equipment PET intake. Compared with PET/CT, PET/MR changed the diagnosis results of 45 (50.6%) patients. ***Conclusion:*** PET/MR is of high value for the detection of small hepatocellular carcinoma, which is significantly better than PET/CT, but some small hepatocellular carcinoma still needs to enhance MR diagnosis.

## EP-0174

### Application value of 18F-FDG PET/MR in postoperative metastasis and restating of gastric cancer

***S. Yun***;
*Hangzhou Panoramic Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

***Aim/Introduction:*** To explore the value of 18F-FDG PET/MR systemic imaging in postoperative metastasis detection and restating of gastric cancer. ***Materials and Methods:*** The postoperative PET/MR and PET/CT imaging of 94 patients with gastric cancer were retrospectively analyzed. On the same day, whole body 18F-FDG PET/CT imaging and PET/MR imaging were performed, taking pathological and clinical diagnosis as the gold standard to compare the differences in the detection rate and restating of metastatic focal. ***Results:*** n 94 patients with gastric cancer surgery, 51 patients with distant metastases were found, with a total of 469 lesions, including 210 lymph node metastasis, 35 peritoneal implant metastasis, 30 Intrahepatic metastasis, 11 intracerebral metastasis, 5 intrapulmonary metastasis and 178 bone metastasis. The detection rate of lymph node and intestinal implant metastasis between the two devices is consistent. PET/MR found 56 more lesions than PET/CT in 28 patients, with significant statistical differences ($\chi 2=28.86$, P<0.01); 20 of them were PET-MR positive, while PET-CT was negative, including 5 brain metastasis and 15 liver metastasis; in addition There were 36 lesions and both devices with negative PET intake, but MR was diagnosed with metastasis, including 4 brain metastasis, 5 liver metastasis and 27 bone metastasis. The detection rate of PET/MR for liver, brain and bone metastasis is significantly higher than that of PET/CT ($\chi 2=30.00$, 18.33, 29.22, P<0.01). PET/CT found 20 more lesions than PET/MR, with significant statistical differences, which are lung and peritoneal implant metastasis; of the 35 lung and peritoneal implant metastasis, 10 have obvious FDG intake, 22 lesions have no intake, and 3 lung metastases are positive for PET-MR, while P ET-CT is negative. Through PET/MR examination, a total of 15 patients changed the stage of PET/CT, with significant statistical differences ($\chi 2=16.30$, P<0.01). ***Conclusion:*** PET/MR is of high value for postoperative metastasis and restating of gastric cancer. The detection rate of craniocerebral, liver and bone metastasis is higher than that of PET/CT, and CT-assisted diagnosis is still needed for lung and peritoneal lesions.

## EP-0175

### Comparative analysis of early and late-phase of [18F] F-Fluorocholine PET/CT adquisition in the assessment of hepatocellular carcinoma

***D. Rivas-Navas***, *J. Fernández-Fernández, E. Triviño-Ibáñez, J. Villa-Palacios, A. Rodríguez-Fernández;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this work is to analyze the differences observed between early and late-phase of [$^{18}$F]F-fluorocholine PET/CT (FCH-PET/CT) acquisition in hepatocellular carcinoma (HCC). ***Materials and Methods:*** We performed a longitudinal, retrospective observational study that included HCC patients who underwent FCH-PET/CT study with early (15 minutes) and late-phase (60 minutes) acquisitions from January 2017 to December 2022. FCH-PET/CT images were analyzed visually and semi-quantitatively, including SUL, MTB (MTVxSUVmean), and SUVratio (SUVmax/SUVliver) parameters. The intensity of uptake, signal-to-background ratio, and quantification parameters were compared between early and late acquisition. ***Results:*** Forty patients were included (mean age: 59.50±10.99 years, 90% male). FCH-PET/CT was positive in 32/40 patients (80%). All findings were visualized in both early and late-phase acquisitions. In the visual analysis, 16/32 (50%) showed higher uptake intensity and/or signal-to-background ratio in early-phase images, while the remaining 50% showed better visualization in late-phase images. The comparative analysis of quantification parameters showed significant differences between early and late-phase acquisitions: SULmax (13.70±3.09 vs. 15.39±3.20, p<0.001), SULpeak (10.19±2.44 vs. 11.17±2.48, p<0.001), SULmean (7.32±1.74 vs. 8.09±1.76, p<0.001) and SULmax of healthy liver (7.81±1.59 vs. 8.94±1.65, p<0.001). ***Conclusion:*** In the assessment of HCC, early and late-phase of FCH-PET/CT acquisition, while showing no significant differences in visual analysis, have significantly higher quantification parameters in late-phase acquisition.

## EP-0176

### Impact of [18F]F-Fluorocholine PET/CT in the management and prognosis of hepatocellular carcinoma.

***D. Rivas-Navas***, *J. Fernández-Fernández, E. Triviño-Ibáñez, J. Villa-Palacios, A. Rodríguez-Fernández;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this work is to evaluate the clinical impact of [$^{18}$F]F-fluorocholine PET/CT (FCH-PET/CT) in the management of hepatocellular carcinoma (HCC) and to analyze the prognostic value of quantification parameters. ***Materials and Methods:*** We performed an observational and retrospective study that included patients with HCC who underwent an FCH-PET/CT study between January 2017 and December 2022. Clinical, biochemical, imaging, and treatment parameters were collected. FCH-PET/CT images were analyzed visually and semiquantitatively, including SUL, MTV, TLG, MTB (MTVxSUVmean), and SUVratio (SUVmax/SUVliver) parameters. The impact of the results on the classification on the Barcelona Clinical Liver Cancer (BCLC) and therapeutic approach were analyzed. Finally, a regression model was adjusted to identify predictors of survival (overall survival [OS] and progression-free survival [PFS]). ***Results:*** Fourty patients were included (mean age: 59.50±10.99 years, 90% men). Ninety percent had cirrhosis, with alcoholic etiology in 45% of cases, and BCLC stage: 0 in 5%, A in 37.5%, B in 25%, and C in 30%. FCH-PET/CT was positive in 33/40 (82.5%) patients, detecting the presence of new lesions in 10/40 (25%) cases. It modified the initial therapeutic approach in 4/40 (10%) patients. 9/40 (22.5%) patients died, with BCLC stage (p=0.04) and MTV (p=0.030), TLG (p=0.014), and MTB (MTB (p=0.014) parameters being significantly associated with mortality. The median PFS was 29.0 months, and the median OS was 34.9 months. Cox regression for PFS showed that BCLC stages (HR=12.76; p<0.01) and MTV>150 (HR=6.14; p=0.032) were independently associated factors with PFS. ***Conclusion:*** FCH-PET/CT is a promising approach in identifying patients with HCC with a worse prognosis, MTV along with BCLC classification being the main factor related to the probability of tumour progression.

## EP-0177

### The prediction value of metabolic parameters of 18F-FDG PET/CT for risk stratification of hypermetabolic gastrointestinal stromal tumors

***L. Zhang***, *W. Cao, Y. Ding, Y. Liu, Y. Deng, H. Chen;*
*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

***Aim/Introduction:*** Most high-risk gastrointestinal stromal tumors (GISTs) are positive uptake of $^{18}$F-FDG. However, some of the GISTs with hypermetabolism are non-high risk based on surgical pathology after curative resection, and hypermetabolic GIST accompanying necrosis and hemorrhage tend to have significant heterogeneity. This study aimed to evaluate the value of various metabolic parameters of $^{18}$F-FDG PET/CT for predicting the risk stratification for hypermetabolic GIST. ***Materials and Methods:*** We retrospectively analyzed 42 hypermetabolic GIST patients who underwent $^{18}$F-FDG PET/CT before curative resection as initial treatment at two centers from 2010 to 2023. Intratumoral-metabolic heterogeneity (heterogeneity index, [HI] and heterogeneity factor, [HF]) and conventional metabolic parameters (standardized uptake value [SUV], metabolic tumor volume [MTV], and total lesion glycolysis [TLG]) of the lesions were determined. MTV and TLG were calculated based on fixed threshold of $SUV_{max}$ at 2.5-3.5, and percentage threshold of SUVmax at 40%-60%. HI = SUVmax/SUVmean and HF was the absolute value of linear regression slope calculated by the least square method from the different thresholds of the ROI (HF1: fixed threshold of SUVmax; HF2: percentage threshold of SUVmax). GISTs were divided into non-high-risk group and high-risk group. The area under the curve (AUC) was used to evaluate the predictive ability of factors for risk stratification. ***Results:*** This study included 42 patients with GIST in hypermetabolism of the $^{18}$F-FDG PET/CT ($SUV_{max}$ > 3.5), including 20 (47.6%) patients with non-high-risk and 22 (52.4%) patients with high-risk. Location, maximum tumor diameter, mitotic count, Pathological features (necrosis or hemorrhage), MTV (2.5, 3.0, 3.5), TLG (2.5, 3.0, 3.5), HI (2.5, 3.0, 3.5), HF1, MTV (40%, 50%, 60%), TLG (40%, 50%, 60%) and HF2 in the high-risk group were significantly higher than those in the non-high-risk group (all P<0.05). To construct the preoperative prediction model, location, maximum tumor diameter, and metabolic parameters (MTV3.0, TLG2.5, HI3.0, HF1) were chosen for logistic regression analyses. In multivariate logistic regression analyses, MTV3.0 (P=0.025, OR: 17.34), location (P=0.05, OR:7.09), and maximum tumor diameter (P=0.029, OR=9.07) were independently correlated with risk stratification. The AUC of the mathematical model of MTV3.0 + location+ maximum tumor diameter was 0.926 compare to the AUC of MTV3.0 was 0.805 (P<0.05). ***Conclusion:*** Various metabolic parameters derived from $^{18}$F-FDG PET/CT were higher in high-risk GIST. MTV3.0, location and maximum tumor diameter were independent risk factors for risk stratification, and the mathematical model could predict risk stratification more effectively for patients with hypermetabolic GIST preoperatively.

## EP-0178

### Prospective study of the diagnostic value of 68Ga-FAPI-04 PET/CT for gallbladder cancer: comparison with 18F-FDG

***L. Liu***, *Y. Huang, Q. Liu, D. Xu;*
*The Second Affiliated Hospital of Chengdu Medical College (China National Nuclear Corporation 416 Hospital), Chengdu, CHINA.*

***Aim/Introduction:*** $^{18}$F-fluorodeoxyglucose (FDG) PET/CT may sometimes not be the best choice for imaging tumors of the digestive system. In contrast, the recently developed tracer $^{68}$Ga-FAPI-04, which targets fibroblast activation protein (FAP), has shown great potential in the evaluation of a wide range of tumors. Studies have indicated its promising alternative to $^{18}$F-FDG in the evaluation of digestive system tumors particularly. The purpose of this study was to investigate the value of $^{68}$Ga-FAPI-04 comparing with $^{18}$F-FDG PET/CT in patients with gallbladder cancer (GBC), including the ability to assess primary tumors, distant metastases, lymph nodes, and peritoneal metastases in patients with GBC and the impact on clinical staging management. ***Materials and Methods:*** This prospective study included 17 patients who underwent ultrasound or MRI and were considered to have primary GBC or recurrence after treatment. All patients underwent $^{68}$Ga-FAPI-04 and $^{18}$F-FDG PET/CT within one week. Final histopathology, imaging, and follow-up results were used as reference standards. Shapiro-Wilk assessment of normal distribution of continuous variables. The Wilcoxon-rank test was used to compare the difference in tumor/background organ ratio (TBR) values and maximum standardized uptake values (SUVmax) between $^{68}$Ga-FAPI-04 and $^{18}$F-FDG in primary tumors, distant, lymph nodes, and peritoneal metastases, Pearson was used for correlation analysis. ***Results:*** A total of 17 patients were included, of whom 13 patients with primary tumors of GBC were positive for $^{68}$Ga-FAPI-04 (100% detection rate), while $^{18}$F-FDG detected 12 of them (92% detection rate). $^{68}$Ga-FAPI-04 was more sensitive than $^{18}$F-FDG in detecting distant metastases (100% VS. 81%), lymph node metastases (99% VS. 94%) and peritoneal metastases (100% VS. 19%) of GBC. $^{68}$Ga-FAPI-04 had higher SUVmax for distant metastases (9.34 ± 4.45 VS. 6.65 ± 3.41, $p < 0.001$) and lymph nodes (8.97 ± 3.63 VS. 6.86 ± 4.00, $p < 0.001$) than $^{18}$F-FDG. There was no significant difference in the uptake of the two tracers in the primary tumors, but the TBR values were significantly higher in $^{68}$Ga-FAPI-04 than in $^{18}$F-FDG (18.24 ± 8.20 VS. 5.21 ± 3.29, $p = 0.001$). $^{68}$Ga-FAPI-04 identified far more peritoneal metastases than $^{18}$F-FDG. Finally, the staging of four patients was revised because of the$^{68}$Ga-FAPI-04 results. ***Conclusion:*** $^{68}$Ga-FAPI-04 is more advantageous than $^{18}$F-FDG in detecting primary tumors, distant metastases, lymph node metastases, and peritoneal metastases in GBC with higher SUVmax and TBR. $^{68}$Ga-FAPI-04 is more promising for staging of GBC.

## EP-0179

### Impact Of FDG PET CT On Management Of Patients With Treatment Naive HCC Intended For Local Surgical/ Ablative Or Embolisational Therapies

***M. SARMA***, *B. S T, W. Jose;*
*Amrita Institute of Medical Sciences and Research, Cochin, INDIA.*

***Aim/Introduction:*** 2-deoxy-2-[fluorine-18]fluoro-D-glucose ($^{18}$F-FDG) PET CT has shown mixed utility in the detection of primary Hepatocellular cancer (HCC) with sensitivities of around 55-64%. FDG PET CT is more useful in detection of regional and distant extrahepatic metastases. We intended to study the impact of FDG PET CT on those patients intended for local management of treatment naïve primary HCC (local surgeries/ablative or embolisational therapies). ***Materials and Methods:*** FDG PET CT scans of 61 consecutive patients of HCC acquired between 2010 and 2020 who were intended for local surgical/ablative or embolisational therapies were retrospectively reviewed to look for change in management following the findings in FDG PET scan. Data on initial plan, findings on FDG PET CT, subsequent management, change in management if any and the reason of change in management were collected. ***Results:*** There was overall change in management in 18 out of 61 patients (29%). Most of the patients plan changed to systemic therapy because of detection of metastatic lesions (10 out of 18 patients). 2 patients plan changed to palliative therapy. In 2 patients, TACE was done instead of surgery while in another 2 patients plan was changed to extended hepatectomy. In another 2 patients, the initial plan of surgery was dropped and patient was lost to subsequent management. Detection of distant metastases (7 out of 18 patients), portal vein involvement (4 out of 18), IVC thrombus (1 out of 18 ), lymphnodal metastases (2 out of 18) and other lobe of liver involvement (4 out of 18 patients) on FDG PET CT were the reasons leading to management changes. ***Conclusion:*** Inspite of its low sensitivity of detecting primary HCC, FDG PET can bring about change in management in patients intended for local surgeries/ablative or embolisational therapies .

## EP-0180

### Diagnostic role of FAPi PET/CT in the detection of peritoneal metastases in cases of stomach and gastroesophageal junction adenocarcinoma

***S. Thakur***, *V. Shukla, M. Manikandan, S. Arvind;*
*Mahamana Pandit Madan Mohan Malviya Cancer Centre, Varanasi, INDIA.*

***Aim/Introduction:*** In this study, our aim was to evaluate the role of 18-flouride (18F) fibroblastic protein inhibitor (FAPi) Positron Emission Tomography/Computed Tomography (PET/CT) for the detection of peritoneal metastases in cases of gastric adenocarcinoma and Sieverts III gastroesophageal junction adenocarcinoma. ***Materials and Methods:*** This was a single institution retrospective study with a study population of biopsy-proven adenocarcinomas involving the stomach and gastroesophageal junction sent to us for baseline staging scans. There were a total of 90 histopathologically proven cases who had undergone FAPi PET/CT for pretreatment baseline evaluation. A composite gold standard of visual assessment of the peritoneum, either by staging laparoscopy or during gastrectomy or CT imaging findings, was taken for comparison of peritoneal metastases found on FAPi PET imaging. Sensitivity, specificity, positive predictive value, and negative predictive value calculated using a 2x2 table were used to assess the diagnostic role of FAPi PET/CT for the detection of peritoneal metastases. ***Results:*** True positives were defined as those that demonstrated a noticeably enhanced uptake of FAPi, tested positive during staging laparoscopy or surgery, or displayed obvious peritoneal metastasis characteristics on CT imaging. 39 of these were present. True negatives were defined as those with no substantial FAPi uptake, no imaging signs of peritoneal metastases on CT, and negative staging laparoscopy or surgical results for peritoneal metastases. These 44 examples were discovered. Seven patients were classified as false negatives because staging laparoscopy or surgery revealed peritoneal metastases even though there was no appreciable increase in FAPi uptake and no imaging abnormalities on CT. No cases that were positive

on FAPi PET and negative on staging laparoscopy, surgery, or CT and could be labelled as false positives were found. Sensitivity: 84.7%, Specificity: 100%, Positive Predictive Value: 100%, Negative Predictive Value: 86.2%, Accuracy: 92% ***Conclusion:*** For the detection of peritoneal metastases in patients of stomach cancer and Sievert III gastroesophageal junction adenocarcinoma, FAPi PET/CT offers good sensitivity and great specificity. With good sensitivity and excellent positive predictive value, it can prove to be a helpful tool for the screening of peritoneal metastases and, consequently, for the detection of peritoneal metastases in the baseline evaluation of adenocarcinoma of the stomach and gastroesophageal junction.

## EP-0181

### Role of 99mTc-Mebrofenin SPECT/CT in preoperative determination of global and segmental liver function

***A. Bakos***[1], *T. Czékus*[1], *I. Farkas*[1], *L. Libor*[2], *Z. Mikó*[1], *S. Nagy*[1], *R. Német*[1], *L. Pávics*[1], *G. Sipka*[1], *S. Urbán*[1], *M. Bukva*[3], *Z. Besenyi*[1];
*[1]University of Szeged Nuclear Medicine Department, Szeged, HUNGARY, [2]University of Szeged Department of Surgery, Szeged, HUNGARY, [3]University of Szeged Department of Immunology, Szeged, HUNGARY.*

***Aim/Introduction:*** The resectability of primary and metastatic liver tumors depends on sufficient functional future liver remnant (FLR) after surgery. Insufficient residual liver remnant results post-hepatectomy liver failure (PHLF), which is the major cause of liver resection mortality. $^{99m}$Tc-mebrofenin hepatobiliary scintigraphy has been demonstrated to predict PHLF. The dynamic $^{99m}$Tc-HBS (hepatobiliary scintigraphy) with delayed SPECT imaging have limited accuracy of the study for segmental function. The aim of our study was to determine the role of dynamic SPECT/CT. ***Materials and Methods:*** 30 patients (18 males, 12 females, mean ages: 62 years, 24-83 years) were involved into the study based on the following criteria: extended liver resection is indicated, clinically proven compensated liver function (according to MELD score and ICG-R15), surgery is not contraindicated anesthetically. Dynamic SPECT imaging was performed for 60 minutes after intravenous administration of $^{99m}$Tc-mebrofenin with 3.2 minutes data collection. Low-dose CT was performed in order to delineate liver segments and for attenuation corrected post processing. Counts were measured in each segmented VOI (liver, liver lobes, blood pool, total field of view) from each SPECT set, and three time-activity curves were generated. The most commonly used cutoff value for FLR filtration for predict PHLF: 2,69 %/min/m$^2$. If the FLR filtration was <2.69%/min/m$^2$, parenchyma modulation was performed, after that a control $^{99m}$Tc-mebrofenin SPECT/CT examination was done. ***Results:*** In overall 30 patients the global liver filtration ( mean: 5.74 %/min/m$^2$±2,44 ) significantly correlated with clinical score: MELD (r=0,43; p<0,01) and with ICG-R15 (r=0,38; p=0,05). In 19/30 patients the measured FLR filtration was sufficient (mean: 4,12 %/min/m$^2$± 1,01), in 11/30 patients the FLR filtration was insufficient (mean: 1.45±0,68 %/min/m$^2$). In these patients the FLR filtration increased significantly (mean: 3,84±1,94%/min/m$^2$, p<0,005) after parenchyma modulation. Ninety day- postoperative mortality was 10% (3/30). One patient died intraoperatively, 1 patient died because of Takotsubo-cardiomyopathy and one patient died because of surgical complication. ***Conclusion:*** The use of $^{99m}$Tc-mebrofenin dynamic SPECT/CT plays an important role in the preoperative planning of extended liver resections to determine global and segmental liver function.

## EP-0182

### Diagnostic Performance of [18F]PSMA-1007 PET/CT on Hepatocellular Carcinoma: a Prospective Clinical Study

***K. Michalski***[1], *F. Reiter*[2], *A. Kosmala*[1], *P. E. Hartrampf*[1], *S. E. Serfling*[1], *T. A. Bley*[3], *A. Geier*[2], *A. K. Buck*[1], *R. A. Werner*[1], *A. Weich*[2];
*[1]University hospital Würzburg - Department of Nuclear Medicine, Würzburg, GERMANY, [2]University hospital Würzburg - Internal Medicine II, Würzburg, GERMANY, [3]University hospital Würzburg - Department of Diagnostic and Interventional Radiology, Würzburg, GERMANY.*

***Aim/Introduction:*** A high expression of prostate-specific membrane antigen (PSMA) is not limited to prostate cancer but can be found on other tumor entities, such as hepatocellular carcinoma (HCC), and could possibly be used for theranostic purposes. Our aim was to investigate the diagnostic potential of the hepatobiliary excreted radiotracer [$^{18}$F]PSMA-1007 on initial staging of HCC. ***Materials and Methods:*** This is a preliminary analysis of an ongoing prospective clinical study (NCT05547919). Five patients with treatment-naïve, histopathological proven HCC underwent [$^{18}$F]PSMA-1007 positron emission tomography (PET) with an unenhanced low-dose computed tomography (CT). All scans were analyzed visually and quantitatively. We assessed SUVmax of the primary tumor and SUVmean of non-affected liver parenchyma and calculated tumor-to-background-ratios (=SUVmax HCC/SUVmean liver, TBR) for each patient. In addition, we correlated local PSMA-positive tumor volume (using a lesion based 50%-threshold approach) with the tumor volume as assessed with contrast-enhanced CT. Presence of local lymph node and distant metastases was noted for [$^{18}$F]PSMA-1007 PET/CT and compared to the results of contrast-enhanced CT of the trunk and magnetic resonance imaging of the upper abdomen. ***Results:*** All primary tumors showed visually a high tracer uptake, which was confirmed on quantitative analysis with a mean SUVmax 37.2 ± 13 (range: 25.2 - 55.5) and a mean TBR 6.1 ± 5.5 (range: 2.6 - 17). CT-based tumor volume in the liver (294.2 ml ± 353.8 ml; range: 8.6 - 856.4 ml) correlated significantly with PSMA-positive tumor volume (132,3 ml ± 131.4 ml; range: 1.1 - 325 ml; Pearson's r = 0.94, p = 0.0188). [$^{18}$F]PSMA-1007 PET/CT did not reveal new distant metastatic lesions compared to contrast enhanced CT. In one patient local lymph node metastases were considered PSMA-negative. ***Conclusion:*** [$^{18}$F]PSMA-1007 can be used for depiction of untreated HCC and shows a high TBR compared to unaffected liver parenchyma. These preliminary results need to be confirmed in further patients of this prospective study.

## EP-0183

### Gallium-68 Prostate-Specific Membrane Antigen (68Ga-PSMA) PET Metabolic Metrics in Patients with Hepatocellular carcinoma with and without Hepatis B Infection

***N. Nyakale***[1,2], *L. M. Harry*[2], *C. Aldous*[3], *A. Maes*[4], *C. van de Wiele*[5], *M. M. Sathekge*[6,7];
*[1]Department of Nuclear Medicine, Sefako Makgatho Health Sciences University and Dr George Mukhari Academic Hospital, Pretoria, SOUTH AFRICA, [2]Department of Nuclear Medicine, University of Kwa-Zulu Natal, Durban, SOUTH AFRICA, [3]Department of Genetics, College of Health Sciences, University of KwaZulu Natal, Durban, South Africa., Durban, SOUTH AFRICA, [4]Katholieke University Leuven, Kortrijk, BELGIUM, [5]Ghent University, Ghent, BELGIUM, [6]Department of Nuclear Medicine, University of Pretoria and Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA, [7]Nuclear Medicine Research Infrastructure (NuMeRI), Pretoria, SOUTH AFRICA.*

***Aim/Introduction:*** Hepatitis B virus (HBV) is the most common cause of chronic liver infection, with most patients developing hepatocellular carcinoma (HCC). 68Ga-PSMA-PET/CT has recently been shown to contribute to the staging and management of HCC. The aim of the study was to investigate the value of 68Ga-PSMA-PET metabolic parameters in patients with HBV with and without HBV. ***Materials and Methods:*** Maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), metabolic tumor volume (MTV) and total lesion activity (TLA) were obtained on 68Ga-PSMA-PET/CT of patients with HCC. Correlation analysis and comparison between groups HBV positive versus negative patients was assessed using non-parametric tests. ***Results:*** There were 12 patients (3 men, 9 women), mean age 45.5 yrs (range 31-56 yrs) studied.The SUVmax values demonstrated a trend for higher SUVmax values in patients with HBV as opposed to HBV negative patients (p=0.070, 31.2(SD:13.2) versus 16.6(SD:10.1) respectively. We could not demonstrate a significant correlation between HBV infection and TLA (p=0.662). ***Conclusion:*** The relationship between 68Ga-PSMA-PET metabolic parameters in the differentiation of HCC patients with HBV and without HBV may warrant further exploration as a potential prognostic tool.

## EP-0184

### Prognostic Value of F18-FDG PET-CT in Patients With Localized Oesophageal Cancer Treated With Neoadjuvant Chemoradiation: The Use of Hopkins Criteria for Treatment Response Assessment

***N. Bin Essa***, *A. Alderaibi, M. Hawkins, J. Bomanji, S. Vöö;*
*University College of London Hospital,*
*London, UNITED KINGDOM.*

***Aim/Introduction:*** Response assessment to definite neoadjuvant chemoradiotherapy (NACRT) of oesophageal cancer is centered on the role of 18F-FDG PET-CT (FDG-PET). Despite the introduction of various (semi-)quantitative measures, the differentiation between residual disease and post-therapy inflammatory change on FDG-PET remains challenging. The goal of the study was to evaluate the Hopkins criteria, a 5-point scale assessment of FDG-PET images, in assessing response to treatment in patients with oesophageal cancer following NACRT. ***Materials and Methods:*** This is a prospective, single-centre study on patients with histologically-proven, localised stage IIA-IIIA, T1-3N0-2M0 oesophageal cancer who were referred to NACRT of curative intent. FDG-PET scans were performed prior and on a 3-montly cycle up to 12 months following NACRT. Follow-up FDG-PET images were evaluated for residual disease using an assessment scale based on the Hopkins Criteria (HC): HC grade 1 (HC1), SUVmax<blood pool; HC2-3, focal uptake of SUVmax<liver or diffuse uptake >liver; HC4, focal uptake>liver and HC5, focal uptake of intense uptake. Scores of HC1-3 were considered to represent non-residual local disease, whereas scores of HC4-5 were interpreted as residual/recurrent disease. Chi-square and Fisher-Freeman-Halton exact-test were used to assess the agreement between the HC grade and gold-standard 1-year clinical follow-up endoscopy/surgery with histological confirmation. Kappa-coefficient was used to assess the interobserver variability. ***Results:*** Of a total of 20 patients, 7/20 (33.3%) were scored as HC1-3 and complete metabolic response on follow-up FDG-PETs, while 13/20 (66.6%) were scored as HC4-5 and indicative of residual or recurrent disease. All HC4-5 cases were confirmed positive for residual/recurrent disease at follow-up. Although 2 HC3 cases proved to be recurrent disease on follow-up, the site of recurrence was outside the level of the assessed primary site of disease. There has been a substantial interobserver agreement regarding the HC staging (p<0.05). Importantly, HC staging significantly outweighed SUVmax (p<0.05), as a solitary measure in assessing disease recurrence. ***Conclusion:*** HC grading proves to be a robust assessment of residual disease in patients with oesophageal cancer following curative NACRT.

## EP-0185

### The Evaluatiȯn Of Relationship Between F18 Fdg Pet/Ct Parameters And Sarcopenia İn Esophagus Can

***M. ACAR TAYYAR***[1], *M. ÖNER TAMAM*[1], *G. B. BABACAN*[1], *M. ŞAHİN*[1], *H. ÖZÇEVİK*[2], *N. GÜRDAL*[3];
[1]*University of Health Sciences, Prof. Dr. Cemil Tascioğlu City Hospital of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*University of Health Sciences, Hamidiye Faculty of Nuclear Medicine, Istanbul, TÜRKIYE,* [3]*University of Health Sciences, Prof. Dr. Cemil Tascioğlu City Hospital of Radiation Oncology, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** This study aimed to evaluate the relationship between semiquantitative metabolic parameters of the tumour, adipose tissue and sarcopenia in PET/CT imaging in esophageal cancers and investigate their effects on overall survival(OS). ***Materials and Methods:*** Between January 2015 and August 2022, 120 patients with esophageal carcinoma who had pre-treatment PET/CT were retrospectively analyzed. Age, gender, body mass index(BMI), primary tumour PET parameters(SUVmax , SUVmean , MTV, TLG), L3 vertebra level muscle surface area(LMA), psoas major muscle PET and CT parameters, C3 vertebra level muscle surface area(CMA), sternocleidomastoid muscle(SCM), PET and CT parameters, visceral and subcutaneous fat tissue PET and CT parameters from the retroperitoneal and abdominal regions, respectively, from the L4-L5 level, and the sarcopenia muscle index were calculated. Using Skeletal Muscle Index(L3 vertebral level muscle surface area / patient height squared; SMI)patients with lower than 45.4 $cm^2/h^2$ in males, 34.4 $cm^2/h^2$ in females were considered sarcopenic. ***Results:*** A strong correlation found between LMA and CMA(p:0.001 r:0.732). CMA was also significantly lower in sarcopenic patients (p:0.025).The surface area of psoas major and SCM muscles found correlated with both LMA and CMA(p:0.001). Subcutaneous fat tissue SUVmax values were higher in sarcopenic patients than non-sarcopenic patients. SCM MTV, SCM TLG, psoas major MTV and SMI found to be significantly lower in patients with distant metastases(p:0.024, p:0.019, p:0.045, p:0.039 respectively). Cox regression analysis performed and higher primary tumour SUVmax, TLG and MTV values found as poor prognostic factors (p=0.007, p<0.001, p<0.001). In the Kaplan-Meier survival analysis overall survival of non-sarcopenic patients found to be significantly higher than sarcopenic patients(Mantel cox log-rank method p:0.011). No correlation found between primary tumour PET parameters and sarcopenia status. ***Conclusion:*** C3 vertebra level measurements are highly correlated with L3 level and its considered it can replace L3 when calculating SMI. SCM and psoas surface area, adipose tissue SUVmax value may predict sarcopenia. According to our findings PET parameters in SCM and psoas major can predict distant metastasis status. Since low muscle index predicts distant metastases and SMI predicts OS those parameters may help clinical course of the disease, and can be measure routinely. Hence 18F-FDG PET/CT allows us to obtain data from both C3 and L3 levels in once, it is also considered superior to conventional imaging modalities on predicting sarcopenia. SMI should be evaluated in all patients since sarcopenia significantly affects overall survival in esophageal cancers.

## EP-0186

### [18F]F-FAPI-74 PET for initial clinical staging in patients with pancreatic cancer : a prospective pilot study

***J. Gil***[1,2], *W. Yun*[3], *H. Choi*[1,2], *J. Paeng*[1,2], *K. Kang*[1,2], *J. Jang*[3], *G. Cheon*[1,2];
[1]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, College of Medicine, Seoul National University, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Surgery, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.*

***Aim/Introduction:*** Fibroblast activation protein inhibitor (FAPI) analogs are newly introduced PET agents for cancer imaging. There is a lack of data using [$^{18}$F]F-FAPI-74 PET in pancreas cancer patients. We evaluated the clinical implication of FAPI PET in initial staging of pancreatic cancer. ***Materials and Methods:*** Nineteen patients who had been diagnosed with pancreatic cancer were prospectively enrolled since October 2021. Sixteen patients underwent surgery. Abdomen CT and FDG PET were taken for staging and FAPI PET was additionally performed. We assessed suspected metastatic lymph nodes (LN) on these imaging studies and compared with the pathologic results. For FAPI PET evaluation, a LN with higher activity than the background was regarded as positive finding. Measured PET parameters were SUVmax, metabolic/FAP-active tumor volume (MTV/FTV), total lesion glycolysis/FAP-activity (TLG/TLF). For measuring volumetric parameters, SUV threshold with 40% of SUVmax was used. We analyzed a relationship of PET parameters with clinical factors; carbohydrate antigen (CA) 19-9 and pathologic tumor volume. Pearson's correlation and paired t-test were used for statistical analysis. ***Results:*** FAPI PET identified metastatic LN in 6 patients while all patients showed no lymph node metastasis on conventional images including FDG PET. Among patients who had pathologically confirmed metastatic LN (n = 10), 60% (6/10) patients had positive LN findings on FAPI PET. The result of correlation between PET volume (FTV and MTV) and pathologic tumor volume was as following: FTV (r=0.14, p=0.62) and MTV (r=0.07, p=0.82). FTV were significantly larger than MTV (t=4.06, p< 0.001). FTV showed a better correlation compared to MTV, though it did not show statistical significance. CA19-9 was moderately correlated with TLF (r=0.54, p=0.02) and TLG (r=0.52, p=0.03). The other PET parameters had no statistically significant correlation with CA19-9. ***Conclusion:*** [$^{18}$F]F-FAPI-74 PET may detect metastatic LN in patients who did not show metastasis on conventional images. FTV tend to be larger than MTV.TLF was correlated with CA 19-9. These results suggested that [$^{18}$F]F-FAPI-74 PET might potentially upstage in patients with pancreatic cancer in terms of tumor extent and LN metastasis.

## EP-0187

### The prognostic value of 18F FDG PET/CT intra-tumoural metabolic heterogeneity in patients with esophageal squamous cell carcinoma treated with Concurrent Chemoradiotherapy or Definitive Chemoradiotherapy(dCRT)

***Z. Zhu****, X. Ma, Q. Xie, X. Yao;*
*The University of Science and Technology of China, Hefei, CHINA.*

***Aim/Introduction***: Esophageal squamous cell carcinoma (ESCC) is a common gastrointestinal malignant tumor and notable for highly heterogeneous. This study aimed to quantify the intra-tumoural metabolic heterogeneity of primary tumour lesions by using $^{18}$F-FDG PET/CT and evaluate the prognostic value of intra-tumoural metabolic heterogeneity in ESCC patients with definitive chemoradiotherapy (dCRT). ***Materials and Methods***: We retrospectively enrolled 194 pretreatment ESCC patients from January 2017 to December 2021 in this study. $^{18}$F-FDG PET/CT images were reviewed and analyzed using Syngo. via software. The semi-quantitative metabolic parameters of primary tumour were measured, including the maximum standard uptake value (SUVmax), metabolic tumour volume (MTV), and total lesion glycolysis (TLG).Heterogeneity parameter (HI-index) were measured and calculated to quantify intra-tumoural metabolic heterogeneity. The outcome endpoint was event-free survival (EFS), including overall survival. Survival analysis was performed using Cox regression models and Kaplan Meier survival plots. Besides, the novel prognostic indices of pretherapeutic nutritional index (PTNI) were developed. ***Results:*** In all 194 newly diagnosed ESCC patients, 129 patients died. The median follow-up period of OS were 17.0 (range 3.6 - 33.6 months). The HI-INDEX (r=0.295, P<0.001) showed moderate correlation with the OS. The pretherapeutic nutritional index (PTNI) also had a weak correlation with the OS (r=0.147, P<0.05). In univariate analysis, sex (P=0.952), age(P=0.197), and clinical staging (P=0.094) were not associated with EFS.The HI-INDEX (P=0.014) and PTNI (P=0.029) remained significant in multivariate analysis.The Kaplan Meier survival analyses demonstrated that patients with higher intra-tumoural metabolic heterogeneity had worse outcomes (log-rank P=0.004). Finally, the Cox-model analysis demonstrated strong relationship between the HI INDEX and overall survival for patients with ESCC($\chi$2=13.217,P=0.021). ***Conclusion:*** The intra-tumoural metabolic heterogeneity of primary lesions in ESCC was an independent prognostic factor for EFS. The combined predictive effect of intra-tumoural metabolic heterogeneity provided prognostic survival information in ESCC patients.

## EP-0188

### Diagnostic Performances Of [18f]F-Fdg Pet, Mri And Pet/Mri In Patients With Newly Diagnosed Pancreatic Adenocarcinoma

***P. Bartoletti***[1], *G. Mango*[2], *S. Serafini*[3], *R. Guastella*[4], *C. Berto*[5], *S. Da Pozzo*[6], *M. Sitara*[1], *G. Fichera*[7], *C. Giraudo*[1], *L. Evangelista*[1];
[1]*Nuclear Medicine Unit, Department of Medicine DIMED, University of Padua, Padova, ITALY,* [2]*2Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [3]*General Surgery, Padua University Hospital, Padova, ITALY,* [4]*General Surgery Universita' degli Studi di Padova, Padova, ITALY,* [5]*Radiology Unit, Department of Medicine DIMED, University of Padua, Padova, ITALY,* [6]*Radiology Unit, Azienda Ospedaliera di Padua, Padova, ITALY,* [7]*Pediatric Radiology Unit, Padua University Hospital, Padova, ITALY.*

***Aim/Introduction:*** To compare diagnostic performances of [18F]F-FDG PET, MRI and [18F]F-FDG PET/MRI in patients with pancreatic adenocarcinoma. ***Materials and Methods:*** From 2017 to 2022, data about patients with suspicious or known pancreatic adenocarcinoma undergoing hybrid [18F]F-FDG PET/MRI scan were retrospectively collected. For each patient, following information was recovered for PET,enhanced MRI and PET/MRI: primary tumor (T), lymph nodes (N) and distant metastasis (M). Histopathology and clinical follow-up were used to establish the final pathological/clinical staging of disease. Diagnostic performance was expressed as sensitivity, specificity, positive and negative predictive value. ***Results:*** From a starting population of 56 patients, 30 (54%) subjects were considered. Median (range) age, CEA, Ca19.9 and bilirubin were 70 (51-85) years, 2.9 (0-54.2) ng/mL, 695.5 (0-35709) U/mL and 17.5 (4.2-345)

mg/dL. [18F]F-FDG PET was positive in 30 (100%), 9 (30%) and 9 (30%) patients, respectively for T, N and M. Conversely, MRI detected primary tumors in all patients, while it was positive for N and M in 15 (50%) and 9 (30%) patients, respectively. Nineteen (63.3%) patients were treated with neoadjuvant chemotherapy, due to the presence of borderline resectable/locally advanced disease. Totally, 13 (46.3%) subjects underwent surgery. Based on histopathological/clinical evaluation, 19 (63.3%) patients showed a lymph node involvement. Sensitivity and specificity of MRI vs. PET vs. PET/MRI regarding lymph nodes, were 52% vs. 28% vs. 60% and 60% vs. 60% vs. 60%, respectively. Moreover, positive predictive value (PPV) and negative predictive value (NPV) for the identification of lymph node involvement were equal to 88% and 23% with FDG PET/MR, therefore slightly higher when compared to PET and MRI alone (PPV: 77% and 86%; NPV: 14% and 20%, respectively). ***Conclusion:*** Our data suggest [18F]F-FDG PET/MRI outperformed MRI and PET for the evaluation of lymph nodes metastasis and could be used in the initial work up of the patients with resectable pancreatic adenocarcinoma.

## EP-0189

### Exploratory data on prostate-specific membrane antigen and vessels encapsulating tumour clusters in hepatocellular carcinomas: are two sides of the same coin?

***R. Zanca***[1,2], *R. Akpinar*[3], *L. Di Tommaso*[1,3], *F. Gelardi*[1,2], *M. Rodari*[2], *M. Sollini*[1,2];
[1]*Department of Biomedical Sciences, Humanitas University, Milan, ITALY,* [2]*Nuclear Medicine, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [3]*Pathology Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY.*

***Aim/Introduction:*** Tumour microenvironment (TME) is an intricated dynamic framework involved in carcinogenesis and drug resistance. Recently, interest in TME as source of potential diagnostic/prognostic factors and therapeutic targets has growth. In hepatocellular carcinomas (HCCs), evidence shows that TME composition and specific vascular patterns contribute to different prognosis. Prostate-specific membrane antigen (PSMA) highlighting cancer-associated neo-vasculature in solid tumours including HCC, is negatively associated with prognosis[1]; vessels encapsulating tumour clusters (VETC) pattern is associated to metastasis, recurrence[2] and seems predict patients who benefit from sorafenib[3]. We report our experience with [18F]PSMA-1007 PET/CT in HCC staging exploring the relationship between imaging and VETC pattern. ***Materials and Methods:*** We retrospectively screened all HCC patients imaged with [18F]PSMA-1007 PET/CT in our Institution. We selected patients who underwent PET/CT for HCC staging and identified those with available HCC tissue samples. We visually scored each HCC lesion on PET/CT as positive if [18F]PSMA-1007 uptake was higher than background at the site of disease, and as negative if uptake was comparable/lower than the background. We further defined as homogenous or heterogenous [18F]PSMA-1007-avid lesions. For each case with available resection or biopsy tissue, we evaluated VETC as previously defined[2] on all available tumour blocks. We also collected clinical and follow-up data. Descriptive statistics was used to analyse data. ***Results:*** From 8/2022 to 04/2023 we identified 11/14 HCC patients (median age 76 years, range 60-80) who fulfilled the above-mentioned criteria. We analysed 32 HCC lesions (Table 1). [18F]PSMA-1007 PET/CT was positive in 9/11 patients. 11/13 [18F]PSMA-1007-avid lesions showed inhomogeneous uptake with a "cold" central area. Among negative lesions, few presented an uptake lower than the background (3/19). Tissue was available for staining in 4/11. The VECT pattern was identified in 2/4 patients and both presented inhomogeneous [18F]PSMA-1007 uptake in all lesions. Both underwent surgery: one recurred 5 months after, while the other one 1 month after surgery was disease free. The other 2/4 patients who did not exhibit the VECT pattern (one died the day after surgery for brain haemorrhage and follow-up is not yet available for the other one) presented mostly [18F]PSMA-1007 negative lesions (5/6). ***Conclusion:*** [18F]PSMA-1007 PET/CT seems promising in HCC. Although data come from exploratory and anecdotal cases, [18F]PSMA-1007 PET/CT positivity might predict the VECT pattern, possibly providing new insights into HCC evolution and prognosis. ***References:*** 1. Clin Transl Gastroenterol. Clin Transl Gastroenterol; 2019;10. 2. Hepatology . John Wiley & Sons, Ltd; 2020;71:183-95. 3. Hepatology; 2019;70:824-39.

## EP-0190

### Ga-68 PSMA PET/CT Imaging Findings of Cholangiocellular Carcinoma

***T. Kissa***, *Z. C. Balaban Genc, X. Niftaliyeva, N. Filizoglu, S. Kesim, K. Öksüzoğlu, F. Çağlıyan, S. Özgüven, F. Dede, T. Ones, H. T. Turoglu, T. Y. Erdil;*
*Marmara University Pendik Research and Training Hospital, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Cholangiocellular carcinoma is the second most common primary tumor of the liver. It accounts for approximately 10% of primary liver malignancies. It is an adenocarcinoma originating from bile duct epithelium. It is more common in men and in advanced age. In this case report, we present the findings of an incidental diagnosis of cholangiocellular carcinoma on Gallium-68 (Ga-68) prostate specific membrane antigen (PSMA) positron emission tomography/computed tomography (PET/CT) in a patient followed for prostate cancer. ***Materials and Methods:*** A 69-year-old man with a history of prostate adenocarcinoma was referred to Ga-68 PSMA PET/CT for restaging due to biochemical recurrence of prostate cancer. Ga-68 PSMA PET/CT showed intense PSMA uptake in the left lobe of the liver with malignant character, which also extended to the right lobe. Subsequent biopsy of the left lobe of the liver revealed a diagnosis of cholangiocellular carcinoma. ***Results:*** Prostate specific membrane antigen is a 750 amino acid glycoprotein enzyme found in the cell membranes of prostatic acinar. It is also expressed in many other tissues such as kidney, small intestine, liver, spleen, intestine, lacrimal and salivary glands, and central and peripheral nervous system. Ga-68 PSMA PET/CT is a commonly used imaging modality for the diagnosis and follow-up of prostate cancer in routine clinical practice. PSMA expression is not specific to prostate tissue. It can also be used in the diagnosis, staging and treatment follow-up of other non-prostate malignancies. However, it has been shown to be useful in the diagnosis of various diseases, including benign and malignant neoplasms and inflammatory/infectious processes (e.g. tuberculosis). ***Conclusion:*** This case demonstrated the variable spectrum of Ga-68 PSMA uptake in prostatic and non-prostatic metastatic lesions and the usefulness of PET/CT in the evaluation of patients with concomitant malignancies for diagnosis and treatment follow-up when conventional imaging modalities fail.

**68Ga-DOTA-TATE in Cervicothoracic, Coeliac and Sacral Ganglia: sites of physiological uptake in the Era of total-body PET/CT**

***E. Triumbari***[1], *Y. Abdelhafez*[2], *D. Morland*[3], *B. A. Spencer*[2], *A. Calabrò*[4], *F. Sen*[2], *R. D. Badawi*[2], *M. Guindani*[5], *L. Nardo*[2]; [1]*Nuclear Medicine Unit, TracerGlab, Rome, ITALY,* [2]*Department of Radiology, UC Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [3]*Service de médecine nucléaire, Institut Godinot, Reims, FRANCE,* [4]*Nuclear Medicine Department, University of Brescia and ASST Spedali Civili di Brescia, Brescia, ITALY,* [5]*Department of Biostatistics, University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** To characterize $^{68}$Ga-DOTA-TATE uptake in sympathetic ganglia and investigate whether total-body (TB) PET/CT scanners have an impact on their detection and quantification compared to conventional scanners. ***Materials and Methods:*** Frequency of visualization, $^{68}$Ga-DOTA-TATE uptake intensity and ganglion-to-background ratio (GBR) were investigated among bilateral cervicothoracic, coeliac and sacral ganglia of patients with neuroendocrine neoplasia who underwent PET/CT on both a conventional scanner and a TB system during their clinical history. Minimum two, maximum six scans per patient were collected. Comparisons between the two scanners' examinations were computed using paired T-test or two proportion Z-test when appropriate. Single predictor analyses were performed using generalized linear mixed effects models. Covariates with p-value <0.05 were included in multivariable analysis. For semiquantitative analysis, differences in $SUV_{max}$ and GBR distribution were assessed using linear mixed effect models with random intercept. ***Results:*** Data were collected from 27 patients (8M, 19F), 102 scans: 54 (53%) on the conventional scanner and 48 (47%) on the TB scanner. The average percentage of positive scans per patient was 87.7±25.7% across all ganglion sites and exams. In only TB PET, the average number of positive scans was 95.7±12.7% compared to 79.6±32.5% for conventional PET (p=0.023), with also a statistically significant increase in detection of cervicothoracic (p=0.012) and coeliac ganglia (p=0.002) alone. In multivariable analysis, use of TB PET/CT was the only significant covariate predicting $^{68}$Ga-DOTA-TATE uptake visualization on a per ganglion basis (odds ratio: 1.8, 95%CI: 1.02-3.19; p=0.042). Semiquantitative analysis showed that $SUV_{max}$ and GBR measured on the two scanners were significantly higher in TB images. ***Conclusion:*** Sympathetic ganglia $^{68}$Ga-DOTA-TATE uptake is a frequent physiologic finding. Higher sensitivity and spatial resolution of TB PET/CT increase frequency of ganglia visualization. The more accurate quantification shows higher levels of uptake of this small anatomic structure in TB PET/CT compared to conventional PET/CT. ***References:*** 1) Ng QK-T, Triumbari EKA, Omidvari N, Cherry SR, Badawi RD, Nardo L. ### EP-0192

**The quantification for the treatment response evaluation of Metastatic Gastroenteropancreatic Neuroendocrine Tumors in Ga-68 DOTATATE PET/CT**

***Z. Koç***[1], *P. Özcan*[1], *E. Sezer*[2], *T. Kara*[3]; [1]*Mersin University Hospital Nuclear Medicine Dpt., Mersin, TÜRKIYE,* [2]*Mersin University Hospital Oncology Dpt., Mersin, TÜRKIYE,* [3]*Mersin University Hospital Pathology Dpt., Mersin, TÜRKIYE.*

***Aim/Introduction:*** The treatment response evaluation by means of Ga-68 DOTATATE PET/CT in Metastatic Gastroenteropancreatic Neuroendocrine Tumors (GEPNET's) needs careful attention due to the subtle changes that might affect decision. The aim of this study is to analyze a new modified method in quantification of the Ga-68 DOTATATE PET/CT in treatment response evaluation of GEP-NET's. ***Materials and Methods:*** 37 patients with diagnosis of metastatik GEP-NET were included in the study. Comparative evaluation of Ga-68 DOTATATE PET/CT images before and after treatment were performed. Quantitative analysis as well as visual interpretation results were compared with oncology follow up. The patients were divided according to oncology follow up results as responders and nonresponders. ***Results:*** The comparative analysis results showed that the difference between mean SUVmax and index values after and before the treatment were not significant for primary lesions. However both the index values were significantly different between groups in metastatic lesions. ***Conclusion:*** Previous studies including large series for response evaluation showed that Ga-68 DOTATATE imaging significantly changed patients management in nearly half of the patients (44%) (1). Additionally the metastatic involvement (90%) and multiple lesions (35%) were determined at first staging in most of the patients included in previous series (2). The diagnostic comparison of the morphologic imaging modalities and Ga-68 DOTATATE PET/CT revealed higher detection rates in previous series; PET/CT determined 22/33 patients who were metastasis negative for liver (3). The results of this study showed that comparison of the uptake of primary tumor might not reflect the response but metastatic lesions should be prefered. SUVmax levels of the metastatic lesions sufficiently reflected the treatment response according to the statistical analysis. In case of discrapancy quantification method might be implicated. ***References:*** Skoura E, Michopoulou S, Mohmaduvesh M, et al. ## EP-0193

### The additional value of SPECT/CT imaging to planar imaging in neuroendocrine tumors

***A. Tsaroucha**, N. Kapsoritakis, O. Bourogianni, G. Lamprakopoulos, M. Stathaki, E. Papadaki, S. Koukouraki;*
*University Hospital of Heraklion, Heraklion,Crete, GREECE.*

***Aim/Introduction:*** To assess the benefit of SPECT/CT imaging compared to planar imaging alone in neuroendocrine tumors (NETs). ***Materials and Methods:*** A total of 83 patients with NETs (33 suspected, 15 small bowel, 13 pulmonary, 8 stomach, 1 large bowel, 2 pancreatic, 1 insulinoma, 3 medullary thyroid cancer, 2 paragangliomas, 5 metastatic NETs of unknown origin) were referred for peptide receptor imaging (33 patients for initial diagnosis, 23 for staging and 27 for follow up/recurrence). 45 patients underwent $^{111}$In-pentetreotide scintigraphy. 4h and 24h whole body (WB) planar imaging was performed in all patients, as well as 24h SPECT/CT tomography in the areas of interest. 38 patients underwent $^{99m}$Tc-EDDA/HYNIC-TOC scintigraphy. 1h static image of the abdomen and 4h WB planar imaging were acquired , as well as 4h SPECT/CT in the areas of interest. The planar and SPECT/CT imaging were interpreted independently and the scans were reported as negative, positive or equivocal. The number of detected lesions was calculated and the change of management due to SPECT/CT contribution was estimated. ***Results:*** 19 out of 45 WB planar $^{111}$In-pentetreotide scans were reported as negative, 10 scans as positive and 16 scans as equivocal. After adding SPECT/CT imaging, the negative scans increased to 25, the positive scans increased to 19 and only 1 remained equivocal. A total of 74 lesions were depicted on planar imaging alone, and SPECT /CT added 26 new/extra lesions. 15 out of 38 WB planar $^{99m}$Tc-EDDA/HYNIC-TOC scans were reported as negative, 14 as positive and 9 scans as equivocal. After adding SPECT/CT imaging, the negative scans remained 15, the positive scans increased to 18 and the equivocal scans decreased to 5, while SPECT /CT added 19 new/extra lesions to 44. Overall, the positive scans were increased from 28,9% to 44,6%, the negative ones from 41% to 48,2%, while the equivocal scans decreased from 30,1% to 7,2%. Overall, 38,1% more lesions were depicted. There was a change in management in 31 out of 83 patients or 37,3% of the patients. ***Conclusion:*** SPECT/CT remains (when PET/CT technology is not readily available) an important diagnostic tool of conventional Nuclear Medicine in evaluating NETs by increasing diagnostic confidence, reducing equivocal scans and leading to change of management in a considerable percentage of the referred patients.

## EP-0194

### 18F-AlF-NOTA-Octreotide PET/CT: Krenning´s score and tumor burden influence by tumor volume and total lesion activity

***M. González Martínez**[1], A. Piana Bezaury[1], I. Pérez Díaz[2], M. Olarte Casas[1];*
*[1]PET/CT unit, UNAM, Mexico City, MEXICO,*
*[2]UNAM, Mexico City, MEXICO.*

***Aim/Introduction:*** To identify and differentiate those patients who are candidates for radionuclide therapy, to obtain their percentage using 18F-AlF-NOTA-Octreotide (Fluoroctreotide) PET/CT, and to correlate tumor burden - which was obtained through the tumor volume and the total lesion activity - with the SUVmax, SUVpeak, and Krenning Score values. ***Materials and Methods:*** Adult patients diagnosed with gastroenteropancreatic neuroendocrine tumor confirmed by histopathology who were evaluated in the PET/CT unit at UNAM using the radiopharmaceutical 18F-AlF-NOTA-Octreotide (Fluoroctreotide) from January to December 2021. Tumor burden estimation by tumor volume and total lesion activity through semi-automated processing with a fixed threshold (default SUVmax of 10 and volume of 1 mL). ***Results:*** A total of 48 patients were evaluated; 31 of them showed some degree of abnormal overexpression of somatostatin receptors, 28 patients (58.33%) were considered positive for significant overexpression of somatostatin receptors (Krenning scores of 2, 3, and 4) and 27 patients (56.25%) were candidates for radionuclide therapy (Krenning scores 3 and 4). A significant directly proportional correlation was found between variables SUVmax, SUVpeak, tumor volume, and total lesion activity. ***Conclusion:*** The percentage of patients with gastroenteropancreatic neuroendocrine tumors who were candidates for radionuclide therapy was 56.25%. The tumor burden was measured by tumor volume and total lesion activity, it was adequately discriminated through semi-automated processing with a fixed threshold (default SUVmax of 10 and volume of 1 mL), and the results obtained from the aforementioned patients correlate with a high Krenning score (3 and 4). Quantifying tumor load by tumor volume and total lesion activity with fluoroctreotide correlates with the Krenning score and helps to determine which patients are candidates for radionuclide therapy.

## EP-0195

### Referral Patterns and Image Results of 2,249 [64Cu]Cu-DOTATATE PET/CT in a European Neuroendocrine Tumor Society Center of Excellence

***M. Loft**[1,2], E. A. Carlsen[1,2], C. B. Johnbeck[1,2], U. Knigge[2,3], M. Andreassen[2,3], S. W. Langer[2,4,5], H. H. Johannesen[1,2], J. Mortensen[1,2,5], L. H. Enevoldsen[1,2], P. Oturai[1,2], A. Kjaer[1,2];*
*[1]Department of Clinical Physiology and Nuclear Medicine & Cluster for Molecular Imaging, Copenhagen University Hospital – Rigshospitalet & Department of Biomedical Sciences, University of Copenhagen, Copenhagen, DENMARK, [2]European Neuroendocrine Tumor Society Center of Excellence at Copenhagen University Hospital – Rigshospitalet, Copenhagen, DENMARK, [3]Departments of Clinical Endocrinology and Surgical Gastroenterology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, DENMARK, [4]Department of Oncology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, DENMARK, [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK.*

***Aim/Introduction:*** Somatostatin receptor PET/CT, using $^{68}$Ga-based tracers or [$^{64}$Cu]Cu-DOTATATE, is pivotal for the management of patients with neuroendocrine neoplasms (NEN) or suspicion thereof. The aim of the study was to perform a systematic analysis of the referral patterns and image results of clinical routine [$^{64}$Cu]Cu-DOTATATE PET/CT to support guidelines and appropriate use criteria development. ***Materials and Methods:*** We included all clinical routine [$^{64}$Cu]Cu-DOTATATE PET/CT performed between 10-April-2018 (start of clinical use) and 02-May-2022 at Rigshospitalet. We performed structured analyses of 1) the referral text and 2) the result report of each scan and categorised the indication and result according to clinical scenarios. The retrospective study was approved by the Directorate of Rigshospitalet (ID:22027516) and the requirement for informed consent was waived. ***Results:*** In total, 2,249 [$^{64}$Cu]Cu-DOTATATE PET/CT were performed in 1,290 patients. The most common indication was monitoring of patients with NEN without clinical evidence of progression accounting for 971 scans (43.2%). Initial staging after histology-verified NEN diagnosis and restaging following curative-intent surgery accounted for 222

(9.9%) and 240 (10.7%) scans, respectively. Selection of peptide receptor radionuclide therapy (PRRT) eligible patients and restaging following PRRT-completion accounted for 95 (4.2%) and 115 (5.1%) scans, respectively. Additionally, 182 (8.1%) scans were performed in the diagnostic work-up of patients with imaging suggesting NEN lesions not amenable for biopsies, and 113 (5.0%) scans in patients both without histology-verified NEN diagnosis and evidence on conventional imaging, but with biochemistry and symptoms suggestive of NEN disease. The result report analysis showed stable disease and progression (PET and/or CT) on 577 (25.7%) and 460 scans (20.4%), respectively. In 299 cases, progression was observed in patients without clinical evidence of progression (30.8% of 971 scans). In 99 cases (21.5% of all 460 progression-positive scans), progression was detected on PET but not CT. In 669 of all 2,249 scans (29.7%), no disease was detected, while confirmation of NEN disease, including primary tumour localisation, was found in 395 cases (17.6%). ***Conclusion:*** Monitoring of patients with NEN without clinical evidence of progression was the most frequent indication accounting for 971 [$^{64}$Cu]Cu-DOTATATE PET/CT, in which disease progression was detected in 299 cases (30.8%). In 99 (21.5%) of all 460 progression-positive cases, progression was observed on PET only. Our study provides real-life data that may contribute to further development of somatostatin receptor PET/CT guidelines for using [$^{64}$Cu]Cu-DOTATATE including appropriate use criteria.

## EP-0196

### Impact on clinical management when using [18F]AlF-NOTA-octreotide instead of [68Ga]Ga-DOTA-SSA PET/CT in neuroendocrine tumor patients: preliminary results

***Aim/Introduction:*** [$^{18}$F]AlF-NOTA-octreotide ([$^{18}$F]AlF-OC) is a promising alternative for [$^{68}$Ga]Ga-DOTA-SSA in PET imaging of the somatostatin receptor (SSTR). Our research consortium has recently shown in a prospective, multicenter trial that [$^{18}$F]AlF-OC is superior to the current gold standard in terms of lesion number detection (1). Our aim is to assess changes in TNM staging and differences in patient management when using [$^{18}$F]AlF-OC PET/CT instead of [$^{68}$Ga]Ga-DOTA-SSA PET/CT in the work-up of neuroendocrine tumor (NET) patients. ***Materials and Methods:*** Seventy-five patients from our multicenter study (1) with a NET were included for retrospective analysis. All patients underwent both [$^{18}$F]AlF-OC and [$^{68}$Ga]Ga-DOTA-TATE or -TOC PET/CT. TNM staging was determined and compared for both tracers. For each patient, the blinded [$^{68}$Ga]Ga-DOTA-SSA or [$^{18}$F]AlF-OC PET/CT images were presented in random order at a multidisciplinary tumor board-like setting to at least two clinical NET experts, a surgeon and a nuclear medicine expert. The images were presented together with clinical information and compared with previous SSTR and [$^{18}$F]FDG PET imaging. After a consensus decision for patient management was recorded, the board was presented with the PET/CT images from the other tracer and a decision was made for the second tracer. Differences in management were classified as major if it entailed an intermodality change and minor if it led to an intramodality change. ***Results:*** We present our preliminary analysis of the first fifty-four patients. Compared with [$^{68}$Ga]Ga-DOTA-SSA, the use of [$^{18}$F]AlF-OC led to TNM staging changes in 7/54 patients (downstaging in 1/7, upstaging in 6/7), resulting in a change in management in 3/7 patients. In total, [$^{18}$F]AlF-OC PET/CT impacted clinical management in 7/54 patients (13.0%), leading to a major change in 5/7 cases (4 patients switched to PRRT and 1 patient switched from SSA to everolimus) and a minor change in 2/7 cases (SSA dose escalation). All seven cases with a difference in patient management between both PET tracers were caused by additional lesion detection by [$^{18}$F]AlF-OC. ***Conclusion:*** In 80.7% of patients, similar TNM and therapy was observed. The use of [$^{18}$F]AlF-OC resulted in TNM changes in 13.0% of the patients. Differences in clinical management were seen in 13.0% of the patients, which were all cases of therapy intensification driven by higher number of lesions detected by [$^{18}$F]AlF-OC PET/CT. ***References:*** 1. Pauwels E, Cleeren F, Tshibangu T, et al. 18F-AlF-NOTA-Octreotide Outperforms 68Ga-DOTATATE/NOC PET in Neuroendocrine Tumor Patients: Results from a Prospective, Multicenter Study. J Nucl Med. 2023 Apr;64(4):632-638.

## EP-0197

### Development of a Semi-Automatic Platform for Whole Body Tumor Segmentation and Radiomic Feature Extraction From 68Ga-DOTATATE PET/CT Using TriDFusion (3DF)

***S. Krebs***, *D. Lafontaine, L. Bodei, M. E. Mayerhoefer, J. Humm, H. Schöder;*
*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Reliable imaging biomarkers facilitating management and outcome prognostication in patients with neuroendocrine tumors (NET) are lacking. $^{68}$Ga-DOTATATE PET/CT is routinely performed to assess somatostatin receptor (SSTR) expression and stage patients with NET. However, manual segmentation of avid lesions to extract quantitative parameters for response assessment and prognostication remains time-consuming and may not be practical in widely metastatic disease. Therefore, we developed a semi-automatic software for tumor segmentation and extraction of radiomic features based on our open-source TriDFusion (3DF) platform . We tested this platform in 38 patients with SSTR-positive gastroenteropancreatic or lung NET imaged with $^{68}$Ga-DOTATATE PET/CT before and after PRRT with available outcome data. ***Materials and Methods:*** Using CT images (of the PET/CT) as blue-print, the TotalSegmentor-3DF machine learning algorithm automatically computed masks for normal organs with physiologic DOTATATE uptake (e.g.; adrenal glands, kidneys), and also identified the

bone and the liver. Then, the PET was resampled based on the CT. To determine the normal liver SUVmean and standard deviation (SD), a region-of-interest was manually placed in the normal liver. For liver lesions, a threshold based on normal liver SUVmean was applied, for bone lesions a fixed SUV-threshold of 3. For the other lesions, a threshold based on average normal liver SUVmean derived from a representative patient cohort was used. Manual corrections, when necessary, were applied. Minimum lesion size was arbitrarily defined as > 0.3 cm3. Multiple output parameters including radiomic features (using 3DF-pyRadiomics) were extracted. ***Results:*** Interim analyses (7 patients, 14 scans) showed segmentation of 186 lesions (116 liver, 10 bone, 19 lung, 57 soft tissue) with mean whole body (wb) tumor volume TV (ml) of 687.45 (range, 5.18-2021.65), wb TLRE (total lesion receptor expression) 10485.74 (range, 55.39-37893.42), wb SUVmean 15.22 (range, 7.42-29.25), wb SUVmax 52.03 (range, 20.63-90.36); thereof mean liver TV of 655.04 (range, 0-1925.81), bone TV 1.33 (range, 0-5.48), soft tissue TV 31.00 (range, 0-201.75). Implementation of machine learning masks and segmentation required about 3.5-4 min per scan, and with manual adjustments, total segmentation time was 5-9 min per case. Radiomic features for individual lesions were extracted. The personalized output report provided lesion uptake metrics and an embedded image graphic facilitating lesion tracking. ***Conclusion:*** Our 3DF tool enables the rapid semi-automatic analyses of whole-body tumor burden and the extraction of radiomic features from $^{68}$Ga-DOTATATE PET/CT even in widely metastatic disease. Further analyses and correlation with outcome are in progress and will be presented.

## EP-0198

### The risk factors of pancreatic neuroendocrine tumor predicted by 18F-FDG and 68Ga-DOTANOC PET/CT before surgery.

***J. Xu****, S. Song;*
*Fudan University Shanghai Cancer Center, Shanghai, CHINA.*

***Aim/Introduction:*** Operation is primary treatment of pancreatic neuroendocrine tumor (pNET). However, the indications for resection and lymph node dissection are still controversial. The purpose of our study was to evaluate the value of $^{18}$F-FDG and $^{68}$Ga-DOTANOC PET/CT to predict the risk factors of pNET before surgery. ***Materials and Methods:*** 109 patients with pNET were retrospectively analyzed, who underwent $^{18}$F-FDG (n=44) and $^{68}$Ga-DOTANOC (n=109) PET/CT for preoperative assessment and underwent surgical resection between July 2021 to December 2022. Operations were performed in two weeks after imaging and 76 patients (69.7%) received lymph nodes dissection. Patients with <3cm pNETs were separately analyzed for evaluating the value of both PET/CT to assist in the selection of lymph node dissection. Clinical characteristics, PET/CT parameters and pathological results were reviewed and compared statistically. ***Results:*** In those who underwent lymph node dissection, twenty patients (26.3%) had lymph node metastasis. The lymph nodes metastasis was missed by $^{68}$Ga-DOTANOC PET/CT in 9 patients which was also missed by $^{18}$F-FDG PET/CT. Tumor size is one of the most important risk factors for pNET. The tumors with vascular tumor thrombus, perineural invasion, high pathological grade, lymph node metastasis and liver metastasis are always with larger maximum diameter. It is observed that $SUV_{max}$ of the primary tumor with vascular tumor thrombus is lower than those without vascular tumor thrombus in $^{68}$Ga-DOTANOC PET/CT (26.2±17.0 vs. 41.5±26.8, P=0.007). $SUV_{max}$ of $^{18}$F-FDG PET/CT ≥ 4.5 was identified as poor prognostic predictor for lymph node metastasis (odds ratio [OR] 7.418, 95% confidence interval [CI] 0.894-61.574, P=0.036) and liver metastasis (odds ratio [OR] 5.228, 95% confidence interval [CI] 1.007-27.143, P=0.049). In the subgroup analysis, there were 78 patients with <3cm pNETs, 49 of which (62.8%) received lymph nodes dissection and only 9 patients (18.3%) had lymph node metastasis. 4 patients with positive lymph nodes were detected by $^{68}$Ga-DOTANOC PET/CT. There was no statistical difference of $SUV_{max}$ of the primary tumor in $^{18}$F-FDG and $^{68}$Ga-DOTANOC PET/CT between those patients with and without lymph node metastasis. In those patients with <3cm pNETs, higher upake of $^{18}$F-FDG in the primary tumor was observed in NET G2 than G1 (8.41±9.99 vs. 2.16±1.12, P=0.004). ***Conclusion:*** $^{18}$F-FDG and $^{68}$Ga-DOTANOC PET/CT before surgery could predict the risk factors of pancreatic neuroendocrine tumor. However, it is insufficient to accurately predict the lymph node metastasis by either $^{18}$F-FDG or $^{68}$Ga-DOTANOC PET/CT in the patients with <3cm pNETs.

## EP-0199

### The use of18F-DOPA PET/CT for the diagnosis of neuroendocrine tumors suspected or confirmed from unkown origin

***A. Rodríguez Pajuelo****, J. Cuenca Cuenca, M. Guerra Gómez, J. Jiménez-Hoyuela García;*
*Virgen del Rocio Univsersity Hospital, Seville, SPAIN.*

***Aim/Introduction:*** The aim of the proyect was to evaluate the diagnostic efficiency of $^{18}$F-fluorodihydroxyphenylalanine ($^{18}$F-FDOPA) PET/CT in patients with suspected neuroendocrine tumor (NET) or NET metastasis from unknown origin. ***Materials and Methods:*** From January 2013 to June 2020, we retrospectively studied $^{18}$F-DOPA PET/CT scans performed in 64 patients (19 men; 45 women) with a mean age of 63 years (range:24-89), referred with the following suspicions: clinical suspicion / elevation of NET tumor markers (n=29) or with suspected/confirmed morphological image for NET. They underwent PET/CT from vertex to femur after intravenous injection of a mean 213.20 MBq (range:167-264) of $^{18}$F-DOPA. The results were confirmed with pathological anatomy in 33 patients and by clinical/radiological follow-up of 81.5 months (range:1-134). Sensitivity (S), specificity (E), positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy values were determined. ***Results:*** The prevalence of disease was 39.0%. Among the patients with $^{18}$F-DOPA PET/CT-positive primary lesion, which were confirmed as NET later (true positives), the obtained mean of SUVmax was 10.8 and of size 24.6 mm. The S and E were 64% and 84.6%, with PPV and NPV of 72.7% and 78.5%. The diagnostic accuracy was 76.5%. Among the patients who were referred for suspicion/ elevated tumor markers, 2/29 had lesions that were confirmed later (in liver and lung). Another 2/29 patients with lesions (in esophagus and duodenum) were found subsequently ruling out the existence of NET. In 2/29 patients, the primary lesion confirmed was not identified by PET/CT, being located in pancreas in both cases. S=50.0% and E=92.0%, PPV=50.0% and NPV=92.0% were obtained, as well as a diagnostic accuracy of 86.2%. In patients whom a lesion suggestive of NET was detected by other morphological tests, lesions were identified by PET/CT in 17/35 patients. Some of which were confirmed pathological anatomy as metastatic NET of unknown origin. In 1/35 patients, multiple lymphatic, bone and skin metastatic lesions were located, confirmed by biopsy, without finding the primary one. S= 66.6% and E=71.4%, PPV=77.7% and NPV=58.8%, and a diagnostic accuracy of 68.5% were reached. ***Conclusion:*** Our data confirmed the good accuracy of $^{18}$F-DOPA PET/CT for the evaluation of

patients with suspected NET, especially for those with symptoms/elevated markers, in whom the presence of a tumor is ruled out with high assurance. The diagnostic error was mainly associated with lesions located in the gastroenteropancreatic tract, probably secondary to the physiological activity of fluorodopa.

## EP-0200

### Impact of Tumor-to-Background Ratio on Training of AI for Liver Metastasis Detection in Neuroendocrine Tumors

***B. Schemmer***;
*Uniklinik Bonn, Bonn, GERMANY.*

***Aim/Introduction:*** The accuracy and robustness of artificial intelligence (AI) in detecting liver metastasis in neuroendocrine tumors (NETs) is potentially affected by various factors, including the tumor-to-background ratio (TBR). In this study, we investigate the impact of TBR on the training of an AI for the detection of liver metastasis in NETs. ***Materials and Methods:*** We used a dataset of 50 DOTATOC-PET whole-body studies of patients with NETs with liver metastasis (mean 2 metastasis per patient) and 50 without liver metastasis to train and evaluate the AI model. The TBR was calculated by dividing the tumor SUVmax by the liver SUVmean in each image. The AI model was trained using labeled images with and without liver metastasis. The AI was specifically not trained to discern subtle metastasis with uptake values below liver uptake. Images were preprocessed and SUV values below liver SUVmean*0.5 do not appear in the training data. Detection was evaluated as successful when there was a corresponding labeled metastasis in the data. To increase the amount of training data, the whole bodies were presented as single image slices, however only images containing the liver were used (~100*100 images). ***Results:*** Our results show that the TBR has a significant impact on the training of the AI model. Training speed was higher with higher TBR, however robustness for analysis of low TBR images was also low. To alleviate this, we modified the training process so that starting with the images with the highest TBR (24.8 in our case) with each iteration more and more images with low TBR (down to 1.2) were introduced. In the test data accuracy of the model increased as the TBR increased, reaching a specificity of 98% when the TBR was greater than 2, while still generating acceptable accuracy with a TBR of 1.05 (83%). ***Conclusion:*** Our study highlights the importance of the TBR in the training of an AI for the detection of liver metastasis in NETs. A high TBR is essential for the accurate training of the AI model, and further research is needed to identify the optimal TBR for the best performance of the model. However for real world applications lower TBR images need to be introduced into the training process, as low TBR is common during therapy staging and remission control (i.e. everolimus).

## EP-0201

### What is the utility of combined 68Ga-DOTATOC and 18F-FDG- PET/CT in the work-up of subjects with neuroendocrine tumors of unknown origin?

***I. Bloise***, *S. Harsini, F. Benard, D. Wilson, J. M. Loree, P. Martineau; BC Cancer, Vancouver, BC, CANADA.*

***Aim/Introduction:*** Neuroendocrine tumors (NETs) are epithelial neoplasms that can arise from most organs, with tumors of unknown origin accounting for 10-14% of all NETs. Identifying the site of the primary lesion and providing accurate staging in these patients can be challenging. The aim of this study was to investigate the value of performing both FDG and $^{68}$Ga-DOTATOC-PET/CT in subjects with NET of unknown origin. ***Materials and Methods:*** We retrospectively reviewed $^{68}$Ga-DOTATOC-PET/CTs performed under clinical trial NCT03583528 at our institution between July of 2018 and November of 2022 on subjects with "NET of unknown origin" or "unknown primary site of disease". As per clinical trial, all subjects underwent both $^{68}$Ga-DOTATOC and $^{18}$F-FDG-PET/CT imaging. Information regarding overall image assessment (positive or negative study), tumors grades, the interpreter's confidence in diagnosis (high, moderate, or low), number of positive lesions (1, 2, 3, 4, 5, 6-10, >10), and location of lesions (lymph nodes, liver, lung, bones) was recorded. ***Results:*** A total of 40 subjects met the inclusion criteria. For each subject, DOTATOC and FDG-PET/CTs were performed within a time interval of 2 months. Tumor grade was available for 32 subjects with 12 (38%), 16 (50%), and 4 (12%) subjects having grade 1, 2, and 3 disease, respectively. 34 (85%) subjects had DOTATOC-avid lesions, while 27 (79%) demonstrated FDG-avid disease. None of the DOTA negative subjects demonstrated FDG-avid lesions. A DOTATOC-avid primary lesion was identified in 12 (35%, high confidence) studies and possibly identified in another 5 (15%, moderate confidence). A possible primary site was identified on FDG-PET in a single (3%, moderate confidence) subject with grade 1 disease. FDG and DOTATOC revealed a similar number of lesions in 12 (30%) subjects with DOTATOC revealing a greater number of lesions in 22 (55%) cases. The single subject with an FDG-positive primary lesion demonstrated a greater number of lesions with DOTATOC. Nodal/hepatic/lung/bone metastases were detected in 48%/50%/8%/38% of patients with DOTATOC, compared to 18%/50%/5%/25% with FDG, respectively. ***Conclusion:*** DOTATOC-PET/CT identified the primary lesion in a much greater proportion of subjects than FDG-PET/CT while benefiting from greater reader confidence. DOTATOC-PET/CT also identified significantly more lesions than FDG-PET/CT and revealed a broader range of organ involvement than that seen on FDG-PET/CT. The inclusion of FDG-PET/CT provided little additional value compared to DOTATOC-PET/CT in the workup of subjects with well differentiated NETs of unknown origin.

## EP-0202

### [68Ga]Ga-DOTATOC PET radiomics supports lymph node metastases detection for accurate surgical planning of well-differentiated pancreatic neuroendocrine tumours patients

***C. Bezzi***[1,2], *P. Mapelli*[1,2], *S. Ghezzo*[1,2], *F. Muffatti*[3], *M. Schiavo Lena*[4], *V. Andreasi*[3], *C. Canevari*[2], *P. Magnani*[2], *S. Partelli*[3], *M. Falconi*[1,3], *A. Chiti*[1,2], *M. Picchio*[1,2];
[1]*Vita-Salute San Raffaele University, Milan, ITALY,* [2]*Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [3]*Pancreatic Surgery Unit, Pancreas Translational & Clinical Research Centre, IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [4]*Pathology Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY.*

***Aim/Introduction:*** Accurate identification of lymph node metastases (LNs) is pivotal for surgical planning of pancreatic neuroendocrine tumors (PanNETs) patients; however, imaging techniques provide poor diagnostic sensitivity [1]. Aim of this study is to investigate whether [$^{68}$Ga]Ga-DOTATOC PET radiomics might improve the identification of LNs in PanNET patients candidate to surgery. ***Materials and Methods:*** Retrospective study including 72 patients (31F-41M, median age: 60y) with histologically proven well-differentiated PanNET who underwent [$^{68}$Ga]Ga-DOTATOC PET (25 PET/MR, 47 PET/CT) at IRCCS San Raffaele (2018-2022). Inclusion criteria were: 1) preoperative [$^{68}$Ga]Ga-DOTATOC PET performed within 1 month from surgery

2) availability of LNs pathology. PET scans were assessed for diagnostic accuracy, sensitivity (SN), and specificity (SP) in regional LNs. Primary tumors were manually segmented on PET scans (two readers). Images were resampled, normalized, and discretized. $SUV_{max}$, $SUV_{mean}$, somatostatin receptor density (SRD), total lesion SRD (TLSRD) and IBSI-compliant radiomic features (RFs) were measured. ComBat method was used to harmonize data. Parameters were standardized and discarded if affected by inter/intra-observer segmentation variability (ICC<0.80) and if highly redundant (Spearman>0.90). Mann-Whitney U test and ROC analysis were used to select the most relevant parameters and build the radiomic signature. Different machine learning (ML) algorithms, including support vector machine (SVM), k-nearest neighbors (kNN) and linear discriminant analysis (LDA), were optimized for prediction of pathological LNs and validated using 10-times repeated 10-fold cross-validation. A control model trained with only $SUV_{max}$ and tumor volume was generated. Average balanced accuracy (bACC), SN and SP were collected and compared (Kruskal-Wallis) among radiomic models, control model, and expert's qualitative examination. ***Results:*** LNs were present in 29/72 patients at pathological examination. [$^{68}$Ga] Ga-DOTATOC PET detected LNs with a diagnostic accuracy=0.64, SN=0.17 and SP=0.95, providing 5/29 true positives (TP) and 24/29 false negatives (FN). The best radiomic model was a LDA (solver="eigen", shrinkage=0.6) trained with a radiomic signature composed of $SUV_{max}$, Sphericity, Skewness, Kurtosis, and Strength. The model, trained on primary tumors' features, provided predictions on pathological LNs with an average bACC=0.71, SN=0.67, and SP=0.75, resulting in an average of 15/29 TP and 5/29 FN and outperforming the control model (bACC=0.61, SN=0.35, SP=0.87, p<0.05) (Table1). ***Conclusion:*** [$^{68}$Ga]Ga-DOTATOC PET radiomic analysis improved PanNET pathological LNs prediction, shifting the diagnostic sensitivity from 0.17 to 0.67. Furthermore, the comparison with the control model proved the role of RFs in providing pivotal, additional information on PanNET pathological LNs assessment, thus supporting surgical planning of PanNET patients. ***References:*** [1]PartelliS. et al., Ann Surg.2022, doi:10.1097/SLA.0000000000005615

## EP-0203

### Role of 68Ga-DOTANOC PET/CT in the assessment of Appendiceal Neuroendocrine Tumors

***R. Goel***, *S. A. Shamim, N. Kumar, S. Rastogi, R. Kumar, C. Bal;*
*All India Institute of Medical Sciences, NEW DELHI, INDIA.*

***Aim/Introduction:*** Appendiceal neuroendocrine tumours (NETs) are rare and usually detected incidentally after appendectomy. Appendiceal NETs typically have a lesser propensity for regional and distant metastases as compared to other types of NETs Appendiceal neuroendocrine neoplasms generally express somatostatin receptors (SSTRs), thus 68Ga-DOTANOC PET/CT helps in defining disease extent and SSTR status, which further helps in their assessment and planning for peptide receptor radionuclide therapy (PRRT) [1, 2]. This study aims to evaluate the role of 68Ga-DOTANOC PET/CT in patients with NET of appendix. ***Materials and Methods:*** Data of 12 patients (mean age 37.2 ± 14.5 years, range 11-56 years, M: F = 7:5) with histologically proven Appendiceal neuroendocrine tumors who underwent 68Ga-DOTANOC PET/CT from January 2018 and March 2023 were reviewed. Two certified nuclear medicine physicians independently reviewed the 68Ga-DOTANOC PET/CT studies. The tumor SUVmax and tumor-to-liver uptake ratios (T/L) were also measured. ***Results:*** There were 12 patients who underwent a total of 24 68Ga-DOTANOC PET/CT scans. Out of the 24 scans, 2 scans were performed at diagnosis for baseline staging, 14 for response assessment, and 8 for follow up post treatment completion. Out of the 2 scans done at diagnosis for baseline staging, 1 showed SUV max = 24, T/L=1.7, and the other showed SUV max = 4.8 with T/L=1.17. One study also revealed metastases to lymph nodes and liver. Out of the 14 scans performed for response assessment, 6 showed complete remission, 6 showed stable disease, and 1 revealed partial response. Disease progression was seen in 1/14 68Ga-DOTANOC PET/CT scans that detected new hepatic subcapsular deposits, peritoneal, omental & serosal deposits, ascites and right pleural effusion. Among the 8 scans performed for follow up, none of the studies revealed any SSTR expressing residual/recurrent disease. ***Conclusion:*** 68Ga-DOTANOC PET/CT may play an important role in staging/restaging, response evaluation, and detection of suspected recurrence in patients with appendiceal NETs which would help in their overall management. However, more studies on a larger patient population are required to validate the same. ***References:*** 1.Bayhan Z, Yildiz YA, Akdeniz Y, Gonullu E, Altintoprak F, Mantoglu B, et al. ## EP-0204

### Clinical impact of [68Ga] Ga-DOTA-TOC PET/CT in the management of neuroendocrine tumors.

***J. Villa Palacios***, *T. Aroui Luquin, D. Rivas-Navas, P. Guijarro-Caba, M. Muros De Fuentes;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** The aim of this study is to determine the usefulness and therapeutic impact of [68Ga] Ga-DOTA-TOC PET/CT on the management of neuroendocrine tumors. ***Materials and Methods:*** A retrospective observational study (from November 2021 to November 2022) was conducted in patients who underwent [$^{68}$Ga] Ga-DOTA-TOC PET/CT study for the diagnosis or suspicion of neuroendocrine tumors. The PET/CT study was performed 60 minutes after intravenous administration of 111-185 MBq of 68Ga-edotreotide. All findings in [$^{68}$Ga] Ga-DOTA-TOC PET/CT were confirmed histologically, by specific imaging tests (ultrasound, CT scan or MRI), and/or clinical follow-up. ***Results:*** According to this protocol 126 patients have been studied (50 men and 76 women, mean age 61 ± 14.5 years). Gastro-pancreatic tumors were the most frequent in 48/126 patients (38.1%), followed by pulmonary carcinoids in 24/126 (19.1%) and others in 19/126 (15.1%). Using WHO 2017 grading, 19.8% of patients had low grade tumor (G1), 33.3% intermediate (G2), and 8.7% high (G3). The diagnostic accuracy of [$^{68}$Ga] Ga-DOTA-TOC PET/CT: TP: 59, TN: 61, FP: 4, FN: 2, S: 0.97 (95% CI 0.92-1.01), E: 0.94 (95% CI 0.88-1.00), PPV: 0.94 (95% CI 0.88-1.00), and NPV: 0.97 (95% CI 0.92-1.01). There were new lesions identified on [$^{68}$Ga] Ga-DOTA-TOC PET/CT in 25/126 patients (19.8%). Of these patients 20 (15.8%) had a change in treatment plan. ***Conclusion:*** [$^{68}$Ga] Ga-DOTA-TOC PET/CT showed high sensitivity mainly due to its ability in detecting lesions unsuspected by other imaging procedures, consequently conducting to a more acurrate treatment.

## EP-0205

### Utility of different semiquantitative parameters of [68Ga] Ga-DOTA-TOC PET/CT and their correlation with neuroendocrine tumors differentiation grade.

***J. Villa Palacios***, *T. Aroui-Luquin, D. Rivas-Navas, M. Muros De Fuentes, R. Sanchez Sanchez;*
*Hospital Universitario Virgen de las Nieves, Granada, SPAIN.*

***Aim/Introduction:*** To correlate the semiquantitative parameters of [$^{68}$Ga] Ga-DOTA-TOC PET/CT with the differentiation grade of neuroendocrine tumors. ***Materials and Methods:*** A retrospective observational study of 125 patients with neuroendocrine tumors who underwent [$^{68}$Ga] Ga-DOTA-TOC PET/CT for initial diagnosis and/or disease follow-up. Patient variables such as sex, age, tumor grade, index Ki67, mitotic index were analyzed. The images were analyzed visually and semiquantitatively by calculating the SUVmax, SUVmean, SULmax, SULmean, total functional volume (TFV), tumor to liver SUVmax ratio ($SUV_{TLR}$), tumor to spleen SUVmax ratio ($SUV_{TSR}$), and tumor to blood pool ratio ($SUV_{TBR}$). ***Results:*** 126 patients (50 men and 75 women), the mean age was 61 ± 14.5 years. Gastropancreatic tumors were the most frequent in 48/126 patients (38.1%), and 46/125 patients (36.8%) had grade 2 tumors. [$^{68}$Ga] Ga-DOTA-TOC PET-CT was positive in 63 patients, and the mean SUVmax of the tumor lesions was 29.1 ± 24.8, SUVmean 16.0 ± 13.3, SULmax: 19.2 ± 16.8, SULmean: 11.2 ± 10.4, TFV (cm3): 76.6 ± 71.6. The $SUV_{TLR}$: 2.5 ± 3.2, $SUV_{TSR}$: 1.02 ± 1.1, and $SUV_{TBR}$:34.6 ± 47.7. The values of $SUV_{TSR}$ and $SUV_{TBR}$ were lower in less differentiated tumors (G3) compared to more differentiated G1 and G2 tumors (P =0.03). Neuroendocrine tumors of pulmonary origin had lower $SUV_{TLR}$ values than gastro-enteropancreatic NETs (P = 0.04). All semiquantitative parameters showed a weak negative linear correlation with Ki67 values (Pearson's r < 0.3). ***Conclusion:*** The $SUV_{TLR}$, $SUV_{TSR}$, and $SUV_{TBR}$ may be an alternative to SUVmax in the semiquantitative evaluation of [$^{68}$Ga] Ga-DOTA-TOC PET-CT, allowing for better discrimination of tumor differentiation.

## EP-0206

### Quantification of 99mTc-EDDA/HYNIC-TOC SPECT/CT: a feasible alternative to68Ga-DOTA-PET in patients with NET disease

***P. Spiridon***[1], *A. Lazar*[1], *R. Maaz*[1], *J. Rabah*[1], *M. Mutuleanu*[1,2], *M. Gherghe*[1,2];
[1]*Nuclear Medicine Department, Institute of Oncology "Professor Doctor Alexandru Trestioreanu", Bucharest, ROMANIA,*
[2]*Nuclear Medicine Department, University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

***Aim/Introduction:*** Neuroendocrine tumors (NET) are a heterogeneous group of malignant diseases originating from neuroendocrine cells, localized mostly in the gastro-entero-pancreatic tract and lungs. The detection of somatostatin receptors (SSTR) expressed on the cellular surface of primary tumors and metastases is crucial for the diagnosis and evaluation of the prognosis in these patients. The aim of our study was to characterize the single photon emission computed tomography/computed tomography (SPECT/CT) uptake pattern of $^{99m}$Tc-EDDA/HYNIC-TOC in NETs in comparison to the physiological uptake of targeted tissues, allowing for a better differentiation between physiological uptake and tumor-related SSTR expression. ***Materials and Methods:*** We performed a retrospective study, including 53 patients who underwent a total of 74 $^{99m}$TcEDDA/HYNIC-TOC scans in our department, as part of their clinical management. The examination protocol included a whole-body scan acquired 2 h after radiotracer administration, and a SPECT/CT performed 4 h post-injection. Maximum standardized uptake values ($SUV_{max}$), normalized to lean body mass, were measured for physiological uptake in liver, spleen and bone tissue and also in hepatic, lymph node and bone metastases. Statistical tests were performed to compare normal uptake and NET disease uptake in the liver, bones and lymph nodes. ***Results:*** The main clinical indications for a SPECT/CT study in our patients were pancreatic neuroendocrine tumor in 18 patients, pulmonary NET in 7 cases, gastrointestinal NET in 13 cases and 15 patients with unknown primary tumor, whose diagnosis at presentation was the presence of liver metastases. These patients performed $^{99m}$TcEDDA/HYNIC-TOC scans for diagnosis/primary staging or for the assessment of residual/recurrent disease. Mean $SUV_{max}$ values for $^{99m}$TcEDDA/HYNIC-TOC were 19.41±13.92 in 62 liver metastases, 14.86±10.11 in 39 lymph nodes and 6.63± 9.83 in 15 bone metastases. The highest normal physiological uptake was observed in the spleen with mean $SUV_{max}$ 10.08±6.10, followed by the liver with 3.74±1.22 and bone 1.04±1.04 g/ml. The differences between malignant and non-malignant lesions were statistically significant in liver and bones, after comparing the $SUV_{max}$ in hepatic and osseous metastases with the physiological uptake (p<0.0001). ***Conclusion:*** The quantitative analysis of $^{99m}$TcEDDA/HYNIC-TOC uptake on SPECT/CT in patients diagnosed with neuroendocrine tumors could represent a good alternative to positron emission tomography (PET) with $^{68}$Ga-labelled peptides for patient management. The uptake patterns in normal and tumoral tissue represents a feasible substitute to $^{68}$Ga-DOTA-PET quantification for peptide receptor radionuclide therapy planning and monitoring in these patients.

## EP-0207

### Prognostic impact of Gallium-68 DOTANOC PET/CECT in metastatic well differentiated Gastro-entero-pancreatic Neuroendocrine Tumors (GEP NETs).

***I. Dev***, *V. Rangarajan, A. Puranik, A. Agrawal, N. Purandare, S. Shah, S. Shrikhande, V. Chaudhari, S. Choudhury, S. Ghosh;*
*TATA MEMORIAL CENTRE, Mumbai, INDIA.*

***Aim/Introduction:*** To evaluate the prognostic value of Ga-68 DOTANOC PET/CECT (DOTA PET) based parameters in assessing progression free survival (PFS) in patients with metastatic well differentiated (WD GEP-NETs). ***Materials and Methods:*** This retrospective study included 85 patients of metastatic WD GEP NETs who underwent DOTA PET for staging/metastatic work up. Of them, 35 patients had primary site in pancreas, 40 in small bowel and remaining 10 at other sites. In 46 out of 85 patients, primary tumor was resected. Patients were stratified into two groups based on median SUVmax of target lesion (highest uptake of either primary/metastatic lesion), liver involvement on DOTA PET calculated as tumor volume measured in three planes involving more than 50% of liver, and resection of primary. PFS was calculated from the date of DOTA PET to the last date of clinical/radiological progression or death due to disease. Survival graphs were drawn using Kaplan Meier method and compared using log rank test. P value < 0.05 was considered significant. ***Results:*** Median PFS was 15 months (Range: 2-54 months). ROC analysis yielded cut-off of 35 for SUVmax of target lesion. PFS in patients with SUVmax 35 was 44 months and for those with SUVmax less than 35 was 24 months (p value 0.003). Patients with more than 50% liver involvement on DOTA PET showed lesser PFS (26 months) than in those with less than 50% involvement (49 months) (p value 0.008). PFS was higher in patients with resection of primary tumor (42 months) than in patients with unresected primary (28 months) (p value 0.039). ***Conclusion:*** Higher SUVmax of target lesion, less than 50% liver involvement on DOTA PET and resection of the primary tumor are statistically significant prognostic factors associated with improved progression free survival. ***References:***

### Role of 68Ga-DOTANOC PET/CT in the assessment of Lung Carcinoids

***S. Shamim**, R. Goel, N. Kumar, G. Arora, S. Rastogi, A. Goyal, R. Kumar, C. Bal;*
*AIIMS New Delhi, Delhi, INDIA.*

***Aim/Introduction:*** Lung carcinoids (LC) are rare malignant neoplasms, accounting for a very small percentage of all lung tumors. The preoperative classification of LC into typical carcinoid and atypical carcinoid and ascertaining extent of dissemination are important factors for deciding treatment and prognosis. Majority of the LC are found to express somatostatin receptors (SSTRs), thus $^{68}$Ga-DOTANOC PET/CT can help in defining disease extent and SSTR status, which further helps in their assessment and management. This study aims to evaluate the role of $^{68}$Ga-DOTANOC PET/CT in patients with Lung carcinoids. ***Materials and Methods:*** We retrospectively reviewed 41 $^{68}$Ga-DOTANOC PET/CT in 32 patients with Lung carcinoids at our institution between January 2017 and March 2023. ***Results:*** There were 32 patients (10 female, 22 males; age 15-63 years) who underwent $^{68}$Ga-DOTANOC PET/CT scans. Out of the 41 scans, 4 scans were done for initial diagnosis of suspected lung carcinoids, 15 scans were performed for baseline staging, 13 for response assessment, 9 for suspected recurrence/surveillance.All 4 scans performed for initial diagnosis of suspected LC revealed SSTR expressing lesions in the lung/bronchus suggestive of lung carcinoids. On histopathological correlation, 2/4 patients were found to have typical carcinoids whereas a diagnoses of sclerosing pneumocytoma and mixed germ cell tumor was made for the other two patients respectively.Out of the 15 scans done at diagnosis for baseline staging, 12 were typical carcinoids whereas 3 were atypical carcinoids. Four of 15 scans also revealed metastases to lymph nodes, liver and skeletal sites.Out of the 13 scans performed for response assessment, 12 showed stable disease and 1 revealed disease progression.Among the 9 scans performed for surveillance/ suspected recurrence, 1 study revealed SSTR expressing hypodense lesions in the liver, whereas the rest showed no SSTR expressing residual/recurrent disease. ***Conclusion:*** $^{68}$Ga-DOTANOC PET/CT may play an important role in staging/restaging, response evaluation and detection of suspected recurrence in patients with lung carcinoids which would help in their overall management. However, more studies on a larger cohort are still required to validate the same.

## EP-0209

### Assessment of glucose metabolism in skeletal muscle and adipose tissue with the use of 2-[18F]FDG PET/CT in patients with ectopic adrenocorticotropin secretion

***M. Opalinska**[1], J. Kokoszka[2], E. Rzepka[1], K. Sitarz[3], A. Sowa-Staszczak[1], A. Gilis-Januszewska[1], A. Hubalewska-Dydejczyk[1];*
*[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, POLAND,*
*[2]Endocrinology, Oncologic Endocrinology and Nuclear Medicine Department, University Hospital in Krakow, Krakow, POLAND, [3]University Hospital in Krakow, Krakow, POLAND.*

***Aim/Introduction:*** 2-[18F]FDG PET/CT, commonly used for neoplastic lesions detection, also allows assessment of the severity of the inflammatory process in muscles. Patients with Cushing's syndrome (CS) demonstrate many metabolic changes involving muscle, adipose tissue and bones, mediated by cytokines and hormones. Ectopic adrenocorticotropin secretion (EAS) accounts for 10-15% of cases of CS and is characterized by high fast-rising cortisol levels leading to deterioration of body composition including worsening of muscle quality. Some mechanisms, involving muscle steatosis leading to myopathy, are known, but their relationship to glucose metabolism is not well investigated. The aim of our study was to assess glucose metabolism with the use of 2-[18F]FDG PET/CT in skeletal muscle and adipose tissue in patients with ectopic ACTH-syndrome. ***Materials and Methods:*** Analysis of 2-[18F]FDG PET/CT scans in 12 patients with EAS in comparison to age and sex-matched control group was performed. On unenhanced CT scans the body composition on cross-sectional computed tomography images at the L3 level - skeletal muscle area (SMA), skeletal muscle index (SMI), visceral fat area (VFA), visceral fat index (VFI), subcutaneous fat area (SFA), subcutaneous fat index (SFI), intermuscular adipose tissue (IMAT), bone density in vertebrae L3 was assessed. Psoas muscle (at the L3 vertebra) and femoris muscle (medial vastus of the quadriceps femoris muscle at the mid-thigh level) metabolic volume (MV), SUV peak, lesion glycolysis (LG) in both right and left muscle groups were evaluated base on the 2-[18F]FDG-PET scan results. The results were related to the hormonal status: ACTH, midnight cortisol, cortisol after 1mg of dexamethasone concentrations. ***Results:*** The comparison of glucose metabolism muscle and fat composition assessed by 2-[18F]FDG-PET and CT respectively, showed inverse correlation between SMI and metabolic volume of femoris muscle (p=0.047). Moreover, ACTH concentration was negatively correlated with metabolic volume and SUV peak of psoas muscle (p=0.044 and p=0.033, respectively). There were no differences between study and control group regarding the prevalence of sarcopenia assessed on SMI, body composition on CT scans and skeletal muscle metabolism on PET scans. ***Conclusion:*** In our patients with EAS, at diagnosis skeletal muscle, fat and bone metabolism were not significantly deteriorated. Lower SMI with increased 2-[18F]FDG activity in femoris muscles may indicate increased inflammatory status in intramuscular adipocytes and fibrotic tissue. Negative correlation between ACTH and glucose metabolism in psoas muscle may potentially reflect better muscle state in patients in better general condition.

## EP-0210

### The evaluation of kidney function using the Somatostatin (SSTR)-targeting radioligands 18F-SiFA-TATE, 68Ga-DOTATATE and 68Ga-DOTATOC in a theranostic setting

***M. Tiling**[1], A. Holzgreve[1], S. Kunte[1], G. Sheikh[1], M. Unterrainer[2,1], P. Bartenstein[1], A. Delker[1], L. Unterrainer[1];*
*[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,*
*[2]DIE RADIOLOGIE, Munich, GERMANY.*

***Aim/Introduction:*** Not only tumor cells but also physiologically renal tissue expresses somatostatin receptors (SSTR), which results in a high renal uptake of SSTR-ligands. Since the application of Lu-177-DOTATATE can lead to nephrotoxicity, the renal function is often evaluated by pre- and inter-therapeutic $^{99m}$Tc-MAG3 renal scintigraphy. Recently, it could be demonstrated that renal $^{18}$F-PSMA-1007 uptake allowed the quantification of renal split function in prostate cancer patients. The analogue evaluation of estimating renal function in patients with neuroendocrine tumors prior, during and after Lu-177-DOTATATE therapy was evaluated. ***Materials and Methods:*** Overall, we correlated MAG3-derived renal function with kidney uptake in SSTR-PET/CT (n=30 $^{18}$F-SiTATE; n=10 $^{68}$Ga-DOTATATE; n=10 $^{68}$Ga-DOTATOC). An obstruction in the

urinary tract system was excluded. For each of the respective PET ligands, a specific threshold of $SUV_{max}$ ($^{18}$F-SiTATE: 25% of $SUV_{max}$; $^{68}$Ga-DOTATATE: 32,5% of $SUV_{max}$, $^{68}$Ga-DOTATOC: 25% of $SUV_{max}$) was applied to delineate the kidneys in correlation with their CT volume surrogate. Split renal function was calculated by two approaches. Firstly, by considering threshold-based kidney volume and $SUV_{mean}$ ($SRF_{TOTAL}$), and secondly based on threshold-based $SUV_{max}$ ($SRF_{SUV}$). $SRF_{TOTAL}$ and $SRF_{SUV}$ were correlated with the MAG3-derived split renal function ($SRF_{MAG3}$). Global renal function was determined by correlating the bilateral total renal tracer uptake (TRU) and MAG3 tubular excretion rate. ***Results:*** Correlation analysis of MAG3 and $^{18}$F-SiTATE showed a weak, but significant correlation between $SRF_{MAG3}$ and $SRF_{TOTAL}$ (r=0.462; $r^2$=0.214; p=0.010) and no correlation between $SRF_{MAG3}$ and $SRF_{SUV}$ (r=-0.044; $r^2$=0.002; p=0.817). Bilateral $^{18}$F-SiTATE uptake (TRU) was not significantly correlated with MAG3 tubular excretion rate (r=0.155; $r^2$=0.024; p=0.413). In the $^{68}$Ga-DOTATOC and $^{68}$Ga-DOTATATE cohorts, renal function evaluated by MAG3, SRF and TRU showed no significant correlation. ***Conclusion:*** Renal $^{18}$F-SiTATE uptake might allow the quantification of quantify split renal function using $SRF_{TOTAL}$ with moderate accuracy and thus might be used to predict renal function; in clinical routine, this approach might lead to early identification of patients with borderline split function even prior to further therapies. In a further step, kidney doses in the post-therapeutic SPECT/CTs should be correlated with PET-derived split renal function to additionally evaluate the impact of SSTR-targeted imaging for dose absorption in correlation with kidney function.

## EP-0211

### Spectrum of hyperuptake findings detected in PET/CT [68Ga]Ga-DOTA-TOC studies. Experience in our center

***S. Bondia-Bescós****, J. Vercher-Conejero, J. Martin-Marcuartu, A. Rodriguez-Gasen, J. Suils-Ramón, M. Perlaza-Jiménez, M. Pudis, B. Hervás-Sanz, J. Díaz-Moreno, M. Cortés-Romera;*
*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, Barcelona, SPAIN.*

***Aim/Introduction:*** To analyze the detection capacity of [$^{68}$Ga]Ga-DOTA-TOC PET/CT for neuroendocrine neoplasms (NEN) as well as other non-neuroendocrine hyper-uptake lesions and their uptake degree. ***Materials and Methods:*** Retrospective study of [$^{68}$Ga]Ga-DOTA-TOC PET/CT performed between April 2019 and December 2022 in patients with or suspected NENs at our center.The diagnosis of non-neuroendocrine hyper-uptake lesions was made according to biopsy, imaging semiology and/or clinical evolution.Semiquantitative analysis of non-neuroendocrine tumors using the $SUV_{max}$ (g/ml). ***Results:*** A total of 324 studies (270 patients: 123 women, mean age 61.6 years) were evaluated. Repeated findings from the same patient were excluded.The most frequent NEN were: gastroenteropancreatic (64%), lung carcinoids (5.1%), paragangliomas/pheochromocytomas (2.6%). The most frequent degree of differentiation in GEP-NEN biopsies was G2, followed by G1 and G3.The primary tumor was detected in 38% of the examinations referred by NEN of unknown primary tumor. The study was negative at 13%. The most frequent hyper-uptake findings not related to NEN were:- Non-neoplastic (63p, 48.8%): reactive adenopathies (13/63), Multinodular goiter, BETHESDA nodules <3 (13/63), BPH/prostatitis (12/63).- Benign neoplasms (21p, 16.3%): meningioma (6/21), miomas (3/21), parathyroid/pleomorphic adenoma (2/21). The average $SUV_{max}$ was 9.38, with a range between 0.83 (cutaneous neurofibroma) and 53.35 (meningioma).- Malignant neoplasms (12p, 9.3%): Invasive breast cancer (ductal/lobular) (3/12), Prostate adenocarcinoma (3/12), Pancreatic adenocarcinoma (2/12). The average $SUV_{max}$ was 5.71 with a range between 1.67 (breast cancer) and 14.03 (intestinal GIST). ***Conclusion:*** [$^{68}$Ga]Ga-DOTA-TOC PET/CT is very useful for localizing NEN of unknown origin and assessing radiopeptide therapy.In our study, hyper-uptake non-neuroendocrine lesions were observed in 1/3 of the patients, of which 25% were of neoplastic origin. The intensity of uptake of the non-neuroendocrine neoplasms detected was variable and we found no apparent relationship with their degree of malignancy. ***References:*** Ambrosini V, Zanoni L, Filice A, et al. Radiolabeled Somatostatin Analogues for Diagnosis and Treatment of Neuroendocrine Tumors. Cancers (Basel). 2022;14(4):1055.Malan, N.; Vangu, M.D.T. ## EP-0212

### 68Ga-DOTA peptides PET/CT radiomic parameters useful to differentiate para-physiological uptake in pancreatic uncinate process from pancreatic NET.

***F. Linguanti****[1], E. M. Abenavoli[2], A. Lombardo[1], V. Briganti[2], F. Mungai[3], L. Antonuzzo[4], D. Lavacchi[4], L. Vaggelli[2], M. Matteini[2], R. Sciagrà[1], V. Berti[1];*
*[1]Nuclear Medicine Unit, Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', University of Florence, Florence, ITALY, [2]Department of Nuclear Medicine, Azienda Ospedaliero-Universitaria Careggi, Largo Brambilla 3, 50134, Florence, ITALY, [3]Department of Radiology, Azienda Ospedaliero-Universitaria Careggi, Largo Brambilla 3, 50134, Florence, ITALY, [4]Medical Oncology Unit, Careggi University Hospital, Largo Brambilla 3, 50134, Florence, ITALY.*

***Aim/Introduction:*** Pancreatic neuroendocrine tumors (pNET) are among the most common neuroendocrine tumors and 68Ga-DOTA peptides PET/CT (PET/CT) represents the gold standard imaging evaluation in their clinical management. However, the pancreatic uncinate process (UP) is often characterized by para-physiological uptake in PET/CT, simulating a pathological radiotracer accumulation with consequently difficulties in imaging interpretation.This study tested the diagnostic value of PET/CT radiomic parameters in the histological differentiation of pNET from para-physiological UP uptake. ***Materials and Methods:*** We retrospectively analyzed 68 patients, with pathology-proven pNET (n=34) and non-pancreatic NET (n=34) with para-physiological increased UP uptake without pancreatic alterations at morphological scans who underwent PET/CT pre-treatment.For all patients, a volume of interest (VOI) both for the pNET and the UP, was manually contoured on PET/CT images and then defined using a thresholding-based model with a cut-off of 50% of the SUVmax. Radiomic parameters were measured using LIFEx software [1].The comparison of parameters between groups was performed using ANOVA test (P<0,005). We performed factor analysis to remove redundancy of cross-correlated variables and discriminant analysis to examine the power of the potential independent predictors. ***Results:*** SUVmax, SUVmean and MTV resulted significant different between two groups and only SUVmax and SUVmean were confirmed in discriminant analysis.Based on our results, several PET textural features resulted significant predictive of tissue characterization. Among first order PET parameters, we found MORPHOLOGICAL_Maximum3Ddiameter, INTENSITY-BASED_MaximumGreyLevel and INTENSITY-BASED_Range that correctly classified more than 85% of subjects.Among second order PET parameters, GLCM_

SumAverage, GLCM_Autocorrelation; GLRLM_ShortRunHighGreyLevelEmphasis and GLRLM_HighGreyLevelRunEmphasis; GLSZM_GreyLevel Variance, GLSZM_NormalisedZoneSizeNonUniformity and GLSZM_SmallZoneHighGreyLevelEmphasis correctly classified more than 85% of subjects. ***Conclusion:*** Imaging radiomics could be useful to better characterize pancreatic tissue, differentiating pNET from para-physiological uptake of UP with an important reduction of 68Ga-DOTA peptides PET/CT pitfalls. ***References:*** [1] Nioche C, et al. Cancer Research. 2018; 78:4786-4789; www.lifexsoft.org

## EP-0213

### β-1600 Q.Clear Reconstruction Improves [68Ga]Ga-DOTANOC Digital PET/CT Image Quality

***E. Fortunati***[1], *N. Bonazzi*[1], *M. Di Franco*[1], *L. Zanoni*[2], *C. Mosconi*[3,4], *S. Civollani*[2], *D. Campana*[3,5], *C. Malizia*[6], *V. Allegri*[2], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*DIMEC, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Radiology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Division of Medical Oncology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [6]*PET Radiopharmacy Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** to assess the preferred Q.Clearβ-level for digital [68Ga]Ga-DOTANOC PET/CT reconstruction vs standard reconstruction (STD) for both overall scan and single lesions' visualisation (for the most-avid finding <1cm and >1cm, respectively). ***Materials and Methods:*** Inclusion criteria: (1) patients with neuroendocrine neoplasms included in a prospective observational monocentric CE-approved study between September2019/January2022; (2) [68Ga]Ga-DOTANOC digital PET/CT and contrast-enhanced-CT (ceCT) performed at our center at the same time-point. Images were reconstructed with STD and with three Q.Clearβ-levels (800, 1000, 1600). Scans were reviewed by two expert nuclear medicine readers, unaware of clinical data, who independently chose the preferred reconstruction for visual quality of both overall scan and single lesions (for the most-avid finding <1cm and >1cm, respectively). Standard of reference to validate PET/CT findings was ceCT (revised by one expert radiologist) and clinical follow-up. Semi-quantitative analysis was performed on STD and β-1600 in target lesions <1cm (t) and >1cm (T) concordant at both PET/CT and ceCT: SUVmax, SUVmean, standard deviation (SD) of the highest uptake target lesion (T and t) and liver-background (L); SUVmax-T/SUVmean-L; SUVmax-t/SUVmean-L; Signal-to-noise liver ratio (SNR-L=SUVmean/SD); Contrast-to-noise ratio (CNR=SUVmeanT-SUVmeanSurroundingBackground/SDBackground). ***Results:*** Overall, 55 patients (age: mean=60.4, median= 63 [23-87]yo) were included. Visual image quality of β-1600 was considered superior over the other reconstructions (100% agreement), for both overall scan and single lesions. PET/CT was positive in 37/55 patients: SNR-L (β-1600 vs STD: mean=9.9 vs 7.3, median=9.9 vs 7.1, range [4.7-15.7] vs [4.6-14.0]) and SD-L (β-1600 vs STD: mean and median=0.5 vs 0.7, range [0.2-1.1] vs [0.3-1.3]) were the only significantly ($p<0.001$) different parameters between β-1600 and STD. Similar results for both SNR-L and SD-L were confirmed ($p<0.001$) in the sub-group analysis of concordant lesions >1cm (T, n=18) and <1cm (t, n=10). Lesions' dependent parameters (SUVmax, SUVmean and CNR) were not significantly different for overall and subgroups (T,t) analyses. The subgroups analysis of PET/CT and ceCT discordant lesions<1cm (n=20 patients), showed that PET was TP in 11/20 (bone), VN in 4/20, FN in 4/20 (liver). ***Conclusion:*** Q.Clearβ-1600 was superior to all other reconstructions for overall image quality and lesions' visualization. Semi-quantitative analyses confirms the typical Q.Clear signal-to-noise suppression: higher SNR of the liver(reference background) was observed for β-1600 vs STD, without any significant change in lesions' dependent parameters. These preliminary results pave the way to the routine use of Q.Clearβ-1600 for image quality optimization (e.g.while SUVmax values are comparable whether Q.Clearβ-1600 or STD is used).

## EP-0214

### Comparison of 68Ga-DOTATATE PET/CT and 68Ga-DOTATATE PET/MR in Detection of Neuroendocrine Tumour Liver Metastasis

***B. Demir***[1], *C. Soydal*[1], *M. Araz*[1], *M. H. Baltacioglu*[1], *D. Kuru Oz*[2], *N. O. Kucuk*[1];
[1]*Ankara University School of Medicine Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara University School of Medicine Department of Radiology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** $^{68}$Ga-DOTATATE is a highly efficient molecular imaging agent that can be used for various malignancies like gastroenteropancreatic neuroendocrine tumours, carcinoid tumours of lung, paraganglioma, pheochromocytoma and neuroblastoma. In this study we aimed to investigate additive value of dedicated 68Ga-DOTATATE liver PET/MRI that was performed after PET/CT compared to standard whole body PET/CT. ***Materials and Methods:*** A total number of 26 patients and 30 pairs of PET/CT and dedicated respiratory gated contrast-enhanced PET/MRI acquired later in same session that was performed between November 2018-January 2023, were included in this retrospective study. Total detected lesion number, SUVmax, SUVmean, metabolic tumour volume (MTV), total lesion $^{68}$Ga-DOTATATE uptake (TL-DOTATATE) and tumour to background ratio (TBR) were noted. Detected lesion numbers were grouped as no lesions, 1 lesion, 2-4 lesions, 5-10 lesions and >10 lesions for analysis. Also for each study signal/noise ratio (Liver paranchyme SUVmean/Standard Deviation) (SNR) and contrast/noise ratio ([Lesion SUVmax-Liver SUVmean]/Standard Deviation of Liver Parenchyma VOI) (CNR) values were calculated. For statistics analysis chi-square test for lesion numbers and Mann-Whitney-U test for SNR and CNR comparison were utilised. ***Results:*** In 15 studies (50%) both modalities were negative for liver metastasis. In the remaining 15 studies PET/CT detected 1 lesion in 5 patients, 5-10 lesions in 4 patients and >10 lesions 6 patients. In the same patients PET/MR detected 1 lesion in 4 patients, 2-4 lesions in 1 patient, 5-10 lesions in 2 patients and >10 lesions in 8 patients. Only in 3 patients PET/MRI detected more lesions than PET/CT. There was not any patients who was negative on PET/CT imaging with positive PET/MRI findings for liver metastasis. SNR was significantly higher in PET/MRI (median 9.45) compared to PET/CT (median 7.49) ($p=0.021$). CNR values were higher in PET/MRI (median 29.39 vs. 17.14) but did not reach significance ($p=0.202$). ***Conclusion:*** Standard whole-body $^{68}$Ga-DOTATATE PET/CT is highly efficient in detection of liver metastasis of neuroendocrine neoplasms. Addition of dedicated liver PET/MRI following whole-body PET/CT imaging had a little additive value for detection of metastasis and may only be helpful in limited number of selected patients.

## EP-0215

### [68Ga]Ga-DOTANOC and [18F]F-FDG PET/CT Tumour Burden Across 3-Grades Functional Scoring

***E. Fortunati***[1], *N. Bonazzi*[1], *M. Di Franco*[1], *L. Zanoni*[2], *C. Mosconi*[3,4], *D. Campana*[3,5], *C. Malizia*[6], *E. Andrini*[5], *V. Allegri*[2], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*DIMEC, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Radiology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Division of Medical Oncology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [6]*PET Radiopharmacy Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** To describe [68Ga]Ga-DOTANOC and [18F]FDG-PET/CT tumour burden in patients (pts) with suspected/diagnosed neuroendocrine neoplasms (NEN) divided according to a 3-grades functional scoring. ***Materials and Methods:*** Pts prospectively enrolled in a monocentric CE-approved-prospective observational study (131/2017/O/Oss) on [68Ga]Ga-DOTANOC PET/CT, and previously also assessed with [18F]F-FDG PET/CT were included. Tumour burden parameters were: Total Receptor volume(RTV) and Total Lesion Activity(TLA=SUVmeanxRTV) on [68Ga]Ga-DOTANOC PET/CT, Metabolic Tumour Volume(MTV) and Total Lesion Glycolisis(TLG=SUVmeanxMTV) on [18F]F-FDG-PET/CT; MTV/RTV and TLG/TLA were calculated. Pts were classified into 3 categories [1]: C1=all lesions [18F]F-FDG-negative and [68Ga]Ga-DOTANOC-positive; C2= all lesions [68Ga]Ga-DOTANOC-positive, ≥1 [18F]F-FDG-positive; C3= ≥1 [18F]F-FDG-positive lesions and at least one of them [68Ga]Ga-DOTANOC-negative. Pts were also classified according to WHO-grade. ***Results:*** 60 pts were studied (median days between PET/CT scans=14[1-99]). 15/60 pts [4G1 (2pancreas, 1ileum, 1colon), 10G2 (5pancreas, 2ileum, 2atypical lung carcinoid (AC), 1CUP), 1G3 (pancreas)] were C1, with median-RTV=13,3(mean:47,4[0,9-349,5]), median-TLA=95,2(mean:462[18-3041,5]). 30/60 pts [7G1 (3pancreas, 3ileum, 1duodenum), 16G2 (5pancreas, 2AC, 4typical lung carcinoid (TC), 3ileum, 1colon, 1CUP), 6G3 (4pancreas, 1colon, 1AC), 1NEC (pancreas)] were C2 with median-RTV=52,5(mean:99,9[2,8-440,7]), median-TLA=606,2(mean:1413,3[4-7498,1]), median-MTV=25 (mean:68,8[1,4-377,6]) and median-TLG=58,3(mean261,2[3,6-1628,7]). 10/60 pts [2G1 (1TC, 1ileum), 4G2 (3AC, 1pancreas), 3G3 (1ileum, 1stomach, 1AC), 1NEC (CUP)] were C3 with median-RTV=8,3(mean:106,1[0-957,9]), median-TLA=18,3(mean:1264,6[0-11964]), median-MTV=41,9(mean:384,6[7,8-1947,6]) and median-TLG=105,3(mean:3231,3[7,5-16288,6]. In 5/60 pts [2G1 (2ileum), 2G2 (1ileum, 1TC), 1G3 (pancreas)] both scans were negative, so they were excluded from the classification. MTV and TLG were not significantly different between C2 and C3, while comparison with C1 (FDG-negative) was of course significative. TLA was significantly higher in C2 vs C3 ($p<0.03$), as a marker of increased heterogeneity, while RTV was not significantly different among groups. MTV/RTV ratio was significantly different across all groups (C2 vs C3, $p=0.002$; others: $p<0.001$). Same results were observed for the TLG/TLA ratio (C2 vs C3, $p=0.018$; others: $p<0.001$). Considering WHO-grading, MTV significantly differed between G2 and G3 ($p=0.015$) while TLG was significantly different in G1 vs G3 ($p=0.027$) and in G2 vs G3 ($p=0.01$). While no differences for RTV, MTV/RTV and TLG/TLA were observed. ***Conclusion:*** Both MTV and TLG increase, not reaching statistical significance, with functional scoring. TLA was the only parameter significantly different between C2 and C3, as a marker of increased heterogeneity. MTV/RTV ratio was significantly different across all groups. ***References:*** [1] Karfis I et al. Prognostic value of a three-scale grading system based on combining molecular imaging with 68Ga-DOTATATE and 18F-FDG PET/CT in patients with metastatic gastroenteropancreatic neuroendocrine neoplasias. ### Correlation Between Dual Tracer Imaging (68 Ga Dotanoc and 18 FDG PET) And Mib Index in WHO Grade 2 NET.

***S. Kale****, A. Puranik, N. Purandare, S. Shah, A. Agrawal, V. Rangarajan, S. Shrikhande, V. Ostwal, A. Ramaswamy, M. Bhandare, V. Chaudhari;*
*TATA MEMORIAL CENTRE, Mumbai, INDIA.*

***Aim/Introduction: Aims:*** To evaluate correlation between Mib index and dual tracer scores (Krenning's and FDG score) and its impact on clinical management.***Introduction: -*** Neuroendocrine tumour are heterogeneous with both intra and inter-lesional heterogeneity which can be portrayed by dual tracer imaging with DOTANOC and FDG PET CT. Well differentiated WHO Grade 2 is a large sub group with lot of tumour heterogeneity within. Here we are calculating correlation between dual tracers scores (Krenning's and FDG score) obtained from imaging and its eventual impact on clinical management. ***Materials and Methods:*** 101 patients grade 2 neuroendocrine who underwent dual tracer PET (DOTATATE PET and FDG PET CT) were chosen. They were divided into three groups as (3-5%), (6-10%) and (11-20%) according to the Mib index. Krenning's and FDG scores were calculated based on MIP images. Chi- square and Spearmen's correlation tests were used to establish correlation between dual tracer scores. Management decisions post dual tracer imaging were analyzed to assess clinical impact. ***Results:*** Chi square and Spearman's correlation tests showed no significant correlation between Krenning's score and Mib index groups. While there is positive correlation found between FDG score and Mib index groups, ($r_s$ =.276) (p value = 0.005). Also, dual tracer imaging changed the management in 36 out of 37 patients who were previously receiving treatment. Out of the 64 patients who underwent scanning post biopsy, 33 patients turned out to be both DOTA and FDG positive (51.56%) and received PRRT + chemotherapy (22/33 patients, 66.67%) making significant impact and 26 patients turned out to be only DOTA scan positive (40.62%). PRRT is the most common treatment chosen (14/26 patients 53.84%). ***Conclusion:*** There is no significant correlation between Krenning's score (DOTA PET CT) and Mib index, while there is positive correlation between FDG score (FDG PET CT) across Mib index in grade 2 NET. Also there is significant clinical impact of dual tracer imaging in grade 2 NET.

### Differentiating subcentimeter lung metastasis in colorectal cancer patients by radiomics and deep learning approaches: a multicenter study

***D. Ma****;*
*Department of Colorectal Surgery, Zhejiang Cancer Hospital, Hangzhou, CHINA.*

***Aim/Introduction:*** Preoperative evaluation of the indeterminate lung nodules is important for individual treatment of colorectal cancer (CRC). We aim to develop and validate discriminative radiomics and deep learning approaches for differentiating subcentimenter lung metastases (LMs) in CRC patients. ***Materials and Methods:*** Models were developed in a primary cohort included 1194 consecutive CRC patients with initial subcentimeter

size LMs on CT. Patients were randomly assigned (7:3) to the training or internal validation cohorts (IVC). Machine learning (ML), deep learning (DL), and the integration of radiomics and DL features were applied to classify the subcentimeter lung nodules as LMs or benign lesions. Two independent external validation cohorts (EVC) consisted of 101 (EVC1) and 40 (EVC2) patients. To verify the generalizability for nodules of smaller sizes, stepwise validations on the subgroups according to the nodule's largest diameter (10, 9, 8, 7, 6, 5, ≤4 mm) were conducted. ***Results:*** The diagnostic accuracy by radiologists was 0.705 in primary cohort. The best ML based on support vector machine (SVM) showed a 0.981 area under the curve (AUC) in IVC, a 0.961 and 0.996 AUC in EVC1 and EVC2. The best integration model showed a 0.973 AUC in the IVC and a 0.943 and 0.974 AUC in EVC1 and EVC2. The DL model showed a 0.953 AUC in the IVC and a 0.907 and 0.951 AUC in EVC1 and EVC2. Stepwise validation demonstrated that with the LM diameter decreasing, the integration model was the most stable with smaller LMs, and was the best for LM ≤5 mm. ***Conclusion:*** Our findings showed that radiomics and deep learning approaches based on CT could improve current diagnostic accuracy of subcentimeter CRC LMs. Specially, novel integration model was the best with LMs ≤5 mm. This study provided an automatic and noninvasive solution for determining subcentimeter LMs in the individual management of CRC.

## EP-0218

### Correlation of 18F-FDG PET/CT Parameters Such As SUVmax, MTV and TLG with Histopathological Characteristics in Colorectal Cancer Patients

***B. Ural***, *B. Okudan Tekin;*
*Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

***Aim/Introduction:*** It has been reported that metabolic parameters such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in 18F-Fluorodeoxyglucose (18F-FDG) PET/CT are diagnostic and prognostic biomarkers of various cancers. Microsatellite instability (MSI) is caused by mutations in DNA mismatch repair genes is found in 10-15% of sporadic colorectal cancers. The aim of this study is to investigate the relationship between metabolic parameters and histopathological features of the primary tumor obtained from 18F-FDG PET/CT for staging before treatment in patients diagnosed with colorectal cancer. ***Materials and Methods:*** Forty-nine patients who underwent 18F-FDG PET/CT for pre-treatment staging between January 2021 and December 2021 and were pathologically evaluated for MSI were included in the study. The demographic data of the cases and the histopathological features of the primary tumor in the pathology report were reviewed retrospectively. Tumor localization (right colon, left colon, and rectum), presence of perineural invasion, presence of lymphovascular invasion, T and N stage, and tumor budding were recorded from the pathology report. Areas of interest (VOI) for primary tumor areas were created from 18F-FDG PET/CT images in the LIFEx version 7.3 program. Maximum standardized uptake value of the primary tumor (SUVmax), MTV, TLG and metastasis status were recorded in PET/CT images in VOI. Statistical analysis was performed with Mann-Whitney U, Chi-square and Kendall's Tau tests using SPSS 23.0 program. ***Results:*** There was a significant difference between T stage and perineural invasion, MSI parameters. There was a significant difference between N stage and perineural and lymphovascular invasion, and differentiation parameters ($p<0.050$). There was a significant difference between the differentiation groups (good, moderate, and poor) in the parameters of perineural and lymphovascular invasion, MSI ($p<0.050$). There was a significant correlation between the degree of differentiation and perineural and lymphovascular invasion, MSI parameters ($p<0.050$). Among the histopathological parameters, only the degree of differentiation was correlated with the MTV values ($p<0.050$). No significant correlation was found between other 18F-FDG PET/CT parameters (SUVmax and TLG) and histopathological parameters. ***Conclusion:*** The expected relationship between histopathological parameters and SUVmax and TLG could not be demonstrated in this study, but there is a significant relationship between MTV and the degree of tumor differentiation. Studies with larger patient groups are needed to predict the histopathological character of colorectal cancer with the 18F-FDG/PET for staging. ***References:*** 1)Frontiers in immunology, 12, 724464.PMID: 34512653 2)Clinical nuclear medicine, 41(10),761-5.PMID: 27556789

### PET/CT Imaging 2 Hours After Injection of [18F]PSMA-1007 Can Lead to Higher Staging of Prostate Cancer Than Imaging After 1 Hour

***E. Hvittfeldt***[1,2], *U. Bitzén*[3], *D. Minarik*[1,4], *J. Oddstig*[1,5], *B. Olsson*[2,1], *E. Trägårdh*[1,2];
[1]*Department of Translational Medicine, Wallenberg Centre for Molecular Medicine, Lund University, Malmö, SWEDEN,* [2]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, SWEDEN,* [3]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund, SWEDEN,* [4]*Department of Medical Physics, Skåne University Hospital, Malmö, SWEDEN,* [5]*Department of Medical Physics, Skåne University Hospital, Lund, SWEDEN.*

***Aim/Introduction:*** [18F]PSMA-1007 is a prostate specific membrane antigen (PSMA) ligand for positron emission tomography (PET) imaging of prostate cancer. Current guidelines recommend imaging 90-120 minutes after injection but strong data about optimal timing is lacking. Our aim was to study whether imaging after 1 hour and 2 hours leads to a different number of detected lesions, with a specific focus on lesions that might lead to a change in treatment. ***Materials and Methods:*** 195 patients underwent PET imaging 1 and 2 hours after injection of [18F]PSMA-1007. Three readers assessed the status of the prostate or prostate bed and suspected metastases. We analyzed the location and number of found metastases to determine N- and M-stage of patients according to the TNM-classification (Tumor, Node, Metastasis). We also analyzed standardized uptake values (SUV) in lesions and in normal tissue. ***Results:*** Significantly more pelvic lymph nodes and bone metastases were found and higher N- and M-stages were seen after 2 hours. In twelve patients (6.1%) two or three readers agreed on a higher N- or M-stage after 2 hours. Conversely, in two patients (1.0%), two readers agreed on a higher stage at 1 hour. SUVs in suspected malignant lesions and in normal tissues were higher at 2 hours, but lower in the blood pool and urinary bladder. ***Conclusion:*** Imaging at 2 hours after injection of [18F]PSMA-1007 leads to more suspected metastases found than after 1 hour, with higher staging in some patients and possible effect on patient treatment.

## EP-0220

### 99mTc-PSMA-SPECT/CT in primary staging of high risk prostate cancer

***K. Liepe***[1], *M. Baehr*[1,2], *T. M. Hoang*[3];
[1]*Klinikum Frankfurt (Oder), Frankfurt (Oder), GERMANY,*
[2]*Campus Virchow-Klinikum, Charité, Department of Diagnostic and Interventional Radiology, Berlin, GERMANY,* [3]*Statistician, Düsseldorf, GERMANY.*

***Aim/Introduction:*** According to current data, PSMA-PET/CT is the gold standard in primary staging and biochemical recurrence of prostate cancer. Unfortunately, the worldwide availability of PSMA-PET/CT is limited by expensive radionuclides, the worldwide availability of PET/CT scanners and restricted low reimbursement rates of public health service. Hence, if PSMA-PET/CT was not available, $^{99m}$Tc-PSMA SPECT/CT could be a valuable alternative. ***Materials and Methods:*** In 84 patients, SPECT/CT were performed using 689±65 MBq 99mTc-MIP-1404 (ROTOP, Dresden, Germany) or PSMA-Tc-API (DSD Pharma, Vienna, Austria). In 38 patients, additional $^{99m}$Tc -MDP SPECT/CT were performed. In 32 patients MRI or contrast enhanced CT were performed additionally. ***Results:*** The patient characteristics were as followed: mean age 70 ± 9 years, mean PSA 21.4 ± 27.2 ng/ml and Gleason scores from 7 to 10. Detection rates were: prostate carcinoma 100 %, local lymph node metastases (N1) 28%, distant lymph node metastases (M1a) 13% and osseous metastases (M1b) 15%. No patient showed metastases in other organs (M1c). Correlation analysis showed a positive correlation of detection rate of extraprostatic tumour manifestations for both Gleason score and PSA level. The detection rate of metastatic disease increased significantly with an initial PSA > 20 ng/ml (n=27) from 27% to 77%. High-risk patients showed higher detection rates than low-risk and intermediate-risk patients in both initial PSA < 20 ng/ml and initial PSA > 20 ng/ml. Compared to $^{99m}$Tc-MDP SPECT/CT, $^{99m}$Tc -PSMA SPECT/CT showed no false negative findings. Compared with local MRI or contrast enhanced CT, $^{99m}$Tc -PSMA SPECT/CT leads to an up-staging in 19% of patients and down-staging of local lymph node metastasis in 7% of patients. ***Conclusion:*** In comparison to the proPSMA study by Hofman M et al., 2021, the following results are concordant: the detection rates of extraprostatic tumour manifestations, the increased detection rates in patients with high-risk Gleason-score, the increased detection rate in patients with an initial PSA > 20 ng/ml and the superiority of PSMA imaging compared to conventional imaging, especially when local lymph nodes metastasis are of interest. $^{99m}$Tc-PSMA-SPECT/CT is a valuable alternative when PSMA PET/CT is not available.

## EP-0221

### Clinical Utility of 68Ga-PSMA PET/CT in Initial Staging of Patients with Prostate Cancer and Importance of Intraprostatic SUVmax Values

***I. Rogic***, *A. Golubic, M. Zuvic, T. Smitran, N. Jukic, D. Huic;*
*University Hospital Centre Zagreb, Zagreb, CROATIA.*

***Aim/Introduction:*** As it is in disease recurrence, providing clinicians with the exact extent of the disease at the time of initial diagnosis is key in the management and individual treatment of prostate cancer (PC). Under-staging, especially in men with high-risk PCa, leaves metastases untreated and may lead to poor treatment outcomes. The goal of our study was to examine the usefulness of $^{68}$Ga-PSMA PET/CT in the initial staging of PC and to check out the possible correlation between prostate-specific antigen (PSA) serum values, WHO grade of the tumor and prostatic SUVmax (standardized uptake value). ***Materials and Methods:*** We retrospectively evaluated 34 studies of patients who underwent $^{68}$Ga-PSMA PET/CT as part of the initial staging of prostate cancer. All our patients had a prostate cancer diagnosis on basis of histological assessment after biopsy and had Gleason score and PSA serum values obtained. ***Results:*** As expected all studies were positive with pathological 68Ga-PSMA uptake in primary prostate lesions. 19 patients had extended disease (59.37%). The mean SUVmax in prostate lesions was 19.4±12.58. WHO group 1 had a mean SUVmax of 6.25, patients with WHO group 2 had a mean SUVmax of 12.78, WHO groups 3 and 4 had the same mean SUVmax of 19.7 while WHO group 5 had a mean SUVmax of 32.27. The mean value of SUVmax of PET studies in the high-risk group was significantly higher than those of low risk (21.68±11 and 10.6±5.42). A positive correlation between gradus group and SUVmax value of prostate lesions was observed (Pearson r=0.548). ***Conclusion:*** In our study, 68Ga-PSMA PET/CT scans detected extended disease in more than half of our patients. Locating disease beyond the prostate gland allowed better-informed clinical decisions and modified initial treatment. A positive correlation was found between intraprostatic SUVmax values and gradus group of prostate cancer. High-risk patients had SUVmax values that were significantly higher than those of low-risk patients. The correlation between Gleason score and SUVmax value can be explained with increased intensity of PSMA expression as the tumor grade increases.

## EP-0222

### Head-to-head comparison of 68Ga-PSMA-11 with 68Ga-P137 in patients with suspected prostate cancer

***T. Han***, *Z. Quan, M. Wang, X. Meng, M. Zhang, J. Ye, G. Li, J. Wang, F. Kang;*
*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** P137 is a novel oxalyldiaminopropionic acid-urea based prostate specific membrane antigen (PSMA) targeting agent. This study compared the uptake patterns of 68Ga-P137 and the FDA-approved PET tracer 68Ga-PSMA-11 for diagnosing prostate cancer (PCa). ***Materials and Methods:*** Twelve patients suspected of PCa were scanned respectively by 68Ga-PSMA-11 and 68Ga-P137 PET/CT, followed by prospective analysis. The tumor-to-background ratio was calculated using normal prostate tissue, blood pool, muscle, and urine as backgrounds. Pathology or follow-up results were used to analyze uptake patterns of benign/malignant lesions and various organs. ***Results:*** Nine patients were diagnosed with PCa and three with benign prostate diseases (BPD). The number and location of primary lesions, lymph nodes (n=5) and bone metastasis (n=10) detected by the two tracers were identical. Maximum standardized uptake value (SUVmax), tumor/normal prostate ratio, as well as semi-quantitative miPSMA-ES and PRIMARY diagnostic scores [1-2] (P all >0.05) showed similar uptake levels of primary lesions between 68Ga-P137 and 68Ga-PSMA-11. Compared to 68Ga-P137, the SUVmax of 68Ga-PSMA-11 was significantly higher for bone metastasis and lymph node metastasis (LNM) (17.1±3.9 vs. 13.2±2.3, 20.3±5.6 vs. 10.5±1.4, P all <0.05). One-hour post-injection, SUVmax of the duodenum (9.0±1.8 vs. 14.9±4.9), kidney (18.2±2.4 vs. 40.9±15.6), and urine (13.9±7.5 vs. 39.8±26.3) were significantly lower for 68Ga-P137 than for 68Ga-PSMA-11 (P all <0.05), whereas the radioactivity accumulation of blood pool and muscle (3.8±0.4 vs. 1.5±0.4, 1.0±0.1 vs. 0.6±0.1, P all <0.05) of 68Ga-P137 was significantly higher than 68Ga-PSMA-11.

***Conclusion:*** The uptake level of 68Ga-P137 has no significant difference to that of 68Ga-PSMA-11 in prostate primary lesions, and their imaging performance are visually equivalent for both primary and metastatic PCa lesions, despite a higher blood pool and muscle background and a lower uptake in bone/LNM lesions. Due to lower urine excretion of 68Ga-P137, primary prostate lesions near the urine can potentially be displayed clearer with 68Ga-PSMA-11. ***References:*** 1. ## EP-0223

### Comparison of 18F-Thretide PET/CT and multiparametric MRI for the detection of intermediate and high risk prostate cancer

***J. Zang***[1], *Y. Yang*[1], *C. Wang*[1], *S. Chen*[1], *W. Miao*[1], *X. Chen*[2], *J. Zhang*[2];
[1]*Department of Nuclear Medicine, the First Affiliated Hospital, Fujian Medical University, Fuzhou, CHINA,* [2]*Departments of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** The main objective of this prospective study was to assess the value of $^{18}$F-Thretide (targeting PSMA) PET/CT Imaging in patients with intermediate- and high-risk prostate cancer (PCa) before planned curative-intent radical prostatectomy (RPE) and pelvic lymph node dissection (PLND), and to compare the $^{18}$F-Thretide PET/CT PET/CT findings with standard of care pelvic multi-parametric magnetic resonance imaging (mpMRI) and bone scintigraphy. ***Materials and Methods:*** A total of 45 patients with biopsy proven PCa (15 intermediate and 30 high risk) were enrolled in this prospective study. All patients underwent $^{18}$F-Thretide PET/CT and MRI, and 36 of them underwent bone scintigraphy. Any drug-related side effects were recorded and the vital parameters of the patients were observed for 1 week. $^{18}$F-Thretide PET/CT findings were correlated with the results of mpMRI and histopathology. ***Results:*** All patients tolerated the $^{18}$F-Thretide PET/CT well. Vital parameters remained stable and no patient reported any new symptoms during the observation period. In the end, a total of 38 of 45 patients underwent curative-intent radical prostatectomy and pelvic lymph node dissection. Of the 45 patients, 37 (82.2%) patients presented with a pathologic mpMRI, and 44 (97.8%) with a pathologic $^{18}$F-Thretide PET/CT ($P = 0.030$). The SUVmax of the primary tumors upon $^{18}$F-Thretide PET/CT was $19.3 \pm 18.6$. There was a low but significant correlation between SUVmax and baseline tPSA ($r = 0.371$, $P = 0.014$), but no correlation between SUVmax and risk stratification. A total of 459 LNs were removed by PLND in 38 patients. The histopathology verified 15 pelvic lymph node metastases in 21.1% (8/38) of the patients, of which 9 lymph nodes of 5 (62.5%) patients have been correctly identified on $^{18}$F-Thretide PET/CT, and 1 lymph node (12.5%) of 1 patient (12.5%) on mpMRI. The sensitivity, specificity, and accuracy of $^{18}$F-Thretide PET/CT in diagnosing pelvic lymph node metastasis were 60.0%, 98.7%, and 97.6%, respectively. Bone metastases and distant metastases (liver) were found in 8 (17.8%) and 1 (2.2%) of the patients on $^{18}$F-Thretide PET/CT imaging, respectively. 2 of 3 patient with bone metastasis who underwent bone scintigraphy showed bone metastases, but the number of lesions displayed were less than $^{18}$F-Thretide PET/CT. ***Conclusion:*** $^{18}$F-Thretide PET/CT shows high diagnostic performance for patients with intermediate- and high-risk prostate cancer and is superior to mpMRI and bone scintigraphy. There is a significant correlation between SUVmax of $^{18}$F-Thretide PET/CT and baseline tPSA

## EP-0224

### The Relationship Of Lymp Node Distance And Disease Parameters In Prostate Cancer Ga-68 PSMA PET/CT Imaging

***C. Aydin***[1], *B. Özdemir Günay*[2], *Ü. Korkmaz*[1], *F. Soyluoğlu*[1];
[1]*Trakya University, Edirne, TÜRKIYE,* [2]*Edirne Sultan Murat I State Hospital, Nuclear Medicine Clinic, Edirne, TÜRKIYE.*

***Aim/Introduction:*** Metabolic staging of prostate cancer, lymph node metastases are divided into pelvic and distant lymph nodes(M1a) (1) The distance between most distant lymph nodes is an independent prognostic marker in lymphomas (2). We aimed to determine distance of lymph nodes to prostate bed and the clinical significance of PET/CT parameters of these lymph nodes. ***Materials and Methods:*** Patients who came to our clinic for staging with diagnosis of prostate cancer ; PET/CT data of patients who did not receive ADT, radiotherapy or chemotherapy were evaluated retrospectively. 67 patients with only lymph node metastasis were included. Measurements were made between middle of the lymph nodes and bladder neck .(Dmax:Measured distance, SDmax:Dmax/Body surface area) PET/CT parameters of the patients' lymph node farthest from the bladder neck (LN 1) and lymph node with the highest SUVmax (LN2); The relationship between patients' Gleason score, ISUP grade, pre-imaging PSA values, presence of PSA recurrence/persistence in patient follow-up, and patient survival were examined separately. Lymph node distance parameters were calculated and compared. The SUVmax, MTV, and activity score of the same lymph nodes were compared with the clinical findings of the patients.(1) ***Results:*** There was a correlation between survival of patients and lymph node distance parameters ($p<0.05$). These parameters were found to be significantly higher in patients who were not alive than in the patients who were alive. SDmax2 was found to be significantly higher in patients with PSA recurrence/persistence (p:0.03)In one-year PSA follow-up, the distance parameter and MTV of LN with a high SUVmax were found to be significantly higher in patients with recurrence/persistence When patients were classified (pelvic and extrapelvic), there was no significant correlation between lymph node distance (SDMax1) and clinical parameters of patients with only pelvic LN metastasis. In patients with extrapelvic LN an increase in SDMax1 was significantly correlated with PSA progression and survival ($p<0.05$) ***Conclusion:*** The lymph node distance parameters were found to be superior to Gleason score and ISUP grade in predicting the survival of patients, PSA recurrence/persistence. Gleason and ISUP scores were unsignificant. This may be due to the short follow-up times and the low number of patients .When two lymph nodes are compared; Increasing distance of lymph node with the highest metabolic activity seems to be more important than increasing distance of farthest lymph node . It can be said that this indicates the importance of metabolic imaging in prostate cancer. ***References:*** 1. DOI: 10.2967/jnumed.117.198119 2.DOI: 10.1016/j.annonc.2020.11.019

## EP-0225

### The Relationship of Tumor SUVmax Value in 68Ga-PSMA PET/CT with Pathological Grade Group Grading System in Patients with Prostate Cancer

***F. Demir***, *S. Karaçavuş, H. Gençer, A. Ozdal, Z. Erdogan, I. Ciftci, F. Cevik, N. Ozhan, H. İsci, M. Kaya;*
*Kayseri City Training and Research Hospital, Kayseri, TÜRKIYE.*

***Aim/Introduction:*** In this study, we aim to investigate the role of the Prostate Gleson Group grading system, which is a relatively new grading system, in the prognosis of the disease, and to examine the relationship of this grading system between tumor parameters in PSMA PET/CT. ***Materials and Methods:*** The patients' pathology results were examined and Grade Group ratings were recorded. PET/CT images were loaded on workstations and PET parameters of the tumor (SUVmax, SUVmean, and tumor volume) were calculated. Data were analyzed in SPSS 22 program. P<0.05 was considered significant. ***Results:*** A total of 114 prostate cancer patients were included in the study. The age, SUVmax, SUvmean, tumor volume, and PSA values of the patients are summarized in Table 1. When we look at the correlation between the grade group and SUVmax, SUvmean, tumor volume, and PSA values; there was a correlation between SUVmax (p=0.010; r=0.241), SUVmean (p=0.06; r=0.258) and PSA (p<0.001; r=0.357) values. When we divided the patients into 2 groups low and medium-high risk groups according to grade group grading; Age, SUVmax SUVmean and PSA values were significantly higher among the medium-high risk group (table 2). When ROC analysis was performed for SUV max, SUVmean and PSA values in the estimation of the pathological medium-high risk group, significant cut-off values were calculated for all three values. When the cut-off value for SUVmax was taken as 9.76, the sensitivity was 69% and the specificity was 57% (AUC: 0.637, p=0.034). Taking 6.02 as the cut-off value for SUVmean, the sensitivity was 68% and the specificity was 61% (AUC:0.64; p=0.030). When a cut-off value of 1.38 was taken for PSA, the sensitivity was 66% and the specificity was 61% (AUC:0715; p=0.001). ***Conclusion:*** According to our study results, the correlation between tumor SUVmax and SUVmean values in Ga-68 PSMA PET/CT and Gleason Group was similar to the correlation between PSA and Gleason Group. SUVmax, SUVmean and PSA values were significantly higher in patients in the medium-high risk group compared to the patients in the low risk group. The cut-off value of 9.76 for SUVmax and 6.02 for SUVmean had significant predictive value in estimating the intermediate-high risk group of patients. The results show that Ga-68 PSMA PET tumor parameters can provide important information in predicting prognosis.

## EP-0226

### Multimodality Approach with 68Ga-PSMA-11 PET/CT in Staging High-risk Prostate Cancer Patients Candidate to Radical Prostatectomy

***G. Rovera***[1], *S. Grimaldi*[1], *M. Oderda*[2], *R. Passera*[1], *M. Falco*[1], *S. Dall'Armellina*[1], *P. Gontero*[2], *D. Deandreis*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Department of Surgical Sciences, Urology Unit, AOU Città della Salute e della Scienza di Torino, Molinette Hospital, University of Turin, Turin, ITALY.*

***Aim/Introduction:*** Accurate primary staging of prostate cancer is essential for treatment planning in high-risk patients. Current guidelines recommend the use of conventional imaging techniques such as computed tomography (CT) and bone scintigraphy for primary staging of high-risk prostate cancer. However, molecular imaging with prostate-specific membrane antigen/positron emission tomography (PSMA-PET/CT) holds potential for improved diagnostic sensitivity compared with conventional imaging. This prospective study aimed to evaluate the $^{68}$Ga-PSMA-11 PET/TC diagnostic performance in the preoperative staging of patients with high-risk prostate cancer and to compare its sensitivity with conventional imaging modalities. The secondary objective was to evaluate the diagnostic accuracy of $^{68}$Ga-PSMA-11 PET/CT in pelvic nodal staging using postoperative histopathology data as reference standard. ***Materials and Methods:*** Patients were enrolled according to the following inclusion criteria: diagnosis of prostate cancer eligible for radical prostatectomy, high-risk classification according to d'Amico criteria (ISUP 4/5 and/or PSA> 20 ng/ml and/or cT3), CT and bone scintigraphy performed within three months of $^{68}$Ga-PSMA-11 PET/TC. Patients with previous treatments, including androgen-deprivation therapy, were excluded. Molecular imaging was performed with standard technique by intravenous injection of 2MBq/Kg of $^{68}$Ga-PSMA-11 and whole-body PET/CT acquisition after 60 minutes. CT and PET/CT detection rates were compared using McNemar's exact test. ***Results:*** Fifty patients underwent $^{68}$Ga-PSMA-11 PET/TC imaging (median age 73 [IQR:67-76] years; median PSA 10.10 [IQR:6.27-19.50] ng/ml). Overall, $^{68}$Ga-PSMA-11 PET/TC detected regional and/or distant metastatic localizations in 56% (28/50) of patients, while CT in 12% (6/50)(p<0.001). Compared with CT, $^{68}$Ga-PSMA-11 PET/TC identified a higher number of suspected metastases in all anatomical regions: N1 46% vs 12% (p<0.001), M1a 10% vs 2% (p=0.13), M1b 22% vs 2% (p=0.002). Moreover, molecular imaging led to a TNM upstaging in 48% of cases, with no understaged patients. Compared with bone scintigraphy (BS), $^{68}$Ga-PSMA-11 PET/TC identified new skeletal metastases in 16% (8/50) of patients, with no BS-only positive cases. Overall, PSMA-PET/CT would lead to a potential change of management in 30% (15/50) of patients staged with conventional imaging (CT+BS). Compared with postoperative histopathology data, $^{68}$Ga-PSMA-11 PET/TC per-patient sensitivity, specificity, positive predictive value, negative predictive value and accuracy for detection of pelvic nodal metastases were 91.7%, 85.7%, 84.6%, 92.3% and 88.5%, respectively. ***Conclusion:*** $^{68}$Ga-PSMA-11 PET/TC showed a high diagnostic performance in primary staging of high-risk prostate cancer: new metastatic localizations were identified in 44% and 16% of cases compared with CT and bone scintigraphy, and a high per-patient nodal staging accuracy was demonstrated at histopathology (88.5%).

## EP-0227

### Location-Based Detection of Low-Uptake Lymph-Node Metastasis of Prostate Cancer in the Pelvis Using PSMA-PET/CT and Artificial Intelligence

***B. Schemmer***;
*Uniklinik Bonn, Bonn, GERMANY.*

***Aim/Introduction:*** Prostate cancer is a leading cause of cancer-related deaths worldwide, early recurrence is a major contributor to its mortality rate. Early detection of lymph node metastasis in the pelvic region in castration resistant prostate cancer with biochemical recurrence is crucial for effective treatment and improved patient outcomes. It is also a diagnostic challenge as PSMA-expression in early recurrence is significantly lower than in overt metastatic disease. Specifically in the pelvis ureter and bladder can mask or imitate metastasis. In this study, we explored the use of artificial intelligence (AI) and PSMA-PET/CT

to detect low uptake lymph node metastasis of prostate cancer in the pelvis using only the location of PSMA expressing lesions visible on PET. ***Materials and Methods:*** We included patients with histologically confirmed prostate cancer after resection who underwent PSMA-PET/CT imaging for biochemical recurrence with at least one PSMA-PET study and two PSA-values per patient (pre- and post intervention), to train and validate our AI model. We included 50 patients, median age 66 years (range, 45-85 years). The majority had intermediate-risk or high-risk disease (72%), most had a PSA-level <1.5 ng/mL (56%). No lymphnodes were surgically removed and most patients also had a probable local recurrence (67%). The AI was based on deep learning and only provided with PET-images of the pelvic region as well PSA-values. The AI was specifically not trained to find any overt metastasis with uptake above liver background. The PET-images were preprocessed, uptake values below blood pool or above liver were no longer present in the training images. Detection was evaluated as successful when there was a PSA-remission after radiation therapy that included the lymphnodes or if there was no remission when lymphnodes were not irradiated. ***Results:*** Our results showed that the AI model was able to accurately detect lymph node metastasis of prostate cancer with a high level of accuracy in cases where human observers were unsure. The model achieved a sensitivity of 96% and a specificity of 74%, indicating its potential for use in clinical settings. ***Conclusion:*** Further refinement is needed to increase specificity and validate our findings, but our results suggest that the early detection of low uptake lymph node metastasis of prostate cancer using only location on PET images as data could have significant clinical implications for the improved detection and treatment of prostate cancer.

## EP-0228

### Value of Ga-68 PSMA PET/CT in ISUP Grade 2 Prostate Cancer Patients

***F. Aghazada***, *M. Demirbilek, O. Sahin, S. Asa, B. Onal, L. Kabasakal;*
*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** The aim of our study is to evaluate the contribution of Ga-68 PSMA PET/CT in the staging of patients with ISUP grade 2 prostate cancer. ***Materials and Methods:*** 72 patients who were reported to have Gleason 3+4 prostate cancer according to TRUS biopsy results and underwent Ga-68 PSMA PET/CT imaging between June 2014 and March 2022 were retrospectively evaluated. Radical prostatectomy was performed in 46 patients after imaging. Pelvic lymph node dissection was performed in 35 patients. All patients were classified according to the PRIMARY score. Patients were divided into two groups as PRIMARY 1-2 (negative) and PRIMARY 3-4-5 (positive). The images were examined for lymph node and bone metastasis. The ability of Ga-68 PSMA PET/CT to predict upgrading in TNM and Gleason scores of patients after prostatectomy was investigated. SPSS V.22 was used. ***Results:*** Pathology results of 2 of the operated patients were reported as Gleason 3+3, 25 as Gleason 3+4, 17 as Gleason 4+3 and higher. Ductal carcinoma was detected in 2 patients. 12 patients were classified as PRIMARY 1-2 and 34 patients were classified as PRIMARY 3-4-5. Ga-68 PSMA PET detected bone metastasis in 1 (2%) patient and pelvic lymph node metastasis in 3 patients. When the 3 patients with lymph node metastasis were examined, it was determined that metastasis was false positive in 1 patient after the operation. Lymph node metastasis was not observed in any of the patients whose operative pathology result was Gleason 3+4, and bone metastasis was detected in only 1 (5%) patient. Pathology results of 35 patients who underwent pelvic lymph node dissection were compared with Ga-68 PSMA PET results. The sensitivity of Ga-68 PSMA PET in detecting lymph node metastasis was 100%, specificity was 97%, positive predictive value was 67%, and negative predictive value was 100%. Postoperative upstaging was observed in 20 patients. According to the results of the chi-square analysis, Ga-68 PSMA PET can predict the prostatectomy outcomes of the patients significantly (p=0.01). ***Conclusion:*** It is thought that Ga-68 PSMA PET does not provide additional contribution compared to conventional imaging methods in the TNM staging of ISUP grade 2 prostate cancer patients due to the low incidence of lymph node (4%) and bone (2%) metastasis detected in our study. . However, application of Ga-68 PSMA PET/CT to patients after biopsy is an acceptable approach since it can predict the outcome of prostatectomy based on the PRIMARY score.

## EP-0229

### Analytical performance validation of aPROMISE platform for prostate cancer tumor burden and index and dominant tumor assessment with 18F-DCFPyL PET/CT.

***C. Lucas Lucas***[1], *A. M. García Vicente*[2], *L. García Zoghby*[2], *J. Pérez Beteta*[3], *P. Borrelli*[4], *M. Amo Salas*[5], *A. Padilla Bermejo*[1], *M. N. Sicilia Pozo*[1], *M. Contreras Ameduri*[1], *M. Cruz Montijano*[2], *F. J. Pena Pardo*[1], *E. Noriega Álvarez*[1], *M. P. Talavera Rubio*[1], *V. M. Poblete García*[1], *Á. M. Soriano Castrejón*[2];
*[1]Nuclear Medicine Department. University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department. University Hospital of Toledo, Toledo, SPAIN, [3]Mathematical Oncology Laboratory. Castilla-La Mancha University, Ciudad Real, SPAIN, [4]Department of Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, SWEDEN, [5]Mathematics Department. Castilla La-Mancha University, Ciudad Real, SPAIN.*

***Aim/Introduction:*** To validate the performance of automated Prostate Cancer Molecular Imaging Standardized Evaluation (aPROMISE) software in obtaining total prostate disease burden in patients with intermediate and high-risk prostate cancer (PCa) who undergo 18F-DCFPyL-PET/CT for staging purpose and to evaluate the interobserver concordance and with the histopathologic analysis in the determination of the index (IT) and dominant tumor (DT). ***Materials and Methods:*** Patients with a recent diagnosis of intermediate/high risk PCa according to D'Amico risk classification underwent 18F-DCFPyL-PET/CT. In Positive-PSMA scans, automated prostate tumor segmentation was performed using aPROMISE software and compared with semiautomatic-manual segmentation using Matlab developed by the Mathematical Oncology group (MOLab). SUVmax, SUVpeak, SUVmean, molecular tumor volume (MTV) and total lesion activity (TLA) were compared with both software. Two observers independently assessed the laterality of DT (the highest SUVmax) and IT (the biggest metabolic volume) from the segmentation with both software. We compared the variables obtained by both software, as well as the interobserver agreement and between each one of them with the histology (DT: the highest Gleason; IT: the highest number of positive core-biopsies) using the intraclass correlation coefficient (ICC) and Kappa (k) for the concordance analysis. ***Results:*** 54 patients were included in the analysis (4 excluded due to negative PET). 85.2% high risk and 43.4% ISUP 4 or 5. In the global analysis, we observed a good correlation between MOLab and aPROMISE with respect to SUVmax followed by TLA and SUVpeak (ICC of 1, 0.950 and 0.833, respectively; p<0.001), without showing significant differences individually for the different ISUP grades and risk categories. However, there

were significant differences between both software according to the different ISUP grades and risk categories, except for TLA with the ISUP grade. DT was located in right lobe for the observers of aPROMISE and MOLab in 31 and 32 patients respectively, with a good agreement (k=0.733; p<0.001) and IT in 32 and 29 patients respectively, with a very good agreement (k=0.812; p<0.001). However, the concordance between observers using both software with histopathology was moderate (p<0.001). ***Conclusion:*** aPROMISE shows a good performance for SUVmax and TLA after segmentation of the prostate tumor compared to MOLab. However, there are significant differences between practically all the semiquantitative variables for the different ISUP groups and risk categories. The interobserver agreement in the determination of DT and IT was good, although it had a moderate agreement with the determination of these parameters in histology.

## EP-0230

### Contribution of 68GA-PSMA-PET/CT to Risk Classification In Prostate Cancer With Gleason Score 6

***Ö. Sahin***, *E. BEYHAN, Ö. E. FENERCİOĞLU, E. ARSLAN, T. F. ÇERMİK, N. ERGÜL;*
*University of Health Sciences, Istanbul Training and Research Hospital, Department of Nuclear Medicine, , Turkey., Istanbul, TÜRKIYE.*

***Aim/Introduction:*** In cases of Gleason Score (GS) 3+3(6) prostate adenocarcinoma (PCa), it is frequently seen that the pathological grade is increased after prostatectomy in daily practice. The aim of the study is to investigate the contribution of 68Ga-PSMA-PET/CT to the detection of cases requiring rebiopsy that will cause a change in the risk classification of patients with GS 6 prostate cancer and to guide the treatment planning correctly. ***Materials and Methods:*** Patients with GS 6 prostate cancer were included in the study. PSMA PET/CT scans performed for "staging" or "restaging" were reviewed retrospectively. With SUVmax and SUVmean values, GS, risk class (low, medium, high), and prostate specific antigen (PSA) values obtained as a result of transrectal ultrasound guided biopsy (TRUS) or radical prostatectomy (RP) correlation was evaluated. In 68Ga-PSMA PET/CT, lesion localizations and involvement pattern in the prostate gland were compared with histopathological findings. ***Results:*** Between January 2016 and February 2023, 68Ga-PSMA PET/CT scans of 112 patients (105 patients staging, 7 patients restaging) with TRUS biopsy result GS6 (3+3) and PSA measurement were performed. Extraprostatic pathological involvement focus was detected in 11/112 (9.8%) patients. Pelvic lymph node metastasis was found in 9 of these patients, extrapelvic lymph node in 3, and bone metastasis in 6 of them. Additional focus of involvement was detected in the prostate gland in 37/112 (33%) patients on 68Ga-PSMA PET/CT.GS6 was detected in 27 of 36 patients who underwent RP. Repeated biopsy result of 1 patient was GS>6. A significant difference was found between the SUVmax and SUVmean values of 34/112 patients who were found to have GS>6 with RP or repeat biopsy and who had an increased risk class by detecting distant metastases on 68Ga-PSMA PET/CT and those whose risk class did not change (p=0.005, p= 0.009). There was a significant difference in SUVmax and SUVmean values of the primary tumor between low, intermediate and high risk groups (p=0.01, p=0.007). Lymph node and bone metastases were detected in 2 of 7 patients in the restaging group. ***Conclusion:*** 68Ga-PSMA PET/CT imaging was found to be effective in detecting the increase in risk class and degree of disease in 34/112 (30%) patients. Our findings show that 68Ga-PSMA PET/CT can be a guide in terms of biopsy repetition and treatment decision, considering the SUVmax value and the involvement pattern of the primary tumor.

## EP-0231

### Comparison of 68Ga-FAPI and 18F-PSMA PET/CT in the Evaluation of Ductal Adenocarcinoma of the Prostate

***C. Liu***, *Q. Xie, T. Liu, Z. Li, C. Guo, Z. Yang;*
*Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA.*

***Aim/Introduction:*** Ductal adenocarcinoma is a rare variant of prostate cancer considered to be more aggressive than pure acinar adenocarcinoma. While PSMA-PET scans have been shown to be helpful in staging and in diagnosing sites of metastatic adenocarcinoma of the prostate, the prostatic ductal carcinoma subtype can show poor PSMA avidity. This study aims to compare $^{68}$Ga-FAPI PET/CT with $^{18}$F-PSMA PET/CT in evaluating prostatic ductal carcinoma. ***Materials and Methods:*** We retrospectively analyzed a cohort of 17 patients with histologically-confirmed prostatic ductal adenocarcinoma who underwent both $^{68}$Ga-FAPI PET/CT and $^{18}$F-PSMA PET/CT for initial staging, recurrence and patient selection for radioligand therapy. Location and number of suspicious lesions revealed by the different modalities were recorded. The tracer uptakes, quantified by maximum standardized uptake value (SUVmax) was compared for paired positive lesions between both modalities using the Wilcoxon signed-rank test. ***Results:*** 12/17 patients for $^{68}$Ga-FAPI PET/CT and 11/17 patients for $^{18}$F-PSMA PET/CT had focal uptake above background in tumor lesions. A total of 47 lesions were recorded. Of these, 34 (72%) were PSMA+ and 36 (76%) were FAP+. There were 13 (27%) FAP+/PSMA− lesions and 11(23%) FAP−/FDG+ lesions. Compared with $^{18}$F-PSMA PET/CT, $^{68}$Ga-FAPI PET/CT depicted more suspected tumor lesions in prostate (7 vs 4) and lung (6 vs 1), less lesions in lymph nodes (5 vs 10) and bone lesions (10 vs 13). The two modalities showed similar performance in the recurrent lesions and suspected metastases in liver and peritoneum. Compared to $^{18}$F-PSMA PET/CT, tumor uptake was significantly lower with FAPI than with PSMA (median SUVmax was 4.0 vs 6.8, P=0.01). In a subgroup analysis, tumor uptake was higher with FAPI than with PSMA in primary prostate tumor (median SUVmax was 12.1 vs. 6.1) and lung lesions (median SUVmax was 2.1 vs. 1.4). ***Conclusion:*** The 68Ga-FAPI PET/CT with 18F-PSMA PET/CT showed heterogeneous uptake in the prostatic ductal carcinoma. We demonstrate that 68Ga-FAPI PET/CT combine with 18F-PSMA PET/CT is useful for detecting tumor lesions in patients with prostatic ductal carcinoma. ***References:*** 1.Ranasinghe W, Shapiro DD, Zhang M, et al. ## EP-0232

### PSMA Immunohistochemistry Staining in Prostate Cancer Primary Lesion and Comparison with [68Ga]Ga-PSMA-PET/CT Findings

***Z. Isik***[1], *G. Güner*[2], *M. Çağlar Tuncalı*[1], *M. Karcaaltincaba*[3], *B. Akdoğan*[4], *D. Akıncı*[3], *M. Tuncel*[1];
[1]*Hacettepe University, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University, Department of Pathology, Ankara, TÜRKIYE,* [3]*Hacettepe University, Department of Radiology, Ankara, TÜRKIYE,* [4]*Hacettepe University, Department of Urology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** PSMA over-expression is well-known in prostate cancer (PCa). Currently it is the main target for theragnostic purposes in Nuclear Medicine. F-18/Ga-68 labelled prostate-specific membrane antigen (PSMA) positron emission tomography/computed tomography PET/CT is a valuable tool for detecting PCa foci with high sensitivity and specificity. The aim of this study is to correlate primary staging (PSMA) (PET/CT) parameters with PSMA-immunochemistry (IHC) features in PCa patients. ***Materials and Methods:*** Fifty-nine patients with PCa who underwent Ga-68-PSMA-11-PET/CT and radical prostatectomy(RP) were included in this prospective study.Visual and semi-quantitative evaluation of the primary tumor was carried out by two nuclear medicine physicians based on 12 segment analyses.Index and non-index tumors in each RP specimen were correlated with PET-CT.Index lesions were defined as tumor foci with largest size and radiotracer uptake.Tumours smaller than <5mm were excluded to avoid partial volume effect.Clinical information(age, iPSA-value,grading group) and PSMA-PET/CT parameters(SUVmax,SUV mean) were compared.PSMA-IHC analysis was based on visual quantification with a four-tiered score(0 = negative,1+ = weak,2+ = moderate,3+ = strong)based on the tumoral cell staining(0:none,1:weak,2:moderate,3:strong). Specimens were also analysed divided according the percentage of IHC staining intensity in the tumor foci.Finally, the percentage of each IHC stained area was multiplied by the intensity score and added up to reach a final H-score (range 0-300). ***Results:*** All 59 patients(median age 66y, PSA 8.97 ng/mL)diagnosed with PCa were in intermediate or high-risk group.Patients ISUP grades were as follows: 2(n:24), 3(n:16), 4(n:3) and 5 in16 patients.Out of these 59 patients, 59 index and 19 non-index lesions were stained.In IHC-PSMA staining for index lesions median negative, 1+, 2+, 3+ positive area percentages and H scores were 8.59(range:0-90), 17.34(range:0-75), 24.83(range:0-100), 49.66(range:0-100) and 215.98 (range:10-300) respectively.PSMA PET detected all non-index lesions with H-score of >200. ISUP scores, pre-op serum PSA and SUVmax were correlated with PSMA 3+ area percentages(rs=0.311, 0.289 and 396 respectively n :59, p<0.05). However, there was no correlation with H scores(p=0.136). Furthermore, SUVmax was correlated with ISUP(rs=0.337, n:57, p=0.01) and preop PSA levels(rs=0.42, n:57, p=0.001).In IHC staining, PSMA PET false negative lesions' PSMA negative areas were significantly higher and high expression areas and H-score were significantly lower than ones detected by PSMA PET/CT(p=0.015). ***Conclusion:*** ISUP score and SUVmax of the primary tumour were correlated with each other and with high PSMA expression area % in IHC staining.PSMA expression parameters were predictors of detected and non-detected lesions in PSMA PET/CT.

## EP-0233

### Comparison of 68Ga-PSMA PET/MRI with PET and mpMRI in concise evaluation of primary prostate tumor and its prognostic value in detection of locally advanced prostate cancer

***L. Uslu-Besli***[1], *B. Bakir*[2], *N. Urganci*[3], *&. Gürses*[3], *S. Özel-Yıldız*[4], *C. Demirdag*[5], *K. Sönmezoglu*[1], *H. Sayman*[1];
[1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University, Istanbul Medical Faculty, Department of Radiology, Istanbul, TÜRKIYE,* [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Pathology, Istanbul, TÜRKIYE,* [4]*Istanbul University, Istanbul Medical Faculty, Department of Biostatistics, Istanbul, TÜRKIYE,* [5]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Urology, Istanbul, TÜRKIYE.*

***Aim/Introduction:*** Our aim in this study is to compare the diagnostic performance of multiparametric prostate MRI (mpMRI), $^{68}$Ga-PSMA PET and PET/MRI in patients with primary prostate cancer who underwent hybrid PET/MRI. ***Materials and Methods:*** Fifty prostate cancer patients, who were planned for radical prostatectomy were included in the study. Patients underwent whole body $^{68}$Ga-PSMA PET followed by regional PET/MRI with mp-MRI. The prostate gland was divided into 6 zones and peripheral zone and transitional zone were evaluated separately. All images were evaluated separately for PET, mpMRI and PET/MRI in terms of lesion location, number of prostate zones with tumor, seminal vesicle infiltration and extraprostatic extension. SUV parameters obtained from PET images and apparent diffusion coefficient (ADC) values obtained from diffusion-weighted imaging were measured for index lesion. ***Results:*** PET/MRI was more sensitive than both PET and mpMRI in detection of index lesions (92% vs 80% and 84%, respectively). Sensitivity and specificity of PET, mpMRI and PET/MRI were 60.8% and 88.2%, 62.4% and 95.8%, 71.3% and 93.3%, respectively in peripheral zone and 51.8% and 95.9%, 50.6% and 100%, 60.2% and 99.5%, respectively in transitional zone. PET/MRI had better diagnostic performance compared to mpMRI in whole prostate gland (p<0.01). While PET and PET/MRI were similar in transitional zone, PET/MRI outperforms PET in peripheral zone (p=0.019). MpMRI had higher sensitivity but lower specificity compared to $^{68}$Ga-PSMA PET in detection of seminal vesicle infiltration (60% vs. 41.7% sensitivity and 86.8% vs. 91.9% specificity) and extra-prostatic extension (60% vs 55% sensitivity and 73.3% vs 83.3% specificity). Accuracy of both $^{68}$Ga-PSMA PET and mpMRI were similar (79.6% and 81.3% for seminal vesicle infiltration; 72% and 68% for extra-prostatic extension). SUVmax and SUVmean values obtained from index lesions were significantly higher in patients with seminal vesicle infiltration, extraprostatic extension of lymphovascular invasion compared to those who were negative. ***Conclusion:*** PET/MRI had higher sensitivity and accuracy compared to PET or mpMRI in both peripheral zone and transitional zone of the prostate gland. Seminal vesicle infiltration, extraprostatic extension, lymphovascular invasion and lymph node metastasis were more common in cases with higher PSMA uptake. Therefore, $^{68}$Ga-PSMA PET may also have prognostic value in prostate cancer patients.Note: This research was financially supported by Istanbul University-Cerrahpasa Scientific Research Projects (BAP Project number: TSA-2018- 26777) ***References:*** 1. ## EP-0234

### Preliminary Clinical Study of a Novel Small-molecule PSMA Inhibitor 68Ga-SC691: Biodistribution, Dosimetry and Prospective Comparison with 68Ga-PSMA-11

***J. Cao***;
*416 Hospital, China National Nuclear Corporation, chengdu, CHINA.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is established as arguably emerging target for the diagnosis and treatment of prostate cancer (PCa), and small-molecule inhibitors targeting PSMA are considered to be the most valuable class of drugs. This prospective study evaluated the safety, biodistribution and effective absorbed dose of a novel Small-molecule PSMA Inhibitor $^{68}$Ga-SC691 in humans and compared its efficacy and biodistribution with $^{68}$Ga-PSMA-11 in PCa patients. ***Materials and Methods:*** Seven healthy subjects and twelve patients with PCa were recruited for this study after reference to inclusion/exclusion criteria. Patients' $^{68}$Ga-SC691 and $^{68}$Ga-PSMA-11 PET/CT images were performed during a treatment-free planning week, with scan-specific parameters kept consistent. PET/CT data were analysed for dosimetric, focal and quantitative data using Hermes Internal Radiation Dosimetry (HIRD, built-in OLINDA / EXM v2.1) and uWS-MI post-processing workstation, respectively. ***Results:*** $^{68}$Ga-SC691 showed good safety in all subjects. $^{68}$Ga-SC691 was mainly excreted by the urinary system. Dosimetry showed that the high absorption organs were mainly kidney (123.43±25.67 μGy/MBq) and bladder wall (171.58±39.46 μGy/MBq), and its biodistribution was similar to $^{68}$Ga-PSMA-11. Compared with $^{68}$Ga-PSMA-11, $^{68}$Ga-SC691 showed lower non-specific organ uptake, especially lower liver uptake. In addition, $^{68}$Ga-SC691 and $^{68}$Ga-PSMA-11 detected the same number and location of PSMA-positive lesions in PCa primary tumor and bone/lymph nodes metastases, and the former had a higher T/NT ratio. ***Conclusion:*** As a novel small-molecule PSMA inhibitor, SC691 may be a valuable choice for PCa imaging and therapy due to its reliable safety, dose distribution and diagnostic efficacy. And Low uptake in non-specific organs makes it promising for theranostics.

## EP-0235

### PSMA PET/MR with parametric Patlak imaging to increase image contrast, better quantification and shorten examination times in patients with suspected prostate cancer.

***M. Gammel****, I. Rauscher, M. Eiber, S. van Marwick, S. Schachoff, R. Tauber, W. A. Weber, S. Nekolla;*
*TUM, Munich, GERMANY.*

***Aim/Introduction:*** In addition to multiparametric magnetic resonance imaging (mpMRI), PSMA-PET is increasingly important for detecting clinically significant prostate cancer (PCa). The aim of this study was to develop a PET/MR protocol in which PET acquisition was started with tracer injection and completed with mpMRI. ***Materials and Methods:*** PSMA PET/MR was performed on 23 patients with suspected PCa using 323±50 Mbq rhPSMA 7.3 for biopsy planning. A 20-minute dynamic PET of the prostate was started with tracer injection, while mpMRI with T2, diffusion-weighted, and contrast-enhanced sequences was simultaneously performed. A static PET/MR of the pelvis was performed after 60 minutes p.i. Parametric images of the Patlak influx constant Ki, were calculated from the dynamic PET and compared to SUV images after 20 and 60 minutes p.i. ***Results:*** PCa was histologically confirmed in all patients. The SUVmean of PCa continuously increased (3.4±2.0, 8.4±6.5, and 10.8±6.8 at 7.5, 17.5, and 62.5 minutes, respectively). Patlak plots showed irreversible uptake kinetics in the tumors. There was a strong correlation between the Ki values and SUVs (r = 0.66). The tumor-to-muscle ratio in the Ki images was 23.5±12.8, compared to 14.6±10.2 in the SUV images ($p < 0.0012$). ***Conclusion:*** The PSMA kinetics and high Ki values suggest that images can be taken after 20 minutes and achieve a good fit of the Patlak analysis. Parametric imaging potentially allows for optimizing PSMA PET-Protocols, as no waiting time between tracer injection and PET is required and no uptake spaces are needed for patients. It would also be possible to use the whole-body scanners to reduce time in whole-body staging. However, this must be evaluated in larger patient cohorts and following a broader approach, not just primary staging.

## EP-0236

### PSMA-PET and PCa: an exploratory analysis beyond the numerical definition of oligometastatic state

***F. Mattana***[1]*, L. Airò Farulla*[1,2]*, G. Marvaso*[3]*, G. Corrao*[3]*, C. Lorubbio*[3,2]*, M. G. Vincini*[3]*, M. Zaffaroni*[3]*, L. Muraglia*[1]*, M. Colandrea*[1]*, C. Fodor*[3]*, F. Ceci*[1,2]*, B. A. Jereczek-Fossa*[3,2]*;*
*[1]IEO European Institute of Oncology IRCCS, Nuclear Medicine Department, Milan, ITALY, [2]Department of Oncology and Hemato-Oncology, University of Milan, ITALY, [3]IEO European Institute of Oncology IRCCS, Department of Radiation Oncology, Milan, ITALY.*

***Aim/Introduction:*** Oligorecurrent Prostate Cancer (PCa) patients are usually defined only on the number of suspected lesions on Conventional Imaging. A deeper understanding of the burden of disease is needed in order to offer the best tailored treatment. First aim of this study is to correlate clinical features with volumetric and semi-quantitative data derived from prostate-specific-membrane-antigen positron-emission-tomography (PSMA-PET). The present study is a spin-off project of the ongoing phase-II randomized clinical trial RADIOSA (NCT03940235). ***Materials and Methods:*** Oligorecurrent PCa patients enrolled within the RADIOSA trial with PSMA-PET scan at first biochemical recurrence were screened for study inclusion. Two experienced nuclear medicine physicians retrospectively reviewed PSMA-PET images blinded to all histopathological and clinical data. PSMA tumor volume(PSMA-TV) and Maximum-standardized-uptake-values (SUVmax) were collected for eligible patients. Patients were stratified according to PSA values both at the first diagnosis and at the oligorecurrence using the median values as cut-off and according to the site of metastases (bone vs lymph node). MedianPSMA-TV and SUVmax were reported for each group. Oligometastatic disease was defined by the presence of 1-3 metastatic lesions on PSMA-PET. ***Results:*** A total of 46 patients were included. Median PSA values at the first diagnosis and at the oligorecurrence were 7.62ng/mL and 1.27ng/mL respectively. Median time between first diagnosis and oligorecurrence was 46 months. A total of 29 patients had lymph nodal only localization (M1a, according to miTNM), while 17 had at least one bone localization (M1b). When stratified according to the median PSA at diagnosis, MedianSUVmax resulted higher in patients with a PSA above the median value while medianPSMA-TV and time to recurrence were comparable in both groups. When patients were stratified according to the medianPSA at recurrence, MedianSUVmax resulted higher in patients with an higher PSA(>1.27)ng/ml, while patients in the lower PSA group had a smaller PSMA-TV(1.75vs2.28cm$^3$). When grouping patients according to the metastatic site, those with at least one bone metastases had a shorter time interval between first diagnosis and recurrence and a lower medianSUVmax. ***Conclusion:*** both at first diagnosis and at recurrence, patients with higher PSA

showed higher medianSUVmax values on restaging PSMA-PET; patients with lower PSA at the oligorecurrence had a lower lesion volume (median PSMA-TV 1.75) and a shorter time at the recurrence. Further studies are needed to better understand the role of volumetric and semi-quantitative parameters derived from PSMA-PET in relation with the clinical outcome. Special thanks to AIRC for the support.

## EP-0237

### The spleen as a reference organ for PSMA expression evaluation according to PROMISE in Prostate cancer imaging with 18F-PSMA-1007 PET/CT: a critical approach

***G. Arsos***[1], *A. Georgiou*[2], *D. Katsampoukas*[2], *V. Mpalaris*[2], *S. Georga*[2], *E. Moralidis*[2];
[1]*3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen. Hospital, THESSALONIKI, GREECE,* [2]*3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen. Hospital, Thessaloniki, GREECE.*

***Aim/Introduction:*** Standardized evaluation of Prostate cancer (ProCa) lesions imaged with PSMA-Ligand PET/CT has been proposed by PROMISE [1]. Scoring of lesions is based on the comparison of their uptake with that of three reference organs (blood pool, liver and parotid gland). For tracers with predominantly hepatic excretion like 18F-PSMA-1007, the spleen is proposed instead of liver. In this context, we critically comment on some concerning features of the spleen as a reference organ. ***Materials and Methods:*** Thirty four men (aged 50-87 years) with ProCa submitted to 18F-PSMA-1007 PET/CT were enrolled, one with abdominal splenosis after splenectomy, none with splenomegaly or haematologic disease. Suspect lesions were scored according to PROMISE. SUVmax, SUVav and radiodensity (RD, in Hounsfield units) of the spleen (spleniculus in one case) and liver were measured in all patients. The agreement of SUVmax, SUVav and RD between spleen and liver was assessed by Bland-Altman statistics, the mean Spleen-Liver difference denoting bias and the standard deviation imprecision. The correlation of SUVmax, SUVav and RD between spleen and liver was assessed by the Lin's Concordance Correlation Coefficient (LCCC) and the correlation of SUVmax and SUVav with age by linear regression analysis. Wilcoxon and One-sample t- tests were used for comparisons. ***Results:*** Mean±SD of SUVmax, SUVav and RD of the spleen and liver were 13.3±4.1, 11.9±3.7, 50.3±6.7 and 17.1±4.9, 14.7±3.8, 60.8±7.1, respectively ($p<0.05$ for all paired comparisons). In 10/34 cases (29.4%), the SUVmax and SUVav of the spleen were higher than the liver. The bias and imprecision of the spleen-liver differences for SUVmax, SUVav and RD were -3.2, -2.3, -10.7 and 6.6, 5.5, 9.6, respectively ($p<0.05$ for all biases). LCCC (95% confidence interval) for SUVmax, SUVav and RD was -0.041 (-0.296-0.218), -0.050 (-0.321-0,228) and -0.012 (-0.157-0.134). Both SUVmax and SUVav of the spleen were negatively correlated with age (r -0.314 and -0.349, respectively), the correlation being significant ($p<0.05$) for SUVav. ***Conclusion:*** 18F-PSMA-1007 SUVmax and SUVav and radiodensity of the spleen and liver differ significantly and are unrelated. Moreover, spleen but not liver, shows a tendency towards reduced uptake with age. Accordingly, spleen and liver must not be considered equivalent for scoring of suspect lesions. Cases with splenectomy or splenomegaly might further hamper the role of spleen as a reference organ. ***References:*** [1] Eiber M et al. Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE): Proposed miTNM Classification for the Interpretation of PSMA-Ligand PET/CT. J Nucl Med 2018

## EP-0238

### Evaluation of imaging, clinical and pathological factors associated with 2-year biochemical recurrence in surgical patients with intermediate- to high-risk prostate cancer: a focus on 68GaPSMA PET and pelvic 3Tesla mpMRI

***M. Celli***[1], *R. Gunelli*[2], *F. Ferroni*[1], *G. Feliciani*[1], *A. Sarnelli*[1], *P. Caroli*[1], *I. Marini*[1], *L. Fantini*[1], *V. Rossetti*[1], *U. De Giorgi*[1], *D. Barone*[1], *V. Di Iorio*[1], *F. Matteucci*[1];
[1]*IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY,* [2]*AUSL della Romagna – Presidio Ospedaliero Morgagni-Pierantoni, Forlì, ITALY.*

***Aim/Introduction:*** To identify staging $^{68}$GaPSMA PET and pelvic mpMRI imaging-based factors, clinical and pathological features associated with 2-year biochemical recurrence in patients with intermediate- to high-risk prostate cancer (PCa) treated with radical prostatectomy ± adjuvant treatment. ***Materials and Methods:*** 26 patients (age range: 48-72 years; median: 61 years) with biopsy-proven PCa (ISUP: 1-5; PSA range: 4,1-37ng/ml; biopsy T: T2a-T2c) were prospectively staged by $^{68}$GaPSMA PET and pelvic mpMRI within six weeks prior to surgery. A 12-segment prostate map was used for tumour localization and quantitation on $^{68}$GaPSMA PET and pelvic mpMRI. Post-surgical adjuvant treatment and follow up were offered as per clinical practice. Non-parametric tests were used to identify imaging-based, clinical and pathological factors associated with 2-year biochemical recurrence: age, screening PSA, PSA density, percent of PCa involved cores (< 50% versus ≥ 50%), maximum PCa core length (< 50% versus ≥ 50%), biopsy ISUP (ISUP4-5 versus ISUP1-2-3), PCa $^{68}$GaPSMA SUVmax (SUVmax ≤ 10 versus SUVmax > 10), intraprostatic PCa extent according to $^{68}$GaPSMA PET (PCa involvement < 3 segments versus ≥ 3 segments) and to mpMRI (< 3 segments versus ≥ 3 segments), pathology ISUP (ISUP4-5 versus ISUP1-2-3), pT stage (pT2 versus pT3) and R status (R0 versus R1). ***Results:*** Pelvic mpMRI identified PCa foci in 24 patients and correctly identified PCa extraprostatic extension in 5 out of 6 patients and seminal vesicle involvement in 2 out of 4 patients. $^{68}$GaPSMA PET identified PCa foci in 24 patients and correctly identified PCa extraprostatic extension in 4 out of 6 patients and seminal vesicle involvement in 3 out of 4 patients. 2-year biochemical relapse was more frequently observed in patients with more than 50% of biopsy cores involved (p: 0.0137) and in patients with PCa foci holding $^{68}$GaPSMA SUVmax higher than 10 (p: 0.008). No statistically-significant difference was found between relapsed and non-relapsed patients in terms of age (p: 0.966), screening PSA (p: 0.936), PSA density (p: 0.440), biopsy ISUP (p: 0.863), maximum PCa core length (p: 0.198), intraprostatic PCa extent on $^{68}$GaPSMA PET (p: 0.340) and on mpMRI (p: 0.302), pathology ISUP (p: 0.612), pT status (p: 0.863), and R status (p: 0.809). ***Conclusion:*** In this cohort of patients with intermediate-to high-risk PCa treated with radical prostatectomy ± adjuvant treatments tumour involvement in less than 50% of biopsy cores and tumour $^{68}$GaPSMA SUVmax lower than 10 hold predictive potential for 2-year biochemical recurrence-free survival.

## EP-0239

### PSMA PET/CT and local disease: a retrospective radiomic analysis based on a single center's experience

***M. Monteiro***[1], *A. M. Ferreira*[1], *A. P. Moreira*[1,2], *R. Silva*[1,2], *G. Costa*[1,3];
[1]*CHUC, Coimbra, PORTUGAL,* [2]*Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL,* [3]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

***Aim/Introduction:*** While prostate-specific membrane antigen (PSMA) PET/CT has established itself as the preferred method for detecting metastatic prostate cancer (PCa), magnetic resonance imaging (MRI) remains the gold standard for evaluating local disease. Nevertheless, the maximum standardized uptake value (SUVmax), commonly used to assess radiopharmaceutical uptake

in the primary tumor, has been shown to correlate with key prognostic factors such as the Gleason score (GS). With advances in PET scanner technology allowing for more accurate radiomic analysis, the potential usefulness of other features in characterising primitive prostate cancer is worth exploring. This study aims to investigate the correlation between various radiomic features, including SUVmax, SUVpeak, metabolic tumor volume (MTV), and total lesion uptake (TLU), and histologic GS and International Society of Urological Pathology (ISUP) grade group obtained from prostate biopsies. ***Materials and Methods:*** A retrospective review of 368 [68Ga]Ga-PSMA PET/CT scans performed between December 2021 and March 2023 on a single digital PET/CT scanner was conducted. Patients who underwent the study in a primary staging setting and showed no evidence of metastatic disease were selected. Spheric or elliptical volumes of interest (VOIs) were manually drawn around primary lesions, taking care to avoid bladder activity. Maximum standardised uptake value (SUVmax) and SUVpeak (the average SUV of a 1 $cm^3$ spheric VOI centered on the region of highest uptake) were directly obtained from the VOIs. Additionally, three different metabolic tumor volumes (MTV10, MTV20, and MTV40) and total lesion uptake values (TLU10, TLU20, and TLU40) were calculated using the same VOI and three different cutoffs in relation to SUVmax (10%, 20%, and 40%). Biopsy data was then retrieved for each patient. ***Results:*** Thirty-nine patients met the inclusion criteria. SUVpeakand SUVmax showed statistically significant correlations with the Gleason score (SUVpeak Spearman's rho=0.434, p<0.05; SUVmax Spearman's rho=0.319, p<0.05) and ISUP grade group (SUVpeak Spearman's rho=0.395, p<0.05; SUVmax Spearman's rho=0.346, p<0.05), with SUVpeakcorrelating slightly better with both parameters. However, there was no statistically significant correlation between metabolic tumor volumes (MTV10, MTV20, MTV40) or total lesion uptakes (TLG10, TLG20, TLG40) and GS or ISUP. ***Conclusion:*** Our study findings suggest that SUVpeak is a more reliable radiomic feature than SUVmax for evaluating local disease in prostate cancer patients. However, no significant correlation was found between MTV and TLG with the Gleason score or ISUP grade group, indicating a need for further refinement in the segmentation of these radiomic features.

## EP-0240

### PSG Score of Tubarial, Submandibular and Parotid Salivary Glands Utilizing 68Ga-PSMA-PET/CT-Scans of Prostate Cancer Patients

***S. Al-Sadoon****, F. Risheq, Z. Risheq, K. Faqeh;*
*Nuclear Medicine PET/CT & Bone Density Center, Amman, JORDAN.*

***Aim/Introduction:*** To characterize tubarial glands; and quantify radiation hazards to tubarial, submandibular and parotid salivary glands by determining their PSG scores utilizing $^{68}$Ga-PSMA-PET/CT-scans. Tubarial glands, located inside nasopharynx and throat cavity are visualized using $^{68}$Ga-PSMA-PET/CT-scans [1]. PSMA receptor targets prostate cancer tissue, and also accumulates in salivary glands. This side effect results in radiation induced toxicity, manifested as xerostomia and dysphagia. Hazards can be quantified using PSG score defined as "prostate lesion $Suv_{max}$/salivary glands $Suv_{max}$" [2]. ***Materials and Methods:*** Nine patients with (Mean±SD): age (68.9±4.9) y, PSA level (16.4±32.0), and biopsy confirmed prostate cancer, underwent $^{68}$Ga-PSMA-PET/CT-scan for evaluation. Tubarial right and left glands considered cylindrical, with functional length=L, diameter=D and size=Z= ($\pi$/4) $LD^2$. $SUV_{max}$ of salivary glands as-well-as prostate lesions were recorded; and PSG scores determined. ***Results:*** Estimated tubarial glands' functional length=3.0±0.6cm, diameter=1.1±0.2cm, and size=2.9 ±1.3$cm^3$. Tubarial, submandibular and parotid glands' $SUV_{max}$ =5.4±2.1, 14.8±2.6, and 14.7±2.8 respectively; with submandibular and parotid being identical. Tubarial glands' $SUV_{max}$ ~1/3 submandibular or parotid. The low tubarials' $SUV_{max}$ is due to limited blood pool. Estimated PSG score for tubarial, submandibular and parotid glands =2.4±1.4, 0.9 ±0.6, and 0.9±0.6 respectively. Most of our patients, submandibular and parotid glands' PSG-scores <1, indicating high radiation risk; while corresponding tubarial glands' PSG-scores >1; indicating lower radiation risk. Strategies reducing radiation toxicity include: keeping patients well hydrated, chewing, medication to block salivary glands, and local anesthetics/histamines [3]. ***Conclusion:*** 1- Tubarial gland considered cylindrical with: functional length-3cm, diameter-1.1cm, and size-3$cm^3$. $SUV_{max}$ = 5.4 reflects low blood pool. 2- Submandibular and parotid glands have similar uptakes ~14.8, and both can be imaging marker. For most patients, corresponding PSG scores <1, and glands became radionuclide therapy dose limiting organ. 3- Screening of prostate cancer patients with $^{68}$Ga-PSMA-PET/CT is recommended before radionuclide therapy. 4- Fractional dose to minimize radiation hazards is recommended for patients with PSG < 1. ***References:*** 1- Matthijs H, et al.The tubarial Salivary gland :A potential new organ at risk for Radiotherapy. ### Therapeutic implications of 18F-PSMA PET/MRI in patients with prostate cancer and biochemical recurrence (PSA < 2 ng/ml) after prostatectomy

***J. Garcia****, A. Compte, M. Kauak, P. Bassa, T. Blanch, J. Pastor, E. Riera;*
*CETIR ASCIRES Grupo biomédico, Barcelona, SPAIN.*

***Aim/Introduction:*** To evaluate the rate of detection of recurrence and to analyse its therapeutic implications for prostate cancer patients already treated with prostatectomy and PSA <2 ng/ml on 18F-PSMA PET/MRI. ***Materials and Methods:*** Prospective study with 20 consecutive prostate cancer patients treated with prostatectomy (mean time since surgery 19 months), and PSA <2 ng/ml, PET/MRI study acquired one hour after IV administration of 185±10% MBq of 18F-PSMA, in dual-phase fashion: Prostate (multi-parametric PET/MRI emission, T1, T2, DWI, Gd). Whole-body (PET/MR emission, T1, T2, STIR, DWI). Two experts in prostate

studies (NM physician and Radiologist) analysed images visually and quantitatively. Lesions were grouped into recurrence in prostatectomy bed; (Tr), pelvic lymph nodes (N1), extrapelvic lymph nodes (M1a), bone metastases (M1b). The Oncology Committee decided the therapeutic strategy to follow upon PET/MRI findings. ***Results:*** Mean PSA was 1.1 ng/ml (0.59-1.90), with mean PSAdT of 8 months. PET/MRI with 18F-PSMA was negative in 6 patients (30%). On per-patient analysis: PET/MRI was positive in 14 (70%) classified as: TrN0M0 (n: 6); T0N1M0 (n: 4); TrN1M0 (n:1); TrN0M1b (n: 1); T0N1M1aM1b (n: 1); TrN1M1aM1b (n: 1). Regarding recurrence site: Tr (n: 9; MRI was superior in 3, and PET in 1); N1 (n: 7) infracentimetric; M1a (n: 2) infracentimetric; M1b (n: 3). As for lesion stratification: 8 were single; 4 oligoM1; 2 multiM1. As for therapeutic implications of a positive study: no change (n: 6); change in volume radiotherapy and ADT (n:4); systemic treatment implementation (n:2). ***Conclusion:*** PET/MRI with 18F-PSMA detected disease in 70% of our prostate cancer patients with PSA levels <2ng/ml after prostatectomy. Disease site detection and patient stratification allowed for a patient-tailored therapy implementation. ***References:*** Fanti S, Minozzi S, Morigi JJ, Giesel F, Ceci F, Uprimny C, et al. ## EP-0242

### Clinical impact of 18F-DCFPyL PET/CT for clinical decision-making in biochemical recurrence of prostate cancer in our province.

***Y. Santaella Guardiola****, J. Rodriguez-Rubio Corona, M. Piñero Fernandez-Reyes, F. Cañete Sanchez, C. Quintana Bolaño, M. Pajares Vinardell;*
*Hospital Puerta del Mar, Cadiz, SPAIN.*

***Aim/Introduction:*** Since July 2021, 18F-DCFPyL PET/CT has been administered as a compassionate-use medicinal product for the diagnosis of biochemical recurrence in patients with castration-resistant prostate cancer, specifically when PSA levels are below 1 ng/mL. This imaging technique has demonstrated higher sensitivity in detecting metastatic disease compared to traditional imaging methods. Our aim was to evaluate how the integration of 18F-DCFPyL PET/CT in the province has impacted patient management. ***Materials and Methods:*** A retrospective study was carried out involving 151 patients who underwent a 18F-DCFPyL PET/CT scan between July 2021 and March 2023 at one of the five hospitals in the province of Cádiz: Hospital de Jerez, Hospital de La Línea, Hospital Puerto Real, Punta de Europa Hospital (Algeciras) and Puerta del Mar Hospital (Cádiz). The median PSA level at the time of the scan was 0.46 ng/mL (range 0.2 - 4.79 ng/mL), with a mean of 0.51 ng/mL. All PET/CT scans were evaluated by a Nuclear Medicine specialist with extensive experience. Descriptive statistics were used to analyze the impact of the scan on the clinical care of 138 patients with biochemical recurrence. For the remaining 13 patients, there was not enough information available to assess the clinical utility of the scan due to the short time elapsed since the test was performed. ***Results:*** Among the 151 patients studied, 93 (61.5%) showed an abnormal uptake of 18F-DCFPyL. These abnormalities included local recurrence in 21 patients, regional lymph node involvement in 53 patients, non-regional lymph node involvement in 10 patients, pulmonary visceral metastases in 5 patients, and bone metastases in 12 patients. Additionally, results were inconclusive in 3 patients (1.9%), and negative in 56 patients (37%). Out of the 138 patients for whom clinical information was available, 70 (50.7%) had a change in their treatment plan based on the scan results, while the treatment plan remained unchanged for 66 patients (47%). ***Conclusion:*** The incorporation of 18F-DCFPyL PET/CT in the province of Cádiz has significantly influenced clinical decision-making (50,7%) in cases of biochemical recurrence in prostate cancer. However, it is yet to be determined whether this will ultimately result in improved survival outcomes for these patients.

## EP-0243

### Evaluation of the Success of 18F-PSMA PET/CT in the Detection of Prostate Cancer Recurrence in Patients with Biochemical Recurrence

***G. Sutcu****[1], C. Soydal[1], M. Araz[1], Y. Urun[2], E. Suer[3], S. Baltaci[3], N. O. Kucuk[1];*
*[1]Ankara University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Ankara University Medical School Department of Medical Oncology, Ankara, TÜRKIYE, [3]Ankara University Medical School Department of Urology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** Prostate cancer is the most common urological cancer in men. PSMA has become an ideal molecular target for both imaging and treatment, since it is a good imaging biomarker for prostate cancer. Widely used form is $^{68}$Ga-PSMA, and its sensitivity for detection of recurrent disease, in especially at low PSA levels (0.2-2.0 ng/mL), is shown to be high. However, it can assess the pelvic region difficult due to excretion from the urinary system. Although it is rarely used, $^{18}$F-PSMA-1007 has been presented a potential advantage for pelvic imaging because of its minimal excretion by the urinary system. In this study, we present our first experience evaluating the success of $^{18}$F-PSMA-1007 PET/CT in patients with biochemical recurrence. ***Materials and Methods:*** This study has a prospective design. After ethical committee approval, 31 patients who were being followed after primary treatment of prostate cancer and had biochemical recurrence were recruited to the study between June 2022 and February 2023. All the patients were underwent whole body PET/CT 45-60 min after iv injection of approximately 333-407 MBq $^{18}$F-PSMA-1007. The images were evaluated for local recurrence, regional, distant lymph node metastases, and bone metastasis. Disease detection rates for all the regions were calculated and mean values of Gleason Scores (GS), PSA levels and PSA doubling time (PSAdt) of PET positive and negative patients were analyzed by Student's T Test. ***Results:*** The mean age of the patients participating in the study was observed at 68.26, the average Gleason score was 7.71, the average PSA at the time of imagining was 10.6, and the PSA doubling time was 139.7 days. Pathological activity in the prostate was observed in 11 (35%) of the 31 patients, and the average SUVmax was found to be 6.55. Regional lymph node recurrence was detected in 12 (38%) patients, distant lymph node metastasis in 10 (33%) patients, and bone metastasis in 9 (30%) patients. The overall detection rate was 76.7%. Median GS of PET positive and negative groups were different (p=0.03). Mean PSAdt of patients with bone metastases and without were different significantly (p=0.01). ***Conclusion:*** Although a small sample group was examined, a high detection rate was observed for $^{18}$F-PSMA-1007. This suggests that $^{18}$F-PSMA-1007 PET/CT may have advantages over other $^{68}$Ga labelled PSMA radiopharmaceuticals, particularly in the evaluation of regional and local relapse in patients with biochemical relapse.

## EP-0244

### Flare phenomenon of 99mTc-bone scintigraphy is a determinant of prognosis in patients with metastatic castration-resistant prostate cancer

***X. Zhang***[1], *K. Nakajima*[2], *H. Horikoshi*[3], *A. Mizokami*[4], *K. Nishimoto*[5], *K. Hashine*[6], *H. Matsuyama*[7], *S. Takahashi*[8], *H. Wakabayashi*[1], *S. Kinuya*[1];

***Aim/Introduction:*** Bone scan index (BSI) has been used in patients with prostate cancer and bone metastasis. Although flare phenomenon during chemotherapy was observed in a subset of patients with metastatic castration-resistant prostate cancer (mCRPC), clinical implications have not been clarified. The aim of this study is to determine the prognosis value of the flare phenomenon on bone scintigraphy in mCRPC patients. ***Materials and Methods:*** A cohort of patients with bone metastatic CRPC (n=72) were included from PROSTAT-BSI registry. BSI was automatically calculated with $^{99m}$Tc-MDP bone scintigraphy. The flare phenomenon was defined as the increase of BSI greater than 10% in the 3rd month after the beginning of therapy, followed by an improvement in BSI three months later. Two-year all-cause death (ACD) and prostate cancer death (PCaD) were analyzed for the flare and no-flare groups. The Cox survival analysis and relationship of predictors to the final outcome were investigated. The effect of androgen receptor axis targeted agents (ARATA), such as Abirateron Abiraterone and Enzaltamide, was also examined. ***Results:*** Flare phenomenon was observed in 26/72 (36%) patients. The 2-year mortality rates were 43.5% and 26.9% in the no-flare and flare groups respectively. In the no-flare group, patients with the higher baseline BSI resulted in higher mortality while no significant difference in mortality was observed in the flare group, irrespective of ACD or PCaD. The baseline BSI>4 showed a significant higher mortality rate in the no-flare group. After accounting for flare phenomenon in addition to other factors, the survival analysis indicated that the increased PSA in 3rd month was a determinant of poor prognosis in the no-flare group especially for the patients with baseline BSI>1, while the PSA change had no impact on survival in the flare group. Regarding pharmaceutical applications, the application of ARATA lead to greater survival in the no-flare group than that in the flare group and had a strong association with the baseline BSI, but had no obvious effect in the flare group. ***Conclusion:*** Favorable prognosis was attainable in mCRPC patients who showed flare phenomenon. Other variables, such as baseline BSI, a change in PSA, and the use of ARATA, may have an impact on the survival of patients who had no flare phenomenon. A follow-up bone scintigraphy at least every three months assisted in determining prognosis for bone metastasis in mCRPC. Early use of ARATA may enable individuals with no flare phenomenon gain a better outcome.

## EP-0245

### Efficacy of 18-F-DCFPyL-PET/CT in the first biochemical recurrence of prostate cancer and its impact on therapeutic management

***I. Obedkova****, A. Prieto Soriano, L. Santamaria Chico, S. Guzmán Ortiz, K. Velasquez Diaz, P. Soares Meneses, M. Grajeda Gallardo, I. Garrido Solesio, M. Mitjavila Casanovas;*
*University Hospital Puerta de Hierro, Majadahonda, SPAIN.*

***Aim/Introduction:*** 18-F-DCFPyL (PSMA) is a radiotracer with already demonstrated results, which in our setting is only for compassionate use. The objective of this study was to evaluate the efficacy of PET-PSMA in patients with biochemical recurrence (BCR) of prostate cancer (PC), as well as its impact on therapeutic management. ***Materials and Methods:*** We prospectively recruited 63 patients (mean age 68 years) with BCR after radical prostatectomy, who underwent PET-PSMA after negative CT, bone scintigraphy and/or PET-choline. The analysis was performed on 27 patients with the first BCR. We evaluated the Gleason score, PSA levels, PSA doubling time (PSADT), PET-PSMA positivity according to EANM guidelines, and the impact of the result on therapeutic management. We used STATA for statistical analysis. ***Results:*** At diagnosis nineteen of twenty-seven patients had low/intermediate risk and eighth of twenty-seven high risk. Ten patients had PSA level of BCR <0.5, twelve patients 0.5-1.99, four patients between 1-1.99 and only one PSA≥2. The PET-PSMA positivity rate was 55.6% (40.7% oligometastatic and 14.8% multimetastatic). Patients with a positive PET-PSMA result had a lower PSADT (mean 5.6 months) than patients with a negative result (mean 6.3 months). A positive study result was obtained in 40% patient with PSA<0.5, which increased to 58.3% in patient with PSA between 0.5-0.99, 75% with PSA between 1-1.99 and 100% with PSA≥2. A change in therapeutic management was proposed in all patients (15) with positive PET-PSMA study result, in 2 of 15 it was not carried out due to patient refusal. Nine of fifteen patients received targeted radiotherapy and 4 of 15 also received hormone therapy. A decrease in a control PSA level was observed in 85% of patients with a change in treatment management. ***Conclusion:*** PET-PSMA is effective in the diagnosis of the first BCR of PC with low PSA levels, causing a change in therapeutic management with subsequent biochemical response.

## EP-0246

### Outcomes of [68Ga]Ga-PSMA-11 PET/CT in biochemical recurrence after brachytherapy

***I. Próspero***[1], *G. Ferreira*[1], *J. C. Ferro*[1], *D. Barbosa*[1], *D. G. Silva*[1], *P. Leite Silva*[2], *S. Fontão de Castro*[1], *J. P. Teixeira*[1], *H. Duarte*[1], *I. Lucena Sampaio*[1];
[1]*Department of Nuclear Medicine, Instituto Português de Oncologia do Porto, Porto, PORTUGAL,* [2]*Cancer Epidemiology Group-Research Center, Department of Epidemiology, Instituto Português de Oncologia do Porto, Porto, PORTUGAL.*

***Aim/Introduction:*** Patients with prostate cancer (PCa) experiencing biochemical recurrence (BCR) after treatment with curative intent are at an increased risk of developing distant metastasis. Nevertheless, patients offered low-dose rate brachytherapy (LDRBT) as monotherapy are usually patients with low-risk PCa, as opposed to patients submitted to other radiotherapy modalities. The aim of this study was to describe the role of prostate-specific membrane antigen (PSMA) PET/CT in clarifying the natural history of BCR after brachytherapy. ***Materials and Methods:*** Retrospective study of 49 men who underwent [$^{68}$Ga]Ga-PSMA-11 PET/CT between October 2017 and December 2022 for suspected

BCR after LDRBT (Iodine-125 seeds; 145 Gy dose). Exclusion criteria included prostate-specific antigen (PSA) bounce and PSA level not in accordance with the Phoenix definition for BCR. Images were reviewed for determination of local recurrence and/or metastasis and PSMA intensity of the detected lesions, expressed as maximum standardized uptake value (SUVmax) and SUVpeak. The association between these PET/CT-parameters and PSA-related variables [PSA doubling time (PSA-DT), PSA velocity (PSAV) and PSA level at the time closest to image acquisition] was analyzed according to Spearman's correlation and Wilcoxon-Mann-Whitney test (α=0,05). The subsequent patient management decision was also registered. ***Results:*** Thirty-three patients were included (median age= 71 years; median initial PSA= 7,83 ng/mL); 64% had an initial biopsy Gleason score= 6 (ISUP grade 1). BCR occurred a median of 58,90 months after LDRBT, with a median PSA-DT of 10,5 months. Median PSA by the time of imaging was 4,89 ng/mL. [$^{68}$Ga]Ga-PSMA-11 PET/CT was positive in 27 patients (82%): 70% had tumor recurrence within the prostate/seminal vesicles (n=19), 33% showed regional lymph node metastasis (n=9) and 30% presented distant metastasis (n=8); 52% (n=14) had only local disease. Median SUVmax of local recurrence was 6,42. No significant association was found between PET/CT-parameters and PSA-related variables. Twenty-four patients also underwent pelvic magnetic resonance imaging (MRI), with concordance between PET/CT and MRI in 67%; in 6 patients (25%) recurrence was detected only on PET/CT. Subsequent therapeutic decision included salvage local procedures (n=10), surveillance (n=8) and hormonal therapy (n=9). ***Conclusion:*** BCR after LDRBT tended to develop locally rather than at distant sites. PSA values and kinetics were not predictive of PCa recurrence location on PSMA PET/CT, which could be explained by variability in PSA measurements and the small sample size of the study. According to PSMA PET/CT results, subsequent patient management included mostly local treatments or surveillance, delaying the introduction of hormonal therapy.

## EP-0247

### Impact of [18F]-DCFPyL (PSMA) PET/CT in the diagnostic and therapeutic impact in the biochemical recurrence of prostate cancer.

***J. Fernández Fernández****, E. Triviño-Ibáñez, D. Rivas-Navas, J. Villa-Palacios, A. Rodríguez-Fernández;*
*Virgen de las Nieves University Hospital, Granada, SPAIN.*

***Aim/Introduction:*** The aim was to evaluate the diagnostic accuracy and the impact therapeutic of [$^{18}$F]-DCFPyL PET/CT in the biochemical recurrence (BR) of prostate cancer (PC) treated with curative intent. ***Materials and Methods:*** An observational and prospective study was performed, including patients with PC treated with radical intent and BR criteria, who underwent an [$^{18}$F]-DCFPyL PET/CT study between October 2020 and August 2022. The images were analysed visually and semi-quantitatively. The results of the PET/CT study were categorised into positive or negative, using anatomical pathology, other imaging tests and/or clinical follow-up as the gold standard. We analysed the impact of the results on the therapeutic attitude and the association of quantitative parameters with PSA kinetics. The reclassification of risk and tumour volume, were was carried out according to the LATITUDE and CHAARTED criteria. ***Results:*** 101 patients were included (mean age: 63.24±6.37 years). They presented a positive [$^{18}$F]-DCFPyL study in 85/101 patients with a detection rate (DR) of 84.2%. Of these patients, 21.8% presented recurrence in the prostatic fossa, 29.7% had pelvic lymph node involvement, 9% had retroperitoneal lymph node involvement and 22.8% presented distant disease. DR increases in line with the increasing of PSA trigger values: PSA from 0.2 ng/ml to 0.5 ng/mL DR 78.3%; PSA from 0.5 ng/ml to 1 ng/ml DR: 89.7%; PSA from 1 ng/ml to 1.5 ng/mL DR:81.3%, PSA over 1.5 ng/mL DR: 100%. Sensitivity and specificity were 0.91 (95% CI 0.85-0.97) and 0.55 (95% CI 0.25-0.84) respectively, positive predictive value (PPV) 0.94 (95% CI 0.89-0.99), negative predictive value (NPV) 0.43 (95% CI 0.17-0.69) with a discriminatory ability (AUC) of 0.65 (95% CI 0.51-0.80, p=0.043). The result of the [$^{18}$F]-DCFPyL study modified the therapeutic attitude in 57/101 patients (56.4%) and reclassified 4/101 patients into high risk and tumour burden. The quantification parameters of the [$^{18}$F]-DCFPyL study showed a moderate-strong significant correlation with PSA kinetics. ***Conclusion:*** [$^{18}$F]-DCFPyL PET/CT presents good performance in the detection of disease in BR of PC even with very low PSA levels, conditioning the modification of therapeutic decisión-making in more than 50% of patients in our series.

## EP-0248

### Analysis of pathological findings in 18F-DCFPyL PSMA PET in recurrence of prostate cancer according to PSMA-RADS classification and E-PSMA overexpression score. Confirmation of results by pathological anatomy, biochemical response or imaging.

***B. Hervás-Sanz***[1]*, J. J. Robles-Barba*[1]*, J. J. Martín-Marcuartu*[1]*, S. Bondia-Bescós*[1]*, M. Pudis*[1]*, J. E. Romero-Herrera*[2]*, G. Reynés-Llompart*[3]*, F. Ferrer-González*[4]*, J. F. Suárez-Novo*[5]*, M. Cortés-Romera*[1]*;*
*[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Radiopharmaceutical Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [3]Radiophysics Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [4]Radiation Oncology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [5]Urology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

***Aim/Introduction:*** To validate our findings with 18F-DCFPyL PET/CT (PET/PSMA) in prostate cancer (PCa) recurrence, classified usings PSMA-RADS classification and E-PSMA score of PSMA overexpression, through subsequent confirmation by pathological anatomy (PA), biochemical response after treatment or complementary imaging techniques. To correlate the results with clinical variables related to the characteristics of the tumor and PSA kinetics. ***Materials and Methods:*** Forty-two patients with positive PET/PSMA (45-81 years old) performed because of PCa biochemical recurrence after radical therapy (PSA 0.21 to 8.5) were included. PET findings were classified according to PSMA-RADS scale and E-PSMA score of PSMA overexpression (OE). These findings were validated by: 1) PA after surgery or biopsy of the highest PSMA-RADS lesion; 2) PSA decrease after radiotherapy/SBRT of the highest PSMA-RADS lesion (patients treated with hormonal or systemic therapy were excluded) or 3) Confirmation of PET/PSMA findings by another imaging technique (MRI, CT, bone scintigraphy, another PET). Results were correlated with the most recent measure of PSA (rPSA), PSA kinetics (dobubling time, velocity, slope), ISUP, D'Amico and initial TNM classification using statistical Chi-square studies of trend and linear regression. ***Results:*** Overall confirmation rate was 88% (37/42): 6/8 by PA, 21/23 by PSA decrease and 10/11 by imaging. We found 26 patients whose highest grade lesion was classified as PSMA-RADS-5 (25/26 confirmed as PCa, although the false positive may be due

to an inadequate lymphadenectomy), 13 PSMA-RADS-4 (9/13 confirmed as PCa) and 3 PSMA-RADS-3D (3/3 confirmed as PCa). Statistically significant relationship was found between rPSA and OE (p=0.00117) and between rPSA and the presence of lesions with higher PSMA-RADS, specially when rPSA>2 (p=0.01316).A slight correlation was also found between ISUP and patients with a confirmed positive result, but no statistical correlation was found between PET/PSMA results and PSA kinetics, D'Amico or initial TNM classification. ***Conclusion:*** PET/PSMA is a fundamental technique for detection of PCa recurrence, with results that in most cases can be confirmed after treatment, biopsy, surgery or image control. PSMA-RADS and E-PSMA classifications help to intuitively categorize the findings and homogenize the reports. In our study, we frequently found lesions with higher PSMA-RADS/E-PSMA scores in those patients with higher PSA.

## EP-0249

### Comparison of Digital Versus Analog 68Ga-PSMA-11 PET/CT Performance in Hormone-sensitive Prostate Cancer Patients with Early Biochemical Recurrence or Persistence

***G. Rovera***[1], *S. Grimaldi*[1], *S. Dall'Armellina*[1], *R. Passera*[1], *M. Oderda*[2], *P. Gontero*[2], *D. Deandreis*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Department of Surgical Sciences, Urology Unit, AOU Città della Salute e della Scienza di Torino, Molinette Hospital, University of Turin, Turin, ITALY.*

***Aim/Introduction:*** Recent progress in PET technology has led to the introduction of new-generation digital PET systems based on solid state detectors, which offer several technical advantages. The aim of this study was to investigate whether the favorable characteristics of digital PET (dPET) compared to previous generation analog systems (aPET) could translate into an improved disease localization in prostate cancer (PCa) patients with early biochemical recurrence/persistence (BCR/BCP) after radical treatment. ***Materials and Methods:*** A retrospective analysis was conducted on four hundred forty (n=440) consecutive $^{68}$Ga-PSMA-11 PET/CT scans performed with either an analog (11/2016-11/2020, n=311) or digital (04/2021-10/2022, n=129) scanner in hormone-sensitive ADT-free PCa patients with early-BCR/BCP (PSA at PET ≤ 2.0 ng/mL), previously treated with radical intent (radical-prostatectomy/radiotherapy). Inferential statistics for continuous/categorical covariates was performed using Mann-Whitney and Fisher's exact tests. The cohorts were tested for homogeneity of baseline clinical parameters (T-stage ≥3a, ISUPgrade ≥3, radical treatment, time-to-recurrence, PSA doubling-time/velocity, adjuvant/salvage treatments). ***Results:*** dPET showed a significantly higher number of positive scans compared to aPET (49%[63/129] vs 37%[116/311], p=0.03), despite a slightly lower median PSA value in the dPET cohort (0.33[IQR:0.26-0.61] vs 0.55[IQR:0.40-0.85] ng/ml, p<0.01). dPET detection rate was significantly higher in both PSA ranges 0.2-0.5 (39%[32/82] vs 25%[34/135], p=0.03) and 0.5-1.0 ng/ml (63%[24/38] vs 41%[53/130], p=0.02), but not for PSA ≥1.0 ng/ml. Regarding lesions localization, dPET identified a higher number of cases with suspected pelvic nodal metastases (miN1, 26%[20/78] vs 14%[17/125], p=0.04) and local recurrences (miTr, 30%[14/47] vs 3%[6/176], p<0.01) in patients with PSA values ≤ 0.5 and 0.5-2.0 ng/ml, respectively. Overall, dPET showed a higher per-patient median number of pathologic findings (PSMA-RADS ≥3) (2[IQR:1-3] vs 1[IQR:1-2], p<0.01), as well as a higher number of multi-metastatic cases (>3 lesions) among N1/M1-positive scans (22%[10/46] vs 9%[9/105], p=0.03). The proportion of uncertain findings (PSMA-RADS 3) among all pathological lesions was significantly lower for dPET than aPET (24%[39/160] vs 39%[60/156], p=0.008), even when stratifying for miN1 lesions (11%[7/65] vs 41%[25/61], p<0.01). Moreover, despite the higher positivity rate of dPET, the number of patients with only uncertain findings was not significantly different (7%[9/129] vs 9%[28/311]). Finally, although the lesion/blood-pool SUVmax ratios were comparable after PSMA-RADS stratification, dPET PSMA-RADS 4 nodal metastases (miN1/M1a) showed a significantly smaller maximum diameter (5[IQR:4-7] vs 7[IQR:5-8] mm). ***Conclusion:*** $^{68}$Ga-PSMA-11 dPET showed a better performance compared to aPET, resulting in a higher scan-positivity rate, a higher number of detected pathological lesion, and a lower rate of uncertain findings.

## EP-0250

### Whole Body Tumour Burden On PET/CT With 18F-DCFPyL Obtained By aPROMISE Platform: Associations With Tumour Biology And PSA Kinetics In Patients With Biochemical Relapse Prostate Cancer.

***L. García Zoghby***[1], *A. García Vicente*[1], *M. Amo-Salas*[2], *P. Borrelli*[3], *C. Lucas Lucas*[4], *A. Padilla Bermejo*[4], *N. Sicilia Pozo*[4], *M. Contreras Ameduri*[4], *M. Cruz Montijano*[1], *F. Pena Pardo*[4], *E. Noriega Álvarez*[4], *M. Talavera Rubio*[4], *V. Poblete García*[4], *Á. Soriano Castrejón*[1];
[1]*University Hospital of Toledo, Toledo, SPAIN,* [2]*Castilla-La Mancha University, Ciudad Real, SPAIN,* [3]*Sahlgrenska University Hospital, Göteborg, SWEDEN,* [4]*General University Hospital of Ciudad Real, Ciudad Real, SPAIN.*

***Aim/Introduction:*** The objective was to analyse the associations between 18F-DCFPyL molecular variables obtained by automatic Prostate Cancer Molecular Imaging Standardized Evaluation (aPROMISE) platform with clinical characteristics and PSA kinetics in patients with biochemical relapse (BR) of prostate cancer (PCa). ***Materials and Methods:*** We analysed 275 patients with BR of PCa after radical treatment. All patients' characteristics were classified in groups before PET/CT scans: grade ISUP group (1-5), recurrence risk (low/medium/high), PSA (PSA≤1ng/ml, 1<PSA≤2 and PSA > 2 ng/ml), PSA doubling time (PSAdt) ≤ or > 6 months and PSA velocity (PSAvel) ≥ or < 0.2 ng/ml/month. All the patients underwent 18F-DCFPyL PET/CT between May 2020 and September 2022. 18F-DCFPyL PET/CT were visually assessed by two experienced nuclear medicine physicians independently. Lesions segmentation in positive 18F-DCFPyL PET/CT scans was performed using aPROMISE platform. We obtained total molecular tumour volume (total_MTV), total tumour lesion activity (total_TLA) and total aPROMISE score (total_aPROMISE), a new radiomic biomarker which is the interaction between volume and intensity by tissue type. We compared clinical characteristics in negative versus positive PET/CT scans by Mann-Whitney test. Associations between molecular variables and patients' characteristics were statistically analysed, categorical variables by ANOVA and Kruskal-Wallis test and quantitative variables by Spearman's correlation. ***Results:*** Sixty-two per cent of the patients were high-risk PCa. 18F-DCFPyL PET/CT scans were positive for PCa recurrence in 165/275 patients (60%). Mean PSA, PSAdt and PSAvel values were significantly different in positive versus negative 18F-DCFPyL PET/CTs (p<0.001; p=0.003; p< 0.001, respectively), with higher PSA level and more unfavourable PSA kinetics in positive than in negative scans. PSA and PSAvel showed significant association with total_MTV [ρ=0.500 (p<0.001); ρ=0.448 (p<0.001), respectively], total_TLA [ρ=0.465 (p<0.001); ρ=0.448 (p<0.001), respectively], and total_aPROMISE

[ρ=0.480 (p<0.001); ρ=0.470 (p<0.001), respectively]. Mean total_MTV, total_TLA and total_aPROMISE values were significantly higher in PSA > 2ng/ml group (13.05±22.34; 69.89±133.37; 24.96±44.88, respectively), PSAdt ≤ 6 months (10.76±21.68; 56.37±117.18; 20.88±43.13, respectively) and PSA ≥ 0.2ng/ml/month (16.07±27.35, 84.57±149.73; 31.38±54.74, respectively) compared to others groups. No significant association was found between grade group and recurrence risk with metabolic variables. ***Conclusion:*** Larger 18F-DCFPyL molecular tumour burden variables assessed by aPROMISE platform were associated to higher PSA values and unfavourable kinetics, defining their utility and robustness compared to other clinical variables, not only in the prediction of positive PET/CT but also in whole-body tumour burden assessment.

## EP-0251

### Influence of Gleason, ISUP grade, initial TNM, PSA values and kinetics on detection rate in prostate cancer recurrence by [18F]DCFPyL PSMA PET/CT

***J. Martin-Marcuartu***[1], *J. Robles Barba*[1], *S. Bondia Bescos*[1], *E. Romero Herrera*[2], *G. Reynes Llompart*[3], *J. Suárez Novo*[4], *F. Ferrer Gonzalez*[5], *S. Ruiz Llama*[6], *M. Cortés Romera*[1];
[1]*Department of MNU-PET/CT (IDI). Hospital Universitari de Bellvitge, Barcelona, SPAIN,* [2]*Department of Radiopharmacy. Hospital Universitari de Bellvitge, Barcelona, SPAIN,* [3]*Department of Radiophysics. ICO Duran i Reynals, Barcelona, SPAIN,* [4]*Department of Urology. Hospital Universitari de Bellvitge, Barcelona, SPAIN,* [5]*Department of Radiotherapy. ICO Duran i Reynals, Barcelona, SPAIN,* [6]*Department of Radiopharmacy. Hospital Germans Trias i Pujol, Barcelona, SPAIN.*

***Aim/Introduction:*** To evaluate the influence of Gleason scale, ISUP grade, initial TNM, PSA values and kinetics on the detection rate (DR) of prostate cancer recurrence studied with [18F]DCFPyL ([18F]PSMA) PET/CT, as well as on the PSMA overexpression intensity (OI) of pathological findings in PET scans. ***Materials and Methods:*** We included 109 patients (45 - 82 years) with biochemical recurrence after radical therapy (PSA 0.20 to 61.4 ng/dl). We evaluated DR in different groups according to Gleason, ISUP grade and initial TNM, most recent PSA (PSAr) stratified according to 0.2-0.5ng/dl; >0.5-1ng/dl, >1-2ng/dl, >2ng/dl, and kinetics (doubling time [DT], speed and slope). The variables were also correlated with the OI of pathological findings (1: uptake between vascular pool and liver, 2: between liver and parotid, 3: >parotid). Statistical studies Chi-square and linear regression were performed to evaluate the correlation between the different variables as well as DT and OI. ***Results:*** Overall DT was 68.8% (75/109), being higher in high-risk patients by TNM (76.9% for T3b vs. 62.2% for T2) or Gleason (81.2% for Gleason 9 vs. <70% for the rest). Statistical significance was found between PSAr with DT (p=0.039) and OI (p=0.0168). Patients with PSAr >2ng/dl had DT 76.2% vs. 47.6% in PSAr 0.2-05ng/dl. OI was grade 3 in 43.5% of positive patients with PSAr >2ng/dl, while in none of the patients with PSAr between 0.2-0.5ng/dl was positive. Regarding kinetics, we did not find statistically significant results, although we did find a trend towards higher DR and OI in patients with short DT. ***Conclusion:*** PET/CT with [18F]DCFpyL is an useful technique for the detection of recurrence in prostate cancer. It has greater efficiency in high-risk patients and in recurrences with PSA from 0.5 because of greater overexpression of PSMA in patients with higher PSA. In our study we found no significant correlation between kinetics and detection rate, although there was a trend regarding doubling time.

## EP-0252

### Attitude and Management Change in Those Patients with Extrapelvic Findings in a PET-CT Study with PSMA

***R. Bellviure-Meiro***[1], *M. Simó Perdigó*[1], *S. Menendez-Sanchez*[2], *C. Franco Monterroso*[1], *I. Navales Mateu*[1], *S. Asadurova*[1], *F. Velázquez*[1], *J. Echeverri Diaz*[1], *N. Calviño*[1], *S. Aguade-Bruix*[1];
[1]*Hospital Universitari Vall d'Hebron, Barcelona, SPAIN,* [2]*Clínica Universidad de Navarra, Pamplona, SPAIN.*

***Aim/Introduction:*** To analyze the rate of extrapelvic findings in PET-CT studies with PSMA in patients with biochemical recurrence of Prostate Cancer (PCa) and PSA <1ng/ml. We also evaluated the change in therapeutic management of these patients. ***Materials and Methods:*** We analyzed a total of 86 PET-PMSA studies carried out during 2022 and 2023. We included those patients with PCa and biochemical recurrence with potentially suspicious findings of extrapelvic tumor disease: retroperitoneal lymph nodes, supradiaphragmatic lymph nodes, bone M1 , lung M1, or others. Change in management was measured according to 3 points: follow-up, stereotactic body radiation therapy (SBRT), or systemic treatment. The confirmation of the findings was made according to biopsy, response to PSA and imaging tests. ***Results:*** The rate of extrapelvic findings in our series was 27.9% (n=24/86). 13.95% showed more than one lesion.5 patients with unique lesions were in the end considered negative in evolutionary studies (chest CT/PET-PSMA): 4 corresponded to rib bone lesions and another to a subpleural nodule. Another patient with a single lesion in the vertebral body that was initially negative by MRI was finally positive by biopsy.Thus, 19 of the 24 patients (79.17%) with extrapelvic findings by PET-PSMA were considered pathological:7 patients were candidates for SBRT: single bone lesion (n=3), pulmonary nodule (n=1), pulmonary hilar adenopathy (n=1), nodal involvement at the pelvic and retroperitoneal level (n=1) and two bone lesions (n=1). Three of these patients continue to respond and the other two show a new biochemical recurrence. The other two are too recent to assess evolution.12 patients received systemic treatment, either for multiple bone lesions, lymph nodes, or a combination of both. One patient showed a lesion on the penis' glans , confirmed by biopsy, associated with inguinal lymphadenopathy and a pelvic bone lesion. ***Conclusion:*** Extrapelvic lesions are frequent findings in PET-CT studies with PSMA with low PSA, being pathological in up to 79.17% of cases. A non-negligible number (20.83%) of the unique lesions do not have a malignant origin (especially in the ribs), so they should be evaluated with caution or a directed study should be carried out.

## EP-0253

### Psma PET/CT Results and Effect on Treatment in Patients with Biochemical Recurrence After Radical Prostatectomy

***K. Akçay***[1], *N. Selcuk*[1], *G. Beydagi*[1], *T. Toklu*[1], *E. Demirci*[1], *Ö. Sönmez*[1], *D. Karaçam*[1], *M. Yücel*[1], *E. Kaymak*[2], *O. Civi*[3], *L. Kabasakal*[4];
[1]*yeditepe university, istanbul, TÜRKIYE,* [2]*İstanbul Başakşehir Çam Sakura Hospital, istanbul, TÜRKIYE,* [3]*istanbul oncology hospital, istanbul, TÜRKIYE,* [4]*İstanbul University-Cerrahpaşa, istanbul, TÜRKIYE.*

***Aim/Introduction:*** Ga-68 Prostate Specific Membrane Antigen (PSMA) PET/CT is recommended for restaging imaging after biochemical recurrence. Radiotherapy (RT) is applied to the prostate bed in Ga-68 PSMA negative cases if the PSA value is below 1.4 ng/ml. In cases with higher PSA levels, hormone therapy (HT) is also administered alongside RT. ***Materials and Methods:***

The aim of study investigate PSMA-PET/CT's impact on treatment planning for biochemical recurrence post-radical prostatectomy without prior treatment. In cases diagnosed with prostate cancer after radical prostatectomy and followed without treatment, 151 patients who underwent PSMA-PET/CT imaging upon biochemical recurrence development and were subsequently followed with or without treatment with PSA monitoring every 3-6 months were retrospectively included in the study. Cases with PSA levels <0.2 ng/mL undetectable were exclusion criteria for the study. ***Results:*** No distant metastases were detected before radical prostatectomy, and the preoperative mean PSA was 11.71±9.11 ng/dl. Postoperative the average rare PSA value detectable was 0.085 ng/ml. The median biochemical recurrence PSA value with persistent increase in at least two different PSA measurements or >0.2 PSA level in a single measurement was 0.45 ng/ml. PSMA-PET/CT (-) was found in 80 patients. In 17 of the 71 patients with PSMA-PET/CT (+), there was a recurrence only in the prostate bed, while 54 had PSMA-PET/CT positivity outside the prostate bed. Bone metastases were found in 24 patient, organ metastases in 7. Progression was detected in the PSA follow-ups of 10 PSMA-PET/CT (-) patients who were followed without treatment, while a significant PSA increase wasn't observed in 6 of them. In 13 of the 16 patients with PSMA-PET/CT (-) who received RT to the prostate bed (median PSA: 0.3625), PSA regression was observed (median PSA: 0.01825) (p <0.005), only 1 patient had an unmeasurable PSA level. On the other hand, PSA progression continued in 2 patients despite treatment. In the PSMA-PET/CT (-) group, PSA regression was observed in 9 of the 13 patients (median PSA: 0.3480) who started RT+HT (median PSA: 0.0060) (p <0.005), and 3 patients had an unmeasurable PSA level. ***Conclusion:*** The localization of the disease is required for salvage treatment in biochemical recurrence. How to treat PSMA-PET/CT (-) cases is a matter of debate. Local recurrence was detected in only 24% of PSMA-PET/CT (+) cases. Therefore, performing RT only to the prostate bed in PSMA-PET/CT (-) cases after biochemical recurrence appears to be a topic that needs to be discussed.

## EP-0254

### Serum values of prostate-specific antigen (PSA) and grade groups according to the International Society of Urological Pathology (ISUP grading), as determinants of [18F]DCFPyL PET/CT positivity in patients with biochemical recurrence of prostate cancer treated with radical prostatectomy.

***A. Peñaherrera Cepeda****, L. Diaz Gonzaga, J. Villanueva Curto, J. Badell Martínez, P. García-Talavera San Miguel, F. Gómez-Caminero López, E. Campaña Diaz, S. Rama Alonso, P. Tamayo Alonso;*
*Complejo asistencial universitario de Salamanca, Salamanca, SPAIN.*

***Aim/Introduction:*** To calculate [18F]DCFPyL PET/CT detection rate according to serum PSA values and ISUP grading, in patients with biochemical recurrence (RBq) of prostate cancer, treated with radical prostatectomy (RP). ***Materials and Methods:*** Were analised 145 PET/CT studies, that were performed with 333 MBq of [18F] DCFPyL from October 2020 to April 2023 (mean age: 69 ± 7 years), all with biochemical recurrence of prostate cancer treated with RP. RBq after RP was defined as a PSA elevation ≥0.2 ng/mL. The sample was subdivided into 4 groups according to the PSA value in ng/mL at the time the PET/CT was ordered into: PSA between 0.2 to 0.5, PSA between 0.51 to 1, PSA between 1.1 to 2 and PSA ≥2. Patients were also classified according to ISUP grading from 1 to 5.Descriptive statistics were used, including median and standard deviation for continuous variables and frequency and percentage for categorical variables ***Results:*** The median baseline PSA level was 0.53 ng/mL (0.20-8.26). [18F]DCFPyL PET/CT was positive in 49% of the studies performed (71 of 145 studies). In patients with PSA levels between 0.2 to 0.5 ng/mL, the detection rate was 37.5%, PSA between 0.51 to 1 was 58.1%, PSA between 1.1 to 2 was 73.3% and PSA ≥2 was 71.4%, the latter group may be underestimated due to the number of patients in this category. Patients with ISUP grading 1, the detection rate was 47.8%, ISUP grading 2 was 46.5%, ISUP grading 3 was 42.5%, ISUP grading 4 was 46.4% and ISUP grading 5 was 75%. ***Conclusion:*** [18F]DCFPyL PET/CT demonstrated an excellent detection rate in patients with biochemical recurrence of prostate cancer, with PSA values > 0.5 ng/mL. With respect to ISUP grading, PET/CT detection was similar in categories 1 to 4, with higher detection in category 5.

## EP-0255

### Usefulness of PET-MR with 18F-DCFPyL in the Diagnosis of Biochemical Recurrence in Prostate Cancer and its Therapeutic Implication

***R. De Teresa****, I. Plaza de las Heras, C. Field, L. García Cañamaque;*
*GRUPO HM HOSPITALES. UNIVERSIDAD SAN PABLO CEU, Madrid, SPAIN.*

***Aim/Introduction:*** To evaluate the usefulness of PET-MR with 18F-DCFPyL in the diagnosis of biochemical recurrence in patients with prostate cancer (PC) and its therapeutic implication. ***Materials and Methods:*** Retrospective analysis from January-22 to January-23, of patients with PC treated with curative intent by radical prostatectomy (RP) or external beam radiotherapy (RT)/brachytherapy with criteria of biochemical recurrence (RBq), being the serum PSA levels between 0.8 and 8.0 ng/ml (mean 3.25 ng/ml) after RT and PSA levels between 0.2 and 4.5 ng/ml (mean 1.68 ng/dl) after PR. Whole-body 18F-DCFPyl PET/MR (4-5 min/bed) was performed, adding multiparametric MRI of the pelvis in selected cases. PET images were acquired 120 minutes after i.v. injection. of the radiotracer and MRI with T2 HASTE, T1 VIBE and DWI sequences. ***Results:*** Thirty-five 18F-DCFPyL PET/MR were performed on 34 patients between 47-76 years of age. Of these, 19/35 (52.7%) were negative and 16/35 positive, detecting disease in 45.7% of the cases, all with negative studies using conventional techniques (CT, bone scintigraphy (OB), MRI) and 4/35 with 18F-choline PET-CT positive (11%). The sensitivity of PET to detect disease was 94%, that of MRI 55%, and that of PET-MR 100%, results similar to those described in the bibliography. Of the positives, 3/16 (18%) presented bone involvement, 1/16 (6%) liver metastasis, 7/16 (43%) lymph nodes, and 5/16 (31%) recurrence in the prostate bed. The PET/MR findings with 18F-DCFPyl modified management in 12/16 patients (33%), expanding the SBRT area in 8/12 (66%), increased bone disease in 2/12 (16%), and active surveillance 2/ 12 (16%). ***Conclusion:*** 18F-DCFPyL PET/MR has been shown to increase diagnostic safety in locoregional and distant tumor detection in patients with PCa in RBq compared to conventional diagnostic techniques (GO, CT, MR) and 18F-choline PET-CT. The findings of the PET/MR with 18F-DCFPyl modified the management of the patient.

## EP-0256

### To evaluate the efficacy of F-18 PSMA -1007 PET/CT to diagnose biochemically recurrent Adenocarcinoma Prostate

***A. Vyas***[1]*, A. Tiwary Vyas*[2]*;*
[1]*Max Superspeciality Hospital Vaishali, New Delhi, INDIA,*
[2]*Janakpuri Superspeciality Hospital, New Delhi, INDIA.*

***Aim/Introduction:*** The aim was to evaluate the efficacy of the F 18-PSMA 1007 PET-CT to diagnose patients with recurrent adenocarcinoma prostate in India. ***Materials and Methods:*** The retrospective analysis of 120 adenocarcinoma prostate patients

with biochemical relapse (mean age 65 ± 9.6 years) and were referred for F-18 PSMA PET-CT. Whole-body PET-CT (from vertex to mid-thigh) was performed 60 min after injection of 370 ± 50 MBq F18-PSMA.85%,45% and 52 % of the patients had received prostatectomy (surgery), androgen-deprivation therapy, and radiotherapy of prostate bed respectively. Radiotherapy with surgery in 35 patients (35%). 13 patients (13%) received all three therapies. The efficacy of F-18 PSMA1007 was compared with biopsy (if available), S. PSA and 3monthly follow up. ***Results:*** Out 120 patients, 115(96 %) patients showed positive finding on F-18 PSMA1007 scan.Median PSA level was 1.1 ng/ml (range 0. 02-60.3 ng/ml).Scan positivity rates were 92%, 96% and 100% respectively with PSA levels ≤ 0.50,0.51-2.5 and >2.5 ng/ml.Overall PET positivity in these patients was 94.1 %(113/120). 02 patients showed false positive PSMA uptake in mediastinal lymphnodes. ***Conclusion:*** F-18 PSMA 1007 PET-CT can diagnose recurrent adenocarcinoma prostate in significantly high percentage of patients with early biochemical relapse, Positive predictive value was found significantly high with low PSA level ≤ 0.5 ng/ml, and may positively impact early detection.Large prospective studies are required. ***References:*** 1. ### Prognostic Value of F-18 FDG PET/CT Metabolic Parameters in Prostate Cancer Patients

***C. Soydal***[1], *M. H. Baltacioglu*[2], *M. Araz*[1], *B. Demir*[1], *N. O. Kucuk*[1];
[1]*Ankara University Medical School, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Sbu Trabzon Kanuni Training and Research Hospital Department of Nuclear Medicine, Trabzon, TÜRKIYE.*

***Aim/Introduction:*** F-18 FDG affinity of prostate cancers is generally low due to parameters such as tumor differentiation level, androgen sensitivity and tumor hypoxia level. Therefore, its routine use in staging and restaging is not recommended. However, F-18 FDG PET/CT may have a prognostic role in castration-resistant-metastatic prostate cancer (CRPC). Therefore, in recent years, it has been recommended to be used in combination with Ga-68 PSMA PET/CT for restaging in patients with CRPC. In this study, we aimed to investigate the prognostic significance of F-18 FDG findings in patients with CRPC who underwent F-18 FDG PET/CT for restaging. ***Materials and Methods:*** The study included patients with CRPC who underwent F-18 FDG PET/CT for restaging. PET/CT findings of the patients, lesion regions with metastasis, number of lesions, standard uptake value SUVmax and SUVmean values of the most active lesion, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) values were retrospectively evaluated. Survival times of patients after PET/CT imaging were calculated and the effect of PET parameters on survival was evaluated by Kaplan-Meier and Cox Regression analyses. ***Results:*** A total of 30 male patients (mean age:64.6±8.0 years) whose clinical follow-up information was available after PET/CT imaging were included in the analysis. All patients had ≥7 Gleason scores. Mean value of SUVmax were calculated as 12.1±7.9, median values of SUVmean, MTV and TLG, 5.0 (min:0 max:35.5), 164 (min:0 max:1890) cm3 and 896 (min:0 max:15777), respectively. Liver and bone metastases were detected in 8 (27%) and 19 (63%) patients, respectively. In Kaplan-Meier analysis, high MTV (p<0.001), high SUVmax (p=0.013), high TLG (p<0.001), presence of liver-bone metastases (p<0.001, p<0.001) and more than 10 lesions (p<0.001) were associated with poor survival. In Cox-regression analysis, higher SUVmax (p=0.022), TLG (p=0.013) and presence of bone metastases (p=0.005) were associated with poor survival. ***Conclusion:*** In routine clinical practice, the indication for the use of F-18 FDG PET/CT in patients with prostate cancer is very limited. However, in recent years, there are publications suggesting that F-18 FDG uptake may have prognostic value in CRPC. F-18 FDG PET/CT can be performed to predict tumor heterogeneity and treatment response, especially in patients who are planned for 177Lu PSMA treatment. The results of our study also revealed that metabolic parameters such as SUVmax and TLG may have prognostic significance. Prospective studies in larger groups will provide a clearer definition of the role of F-18 FDG PET/CT in prostate cancer patients.

## EP-0258

### Role of 68Ga/18F-PSMA PET/CT in the Secondary Staging of Prostate Cancer patients as a guide for clinicians

***P. Mammucci***, *C. Ferrari, V. Lavelli, C. Battisti, N. C. Merenda, G. Rubini;*
*A.O.U. Policlinico di Bari, Bari, ITALY.*

***Aim/Introduction:*** We aim to evaluate the diagnostic performance of radiolabeled-PSMA-PET/CT in patients with recurrent (BCR) or persistent (BCP) prostate cancer (PCa) after primary treatment and to compare the results with patient features. Furthermore, we investigate the potential impact of PET findings on clinical management and therapeutic decision-making. ***Materials and Methods:*** $^{68}$Ga/$^{18}$F-PSMA-PET/CT of 70 consecutive BCR/BCP PCa patients, performed between November 2022 and March 2023, were included. Histological, biochemical, and clinical features were collected: PSA value at time of the scan, PSA doubling time (PSAdt), Gleason Score (GS:<8 or ≥8), EAU BCR risk group, ISUP, surgical margins and ongoing hormonal therapy (HT). Clinical follow-up was performed for each patient to obtain further data, including post-PET PSA values, diagnostic investigations, and start/change treatment. Chi-square, Fisher's exact, and Mann-Whitney U tests were employed to analyze the correlation between PET/CT detection rate (DR) and patient features. ROC curve analysis defined the optimal PSA cut-off value to accurately predict PET response. In addition, sensitivity, specificity, accuracy, PPV, NPV were calculated in all sample and into PSA-subgroups defined by the PSA cut-off, considering clinical follow-up as the gold standard. A p<0.05 was considered statistically significant. ***Results:*** Mean age was 71y (range:53-85y), mean PSA 1.03 ng/mL (range:0.0-5.23), mean PSAdt 13.8 months (range:0.8-70.7), and median GS was 7 (range:6-10). Thirty-seven/70 patients (53%) had a positive PET/CT: 16/37 (43%) in prostate bed, 17/37

(46%) in lymph nodes, and 15/37 (40%) in bone. A positive PET/CT was shown in 14/36 patients with PSA≤0.7 (38.9%, p=0.016), in 16/23 with GS≥8 (69.5%, p=0.048), and in 15/17 patients with ongoing HT (88%, p=0.001), with statistically significant differences. The optimal PSA cut-off to predict a positive PET/CT was 0.74 ng/mL (AUC 0.63, 95% CI 0.49-0.76). The overall PET/CT sensitivity, specificity, PPV, NPV were 67.3%, 81.2%, 91.6%, and 44.8%, respectively, reaching an accuracy of 70.7%. Considering PSA-subgroups (≤0.7 and >0.7), sensitivity, specificity, PPV, NPV, and accuracy were: 50%, 72.7%, 78.5%, 42.1%, 57.6%, and of 84.6%, 100%, 100%, 60%, 87.5%, respectively. PET/CT results modified clinical management in 32/37 (86.5%) of positive patients, guiding specific treatments such as HT (14/32, 43.7%), nodal or prostate bed ERT/SBRT (13/32, 40.6%), both HT/RT (3/32, 9.3%), and chemotherapy (2/32, 6%). ***Conclusion:*** Radiolabeled-PSMA-PET/CT has proven to be effective in the disease detection of BCR/BCP PCa patients, especially for PSA>0.7. As confirmed by our data, nowadays radiolabeled-PSMA-PET/CT represents an essential tool to guide clinical decisions with a patient-based approach.

### Dual time psma pet/ct with diuretics and contrast to detect prostate cancer pelvic metastases: is there a benefit?

***T. Tognoli***[1], *M. R. F. Camacho*[2], *A. O. Santos*[1], *M. C. L. Lima*[1], *B. J. Amorim*[1], *U. Ferreira*[1], *E. Etchebehere*[1];
[1]*State University of Campinas (UNICAMP), CAMPINAS-SP, BRAZIL,* [2]*MND Campinas, CAMPINAS-SP, BRAZIL.*

***Aim/Introduction:*** The renal excretion of PSMA radiotracer may render PSMA PET/CT imaging interpretation difficult to identify local recurrence and lymph node metastases in prostate cancer patients. AIM: To evaluate the best acquisition method to increase the detection rate of local recurrence and pelvic metastases on PSMA PET/CT by performing dual time-point imaging (delayed imaging) after hyperhydration, diuretics, and contrast enhancement. ***Materials and Methods:*** Patients with prior history of prostate adenocarcinoma underwent PSMA PET/CT for primary staging or due to biochemical recurrence. PSMA PET/CT acquisition consisted of delayed pelvic imaging after hyperhydration, diuretics, and excretory-phase contrast. SUV values obtained in local recurrence lesions, locoregional lymph node metastases, and bone metastases in the early and delayed PSMA PET/CT images were compared. ***Results:*** A total of 182 patients (medians: age = 66.5; Gleason score = 7.0; total PSA = 1.5) underwent PSMA PET/CT. Twenty-one patients (12%) were scanned due to primary staging, and 161 patients due to biochemical recurrence (88%). Delayed images (with only hyperhydration, without contrast or diuretics) increased diagnostic certainty in identifying local recurrence in 26.6% of patients and locoregional lymph nodes in 25%. There was a significant increase in SUV values in the delayed images compared to early images in the local recurrence (p<0.0001), locoregional lymph node metastases (p<0.0001), and bone metastases (p<0.0199). Adding excretory-phase contrast to the delayed images increased diagnostic certainty in identifying local recurrence in 9.4% of patients and locoregional lymph nodes in 8.3%. The use of diuretics only in delayed images (without excretory-phase contrast) increased diagnostic certainty in identifying local recurrence in 14% of patients; while for identifying pelvic lymph nodes increase was only mild (2.8%). The association of diuretics with excretory-phase contrast increased the diagnostic certainty in identifying local recurrence in 15.6% of patients and locoregional lymph nodes in 5.6%. ***Conclusion:*** Delayed PSMA PET/CT images increase the diagnostic certainty of identifying local recurrence and locoregional metastases in prostate cancer patients. The addition of diuretics increases diagnostic certainty and may be useful in selected cases. However, the addition of excretory-phase contrast (regardless of the use of diuretics) only mildly impacted diagnostic certainty and may be omitted. ***References:*** Freedman-Cass D et al. NCCN Guidelines Version 4.2022 Prostate Cancer. Morawitz J et al. Is there a diagnostic benefit of late-phase abdomino-pelvic PET/CT after urination as part of whole-body 68Ga-PSMA-11 PET/CT for restaging patients with biochemical recurrence after radical prostatectomy? ## EP-0260

### Ultrafast & Fast F18-PSMA 1007 PET/CT Acquisition in the Era of Digital PET/CT System; Single Institution Experience

***A. Sadeq***[1], *Z. Alqallaf*[1], *I. Abdelrahman*[1], *M. Ibrahim*[1], *L. Ghadhanfer*[2], *F. Marafi*[1];
[1]*Jaber AlAhmad center for Molecular Imaging, Shuwaikh medical area, KUWAIT,* [2]*Faculty of Allied health sciences- Kuwait University, Jabriya, KUWAIT.*

***Aim/Introduction:*** Recent advancement in digital PET/CT cameras adds to sensitivity of scanners with refined specifications including count statistic, time-to-flight ratio and camera resolution. $^{18}$F-PSMA-1007 PET/CT is a time-consuming exam with radiation exposure concerns as it's used frequently for staging and restaging of prostate cancer. Reducing the acquisition time enhances quality by improving the patient compliance, radiation exposure, reduces costs of operating scanner personnel & cost-effectiveness. $^{18}$F-PSMA-1007 PET/CT is emerging standard of care in prostate cancer used to evaluate biochemical recurrence, detection, staging and assessing therapy response. Our objective was to explore viability of reducing acquisition time of positron imaging by up to 25%. ***Materials and Methods:*** Human subjects involved in the trial were referred for $^{18}$F-PSMA-1007 PET/CT to stage and restage prostate cancer by injecting 0.08mCi/Kg with average injected dose of 6.3mCi. After uptake period of 99 minutes, images of the vertex to mid-thigh were acquired on digital PET/CT scanner. A PET acquisition using institution routine imaging parameters were acquired. Images were reconstructed retrospectively from data in list mode to 15 sec./bed and 30 sec./bed using 128x128 matrix size and 2 sets, 8 subsets of OSEM iterative reconstruction. Images were interpreted by two nuclear medicine physicians. The images quality were evaluated in terms of contrast, resolution & lesions. ***Results:*** Acquired Images were retrospectively reconstructed in 15 sec/bed & 30 sec/bed in ultrafast and fast-acquisition PET with estimated total time around 2:15 minutes and 4:30 minutes, respectively. While normal routine scan would have been required in 16 minutes. Images were then reconstructed as per imposed parameters and image quality appeared consistent in the eyes of the readers. The study was done on total of 20 patients, 12 of whom were from BMI group <33.3. There were 6 patients' part of BMI group 33.4-40. The

remaining 2 patients had BMI of >40. Images of ultrafast and fast PET were noisier when compared to the routine PET; specially of BMI >40. However, all lesions were identical in obtained images, ultrafast, and fast acquisitions reconstructions. ***Conclusion:*** The successful results of this study show promising untraveled route for future of PSMA PET broadening our horizon on capability of newly acquired technological advancements. Applying ultrafast & fast PET acquisition for $^{18}$F-PSMA-1007 PET/CT study in digital system allows scanning patients faster, increasing the number of studies/day. Claustrophobic and ill-patients who are reluctant to complete the lengthily procedure might benefit from such approach.

## EP-0261

### Multimodal Radiomics Features of periprostatic adipose tissue from 18F-PSMA-1007 PET/CT to predict Persistent Prostate-Specific Antigen

***S. Bian***;
*the First Affiliated Hospital of Wenzhou Medical University, Wenzhou, CHINA.*

***Aim/Introduction:*** Periprostatic adipose tissue (PPAT) indexes are linked to the prognosis of prostate cancer (PCa). The serum prostate-specific antigen (PSA), as a routine indicator for monitoring PCa, indicates poor prognosis when it rises after radical prostatectomy. This study aimed to investigate the performance of predicting persistent PSA based on PPAT-related multimodal radiomics features (RFs) from $^{18}$F-PSMA-1007 PET/CT. ***Materials and Methods:*** A total of 221 PCa patients who underwent $^{18}$F-PSMA-1007 PET/CT were retrospectively analyzed. Patients were randomly divided into the training and testing cohort. Both PET and CT radiomics features were extracted from $^{18}$F-PSMA-1007 PET/CT medical images. The robust and the most predictive 25 RFs (12 CT RFs and 13 PET RFs) were selected to calculate Rad-score after maximum relevance and minimum redundancy and the least shrinkage and selection operator analysis. The performance of different models was assessed. ***Results:*** A multimodal radiomics model was developed based on logistic analysis with an AUC of 0.79 [95% confidence interval (95% CI), 0.71 - 0.87] and 0.72 (95% CI 0.55 - 0.88) in the training and testing cohort, respectively. The combined model, which contained the Rad-score and the predictive clinical variables, achieved optimal performance with an AUC of 0.85 (95% CI 0.78 - 0.91) and 0.77 (95% CI 0.62 - 0.91) in the training and testing cohort, respectively. The calibration curves were well-calibrated both in the training and testing cohorts according to the actual and predictive rate of persistent PSA. Decision curve analysis also demonstrated the better clinical utility of the combined model against the others. ***Conclusion:*** The radiomics-clinical combined model can provide a novel tool for preoperatively individualized prediction of persistent PSA among PCa patients.

## EP-0262

### Association between blood-derived circulating-tumor DNA and $^{68}$Ga-PSMA-HBED-CC PET/CT findings

***K. Kluge***[1,2], *H. Einspieler*[1], *D. Haberl*[1], *C. Spielvogel*[1,2], *S. Stoiber*[3,2], *M. Hacker*[1], *L. Kenner*[3,2], *A. Haug*[1,2];
[1]*Medical University of Vienna - Dept. of Nuclear Medicine, Vienna, AUSTRIA,* [2]*Medical University of Vienna - Christian Doppler Lab for Applied Metabolomics, Vienna, AUSTRIA,* [3]*Medical University of Vienna - Dept. of Pathology, Vienna, AUSTRIA.*

***Aim/Introduction:*** Functional imaging with prostate-specific membrane antigen (PSMA) ligands and the analysis of circulating-tumor DNA (ctDNA) derived from liquid biopsies both have been shown to enable minimally-invasive detection and monitoring of prostate cancer (PCA). The present study aims to contextualize these methods in assessing total tumor burden (TTB) in men with PCA. ***Materials and Methods:*** 177 men (50-87 years, 184.6 MBq ± 17.9) with histological-proven prostate cancer who underwent $^{68}$Ga-PSMA-HBED-CC PET/computed tomography (CT) and blood sampling between March 2018 and August 2021 at the University Hospital Vienna were prospectively recruited. We here report on the first 20 consecutive patients (57-84 years, 182.6 MBq ± 16.7) (analysis currently ongoing) who underwent cell-free DNA (cfDNA) extraction and ctDNA quantification by low-pass whole-genome sequencing (lpWGS) based on copy number variation (CNV) profiles(1,2)(Table 1). PSMA-positive tumor lesions were delineated manually on a dedicated workstation and quantitative PET parameters were extracted. Correlations between the PET-derived metabolic tumor volume (MTV) and blood-derived cf- and ctDNA concentrations and percentages were assessed using Spearman's or Pearson's coefficients according to the data distribution. The differences in mean ctDNA concentrations according to MTV quartiles were assessed with the ANOVA. The alpha risk was set for all statistical analyses to 5%. ***Results:*** A moderate positive correlation was found between cfDNA concentrations and MTV (r=0.5; p=0.024), ctDNA concentrations and MTV (r=0.52; p=0.018) as well as ctDNA percentage and MTV (r=0.5; p=0.024). Mean concentrations of ctDNA (ng/µL) were 0.054 (SD 0.015), 0.15 (SD 0.098), 0.12 (SD 0.1), 3.19 (SD 4.37) for patients in the MTV (ml) first quartile (Q1) (0 - 0.2), Q2 (0.2 - 5.4), Q3 (5.4 - 39.0) and Q4 (39.0 - 1099.1), respectively (p=0.098). ***Conclusion:*** Our preliminary findings suggest that functional PSMA imaging and blood-derived ctDNA yield associated estimates of TTB, while PSMA PET/CT provides unmatched spatial and quantitative granularity in assessing tumor burden and extent.

## EP-0263

### Evaluation of therapeutic response with 68Ga-prostate-specific membrane antigen (PSMA) PET/CT after androgen deprivation therapy in patients with prostate carcinoma

***M. Dyankova***[1,2], *T. Stoeva*[1], *Z. Dancheva*[1], *S. Chausheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Imaging Diagnostics, Interventional Radiology and Radiotherapy, Varna, BULGARIA,* [2]*St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA.*

***Aim/Introduction:*** There are insufficient reports of response assessment applying $^{68}$Ga-PSMA PET/CT in androgen deprivation therapy (ADT) of naive prostate cancer (PC) patients. The aim of this study was to analyze response to ADT with $^{68}$Ga-PSMA PET/CT in patients with hormone-naive PC and to confirm the assumption of a differential therapeutic response for different localizations of malignant involvement: primary tumor, regional nodal, distant nodal, as well as distant metastatic (bone and visceral) involvement. ***Materials and Methods:*** The retrospective study included 55 patients who met the following criteria: PC patients with a baseline/ staging $^{68}$Ga-PSMA PETCT scan and a restaging scan to monitor treatment effect in a time range of 3-12 months after ADT. Alteration in radiopharmaceutical activity in the prostate

gland/ primary tumor, involved regional and distant nodes as well as distant metastases were semiquantitatively evaluatived on double scans applying maximum standardized uptake value (SUVmax). Treatment response was defined as complete or partial response (CR, PR) or progressive disease or stable disease (PD, SD), and correlated with well-known prognostic markers. ***Results:*** A total of 110 scans of 55 patients (of which 21 were metastatic, M+) were analyzed. After a median of 6 months of ADT, a complete response (CR) was defined for patients according to the different locations of malignant involvement as follows: for the primary tumor - 0.0%, for regional lymphadenopathy - 18 (25.0%), for distant lymphadenopathy - 13 (21.7%), for distant metastases- 3 (14.3%). Disease progression (PD) was defined for patients according to the different localizations of malignant involvement as follows: for the primary tumor- 10 (18.2%), for regional lymphadenopathy- 7 (9.7%), for distant lymphadenopathy- 8 (13.3%), for distant metastases- 8 (38.1%). Treatment response for the primary tumor was not significantly correlated with any of the prognostic markers. Therapeutic response for regional lymphadenopathy was better in M0 compared with M+ disease (CR 39.0% vs 3.4%, p = 0.003). Oligometastases showed a superior therapeutic response compared to polymetastases (CR/PR 63.4% vs. 10.2%, p = 0.05). The decrease in SUVmax of the primary tumor was positively associated with a reduction in the levels of the tumor marker/ serum prostate-specific antigen (PSA), p = 0.07. ***Conclusion:*** Nodal (regional and distant) as well as distant metastatic lesions (bone and visceral) seem more likely to respond to ADT than primary prostate tumor. Persistent increased PSMA-expression may serve as new target for a selective local therapy for appropriate patients with oligometastatic PC.

## EP-0264

### Comparing the Diagnostic Efficacy of 99m Tc-PSMA SPECT/CT Scanning After 75 Minutes and 4 Hours of Radiotracer Injection in Men with Prostate Cancer

***A. Aghaee***[1], *A. Sahebkari*[1], *S. Soltani*[2], *H. Ghorbani*[3], *K. Aryana*[1], *K. Sadri*[1];
[1]*nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,*
[2]*kidney translantation research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,*
[3]*kidney transplantation research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** Prostate-Specific Membrane Antigen (PSMA) is overexpressed in primary and metastatic prostate carcinoma (PCa) and could be targeted by a Tc-99m-HYNIC-PSMA11 scan for detection of metastases. Despite extensive studies, data on the most appropriate interval between radiopharmaceutical injection and image acquisition is scarce. We compared the metastasis detection rates of the Tc-99m-HYNIC-PSMA11 scan between 75-minute and 4-hour intervals of radiopharmaceutical injection. ***Materials and Methods:*** From May 2021 to May 2022, we studied 30 consenting men with pathologically confirmed PCa who were referred to our tertiary hospital for a PSMA scan due to primary staging, biochemical recurrence, pre-177Lu-PSMA therapy, or surveillance. 75-minute and 4-hour 99mTc-PSMA SPECT-CT scan performed following injection of the radiopharmaceutical. The scan's metastasis detection rates were evaluated in 75-minute and 4-hour intervals. ***Results:*** The mean age of patients was 68.43±9.61 years, with a median PSA of 4.19 ng/ml and a median Gleason Score of 8. Nine cases had negative Tc99m-PSMA11 scans, while 21 had positive scans (8 cases with bone, 2 with lung, 4 with lymph node, and 7 with multiple organ metastases). All metastases were detected in both checkpoints, except for one patient, where 75-minute images detected three pelvic metastatic lymph nodes, while four were seen in the 4-hour scan. This small missed right external iliac lymph node did not change the patient's management. ***Conclusion:*** We found no significant difference in the detection rate of metastatic lesions in 75-minute and 4-hour intervals. These findings could help decrease crowdedness, provide efficient scheduling, and improve patient satisfaction in nuclear medicine departments.

## EP-0265

### Comparison of the 18F-PSMA-1007 and 18F-FAPI-42 PET/CT in the evaluation of prostate cancer and correlation between PSMA and FAPI uptake

***X. Mu****, M. Li, W. Fu;*
*Department of Nuclear medicine, Affiliated hospital of Guilin medical university, Guilin, CHINA.*

***Aim/Introduction:*** To compare $^{18}$F-PSMA-1007 PET/CT with $^{18}$F-FAPI-42 PET/CT in evaluating prostate cancer, and investigate the correlation between PSMA and FAPI uptake of lesions. ***Materials and Methods:*** In this prospective study conducted from January 2022 and October 2022, images from participants with prostate cancer who underwent both $^{18}$F-PSMA-1007 with $^{18}$F-FAPI-42 PET/CT examination were analyzed. The tracer uptake, quantified by maximum standardized uptake value ($SUV_{max}$) and target-to-background ratio (TBR), were compared for paired positive lesions between both modalities. The correlation between PSMA and FAPI uptake for positive lesions was analyzed. ***Results:*** Twenty-nine participants with prostate cancer (median age, 68 years; range: 55-83 years) were evaluated. A total of 19 prostate, 75 LN, 101 bone, and 10 lung positive lesions were detected and analyzed. From semiquantitative evaluation, the SUVmax and TBR of primary or recurrent tumors, positive lymph nodes, bone lesions, and pulmonary lesions at $^{18}$F-PSMA-1007 PET/CT were all higher than those at $^{18}$F-FAPI-42 PET/CT (all, $P < 0.01$). A positive correlation was observed in positive lesions ($r=0.27$, $P < 0.0001$), especially in LN lesions and bone lesions ($r=0.46$ and $r=0.44$, respectively, all $P < 0.0001$). ***Conclusion:*** $^{18}$F-PSMA-1007 PET/CT showed superior ability than $^{18}$F-FAPI-42 for the evaluation of prostate cancer. Nevertheless, PSMA expression may correlate positively to FAP expression for prostate cancer. ***References:*** 1. Sung H, Ferlay J, Siegel RL, Laversanne M, Soerjomataram I, Jemal A, et al. ## EP-0266

### Evaluating the diagnostic value of early static and delayed imaging of 68Ga-PSMA-11 PET/CT in detection of prostate bed recurrence and regional lymph node metastasis in prostate cancer patients

***A. Aghaee***, *Z. Bakhshi, V. Roshan Ravan, K. Aryana, N. Norouzbeigi;*
*nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** One way to improve the accuracy of [68Ga] Ga-PSMA-11 PET/CT scans is to perform multi-time point acquisitions. The aim of this study is to evaluate the use of early and delayed imaging in PCa patients with different indications such as staging, Biochemical Recurrence (BCR), and response to treatment. We also examined the changes in pathologic lesion SUVmax among different locations and phases. ***Materials and Methods:*** 138 PCa patients were included in a single-center retrospective study for multiphasic [68Ga] Ga-PSMA-11 PET/CT. Patients underwent standard imaging, early imaging immediately after injection in 4-minute static acquisition, and delayed imaging, 2.5 to 3 hours after injection, both from the pelvic field. ***Results:*** The study evaluated 138 PCa patients, with an average age of 67.72 ± 8.70 years, a median PSA level of 7.45, and an interquartile range of (1.11-23.13), as well as Gleason scores ranging from 3+3 (3.6%) to 5+5 (4.2%). The positivity rates for PSMA-avid lesions in the early, whole-body, and delayed images were 71.5% (93/130), 73.9% (77/110), and 70% (77/110), respectively. In the early, total, and delayed phases, the total number of PSMA-avid lesions were 305, 340, and 239, respectively. The highest SUVmax (96.98) was associated with the external iliac node lymph. The detection rates for local recurrence in the early, whole-body, and delayed phases were 13.8% (18/130), 15.9% (22/138), and 17.3% (19/110), respectively, with no significant change (p=0.5). The detection rates for lymph node metastases were 23.8% (31/130), 29% (40/138), and 28% (30/110), with a significant difference observed between the early and whole-body phases (p=0.016). The detection rates for osseous lesions in the early, whole-body, and delayed images were 28.46% (37/130), 27.53% (38/138), and 21.81% (24/110), respectively, with no significant difference found (p=0.139). ***Conclusion:*** no significant differences were observed in the detection rates of bone lesions across the three phases. However, the early phase missed a focus of osseous metastasis in five patients. In two patients, the delayed images contributed to a change in disease stage during the whole-body phase, while the early phase images did not reveal any changes in disease stage. Whole-body images led to a change in the disease stage for 12 patients during the early phase, but no changes were seen during the delayed phase. The early phase was more effective in differentiating local bladder invasion but was less successful in identifying prostate bed lesions, seminal vesicle invasion, and lymph node metastases.

## EP-0267

### Quantitative MRI parameters adds value in PSMA PET/MR for improving diagnostic specificity of Prostate Cancer with SUVmax<12

***W. Ma***, *J. Wang, Z. Quan, F. Kang, J. Wang;*
*Fourth Military Medical University, Xi'an, CHINA.*

***Aim/Introduction:*** MRI has been widely used but was influenced by reader experience due to the lack of objective and quantitative parameters. The adding diagnostic value of quantitative MRI parameters in PSMA PET with SUVmax<12 was investigated in this study. ***Materials and Methods:*** Between August 2021 and July 2022, patients with suspected PCa scheduled for a clinically indicated PSMA PET/MR study for initial diagnosis of prostate cancer before any therapy were retrospectively collected. All of patients underwent non-targeted ultrasound guided systematic biopsy (at least 12 cores) combining with follow-up or surgical excision. MR acquisition sequences included T1WI, axial, coronal, sagittal T2WI and diffusion-weighted imaging with b value of 1500 s/mm$^2$. Besides, ADC, $T_1/R_1$, $T_2/R_2$ and PD mapping value were analyzed by quantitative MRI with MAGiC sequence. Two nuclear medicine physicians reviewed the images independently. The diagnostic value of PET/MR was analyzed based on patient and lesion respectively. According to $^{68}$Ga-PSMA-11 uptake in prostate, 1-2 lesions per patient was identified for the final analysis. The specificity, sensitivity, accuracy, and area under the curve of PET/MRI quantitative parameters were analyzed based on patient and lesion respectively. ***Results:*** 48 men patients (mean age, 66.8 ± 6.4 years [range: 53-83]) with 82 lesions (1-2 lesions per patient) were included finally, with SUVmax lower than 12. On patient-level analysis, 31 patients were suspected as PCa after PET imaging, including 22 patients were proved to be negative. The sensitivity of PET was 100%, a lower specificity was 68% for initial diagnosis. On lesion-level analysis, the specificity, sensitivity, and accuracy were 32.61%, 94.44%, and 59.76% when the SUVmax cutoff value was 4. The diagnostic accuracy of SUVmax (4-12) was improved with $T_2/R_2$ mapping by increasing specificity of PET from 59.76% to 80.49%. ***Conclusion:*** Quantitative MRI could add value for PSMA-PET to improve diagnostic accuracy of the intra-prostatic cancer with SUV<12. PSMA PET showed good agreement and has become an effective "one-stop-shop" imaging method for prostate cancer.

## EP-0268

### 68Ga-PSMA-PETCT for the evaluation of pulmonary nodules in patients with prostate cancer

***G. Mateva***, *P. Bochev, N. Novoselska;*
*Acibadem CityClinic Mladost, Sofia, BULGARIA.*

***Aim/Introduction:*** The purpose of this study was to investigate the incidence of reported lung nodules on 68Ga-PSMA PET/CT studies and to establish what part of the patients with reported lung nodules had metastatic lung disease. ***Materials and Methods:*** We evaluated retrospectively the reports of 68Ga-PSMA PET/CT scans of 505 prostate cancer patients available in our database for reported lung nodules. We considered all available previous and follow-up clinical information, the expression of PSMA, and also compared with the contrast-enhanced CT reports, where available. ***Results:*** We established that 73 out of 505 patients (15,5%) had one or more lung nodules reported. In 34 of them (47% of the patients with lung nodules) the findings were benign and no follow-up was recommended (including data from CT, where available). For 16 of the patients (13% of the patients with lung nodules) CT recommended follow-up to exclude metastatic disease, while 68Ga-PSMA PET/CT dismissed the suspicion. In five patients (6,9 % of the patients with lung nodules) where CT reported pulmonary metastases, 68Ga-PSMA PET/CT disagreed, and benign nodules were reported. In 10 patients (2% of the whole investigated cohort) 68Ga-PSMA PET/CT reported metastatic pulmonary disease. 6 patients (1,2%) had nodular pulmonary lesions, which were evaluated as malignant but with probable etiology different from prostate carcinoma, based on the PSMA expression and the CT features- in 5 of them primary lung carcinoma was histologically proven and in one patient there

were pulmonary metastases from rectal cancer. Only two patients from the group had PSMA-positive lung lesions that remained unclear after the 68Ga-PSMA PET/CT and additional follow up or biopsy was recommended. ***Conclusion:*** 68Ga-PSMA PET/CT is an accurate and reliable method for diagnosis of pulmonary metastases from prostate cancer and differentiating them from benign pulmonary lesions and metastases from other malignant diseases.

## EP-0269

### Optimizing PSMA Scintigraphy Imaging Protocols for Prostate Cancer in Resource Limited Settings

***O. Kolade***[1], *A. Ayeni*[1,2], *J. Holness*[3], *A. Brink*[1], *S. More*[1];
[1]*University of Cape Town / Groote Schuur Hospital, Cape Town, SOUTH AFRICA,* [2]*Klerksdorp/Tshepong Hospital Complex, Klerksdorp, SOUTH AFRICA,* [3]*Stellenbosh University, Cape Town, SOUTH AFRICA.*

***Aim/Introduction:*** In developing countries, unfavourable Prostate Cancer (PCa) outcomes are outsized, compared to high-income countries. To bridge this disparity-gap, interest is growing in optimising PCa solutions for the less-resourced world. [$^{68}$Ga] Ga-PSMA PET/CT is out of reach for most low-to-lower-middle-income countries, as over 90% of them do not have PET units. [$^{99m}$Tc] Tc-PSMA scintigraphy (PS), though a viable alternative devoid of PET's capital demands, has largely only been evaluated within the context of multi field-of-view (FOV) SPECT/CT protocols. The practical reality is that many-to-most developing world nuclear medicine centres do not have access to SPECT/CT and only have access to planar gamma cameras or at best those with SPECT capabilities.Therefore, we aimed to explore optimisations for PS imaging protocols for resource limited settings by comparing findings from planar acquisition, with multi FOV SPECT and multi FOV SPECT/CT. Thus, exploring acquisitions that may be eliminated without significantly impacting interpretation and patient management. ***Materials and Methods:*** Patients with histologically proven PCa who also had both planar & multi-FOV SPECT/CT [$^{99m}$Tc]Tc-PSMA scans were included. Planar, SPECT, and SPECT/CT images were randomly interpreted individually and unanimously by three Nuclear Medicine Physicians blinded to clinical history. The prostate gland/bed, seminal vesicles, lymph nodes, skeleton, and viscera were specifically assessed. Sites were classified as positive, negative, or equivocal. Findings across modalities were then compared for each patient. Consensus SPECT/CT reporting served as the reference ***Results:*** 96 patients were included, with a head-to-head comparison of their PS planar, SPECT and SPECT/CT images. Prostatic PSMA uptake assessment was inadequate on planar imaging (14%) compared to SPECT (90%), and SPECT/CT (99%). Assessing seminal vesicle involvement was impossible on planar and SPECT imaging, compared to SPECT/CT. However, planar imaging adequately detected nodal, and skeletal lesions; SPECT though marginally better, frequently introduced diagnostic doubt via decreased specificity and false negatives- SPECT/CT satisfactorily resolved these doubts. Visceral metastasis determination was difficult on planar and SPECT, compared to SPECT/CT. No prostate-related lesions were missed on SPECT or SPECT/CT by limiting the imaged field-of-view to vertex-to-midthighs from planar whole-body acquisition ***Conclusion:*** Our findings reiterate the superiority of SPECT/CT over planar and SPECT imaging, hence the recommended single-best PS protocol should be a multi FOV SPECT/CT, if no resource limitations exist. However, in certain circumstances, if interpreted with caution, planar and SPECT PS may be adequate, especially in resource limited settings. Furthermore, limiting the FOV to exclude the distal lower limbs may provide additional time-based optimisations.

## EP-0270

### AI18F-PSMA-617 PET Quantitative Analysis for Prostate Cancer Diagnosis: A Comprehensive Study

***B. Liu***[1], *G. Hu*[2], *X. Wang*[2], *L. Huo*[2], *H. Ding*[1], *H. Zhang*[1];
[1]*Tsinghua University, Beijing, CHINA,* [2]*Peking Union Medical College Hospital, Beijing, CHINA.*

***Aim/Introduction:*** Quantitative analysis of PET dynamic imaging can obtain tissue metabolism information derived from the kinetic modeling of the perfusion process. This provides additional diagnostic information and overcomes the limitations of semi-quantitative SUV, which is of limited clinical value. The objective of this study is to assess the potential uses of quantitative parameters obtained from AI$^{18}$F-PSMA-617PET imaging for detecting and characterizing prostate cancer (PCa) lesions. ***Materials and Methods:*** This study included 12 PCa patients who underwent a 60-minute dynamic AI$^{18}$F-PSMA-617 PET scan. Volumes of interest (VOIs) were manually defined for tumors, normal tissues, and iliac vessels for extracting image-derived blood input functions. Time-activity curves (TACs) were generated by calculating the maximum standard uptake value (SUVmax) for tumors, and the average standard uptake value (SUVmean) for iliac vessels and normal tissues. The two-tissue compartment models (2TCM) were applied to calculate kinetic parameters, such as K1, k2, k3, k4, and fractional blood volume (Vb), which were subsequently used to calculate tissue global influx (Ki), binding potential (BP), and distribution volume (Vd). The modeling effect was evaluated using the R-square ($R^2$) test, where higher values indicate better fitting. Statistical analysis involved using paired t-test, non-parametric Wilcoxon rank-sum test, and receiver operating characteristic (ROC) analysis. ***Results:*** The evaluations of the models are as follows. With $R^2$ value of 0.838±0.132 and 0.805±0.085 in tumor lesions and normal tissues, respectively, indicating 2TCM model with k4 had better fitting effect based on $R^2$ value than without k4. The quantitative study showed that Ki, BP, and Vd had significant differences between tumor lesions and normal tissues ($P<0.005$). ROC analysis revealed that Ki had an area under the curve (AUC) of 0.927 ($P<0.005$), BP had an AUC of 0.979 ($P<0.0001$). Especially, Vd had an AUC equals to 1 ($P<0.0001$) with cut-off value of 1.944. ***Conclusion:*** In conclusion, the best model to describe the kinetic analysis of AI$^{18}$F-PSMA-617 would be the reversible two-tissue compartment model. The net influx rate Ki and the distribution volume Vd show an obvious difference between tumor lesions and normal tissues, could be applied to the clinic to identify the lesion area.

## EP-0271

### The Effect of Folate on [68Ga]Ga-PSMA-11 Organ and Tumor Uptake: Predictions Using Physiologically Based Pharmacokinetic Modelling

***H. Siebinga***[1,2], *J. J. M. A. Hendrikx*[1,2], *A. D. R. Huitema*[2,3,4], *B. J. de Wit - van der Veen*[1];
[1]*Department of Nuclear Medicine, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Department of Pharmacy and Pharmacology, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS,* [3]*Department of Clinical Pharmacy, University Medical Center Utrecht, Utrecht University, Utrecht, NETHERLANDS,* [4]*Department of Pharmacology, Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS.*

***Aim/Introduction:*** It is hypothesized that folate intake might reduce accumulation of PSMA-directed peptides due to competitive binding to the PSMA-receptor and, thus, folates could affect diagnostic imaging and radioligand therapy in prostate cancer. However, the exact relationship between folates and PSMA-ligands is not well established. Therefore, we developed a

physiologically based pharmacokinetic (PBPK) model to predict the effect of folate intake on [$^{68}$Ga]Ga-PSMA-11 uptake in salivary glands, kidney and tumors. ***Materials and Methods:*** A PBPK model was developed for [$^{68}$Ga]Ga-PSMA-11 and folate (folic acid and its metabolite 5-MTHF), with compartments added that represent salivary glands and tumor. Model evaluation for [$^{68}$Ga]Ga-PSMA-11 was performed with patient data from two different studies [1,2], while for folate data from literature were used [3,4]. Using the final model, the effect of varying folate doses on relative differences in [$^{68}$Ga]Ga-PSMA-11 accumulation in salivary glands, kidney and tumor compartments was predicted. Folate doses were selected to represent intake by means of folate-containing food (150 µg), vitamin supplements (400 µg) and folate tablets (5 and 10 mg). In addition, predictions were made for patients with different tumor volumes (10-1000 mL). ***Results:*** PBPK model predictions adequately described data for both [$^{68}$Ga]Ga-PSMA-11 and folates. Predictions of folate doses of 150 and 400 µg showed no clinically relevant effect (<23.5% relative difference) on salivary gland and kidney uptake. However, for 5 and 10 mg, a relevant decrease in salivary glands (34 and 36%, respectively) and kidney uptake (32 and 34%, respectively) was predicted. None of the included folate doses showed a relevant effect on tumor accumulation. Lastly, different tumor volumes did not influence the effects of folate intake on [$^{68}$Ga]Ga-PSMA-11 distribution. ***Conclusion:*** High folate doses (5 and 10 mg) were predicted to decrease [$^{68}$Ga]Ga-PSMA-11 salivary gland and kidney uptake, while intake by means of folate-containing food or vitamin supplements was predicted to show no relevant effects. [$^{68}$Ga]Ga-PSMA-11 tumor uptake was not affected by folate intake in the dose range studied and tumor volume differences were not expected to impact folate effects. These predictions could guide trial design aimed at using folates to reduce toxicity during PSMA-based radioligand therapy.

## EP-0272

### PSMA PET/CT correlates with biochemical response in patients with prostate cancer undergoing High-Intensity Focused Ultrasound (HIFU) focal therapy

***E. Lopci****, G. Lughezzani, V. Fasulo, D. Maffei, A. Saita, P. Colombo, R. Hurle, K. Marzo, L. Leonardi, R. Peschechera, A. Benetti, S. Zandegiacomo, L. Pasini, J. Jandric, R. Zanca, P. Casale, M. Rodari, L. Balzarini, G. Guazzoni, N. Buffi, M. Lazzeri;*
*IRCCS - Humanitas Research Hospital, Rozzano MI, ITALY.*

***Aim/Introduction:*** Recent advances in PCa imaging with PSMA PET/CT offer new opportunities to detect PCa foci and monitor response to treatment. The current study is designed to evaluate the role of PSMA PET/CT for response assessment in PCa patients candidate to High-Intensity Focused Ultrasound (HIFU) focal therapy. ***Materials and Methods:*** Patients treated with HIFU FT for localized PCa and enrolled from October 2020 to April 2022 in an ongoing, prospective, single-center cohort study were considered for the analyses. Inclusion criteria: PSA <20ng/mL, radiological stage ≤T2bN0M0, ISUP grade 1-3, PSMA PET/CT at baseline and at response evaluation. Follow up included: PSA at 3, 6 and 12 months; PSMA PET/CT between 6-12 months post treatment. Biochemical response and PET response were statistically correlated: SUVmax and SUVratio to background of the target lesions were used as semi-quantitative parameters for PSMA PET/CT, together with their variations before and after HIFU FT (i.e. ΔSUVmax and ΔSUVratio). ***Results:*** Overall, 32 patients out of the 46 enrolled have completed all study procedures and met inclusion criteria for the current analysis. Median age was 67,5 years (95%CI 63-71) and median initial PSA (iPSA) was 6.3 ng/mL (95%CI 5.4-8.7). ISUP score was 1 in 20 (62.5%) patients. Median SUVmax and SUVratio before treatment resulted 4.1 (95%CI 3.3-6.9) and 1.4 (95%CI 1.3-1.9), respectively. At 3 months post-HIFU, 25% of the patients obtained a PSA response ≥50%; whereas at 6 months and 12 months, PSA responses were 32% and 45%, respectively. Median SUVmax and SUVratio post-treatment resulted 2.7 (95%CI 2.3-4.6) and 0.9 (95%CI 0.8-1.3). Median ΔSUVmax was -14.2% (95%CI -35.8 to -2.5) and ΔSUVratio resulted -25.2% (95%CI -45-4 to 3.3). Baseline SUVmax (P = 0.049) and SUVratio (P = 0.008) significantly correlated to PSA response at 6 months post-HIFU; also ΔSUVratio significantly correlated to PSA response at 12 months post-treatment (P = 0.009), while ΔSUVmax showed only a borderline correlation to response at 1 year post-HIFU (P = 0.069). ***Conclusion:*** PSMA-PET may be a useful tool for monitoring response in PCa patients undergoing HIFU Focal Therapy. Baseline SUV and its variation can predict biochemical response at 12 months post-treatment.

## EP-0273

### Guiding metastases-directed therapy with Prostate-Specific Membrane Antigen (PSMA) PET/CT improves the oncological outcome of oligometastatic prostate cancer patients

***Aim/Introduction:*** Oligometastatic prostate cancer (PCa) is an emerging disease state characterized by a limited number of metastatic locations. Metastases-directed therapy (MDT) with stereotactic body radiotherapy (SBRT) has been shown to decrease the tumor burden, potentially delaying systemic treatments and improving the long-term oncological outcome. In this setting, a more accurate disease staging may lead to more patients receiving the appropriate treatment, with expected better results. On these bases, we verified the impact of using next-generation compared to conventional imaging as a guide for MDT in a real-world multicentric cohort of PCa patients. ***Materials and Methods:***

We retrospectively recruited 256 de-novo oligometastatic or oligorecurrent PCa patients submitted to imaging-guided MDT in six tertiary-level cancer Centers. Inclusion criteria were: (i) histologically-confirmed diagnosis of PCa; (ii) imaging evidence of ≤5 pelvic, extra-regional nodal (M1a), or bone metastases (M1b); (iii) upfront MDT delivered through SBRT±systemic therapy guided by either bone scan+CT/MRI (conventional imaging), [18F]F-Fluorocholine, [68Ga]Ga-PSMA-11 or [18F]-PSMA-1007; (iv) availability of the subsequent clinical follow-up. Progression after MDT was defined as either biochemical recurrence (PSA raise ≥2 ng/dL and 25% above nadir), radiological or clinical progression, subsequent treatment changes, or death. Clinical, laboratory and imaging parameters were assessed as predictors of Progression-Free Survival (PFS, primary endpoint of the study). ***Results:*** At the time of MDT, 80.5% of patients presented oligorecurrent PCa, and 22.7% had Castration-Resistant PCa (CRPC). Prostate-Specific Antigen (PSA) levels before MDT were 3.76±6.22 ng/mL. MDT was guided by conventional imaging, choline PET/CT, or PSMA PET/CT in 5.1%, 63.7% and 31.2% of patients, respectively. After MDT, the PSA nadir was 2.58±8.97 ng/mL. The median follow-up was 30.8 months. At the univariate analysis, predictors of PFS were the CRPC status at the time of MDT (p=0.013), the PSA pre-MDT value (p<0.001), oligorecurrent compared to de-novo oligometastatic disease (p=0.030), the number of metastatic lesions (p=0.038), the presence of bone metastases (p=0.006), and the PSA nadir after MDT (p<0.001). Notably, the use of either conventional imaging or choline PET/CT compared to PSMA PET/CT significantly predicted PFS (p<0.001 for both). The multivariate analysis confirmed imaging modalities guiding MDT and the PSA nadir as the sole independent predictors of PFS (p<0.001 for both). Patients receiving MDT guided by conventional imaging, choline PET/CT, or PSMA PET/CT showed significantly different median PFS (5.8 vs. 13.1 vs. 34.5 months, respectively, p<0.001). ***Conclusion:*** Using next-generation imaging with PSMA PET/CT favorably impacts the oncological outcome of oligometastatic PCa patients treated with MDT.

## EP-0274

### Treatment response evaluation with PSMA-PET/CT imaging in patients with metastatic castration-resistant prostate cancer (mCRPC)

***F. Kleiburg***[1,2], *L. F. De Geus-Oei*[1,2,3], *S. A. C. Luelmo*[2], *R. Spijkerman*[1,2], *F. A. J. Toonen*[4], *F. Smit*[4], *T. van der Hulle*[2], *L. Heijmen*[2];
[1]*University of Twente, Enschede, NETHERLANDS,* [2]*Leiden University Medical Centre, Leiden, NETHERLANDS,*
[3]*Delft University of Technology, Delft, NETHERLANDS,*
[4]*Alrijne Hospital, Leiderdorp, NETHERLANDS.*

***Aim/Introduction:*** Treatment response evaluation in mCRPC patients with serum prostate-specific antigen (PSA) levels can be insufficient and unreliable. This study aimed to assess the value of PSMA-PET/CT imaging for treatment response evaluation at set time points in patients with mCRPC, compared to PSA. ***Materials and Methods:*** 58 mCRPC patients who received treatment response evaluation with [$^{18}$F]-PSMA-1007-PET/CT imaging for 67 treatment lines in total were included in this retrospective study. In case of treatment with enzalutamide or abiraterone (n=33), the treatment response PSMA-PET/CT was made after three months of treatment. In case of treatment with chemotherapy (n=34), the treatment response PSMA-PET/CT was made after the last administered dose (range 6-9 cycles of chemotherapy), or when progression was suspected. PSA levels, visual response on PSMA PET/CT imaging, as well as $SUV_{max}$, total tumour volume (PSMA-TV, calculated with an SUV = 4 threshold) and total-lesion uptake (TL-PSMA) on the pre-treatment and treatment response evaluation PSMA-PET/CT scans were collected. Biochemical response and PSMA-PET/CT response definitions were consistent with previous literature (1,2). ***Results:*** Biochemical response and overall response on PSMA-PET/CT were discordant in 31 out of 67 cases (46%). In 28 of these cases (90%), overall response on PSMA-PET/CT was worse than the biochemical response. 19 patients showed progression of disease on PSMA-PET/CT and no PSA progression compared to PSA before therapy: in 8 patients rising PSA levels were seen around the time of the PSMA-PET/CT scan, in 4 patients biochemical progression was seen 3 to 4 months later, in 2 patients the PSMA-PET/CT scan was followed by evident clinical deterioration and in 5 patients treatment change decisions were purely based on the PSMA-PET/CT scan. In univariate Cox regression analyses, the visual overall response on PSMA-PET/CT, the response of the worst responding lesion, and the relative changes (%) in PSMA-TV and TL-PSMA were all significant predictors of biochemical progression-free survival and overall survival (p ≤ 0.01 for all). For overall survival, these PET parameters were more significant predictors than relative change in PSA (p = 0.03). ***Conclusion:*** PSMA-PET/CT imaging is more accurate in evaluating treatment response in mCRPC patients than PSA levels. In some patients, PSMA-PET/CT can detect progression of disease earlier than PSA. Also, several PET parameters are significant predictors of biochemical progression-free survival and overall survival. A follow-up study on the cost-effectiveness of response monitoring with PSMA-PET/CT imaging in these patients will follow. ***References:*** (1) https://doi.org/10.1200%2FJCO.2015.64.2702 (2) https://doi.org/10.1007/s00259-020-04934-4

## EP-0275

### Radium-223 response assessment and outcomes prediction using 68Ga-PSMA PET/CT: RECIP 1.0 vs PPP criteria

***Q. Shagera****, P. Flamen, C. Artigas;*
*Jules Bordet Institute, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.*

***Aim/Introduction:*** Treatment monitoring of Radium-223 dichloride ($^{223}RaCl_2$) can be challenging. Conventional imaging techniques are limited in the setting of bone-only metastatic disease, and diagnosis of progression is frequently delayed. PSMA-PET/CT imaging has shown high accuracy in the early detection of prostate cancer lesions. Two PSMA-PET-based response criteria have been proposed and tested in $^{177}$Lu-PSMA radioligand therapy and taxane-based chemotherapy, demonstrating its potential use as a prognostic biomarker. However, this has not yet been evaluated for $^{223}RaCl_2$. Therefore, we aimed to evaluate the prognostic value of PSMA-PET/CT response criteria in metastatic castration-resistant prostate cancer patients (mCRPC) receiving $^{223}RaCl_2$. ***Materials and Methods:*** This retrospective study included 28 mCRPC patients who received $^{223}RaCl_2$ and had two $^{68}$Ga-PSMA-11 PET/CT scans performed: a) baseline PET within one month before treatment initiation and b) interim PET two weeks after the 3$^{rd}$ cycle. Visual and quantitative PET image analyses were performed, and patients were dichotomized into progressive (PD) and non-PD according to Response Evaluation Criteria in PSMAimaging (RECIP1.0)[1] and PSMA-PET Progression criteria (PPP)[2]. PSMA total tumor volume was measured using the SUV=3 threshold method, and the new lesions were recorded. The cox-regression hazard model

was used for univariate survival analysis. Survival probability was analyzed using the Kaplan-Meier method and the log-rank test. Harrell's concordance index (C-index) was evaluated for both criteria. ***Results:*** Patients were treated with a median of 5 cycles of $^{223}RaCl_2$. Sixteen (43%) and 18 (64%) patients had PD according to RECIP1.0 and PPP, respectively. Among patients with PD at interim PET, 21% presented with new sites of extraskeletal disease. After a median follow-up of 16 months, 20 (71%) patients died. Patients with PD showed a higher risk of death than non-PD according to RECIP1.0 (HR=2.9; 95%CI, 1.14-7.46; p=0.029) and to PPP (HR=2.8; 95%CI, 1.04-7.64; p=0.042). For both criteria, the median OS was shorter for PD than non-PD (36 vs. 12 months, Log-rank; p<0.05). The C-index was higher for RECIP1.0 (0.66, 95%CI, 0.56 - 0.75) compared to PPP (0.63; 95%CI, 0.53 - 0.73). ***Conclusion:*** This study shows that PSMA-PET/CT imaging is a useful tool for monitoring radium-223 treatment. Both PSMA PET/CT response criteria (RECIP1.0 and PPP) perform similarly predicting OS at interim after 3 cycles of $^{223}RaCl_2$. PSMA-PET may overcome the limitations of conventional imaging in assessing the response to $^{223}RaCl_2$. Further prospective validation in a larger population is needed. ***References:*** [1]Gafita A, J Nucl Med. 2022;63(11):1651-8. [2]Fanti S, J Nucl Med. 2020;61(5):678-82.

## EP-0276

### [68Ga]PSMA-11 PET/CT response in metastatic prostate cancer following systemic therapy

***P. Aravind***[1], *T. D. Barwick*[2,1], *S. Dubsash*[1], *M. J. Connor*[2], *H. Tam*[2], *F. A. Mauri*[1], *H. U. Ahmed*[1,2], *E. O. Aboagye*[1];
[1]*Imperial College London, London, UNITED KINGDOM,* [2]*Imperial College Hospital NHS TRUST, London, UNITED KINGDOM.*

***Aim/Introduction:*** There is paucity of data regarding ($^{68}$G)-PSMA-11 PET response in metastatic prostate cancer (mPC), and as conventional imaging has limitations in this setting, we aimed to investigate ability of ($^{68}$G)-PSMA-11 PET/CT to detect response post-systemic therapy in mPC. We also assessed the relationship between ($^{68}$G)-PSMA-11 PET/CT uptake with PSMA expression by immunohistochemistry, prostate specific antigen (PSA) response and conventional imaging response. ***Materials and Methods:*** In this exploratory phase 2 imaging sub-study (of IPL2-ATLANTA[1]) newly diagnosed mPC underwent ($^{68}$G)-PSMA-11 PET/CT at baseline and on completion of taxane- based chemotherapy or 6 months of Enzalutamide. Lesion $SUV_{max}$,TBR (Tumour to background ratios), PSMA expression score and Total tumour volume (50%$SUV_{max}$ threshold) were documented. PSMA response using RECIP criteria was compared to RECIST 1.1 response at 6 months. Where available, post treatment prostatic biopsies were analysed for PSMA expression and Ki67. Biochemical response (BR) was defined as undetectable or at least 50% decrease in PSA from baseline. Concordance between PET response, RECIST 1.1 response and BR were evaluated using Kendall's coefficient. Survival data was collected. Kaplan Meier and Cox regression analysis performed. ***Results:*** 15 patients completed both scans. RECIST 1.1 responses were 2 complete response and 13 partial response. PET RECIP (and intraprostatic $\Delta SUV_{max}$) responses were 3 complete responders (-75%), 11 partial responders (-69%) and 1 progressive disease (+16%). Of note some patients showed complete intraprostatic response but had residual extraprostatic disease. BR was, however found in all patients: median PSA decrease was 99.5% (range: 94.7-100%). Baseline total tumour volume parameters on PSMA PET/CT were predictive of RECIST 1.1 response(Wilcoxon p<0.001). Concordance between RECIP and RECIST 1.1 was 80% (n=12/15). PET RECIP response was concordant with BR in 6/15 patients (p=0.058), Kendall's concordance coefficient 0.24. Of the 5 patients with available post-treatment prostatic biopsies, 2 had PSMA and Ki67 expression that were unrelated to PSMA uptake. After follow-up of 36 months, the median OS was 18 months in complete RECIP responders, 21 months in partial RECIP responders and 17 months in progressive disease. RECIP, age, BR, RECIST 1.1, therapy type were not significant in multivariable Cox regression, while $\Delta TBR_{sum}$ was significant. ***Conclusion:*** PSMA PET response ($\Delta TBR_{sum}$) but not BR, strongly predicted OS. Baseline total tumour volume was predictive of RECIST 1.1 response. ***References:*** 1. MJ Connor et al. Additional treatments to the local tumour for metastatic prostate cancer-assessment of novel treatment algorithms (IP2-ATLANTA): protocol for a multicenter phase II randomised controlled clinical trial.BMJOpen2021;11:e0429532

### The use of clinical, laboratory, and imaging parameters to interpret bone focal uptakes in hormone-sensitive prostate cancer patients imaged with [18F]-PSMA-1007 PET/CT

***F. D'Amico***[1], *A. Signori*[1], *D. Albano*[2], *M. Riondato*[3], *F. Dondi*[2], *T. Di Raimondo*[1], *L. Sofia*[1], *F. Lanfranchi*[1], *C. Ghersi*[3], *A. Democrito*[3], *G. Fornarini*[4], *C. Marini*[5], *F. Bertagna*[2], *S. Morbelli*[1], *G. Sambuceti*[1], *M. Bauckneht*[1];
[1]*Department of Health Sciences, University of Genoa, Genova, ITALY,* [2]*Nuclear Medicine, University of Brescia and ASST Spedali Civili Brescia, Brescia, ITALY,* [3]*Nuclear Medicine Unit, IRCCS, Ospedale Policlinico San Martino, Genova, ITALY,* [4]*Medical Oncology Unit 1, IRCCS Ospedale Policlinico San Martino, Genova, ITALY,* [5]*CNR, Institute of Molecular Bioimaging and Physiology (IBFM), Genova, ITALY.*

***Aim/Introduction:*** Improved logistics and availability led to a rapid increase in the clinical use of [18F]-PSMA-1007 for prostate cancer (PCa) PET imaging. However, clinical observations found the frequent occurrence of unspecific bone uptakes (UBU) compared to other PSMA-targeted tracers. In the clinical setting, UBUs might be erroneously interpreted as metastases, potentially leading to inadequate treatment planning of over-staged patients. We thus verified whether clinical, laboratory, and imaging parameters might predict the presence of metastases in PCa patients showing [18F]-PSMA-1007 bone focal uptakes, thus potentially guiding image interpretation. ***Materials and Methods:*** We retrospectively analyzed 329 [$^{18}$F]-PSMA-1007 PET/CT scans performed in histology-proven PCa patients in two tertiary-level cancer centres, looking for the presence of bone [$^{18}$F]-PSMA-1007 focal uptakes. The sole exclusion criterion was castration-resistant PCa. For each tracer bone uptake, the PSMA visual score was recorded. The point of maximum tracer uptake (assessed by measuring the maximum standardized uptake value, SUVmax) was selected as the centre of a volume of interest (VOI), drawn by the threshold method (40%SUVmax) to calculate SUVmean, PSMA-tumor volume (PSMA-TV), and total lesion PSMA (PSMA-TL). Relocating the same VOI on CT images, mean and maximum Hounsfield Units (HU) were also extracted. Clinical and laboratory data at the time of [$^{18}$F]-PSMA-1007 PET/CT were collected from the electronic medical record. Finally, a composite reference standard including follow-up histopathology, lab or imaging data was assessed to disclose PCa metastases and UBUs. ***Results:*** 362 bone [18F]-PSMA-1007 focal uptakes were identified from 195/329 PCa patients (59.2%). According to the reference standard, 146/362 (40.3%) of bone [18F]-PSMA-1007 focal uptakes corresponded to PCa metastases. At the univariate per-lesion

analysis, Prostate-Specific Antigen (PSA) at the time of PCa diagnosis (p=0.002), the administration of androgen-deprivation therapy (ADT) at the time of [18F]-PSMA-1007 PET/CT (p<0.001), the site of bone [18F]-PSMA-1007 uptake (p=0.0045), SUVmax (p<0.001), PSMA visual score (p<0.001), TL-PSMA (p=0.002), HUmean (p=0.001), and HUmax (p=0.001) were associated with the presence of PCa metastases. At the multivariate analysis, ADT at [18F]-PSMA-1007 PET/CT (p<0.001), SUVmax (p<0.001) and HUmean (p=0.001) resulted in independent predictors of bone metastases. Combining these parameters in a prognostic model, the area under the receiver-operating-characteristic curve (AUC) resulted in 0.86. ***Conclusion:*** Bone focal uptakes occur in more than half of hormone-sensitive PCa patients imaged with [18F]-PSMA-1007 PET/CT. Considering the administered treatment at the time of imaging, SUVmax, and HUmean, and combining these data in a prediction model may improve their interpretation, potentially avoiding over-staging.

## EP-0278

### Modified PROMISE Criteria for Standardized Interpretation of Gastrin Releasing Peptide Receptor (GRPR)-targeted PET

***H. Duan***, *G. A. Davidzon, F. Moradi, T. Liang, H. Song, A. Iagaru; Stanford University, Stanford, CA, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** Multiple image interpretation criteria were developed to standardize interpretation of PSMA-targeted PET. As up to 10% of prostate cancer (PC) do not express PSMA, other targets such as gastrin releasing peptide receptor (GRPR) were evaluated. GRPR-targeted imaging has been slowly increasing in usage at staging and biochemical recurrence (BCR) of PC. We therefore propose an interpretation criteria for GRPR-targeted PET using a modified Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE) (1, 2) criteria (mPROMISE). ***Materials and Methods:*** $^{68}$Ga-RM2 PET data from initially prospective studies performed at our institution were retrospectively reviewed: 44 patients were imaged for staging and 100 patients for BCR PC. Two nuclear medicine physicians independently evaluated PET according to the mPROMISE criteria. A third expert reader served as standard reference. Interreader reliability was computed for GRPR expression, prostate bed (T), lymph node (N), skeleton (Mb), and organ (Mc) metastases, and final judgment of the scan. ***Results:*** The interrater reliability for GRPR PET at staging was moderate for GRPR expression (0.59; 95% confidence interval [CI] 0.40, 0.78), substantial for T-stage (0.78; 95% CI 0.63, 0.94), and almost perfect for N-stage (0.97; 95% CI 0.92, 1.00) and final judgment (0.92; 95% CI 0.82, 1.00). The interreader agreement at BCR showed substantial agreement for GRPR expression (0.70; 95% CI 0.59, 0.81) and final judgment (0.65; 95% CI 0.53, 0.78) while almost perfect agreement was seen across the major categories (T, N, Mb, Mc). Acceptable performance of the mPROMISE criteria was found for all subsets when compared to the standard reference. ***Conclusion:*** Interpreting GRPR-targeted PET using the mPROMISE criteria showed its reliability with substantial or almost perfect interrater agreement across all major categories. This proposed standardized reporting system will aid clinicians to decrease the level of uncertainty, and clinical trials to achieve uniform evaluation, reporting, and comparability of GRPR-targeted PET. ***References:*** 1. Eiber M, Herrmann K, Calais J, Hadaschik B, Giesel FL, Hartenbach M, et al. ## EP-0279

### Consensus statements on Prostate Specific Membrane Antigen (PSMA)-Targeted Surgery - outcomes from an international multidisciplinary panel

***F. van Leeuwen***[1], *A. Berrens*[2], *the PSMA-guided surgery panel, H. van der Poel*[2];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,*
[2]*NETHERLANDS cancer institute, Amsterdam, NETHERLANDS.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) has greatly changed the identification of prostate cancer (PCa) on imaging and is increasingly used for image-guided therapy. Surgical therapies based on PSMA are being explored in various surgical settings (open, laparoscopic, robotic), employing different technologies, and for both de novo and salvage PCa indications. We aimed to define universal clinical needs, the relationship between these needs and current/ future technological enablers, and the best way to gather evidence on the topic. To achieve this, a Delphi consensus was conducted with the current experts in the field of PSMA-targeted surgery. ***Materials and Methods:*** A steering committee (urologic end-users (46%), enabling nuclear medicine physicians (31%) and researchers (23%)) set up a questionnaire (105 statements that could be answered using a 9-point Likert scale; 1 (disagreement) - 5 (neutral) - 9 (agree), or cannot answer) and distributing it through SurveyMonkey® for anonymous answering. Following evaluation, a second round of 16 statements was distributed (89% response rate). Consensus was defined using the disagreement index (DI). DI was assessed using the research and development project (RAnd)/University of California, Los Angeles (UCLA) appropriateness method (1). ***Results:*** 86 international panel participants answered the questionnaire (62 (72.1%) clinician; 7 (8.1%) industry; 13 (15.1%) scientists and 4 (4.7%) other), most with a urological background (57.0%), followed by nuclear medicine (22.1%). Consensus was obtained on key aspects of the procedure: 1) the guiding PSMA PET/CT needs to be taken <1 month before surgery, 2) time between injection of the imaging agents used for surgical guidance and surgery is preferably 16-20 hours, 3) PSMA-targeting is most valuable for the identification of nodal metastases outside of the template, 4) Gamma- and fluorescence imaging (including signal-to-background assessments) prove to be the preferred guidance modalities, and 5) randomized controlled clinical trials with outcome and performance assessments as readout are required to gather clinical evidence. Regarding the surgical margin assessment, the view on the value of PSMA-targeted surgery was neutral or inconclusive. High "cannot answer" response rates indicated further study is necessary to address knowledge gaps in areas such as the use of Cerenkov or beta-emissions. ***Conclusion:*** Until the required clinical evidence is acquired, the present Delphi consensus helps provide guidance for clinicians and researchers that implement PSMA-targeted surgery or develop technologies for this indication. ***References:*** 1) Fitch K, Bernstein SJ, Aguilar MD, et al. The RAnd/UCLA Appropriateness Method User's Manual. Transformation. 2001;(http://www.rand.org/publications/MR/MR1269/):109

## EP-0280

### Evaluation of [18F]DCFPyL excretion in the saliva of patients with prostate cancer

***B. Fernandes***[1], *J. Roy*[1], *F. Basuli*[2], *Y. McKinney*[1], *B. M. Warner*[3], *E. Mena*[1], *L. Lindenberg*[1], *B. Turkbey*[1], *P. Choyke*[1], *F. I. Lin*[1]; [1]*Molecular Imaging Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD, UNITED STATES OF AMERICA,* [2]*Chemistry and Synthesis Center, National Heart, Lung, and Blood Institute, National Institutes of Health, Rockville, MD, UNITED STATES OF AMERICA,* [3]*National Institute of Dental and Craniofacial Research, National Institute of Health, Bethesda, MD, UNITED STATES OF AMERICA.*

***Aim/Introduction:*** PSMA-Targeted Radionuclide Therapy (TRT) is a new exciting treatment in prostate cancer (PC) patients, especially those whose tumor overexpresses prostate-specific membrane antigen (PSMA). One concern with using PSMA-based TRT is the high uptake of the therapeutic agent in salivary glands, leading to xerostomia. Although PSMA seems to accumulate in the salivary glands, its function and fate after uptake are not well known. In this study, we investigated whether there is any excretion of the PSMA-TRT in the patient's saliva after uptake from a systemic injection, using [$^{18}$F]DCFPyL. ***Materials and Methods:*** Ten patients with histologically-confirmed prostate cancer and a Gleason Grande ranging from 6 to 9, received 6±0.33 mCi of [$^{18}$F]DCFPyL and were scanned for 60 min. Saliva samples were collected from all patients at different time points (0, 15, 30, 60, and 120 minutes) post-radiotracer injection. The [$^{18}$F]DCFPyL uptake was measured over 120 minutes using a gamma counter and expressed as %ID/g and mean %ID/g of [$^{18}$F]DCFPyL. The non-specific binding was evaluated by the percentage of [$^{18}$F] DCFPyL at 120 minutes time-point in the saliva supernatant and the pellet post-extraction of saliva in acetonitrile for five of the ten patients. The radiometabolites were analyzed by thin-layer chromatography (TLC) using the saliva supernatant sample and the parent tracer as a reference. Differences between groups were considered significant when $p<0.05$, and correlations were analyzed by Pearson (r, parametric data) method and were considered positive and statistically significant when $r>0.5$ and $p<0.05$. ***Results:*** All patients' scans showed high uptake of [$^{18}$F] DCFPyL in the salivary glands and excretion into the saliva at 120 min. A significant difference in the tracer content in the saliva was shown at 30 min ($p=0.03$), 60 min ($p<0.0001$), and 120 min ($p<0.0001$) after systemic tracer injection when compared to the baseline time point (0 min). A positive correlation ($r=0.99$, $p=0.0005$) was found between [$^{18}$F]DCFPyL uptake and time points. Of the [$^{18}$F]DCFPyL found in the saliva, 98% was in the form of the intact [$^{18}$F]DCFPyL found in the supernatant, while approximately 2% was found bound to various proteins in the cellular pellet after centrifugation. ***Conclusion:*** Systemically injected [$^{18}$F]DCFPyL shows uptake into the salivary gland, a portion of which is then secreted unbound and intact into the saliva. The amount secreted increases over time and has not peaked by 120 minutes after tracer injection.

## EP-0281

### Clinical Application of 18F-Thretide PET/CT and Early PET/CT Scan in Prostate Cancer

***X. Cheng***[1,2], *G. Hou*[1,2], *X. Wang*[1,2], *X. Chen*[3,4,5], *Y. Wang*[1,2], *V. Jakobsson*[3,4,5], *X. Shen*[1,2], *J. Zhang*[3,4,5], *R. Zheng*[1,2]; [1]*Department of Nuclear Medicine (PET-CT Center), National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA,* [2]*Department of Nuclear Medicine (PET-CT Center), National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Langfang, CHINA,* [3]*Department of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [4]*Nanomedicine Translational Research Program, NUS Center for Nanomedicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [5]*Clinical Imaging Research Centre, Centre for Translational Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

***Aim/Introduction:*** Recent studies have demonstrated the potential of PET/CT with $^{18}$F-labelled prostate-specific membrane antigen (PSMA) as a promising method for prostate cancer (PCa) diagnosis. The aim of this study is to assess the clinical value of $^{18}$F-Thretide (Al$^{18}$F-PSMA-BCH) PET/CT and early scan with $^{18}$F-Thretide PET/CT in detecting and staging PCa. ***Materials and Methods:*** From November 2022 to April 2023, a total of 62 PCa patients were referred to our department for $^{18}$F-Thretide PET/CT for clinical diagnosis, staging or restaging. Whole-body PET/CT scans were conducted at a median time of 77 minutes post-injection (p.i.) (range: 59-139 min); single-bed pelvic early PET/CT scans were performed with a PET emission duration of 2 minutes, starting at a median time of 186 s p.i. (range: 165-420 s). Visual analysis of images was performed followed by semiquantitative standardized uptake value (SUV) analysis of pathologic lesions, healthy bladder, and other surrounding healthy tissues in both early PET/CT scans and routine scans. ***Results:*** As of now, 47 patients have bone scans available for analysis, of which 2 patients were diagnosed with widespread bone metastasis based on both bone scans and $^{18}$F-Thretide PET/CT. For the remaining patients, PET/CT identified 134 positive bone lesions and bone scans detected 95 positive bone lesions. Of these, 79 lesions on PET/CT and 29 lesions on bone scans were determined to be indicative of bone metastasis. The target to bladder (T/BL) ratios for primary lesions increased from 0.76±0.95 in routine scans to 12.02±11.68 in early PET/CT scans ($p<0.001$), while the T/BL ratios for metastases and local recurrence increased from 0.34±0.31 in routine scans to 5.42±4.87 in early PET/CT scans ($p<0.001$). However, the SUVmax values of other surrounding tissues were found to be higher in early PET/CT scans compared to routine scans (external iliac vessels: 8.46±1.94 vs. 2.89±0.52; inferior vesical artery: 4.49±1.48 vs. 2.34±0.34; gluteus maximus muscle: 1.19±0.35 vs. 0.84±0.25). Of the 16 patients who underwent surgery prior to PET/CT scans, early PET/CT scans improved the detection rate of local recurrence from 1/16 to 4/16. ***Conclusion:*** $^{18}$F-Thretide PET/CT has shown to be a valuable imaging modality in the management of patients with PCa. Early PET/CT scan can improve the detection accuracy and rate of local recurrences and provide additional information for lesions that are challenging to distinguish from urinary uptake on routine scans.

## EP-0282

### Dual tracer PET/CT with 68Ga-PSMA and 18F-FDG in patients with prostate cancer

***Y. Zhang**, M. Su;*
*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** The $^{68}$Ga-prostate specific membrane antigen (PSMA) positron emission tomography/computed tomography (PET/CT) is routinely used for tumor detection and staging in prostate cancer, but 5-10% of primary tumors have low PSMA ligand uptake.[1] The Gleason score is a significant predictor for PSMA-FDG+ lesions.[2] In this study, we aimed to investigate the value of dual tracer PET/CT with $^{68}$Ga-PSMA and $^{18}$F-FDG in prostate cancer patients. ***Materials and Methods:*** Patients with Gleason score (GS) of 8-10 were included prospectively (Trial number: ChiCTR2200066582). All patients underwent both $^{68}$Ga-PSMA and $^{18}$F-FDG PET/CT within one week. The patients were divided into initial staging group (Group A) and biochemical failure/recurrence group (Group B). Lesions were classified into PSMA (- or +) and FDG (- or +), and the position of the lesions was recorded. ***Results:*** Fifty-two patients were included based on inclusion and exclusion criteria. There were 21 patients (median age 67 years, IQR 61-72 years) in group A and 31 (median age 65 years, IQR 57-71 years) in group B. 16, 33, and 3 patients had GS 8, 9, and 10 respectively. Overall, 624 lesions were detected in 49 of the 52 patients, and 3 patients with GS 8 in group B were negative in both scans. The PSMA-FDG+ lesion was only found in 12 patients with GS 9-10 (11 [91.7%, 11/12] patients with GS 9, and 1 [8.3%, 1/12] patient with GS 10). For the group A patients, there were 15 (15/21, 71.4%) patients with 209 PSMA+FDG- lesions, 18 (18/21, 85.7%) patients with 88 PSMA+FDG+ lesions, and 2 (2/21, 9.5%) with 20 PSMA-FDG+ lesions (1 primary lesion and 19 parenchymatous organ lesions). For the group B patients, there were 18 (18/29, 62.1%) patients with 92 PSMA+FDG- lesions, 21 (21/29, 72.4%) patients with 111 PSMA+FDG+ lesions, and 10 (10/29, 34.5%) with 104 PSMA-FDG+ lesions (2 primary lesions, 13 regional lymph node metastases, 30 distant lymph node metastases, 11 bone metastases, and 48 parenchymatous organ lesions). ***Conclusion:*** Prostate cancer patients with Gleason score 9-10 may be detected PSMA-FDG+ lesions. It may have an impact on the therapeutic choice. ***References:*** 1. P. S. Chakraborty, M. Tripathi, K. K. Agarwal, et al. ## EP-0283

### Improvement of Gleason Grading prediction in Prostate Cancer Stratification for Radical Prostatectomy: a Machine Learning-based Theronostic Multi-omics Study

***J. Ning**[1], C. P. Spielvogel[1,2], D. Haberl[1], K. Trachtova[1], S. Stoiber[1], S. Rasul[1], V. Bystry[1], E. Gurnhofer[1], G. Timelthaler[1], L. Papp[1], M. Schlederer[1], M. Hacker[1], A. Haug[1], L. Kenner[1];*
*[1]Christian Doppler Lab for Applied Metabolomics, Medical University of Vienna, Vienna, AUSTRIA, [2]JN and CPS shared the first authorship, Vienna, AUSTRIA.*

***Aim/Introduction:*** In this study, we aim to integrate clinical data, radiomics data, genomics data and pathomics data using high-throughput machine learning (ML) model to predict the Gleason grading of prostate cancer (PCa) for smart and precise patient stratification for radical prostatectomy (RP) and compare its predictive performance with that of needle biopsy. ***Materials and Methods:*** Study Design Totally, 146 patients with histologically confirmed PCa from the clinical trial (NCT02659527) were enrolled in this study, all of whom underwent $^{68}$Ga-PSMA-11 PET/MR before RP between May 2014 to April 2020 in the nuclear medicine department of Vienna General Hospital.Radiomics Acquisition$^{68}$Ga-PSMA-11 PET/MR images were collected and volumes of Interest (VOIs) were delineated on Hermes, from whom radiomics features were computed using the PyRadiomics. Genomics AcquisitionDNA was isolated from FFPE samples. Whole exome sequencing analysis was performed. Functional pathways were quantified using multiple established in silico tools including EVE, CADD and PolyPhen scores. Pathway status and clinical characteristics were associated with BCR using Cox proportional hazard models. Pathomics Acquisition. We constructed TMA from RP specimens. Immunohistochemical analysis was performed using the automated staining platform DAKO Omnis. PSMA, AR, Ki-67, PSA, FASN, IL6ST, CDK2, CD3, STAT3, NKX3.1, TBb were selected as biomarkers and stained in TMA slides.ML-based Data IntegrationTo find the best ML model, 5 ML-based models including RF, XGB, KNN, SVM, IGR were used. The classification results were validated using 100-fold Monte Carlo cross-validation to ensure robustness of performance metrics. ***Results:*** The distribution of gene mutation profile with frequency of ≥10% cases are sparse. So in subsequent ML-based analysis, only pathway-level data were used considering balanced grouping standards. The AUC, ACC, SNS, SPC, PPV and NPV of 5 ML-based approaches were respectively calculated and the resulting RF classification algorithm gave the best performance with 0.87, 0.78, 0.83, 0.72, 0.80, 0.80. Compared to needle biopsy, the performance of machine learning algorithm to predict Gleason grading is better. The SPC, PPV, ACC and AUC were elevated by 18% (0.61 vs 0.72), 7% (0.75 vs 0.80),1% (0.77 vs 0.78) and 11% (0.75 vs 0.87) respectively while the SNS and NPV were decreased by 7% (0.89 vs 0.83) and 1% (0.81 vs 0.80). ***Conclusion:*** In conclusion, our findings demonstrate that our multiomics-based ML model has the better performance for the prediction of Gleason grading than the current clinical baseline, which facilitates the clinical decision-making and personalized management of PCa.

## EP-0284

### Assessment of Response Evaluation Criteria in PSMA PET/CT (RECIP 1.0) in Metastatic Castration-Resistant Prostate Cancer

***A. Gafita**[1], L. Djaileb[2], I. Rauscher[3], W. P. Fendler[4], B. Hadaschik[4], J. Czernin[5], K. Herrmann[4], S. P. Rowe[1], J. Calais[6], M. Rettig[6], M. Eiber[3], M. Weber[4], M. R. Benz[6], A. Farolfi[7];*
*[1]Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA, [2]University Grenoble Alpes, Grenoble, FRANCE, [3]Technical University Munich, Munich, GERMANY, [4]University Hospital Essen, Essen, GERMANY, [5]University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, [6]University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, [7]University of Bologna, Bologna, ITALY.*

***Aim/Introduction:*** To assess the agreement of Response Evaluation Criteria In PSMA-PET/CT (RECIP) determined using tumor segmentation software (quantitative RECIP) with RECIP determined by visual reads of nuclear medicine physicians (visual RECIP) for response evaluation in metastatic castration-resistant prostate cancer. ***Materials and Methods:*** This multicenter retrospective study at three academic centers included men who received $^{177}$Lu-PSMA treatment between December 2014

and February 2019. PSMA PET/CT at baseline and 12 weeks were assessed visually by five readers for changes in total tumor volume (TTV) and for new lesions. Quantitative changes in TTV were also measured using tumor segmentation software. The status of new lesions was combined with visual changes in TTV to determine visual RECIP and with quantitative changes in TTV to determine quantitative RECIP. The primary outcome was the agreement between visual vs quantitative RECIP and interreader reliability of visual RECIP by Fleiss kappa. The secondary outcome was the association of visual RECIP with overall survival (OS) by Cox regression. ***Results:*** 124 men (median age, 73 years; IQR, 67-76 years) were included. 40/124 (32%) and 84/124 (68%) men had quantitative RECIP-progressive disease (PD) and non-PD, respectively. Agreement between visual versus quantitative RECIP was excellent (κ=0.89; 118/124 [95%]). Agreement among readers in classifying visual RECIP-PD vs non-PD was excellent (κ=0.81; 103/124 [83%]) men. RECIP-PD was associated with significantly shorter OS compared to non-PD (HR 2.55; 95%CI: 1.71, 3.81; P<0.001). ***Conclusion:*** Visually assessed Response Evaluation Criteria In PSMA PET/CT (RECIP) demonstrated excellent agreement with quantitative RECIP and excellent interreader reliability. This can be readily implemented in clinical practice for response evaluation in men with metastatic castration-resistant prostate cancer undergoing $^{177}$Lu-PSMA therapy.

## EP-0285

### Association of Blood Count Parameters and Non-metastatic Bone Uptake at [18F]PSMA-1007 PET — Could Osteoporosis Be the Key to Unravel this Conundrum?

***G. Ninatti***[1], *C. Pini*[1], *R. Camedda*[2], *F. Gelardi*[3], *L. Antunovic*[4], *C. Landoni*[1,5], *P. Mapelli*[4], *M. Picchio*[6,4], *M. Sollini*[3,7], *A. Chiti*[6,4];
[1]*University of Milano Bicocca, Monza, ITALY,* [2]*University of Rome Tor Vergata, Rome, ITALY,* [3]*Humanitas University, Pieve Emanuele, ITALY,* [4]*IRCCS San Raffaele Scientific Institute, Milan, ITALY,* [5]*IRCCS-San Gerardo, Monza, ITALY,* [6]*Vita-Salute San Raffaele University, Milan, ITALY,* [7]*IRCCS Humanitas Research Hospital, Rozzano, ITALY.*

***Aim/Introduction:*** A limitation of PET imaging with the PSMA-targeting radiopharmaceutical [$^{18}$F]PSMA-1007 is represented by non-metastatic bone uptake, reported in up to 72% of cases [1], possibly leading to misdiagnosis. Underlying benign bone marrow/bone disorders have been suggested as the possible cause [2,3]. Our hypothesis is that osteoporosis plays a key role in this phenomenon. Therefore, we investigated the association between blood count parameters - known markers of this condition [4] - and the occurrence of non-metastatic bone uptake. ***Materials and Methods:*** We retrospectively analysed treatment-naïve patients with a confirmed diagnosis of prostate adenocarcinoma who underwent staging [$^{18}$F]PSMA-1007 imaging and blood count within 3 months. All patients with confirmed metastases, synchronous malignancy and/or active inflammatory processes were excluded. Qualitative analysis of [$^{18}$F]PSMA-1007 images was performed independently by three experienced nuclear medicine physicians. Selected patients were divided in two groups according to the presence/absence of non-metastatic bone uptake. Clinical information (age, Gleason score, iPSA) and blood count parameters were collected. The median value of blood count parameters in the two groups was compared using the Kruskall-Wallis test. ***Results:*** We analyzed 63 patients (median age: 67). The most prevalent Gleason scores were 4+3 (33%) and 4+5 (24%); median iPSA was 7.88 ng/mL (IQR 5.4-10.5). Forty-one patients had no bone findings while 22 had non-metastatic bone uptake at [$^{18}$F]PSMA-1007 PET, most commonly in the ribs (64%) and pelvic bones (59%). No statistically significant difference in clinical parameters between the two groups was found. Median neutrophil count was significantly higher in patients with non-metastatic bone uptake compared to those without (4600/mm3 vs. 4000/mm3, p=0.0387). ***Conclusion:*** In our cohort, non-metastatic bone uptake at [$^{18}$F]PSMA-1007 PET was observed in about 1/3 of patients. Patients with non-metastatic bone uptake had a significantly higher median neutrophil count than those without any bone findings. Given the prevalence of the finding and the molecular alterations induced by osteoclastogenic processes, we may speculate that [$^{18}$F]PSMA-1007 non-metastatic bone uptake could be an effect of underlying osteoporosis. We will further investigate this hypothesis in a larger population and explore the role of more specific markers of osteoporosis, in a prospective setting. ***References:*** 1. Hoberück, et al. . ## EP-0286

### The Impact of 18F-DCFPYL Specific Activity on Organ Uptake

***G. Chaussé***[1], *S. Plaha*[2];
[1]*McGill University, Montreal, QC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA.*

***Aim/Introduction:*** During the production 18F-DCFPYL, chemical compounds are left unlabeled, which decreases specific activity. The theoretical maximum specific activity (also called carrier-free specific activity or CFSA) when all molecules are labeled is calculated based on molecular weight of the final product, decay properties of the radioisotope and the number of attached radioisotopes per pharmaceutical. One can measure the mass of labelled compound using the ratio of its specific activity relative to the CFSA. Biodistribution of 18F-DCFPYL PET imaging can be calculated as "Total Body Uptake" (sum of the product "Volume X SUVmean" of all organs with uptake). We investigated if: 1- specific activity and mass of radiopharmaceutical of 18F-DCFPyL affect the uptake of certain organs (salivary glands, liver, kidneys) (inter-individual comparison), 2- whether the effect (or absence thereof) held true for the same individual at different times (intra-individual comparison). ***Materials and Methods:*** 111 prostate cancer patients underwent a total of 122 PET/CT scans two hours following intravenous injection of $^{18}$F-DCFPyL as part of a clinical trial (NCT02899312). Informed consent was obtained prior to any procedure in conformity with local ethic committee recommendations and in accordance with the ICH E6 guidelines and Declaration of Helsinki. Images were manually segmented using tools from a commercially available software (MIM software, v.7.0). Segmented organs were the salivary glands, lacrimal glands, liver, spleen, kidneys, and bowel. The bladder is considered excreted and therefore excluded. For each scan, specific activity of the production batch, obtained in the logs of the production facility, was decay corrected for time of injection of $^{18}$F-DCFPyL. The mass of radiopharmaceutical was calculated and normalized for patients' body weight, PSMA-accumulating organ volume and total body uptake. (1) A cohort of 100 PET/CTs were used for interindividual comparison. (2) 22 additional PET/CT scans with repeated PET/CT were used for intraindividual comparison. .For each normalized mass of radiopharmaceutical (by body weight, organ volume or total body uptake), patients were divided into two groups, either above or below the median. A student T test was used to compare the groups. ***Results:*** There was no statistical significance found for tracer uptake in high and low specific activity groups for both hot and cold compounds in kidneys, livers, or salivary glands. Similarly, there was no statistical significance found in organs in the repeat cohort. ***Conclusion:*** 18F-DCFPYL specific activity does not appear to impact its biodistribution.

## EP-0287

### Can Ga-68 PSMA PET/CT Parameters Predict Progression in Hormone-Sensitive De Novo Metastatic Prostate Cancer

***S. Aksu***[1], *B. B. Demirel*[1], *S. Gülbahar Ateş*[1], *Ö. Ateş*[2], *G. Uçmak*[1];
[1]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Medical Oncology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study is to investigate the role of staging Ga68 PSMA PET/CT parameters in predicting disease progression after first-line standard treatments (androgen deprivation therapy(ADT)±docetaxel) in patients with de novo metastatic hormone-sensitive prostate cancer(mHSPC). ***Materials and Methods:*** Patients who had metastases in staging Ga68 PSMA PET/CT and were followed up after first-line standard treatments were included in this study. The patients' demographic and pathological characteristics, total PSA(tPSA) levels were recorded. The differences between the tPSA at diagnosis and the lowest tPSA achieved after treatment were calculated(delta tPSA). The standardized uptake values(SUVmax) of prostate gland, lymph nodes and distant metastasis(Table 1), liver SUVmean values were recorded. The presence and date of progression based on clinical and imaging findings were recorded. Cox regression analysis was performed to investigate factors predicting progression after treatment, and Kaplan-Meier analysis was conducted to determine progression-free survival(PFS). ***Results:*** The mean age was 67.6±8.4(48-84) years. The median tPSA at diagnosis was 103(8-6109) ng/ml. The median lowest tPSA and the delta tPSA were 0.5(0-32)ng/ml, and 102.7(7.9-6178)ng/ml, respectively. The median follow-up period was 13.0(4.0-45.0) months. Progression was observed in 21(52.5%) patients (median tPSA of 6(1-51)ng/ml). Eighteen(45%) of the patients were receiving ADT, 22(55%) were receiving ADT+docetaxel treatment. A low-to-moderate positive correlation was found between the delta tPSA and the SUVmax value of bone metastasis(p=0.042, r: 0.336). Only the lowest tPSA achieved after treatment was found to be associated with progression (p<0.001, OR:0.091, %95 CI:1.042-1.143) in univariate analysis and it was shown that it has diagnostic value in ROC analysis(AUC:0.853, %95 CI:0.740-0.962, p<0.001). When the threshold value for the lowest tPSA value was set at 0.45ng/ml, the sensitivity and specificity for predicting progression were found to be 76.2% and 73.7%, respectively. The mean PFS was 24.5 (%95 CI: 19.01-29.95) months in all patient groups, the mean PFS was 34.5(27.09-42.28) months in those with a lowest tPSA <0.45ng/ml and 15 (%95 CI: 11.08-18.90) months in those with a lowest tPSA >0.45ng/ml. ***Conclusion:*** In high-risk prostate cancer patients, although it is known that Ga68 PSMA PET/CT successfully determines disease staging and extent, our study revealed that PSMA expression intensity in de novo mHSPC patients was not significant in predicting progression. In addition, we emphasize the importance of the lowest tPSA achieved after standard primary treatments as a significant factor in predicting PFS, and the need for personalized tPSA follow-up intervals on a patient-by-patient basis.

## EP-0288

### Reducing the frequency of prostate cancer biopsy by F18-rhPSMA7.3 PET/MR

***T. Hekimsoy***[1], *S. Kleiner*[1], *M. Heck*[2], *K. Schwamborn*[3], *M. Eiber*[1], *W. Weber*[1];
[1]*Department of Nuclear Medicine, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY,* [2]*Department of Urology, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY,* [3]*Department of Pathology, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY.*

***Aim/Introduction:*** Systematic biopsy of the prostate is the current standard for the workup of patients with suspected prostate cancer. However, the procedure is associated with significant morbidity and its sensitivity for the detection of clinically significant prostate cancer (csPC) is limited by sampling errors. In the present study we evaluated whether PSMA PET/MR can potentially reduce the need for systematic biopsies in patients with suspected prostate cancer. ***Materials and Methods:*** We retrospectively analyzed F18-rhPSMA7.3 PET/MR scans of patients who were clinically suspected to have prostate cancer and underwent imaging for planning of prostate biopsy. Patients with symptoms of acute prostatitis were excluded. We analyzed multiparametric MR images using the PI-RADS score and PET images using SUVmax. In addition, we tested a score (CS) which combines information from both PET and MRI by adding the PI-RADS score to SUVmax. All patients underwent histological confirmation within 90 days following the PET/MR scan. ***Results:*** 55 consecutive patients were included, 29 of which were eventually diagnosed with csPC (ISUP ≥ 2) on histology. The diagnostic performance of the three approaches to diagnose csPC are summarized in the table. For further analysis, we defined two operational points on the ROC curve: one for the sensitivity at 100% specificity and the other for the specificity at 90% sensitivity (Table 1). When patients meet the 100% specificity criteria (where the likelihood of csPC is so high that biopsy confirmation is unnecessary before surgery) or meet the 90% sensitivity criteria (where clinically significant prostate cancer is similarly unlikely as after a negative biopsy), biopsy could potentially be avoided. Biopsy would only be considered for patients with intermediate likelihood of prostate cancer based on imaging. Following this approach biopsy could been avoided by MR, PET, and PET/MR in 18%, 45%, and 51% of the patients. ***Conclusion:*** Our analysis indicates that F18-rhPSMA7.3 PET/MR has the potential to markedly reduce the number of prostate biopsies when compared to MR alone. Such an approach could significantly decrease the discomfort and morbidity associated with unnecessary biopsies. Further prospective studies are needed to confirm these findings and validate the clinical utility of PSMA PET/MR in this setting.

## EP-0289

### Prediction of Lymph Node Metastasis in Differentiated Thyroid Cancer Based on Radiomics Models: A Meta-analysis and Systematic Review

***J. Mu***, *Y. Cao, X. Zhong, W. Diao, Z. Jia;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** The accurate clinical diagnosis of lymph node metastasis plays a crucial role in the treatment of differentiated thyroid cancer (DTC). This study aims to explore and summarise a more objective approach to detect cervical malignant lymph node metastasis of DTC via radiomics models. ***Materials and Methods:*** The PubMed, Web of Science, MEDLINE, EMBASE, and Cochrane databases were searched for all eligible studies. The search period is from the beginning to August 2022. Articles that used radiomics models based on ultrasound, computed tomography

or magnetic resonance imaging to assess lymph node metastasis preoperatively were included. Characteristics and diagnostic accuracy measures were extracted. Bias and applicability judgments were evaluated using the revised QUADAS-2 tool. The estimates were pooled using a random-effects model. Additionally, a leave-one-out meta-analysis was conducted to assess the heterogeneity. ***Results:*** Twenty-nine radiomics studies with 6160 validation set patients were included in the qualitative analysis, and 11 studies with 3863 validation set patients were included in the meta-analysis. Four of them had an external independent validation set. The studies were heterogeneous, and a significant risk of bias was found in 29 studies. Meta-analysis showed that the pooled sensitivity and specificity for preoperative prediction of lymph node metastasis via US-based radiomics were 0.81 (95% CI, 0.73-0.86) and 0.87 (95% CI, 0.83-0.91), respectively. ***Conclusion:*** Although radiomics-based models for lymphatic metastasis in DTC have demonstrated moderate diagnostic capabilities, future research should focus on broader data, standardised radiomics features, robust feature selection, and model exploitation.

## EP-0290

### Contribution of Neck Ultrasonography to Patient Management in Patients with Differentiated Thyroid Carcinoma with Excellent Response to Therapy

***I. Hekimsoy***[1], *M. Guven*[2], *R. Tokac*[2], *G. Kavukcu*[3], *A. Akgun*[2];
[1]*Department of Radiology, Torbali State Hospital, Izmir, TÜRKIYE,* [2]*Department of Nuclear Medicine, Ege University, Izmir, TÜRKIYE,* [3]*Department of Radiology, Ege University, Izmir, TÜRKIYE.*

***Aim/Introduction:*** Neck ultrasonography (US) and serum thyroglobulin (Tg)/ antithyroglobulin (anti-Tg) values are used to determine local recurrence after radioactive iodine (RAI) treatment in patients diagnosed with Differentiated Thyroid Carcinoma (DTC). US has been reported as the best method by the American Thyroid Association (ATA), even in cases with undetectable serum Tg values. In this study, we aimed to evaluate the contribution of US imaging to patient management in long-term follow-up in a group of patients with DTC with low risk and an excellent response after RAI treatment. ***Materials and Methods:*** Records of 296 patients (261 females, 35 males) who were treated with total thyroidectomy and achieved excellent response after I-131 treatment between 1996 and 2017, were analyzed retrospectively. ***Results:*** In the histopathological evaluation, 280 of the patients were diagnosed with papillary, 14 with follicular, and 2 with papillary and follicular thyroid carcinoma. Twenty three of 296 patients (7.7%) had metastatic lymph nodes at the time of diagnosis. Patients received 30-175 mCi (mean: 101 mCi) RAI and were followed for a mean of 12.5 months (range 58-312 months). An average of 9.6 (range 4-20) US examinations were performed per patient. In 62.1% (184/296) of the patients, no structural disease was detected with US during the follow-up period. Findings compatible with granulation tissue or non-functioning avascular thyroid tissue in the thyroid bed were reported in 24.6% (73/296). US examinations were repeated in our center in 2 patients with suspicion of recurrence in the thyroid bed on US performed in another center, and the findings were compatible with surgical hemostatic material. FNAB of suspicious lymph nodes identified with US was performed in 14 patients and revealed benign cytology in 12. In 2 patients with papillary thyroid cancer with metastatic lymph nodes at the time of diagnosis, suspicious lymph nodes were detected with US on the 30th and 42nd months respectively. Lymph node dissection was performed upon malignant cytology on FNAB. Suspicious lymph nodes in 5 patients were not suitable for FNAB due to the localization or small size and were stable in follow-up US examinations. ***Conclusion:*** Our findings showed that in patients with DTC who have an excellent response after RAI ablation and were low risk according to ATA criteria, US can detect metastatic lymph nodes during follow-up at a low rate. On the other hand, it leads to unnecessary investigations and interventions and does not contribute significantly to patient management.

## EP-0291

### Role of Thyroid Scintigraphy with pertechnetate in Congenital Hypothyroidism

***A. Marques***[1], *J. Carvalho*[2], *F. Abreu*[1];
[1]*Instituto de Medicina Nuclear da Faculdade de Medicina da Universidade de Lisboa, Lisboa, PORTUGAL,* [2]*Centro Hospitalar de Lisboa Ocidental, Lisboa, PORTUGAL.*

***Aim/Introduction:*** Congenital hypothyroidism (CH) is the most preventable cause of neurodevelopmental disability with varying etiology. We analyzed our hospital´s pediatric population with CH, reviewed the different scintigraphic patterns and correlated them with TSH levels in order to assess the role of thyroid scintigraphy in the etiologic workup of CH. ***Materials and Methods:*** Children with CH referred to our Nuclear Medicine Department between January 2021 and March 2023 for thyroid scintigraphy were retrospectively included in this study. After one month thyroxine therapy withdrawal, venous samples of TSH were taken on the same day as each thyroid scan. Scintigraphic images were carried out with a pinholle or parallel collimator 20 minutes following intravenous injection of sodium pertechnetate ($Na[^{99m}Tc]TcO_4$). Average injected ativity was 111 MBq. ***Results:*** A total of 44 patients were studied (21 girls and 23 boys) with a mean age of 3 years (range 2 - 5 years). Out of all the patients, 13 (30%) were found to have a normal thyroid site and normal uptake, 1 (2%) was found to have a normal site and decreased uptake, 5 (11%) were found to have a normal site and increased uptake, 16 (36%) had no uptake and 9 (21%) had ectopic uptake. The TSH levels on the same day as scintigraphy ranged from 1,38 to 853 mU/L, with significantly higher median TSH levels seen in the no uptake and ectopic uptake groups (282 and 249 mU/L, respectively) compared with the normally sited thyroid uptake patients. ***Conclusion:*** Thyroid scintigraphy with pertechnetate gives an important diagnostic contribution in most cases of congenital hypothyroidism, especially in ectopic thyroid tissue or suspected agenesis. However, its limitations in excluding possible dyshormonogenesis or differentiating transient from permanent hypothyroidism in normally located thyroid uptake highlights the need of always having a strict correlation with ultrassound findings and laboratory results.

## EP-0292

### Semiquantitative analysis of 99mTc MIBI thyroid scan in patients with amiodarone induced thyrotoxicosis

***L. Fischer***[1,2], *N. Girotto*[1,2], *T. Bogović Crnčić*[1,2], *M. Ilić Tomaš*[1,2], *S. Grbac-Ivanković*[1,2], *M. Mavrinac*[3];
[1]*Department of Nuclear Medicine, Faculty of Medicine, University of Rijeka, Rijeka, CROATIA,* [2]*Clinical Department of Nuclear Medicine, Clinical Hospital Centre Rijeka, Rijeka, CROATIA,* [3]*Department of Medical Informatics, Faculty of Medicine, University of Rijeka, Rijeka, CROATIA.*

***Aim/Introduction:*** $^{99m}$Tc-MIBI thyroid scan has proven useful in distinguishing amiodarone induced thyrotoxicosis caused by underlying thyroid disease, AIT-1, from AIT-2 induced by thyroid cell damage. Since mixed forms are also identified (AIT-3), differentiation is not always straightforward. To increase diagnostic performance and help the choice of therapy, we introduced semi-quantitative method for MIBI uptake analysis. ***Materials and***

***Methods:*** In 36 patients (26 men, 10 women, mean age 67 years) treated with amiodarone 2 months to 9 years (average 2.32y) with mean amiodarone therapy dose of 150 mg (25 - 400 mg), thyrotropin (TSH), free thyroxin (FT4), free triiodothyronine (FT3) and thyroid auto antibodies against peroxidase, thyroglobulin and TSH receptor (TPO-Ab, TgAb, TSI) were determined. Ultrasonography was performed with vascularization assessment (0 = normal, 1 = moderate and 2 = markedly increased). Planar scintigraphy with 99mTc-MIBI was performed 10 minutes after administration of 370 MBq 99mTc-MIBI. Semiquantitative analysis of MIBI uptake was performed by drawing two regions of interest (ROI): over the whole thyroid and single background region beneath the thyroid. Target to background ratio was calculated by subtracting the average number of counts of background ROI from the thyroid ROI, normalized with the average counts in back¬ground ROI. The results were divided by percentiles in 3 groups; ratios between 66-100 percentile were classified as AIT-1, between 0-33 percentile as AIT-2 and between 33 and 66 percentile as AIT-3. Comparisons of groups were made by one-way analysis of variance (ANOVA). Post-hoc Scheffe test was used to calculate the differences between groups. ***Results:*** TSH was suppressed in all patients (TSH mean 0,0023 mIU/L, range 0.004 - 0.336), FT4 mean was 35,35 pmol/L (range 8,2 - 100), FT3 mean was 8,57 pmol/L (range 4,3 - 44,6). Elevated TPO-Abs were detected in 7, TgAbs in 4 and TSI in 6 patients. Ultrasonographically increased vascularization was observed in 8 patients (in 6 moderately and markedly in 2), the rest had normal results. Semiquantitative analysis identified high ratio representing high MIBI accumulation (AIT-1) in 13 patients, low uptake (AIT-2) in 12 patients and intermediate (AIT-3) in 11 pts. The difference between groups was statistically significant ($p<0.05$). ***Conclusion:*** Semiquantitative interpretation of 99mTc-MIBI uptake in thyroid can improve diagnostic accuracy and helps distinction between the types of AIT. Further investigations are necessary to classify the mixed group more accurately. Supported by University of Rijeka: project (uniri-pr-biomed-19-141495).

## EP-0293

### The prevalence of pre-thyroidectomy thyroid function test abnormalities among patients with differentiated thyroid carcinoma: A descriptive study

***A. Aghaee****, s. barashki, s. zakavi;*
*nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

***Aim/Introduction:*** The present study aims to assess pre-thyroidectomy thyroid hormone disturbances among patients suffering from differentiated thyroid carcinoma (DTC). ***Materials and Methods:*** This retrospective study was performed from September 2020 to March 2021. We analyzed the hospital files of 710 patients with DTC who underwent thyroidectomy and referred to nuclear medicine department from April 2013 to September 2019. Demographics, TNM stage, pre-surgery thyroid function tests, time-interval to achieve a complete response, recurrence rate, one-year response, final response, and the need for alternative treatment modalities were extracted. Then, we analyzed the potential association of pre-surgery TSH levels with the initial disease stage and treatment response. Chi-Square, Analysis-of-variance, and Kruskal-Wallis tests were used where appropriate. ***Results:*** The mean age of participants was 40.39 ± 13.85 years. History of Hashimoto's disease was detected in 130 (18.3%) patients. Multi-focal DTC was found in 221 (31.2%) patients. Lymph node involvement was significantly higher among men ($p = 0.001$). Men also had significantly higher thyroglobulin levels ($p = 0.025$). No statistically significant association was found between pre-surgery thyroid function status and TNM stage or multifocality of the malignancy. Baseline thyroid function tests also did not show a statistically significant relationship with thyroglobulin, anti-thyroglobulin antibody, time to first excellent response, and follow-up duration. ***Conclusion:*** Baseline thyroid function status may not change the outcome of DTC. It could also be plausible that thyroid dysfunction before surgery would not increase invasiveness nor impact the treatment-response of the tumor compared to euthyroid patients.

## EP-0294

### Prognostic role of minimal extrathyroidal tumor extension (mETE) in the follow-up of patients with papillary carcinoma (PC) unaffected by other risk factors.

***A. Marongiu****, S. Nuvoli, S. Vargiu, P. Solinas, A. Spanu, G. Madeddu;*
*Unit of Nuclear Medicine, University of Sassari, viale S. Pietro 8 - 0700 Sassari, Italy, Sassari, ITALY.*

***Aim/Introduction:*** Minimal extra-thyroid tumor extension (mETE) clinical relevance is still debated, in particular in determining its role as outcome predictive factor, and a long-term follow-up is required to detect outcome differences. We further investigated whether mETE impact exists on PC prognosis during follow-up after total thyroidectomy and radioiodine ablation. ***Materials and Methods:*** Among large PC patient groups with mETE, we retrospectively enrolled 84 cases with no other risk factors, such as gross ETE, neck lymph node and distant metastases, multifocality/multicentricity, and aggressive PC variants; 65 patients were females and 19 males, and 42 were aged < 55 and 42 ≥ 55 years. Seventeen patients had tumor sizes ≤ 10 mm and 67 > 10 mm. Comparatively, we enrolled 190 matched age/sex control PC patients without both mETE and the other risk factors, as above. During long-term follow-up, all patients underwent whole body scan (WBS) and SPECT/CT after 185 MBq $^{131}$I dose; radiologic procedures, serum thyroglobulin and AbTg levels were also sequentially checked. ***Results:*** During follow-up, 14/84 (16.7%) patients underwent metastases and WBS detected 7 lesions (all unclear) in 6 cases, while SPECT/CT evidenced 26 lesions (24 neck, 1 mediastinum, 1 spine) in 14 patients, characterizing all WBS unclear lesions. Thyroglobulin was undetectable in 3 cases, < 5.0 ng/ml in 7 cases, >10 in 4 cases. Among 190 controls, 13 (6.8%) cases underwent metastases, WBS evidencing 7 lesions (6 classified as unclear in the neck and one lung metastasis) in 6 cases; SPECT/CT identified 18 metastases in 13 patients (16 neck, 1 lung, 1 bone). Thyroglobulin was undetectable in 2 cases, < 5.0 ng/ml in 8 cases, between 5.0-10.0 in 2 cases, and >10 in 1 case. AbTg were under cut-off in all patient groups. The univariate analysis showed an increased risk of developing metastases in mETE patients, Odds Ratio 2.72 (95% C.I. 1.22-6.08) p=0.01; disease-free survival (DFS) in mETE cases was significantly (p=0.009) lower than in PC patients without mETE. ***Conclusion:*** PC patients with mETE and without other risk factors at surgery showed unfavorable tumor course during follow-up, with mETE as a worse outcome significant predictor on univariate analysis than PC patients without mETE, with a higher rate of recurrences and decreased DFS. Metastases were better identified by SPECT/CT than WBS in all patient groups. More careful surveillance during follow-up must be done in PC patients with mETE also when it is apparently the only identified risk factor.

## EP-0295

### 68Ga FAPI-PET CT in patients with rising calcitonin after treatment of medullary thyroid carcinoma and negative conventional and nuclear imaging - pilot cases.

***P. Bochev***, *G. Mateva, N. Novoselska;*
*Acibadem Cityclinic Mladost UMBAL, Sofia, BULGARIA.*

***Aim/Introduction:*** Patients with medullary thyroid cancer (MTC) who experience calcitonin elevation/biochemical recurrence after initial treatment are a serious diagnostic and treatment challenge. In this scenario workup includes neck ultrasound and CT of chest/abdomen. Although not uniformly utilized, 18F -FDG, 68Ga DOTA - somatostatin receptor imaging and 18F-DOPA could be considered a second line imaging (with F-DOPA being of very limited availability). Despite various diagnostic tests, imaging frequently fails to localize disease. Recently introduced 68Ga FAPI radiopharmaceutical showed potential in cancer imaging and seems to be positive in MTC, based on few published cases, which can be considered a background for testing feasibility in specific scenarios Aim: Pilot assessment of feasibility of 68Ga FAPI PET/CT in imaging negative MTC patients with rising calcitonin ***Materials and Methods:*** We present two cases of patients, operated for MTC and gradually elevating calcitonin levels, who failed to localize tumor recurrence on conventional imaging, as well as on FDG and 68Ga DOTA- somatostatin receptor imaging. In both patients 68Ga FAPI-04 PET/CT was performed. ***Results:*** The scans revealed a liver metastasis in one patient and lung metastases and local recurrence in the other, all FAPI positive. None of the lesions was eligible for biopsy, so diagnosis was confirmed by progression on follow-up imaging in one patient and treatment response after vandetanib treatment in the other (follow up of 12 months). ***Conclusion:*** 68Ga FAPI PET/CT appears feasible in MTC patients with rising calcitonin levels and further implementation studies seem to be justified.

## EP-0296

### The total volume of lung metastases from thyroid cancer based on infer artificial intelligence can predict abnormal lung function

***M. Qi***, *R. Huang, S. Huang;*
*Department of Nuclear Medicine, West China Hospital of Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Lung metastasis (LMs) from differentiated thyroid cancer (DTC) is the most common distant metastasis in patients with DTC. The clinical symptoms are often not obvious when the volume of LMs is small. However, respiratory failure resulting from lung involvement may be the most common cause of death in DTC patients with LMs in advanced disease. Therefore, the main purpose of this study was to explore whether the total volume of LMs from DTC affected the lung function of DTC patients with LMs and how aspect it affected lung function. ***Materials and Methods:*** 47 DTC patients from February 2016 to February 2023 in our center for initial radioiodine therapy after thyroidectomy were reviewed retrospectively. Clinical characteristics, chest computerized tomography (CT), lung function indexes, the number and total volume of LMs were collected. The total volume of LMs from DTC was obtained by Infer Artificial Intelligence (AI). According to the indexes of lung function, the patients were divided into normal lung function group and abnormal lung function group. Abnormal lung function includes ventilatory dysfunction composed of obstructive ventilatory dysfunction (OVD) and restrictive ventilatory dysfunction (RVD),lung diffusion capacity defect (LDCD) and small-airway dysfunction (SAD). The difference of total volume of LMs was compared between normal and abnormal groups. The cut-off value of the total volume of LMs used to predict abnormal lung function was obtained according to the receiver operating characteristic (ROC) curve. ***Results:*** Among them, 17.0% (8/47) had RVD, 8.5% (4/47) had OVD, 34.0% (16/47) had SAD, and 17.0% (8/47) had LDCD. There were significant differences in the total volume of LMs between the normal and abnormal groups with OVD, SAD, and LDCD. The cut-off values of SAD, OVD and LDCD were 7860.64mm$^3$, 9301.85 mm$^3$, and 15071.59 mm$^3$, severally. ***Conclusion:*** The total volume of LMs can affect lung function and it was also predictive for different types of lung dysfunction including OVD, SAD and LDCD. FEV1 / FVC, MMEF%, and V50% have negative correlation with the total volume of LMs.

## EP-0297

### SOP for cervical ultrasound cine loops on DTC follow-up

***P. Seifert***, *M. P. Sopuschek, M. Freesmeyer;*
*Clinic of Nuclear Medicine, Jena, GERMANY.*

***Aim/Introduction:*** DTC patients require lifelong cervical ultrasound (US) follow-up. However, no standardized procedure recommendations exist and the role of retrospective analyses of video sequences (cine loops) is not reported. The purpose of this study was to investigate the diagnostic value of a SOP for the acquisition of ultrasound cine loop in the follow-up of DTC patients. ***Materials and Methods:*** Restrospective evaluation of all US examinations of DTC patients between JAN 2010 and FEB 2018 at a university nuclear medicine clinic. Analysing the additional diagnostic benefit over conventional examination results that arose from cervical US cine loops stored on the local PACS: (A) no clinical relevance, (B) confirmation of a new finding seen on conventional live ultrasound, (C) identification of a new finding not seen on conventional live ultrasound, (D) invalidation of a new finding seen on conventional live ultrasound. ***Results:*** A total of 5.512 US examinations in 652 patients (72% female, median age of 50 years) with 67% PTC, 29% FTC and 4% other DTC were evaluated, UICC I (79%), II (12%), III+IV (6%). In 82 patients (12.6%) a clinically relevant finding was identified on the US cine loop (B=11, C=6, D=78). Additional time consumption for the acquiration of the US cine loops was approx. 1 minute per investigation. ***Conclusion:*** The introduced SOP for the acquisition of cervical cine loops in the follow-up of DTC patients was easy and fast to apply. More than every tenth patient showed a clinical benefit of the additionally applied cine loops. We recommend the SOP for applicaiton in clinical routine. ***References:*** Ultrasound Cine Loop Standard Operating Procedure for Benign Thyroid Diseases-Evaluation of Non-Physician Application.Seifert P, Maikowski I, Winkens T, Kühnel C, Gühne F, Drescher R, Freesmeyer M.Diagnostics (Basel). 2021 Jan 4;11(1):67. doi: 10.3390/diagnostics11010067.

## EP-0298

### [68Ga]Ga-PSMA-11 PET/CT in Thyroid Cancer - Preliminary Results

***K. Zajkowska***, *M. Wojewódzka-Mirocha, P. Cegła, A. Sackiewicz, P. Ochman, J. Januszkiewicz-Caulier, A. Żyłka, M. Dedecjus;*
*Department of Oncological Endocrinology and Nuclear Medicine, Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, POLAND.*

***Aim/Introduction:*** Prostate-specific membrane antigen (PSMA) is expressed in prostate cancer cells and in some of the nonprostatic solid tumors including thyroid cancer. The aim of this ongoing study is to determine the utility of [68Ga]Ga-PSMA-11 PET/CT

in detecting local recurrence and distant metastases of thyroid cancer. ***Materials and Methods:*** So far 18 patients were enrolled for this single-institution prospective study: 13 patients with differentiated thyroid cancer (DTC) after total thyroidectomy and radioiodine treatment with serum thyroglobulin (Tg) elevation and negative iodine scintigraphy, and 5 patients with medullary thyroid cancer (MTC) after total thyroidectomy with serum calcitonin (Ct) elevation. In all the patients [68Ga]Ga-PSMA-11 PET/CT was performed. Patients with negative or inconclusive PSMA imaging were qualified for [18F]F-FDG PET/CT. ***Results:*** In DTC patients (Tg 0.45-2076.0 ng/mL, mean 295.92 ng/mL, median 57.57 ng/mL) [68Ga]Ga-PSMA-11 PET/CT was positive in 4/13, inconclusive in 3/13 (heterogenous radioligand uptake in lesions) an negative in 6/13 cases. Patients with negative or inconclusive PSMA imaging were qualified for [18F]F-FDG PET/CT. Up-to-date [18F]F-FDG PET/CT was performed in 5/9 patients and was positive in 1 case (pulmonary metastasis negative in PSMA), negative in 3 and inconclusive in 1 case (inconclusive also in PSMA). The lesions that shown PSMA-11 uptake were localized in thyroid bed (in 2 patients), lymph nodes (2), lungs (1) and bones (1). In MTC patients with negative imaging studies (Ct 496.7-7088.0 pg/mL, mean 2380.1 pg/mL, median 967.8 pg/mL) [68Ga]Ga-PSMA-11 PET/CT was negative in all cases (4/4), as well as [18F]F-FDG PET/CT preformed 3 months later. In MTC patient with known lesion [68Ga]Ga-PSMA-11 PET/CT was positive and revealed intense PSMA-11 uptake in superior mediastinal mass. ***Conclusion:*** In DTC [68Ga]Ga-PSMA-11 PET/CT was positive in 4/13 and not inferior to [18F]F-FDG PET/CT in 8/9 patients (4 PSMA positive, 3 PSMA and FDG negative, 1 PSMA and FDG inconclusive). The main advantage of [68Ga]Ga-PSMA-11 PET/CT in DTC patients is no need for TSH stimulation. In MTC patients with negative CT and MR imaging [68Ga]Ga-PSMA-11 PET/CT was insufficient as well as [18F]F-FDG PET/CT. In MTC patient with known lesion [68Ga]Ga-PSMA-11 PET/CT was positive. More results are needed to draw the conclusions about utility of [68Ga]Ga-PSMA-11 PET/CT in thyroid cancer.

## EP-0299

### Differentiated thyroid carcinoma: correlation between thyroglobulin, basal anti-thyroglobulin antibodies and post-ablative treatment study.

***B. Hervás-Sanz****, A. Rodríguez-Gasén, J. Suils-Ramon, M. P. Perlaza-Jiménez, M. Pudis, S. Bondia-Bescós, J. L. Díaz-Moreno, J. L. Vercher-Conejero, M. Cortés-Romera;*
*Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

***Aim/Introduction:*** Differentiated thyroid carcinoma (DTC) is the most common endocrine neoplasm. It affects young patients and its mortality has been increasing in recent years. That is the reason because those patients diagnosed with DTC require close monitoring. Such monitoring is usually done with thyroglobulin values.The aim of this study is to evaluate, in patients with DTC, the relationship between baseline thyroglobulin (bTg), stimulated thyroglobulin and baseline antithyroglobulin antibodies (AbTg) with the detection of residual tumoral pathology after the first ablative treatment following total thyroidectomy. ***Materials and Methods:*** Retrospective analysis of those patients (p) who received an ablative dose (100 mCi) of radioiodine, between 2017-2020, in our center, 30-90 days after total thyroidectomy.The analyzed parameters were: bTg, baseline AbTg, stimulated thyroglobulin and presence of pathological uptake (locoregional adenopathies and/or metastases) in the planar total body scan (PTBS) at 7 days post-treatment. ***Results:*** We obtained 295p (221 women and 74 men), mean age 50 years (range 20-85), with DTC (240 papillary, 35 follicular, 10 Hürthle cell, 5 papillary + follicular and 5 poorly differentiated). Of the 295p, 261p received exogenous stimulation after two doses of TSHrh and 34p received endogenous stimulation with withdrawal of levothyroxine for 4 weeks prior.Out of the total, 74p had bTg >1ng/mL. Of these, 65% (48 out of 74) showed positive PTBS. Of the 221p with bTg values <1ng/mL, 132p had detectable stimulated thyroglobulin and, of these, 42 had positive PTBS (32%). Of those with undetectable stimulated thyroglobulin (89), 15p had positive AbTg, and of these, 6 had positive PTBS. ***Conclusion:*** In our series of over 100p, the rate of detection of metastatic disease on PTBS post-ablative treatment is higher the higher the thyroglobulin value.Positive baseline AbTg levels also play an important role, as PTBS has detected metastatic disease in 40% of these patients despite undetectable thyroglobulin levels. All these data could be taken into account in the future for precise dose adjustment in radioiodine ablative treatments.

## EP-0300

### Does the duplication time of thyroglobulin have any use as a predictor factor on the detection of recurrence and or metastasis in the differentiated thyroid cancer in the 2-[18F]fluoro-2-deoxy-d-glucose PET/CT.

***D. Rodriguez Oviedo****, B. Manzarbeitia Arroba, M. Tagliatori Nogueira, M. Alvarez Moreno, C. Galindo, M. De La Rubia Marcos, M. Garcia Alonso, C. Paniagua Correa, C. Sandoval Moreno;*
*Hospital Universitario de Getafe, Madrid, SPAIN.*

***Aim/Introduction:*** Determinate how useful the doubling time thyroglobulin (Tg-DT) is as a predictor factor in the detection of recurrence and or metastasis in the 2-[18F]fluoro-2-deoxy-d-glucose (2-[18F]FDG) PET/CT in patients with differentiated thyroid cancer (DTC), positive thyroglobulin (Tg), and negative anti-thyroglobulin antibodies (Tg-ab). ***Materials and Methods:*** The inclusion criteria were (1) patients diagnosed with DTC treated surgically and I-131 ablation therapy (2) negative Tg-ab serum levels (3) at least 3 Tg serum levels measurements during the follow-up (4) at least one [18F]FDG) PET/CT after treatment (5) pathology results of those with positive [18F]FDG) PET/CT. ***Results:*** 50 patients met the inclusion criteria, 15 of them the (2-[18F]FDG) PET/CT didn't find any signs of recurrence and or metastasis, the others 35 patients received positive results for recurrence and or metastasis. [18F]FDG) PET/CT sensitivity, specificity, positive predictive value (VPP), and negative predictive value (VPN) results were 95%, 96%, 97%, and 90% respectively. ***Conclusion:*** We found that a small Tg-DT has a higher probability of a positive [18F]FDG) PET/CT for recurrence and or metastasis. The Tg-DT area under the curve (AUC) analysis to predict the presence of recurrence or metastasis on the [18F]FDG) PET/CT of DTC was 8 months (sensibility 93%, specificity 89%, AUC= 0.90).

## EP-0301

### Comparative Study of [68Ga]Ga-DOTA-FAPI-04, [68Ga]Ga-DOTATATE and [18F] -DOPA in Imaging of Medullary Thyroid Carcinoma: A Case Series and 18F-DOPA in Imaging of Medullary Thyroid Carcinoma: A Case Series

***G. dos Santos****[1,2], A. Quagliata[1], E. Silvera[1,2], R. Castro[1], A. Banchero[1], A. Damian[1], I. Cordero[1], K. Suanes[1], O. Alonso[1,2], E. Savio[1], P. Duarte[1], J. Gambini[1];*
*[1]CUDIM, Uruguayan Center Of Molecular Imaging, Montevideo, URUGUAY, [2]Hospital de Clínicas Dr. Manuel Quintelas, Montevideo, URUGUAY.*

***Aim/Introduction:*** The management of medullary thyroid carcinoma (MTC) remains a challenge due to its heterogeneous presentation and variable clinical course. Molecular imaging has emerged as a promising tool for the diagnosis and management of MTC. Radiotracers such as [$^{68}$Ga]Ga-DOTA-FAPI-04, [$^{68}$Ga] Ga-DOTATATE and [$^{18}$F] -DOPA have shown potential in the imaging of neuroendocrine tumors, including MTC. However, there is limited comparative data on the performance of these radiotracers in MTC patients. The aim of our work is to compare the role of these tracers in the imaging of three MTC patients. ***Materials and Methods:*** Three patients with histologically confirmed MTC were included in this study and all patients underwent imaging with [$^{68}$Ga]Ga-DOTA-FAPI-04, [$^{68}$Ga] Ga-DOTATATE and [$^{18}$F] -DOPA on separate occasions. The radiotracers were administered according to established protocols. Imaging was performed using a PET/CT scanner. Images were interpreted by experienced nuclear medicine physicians and evaluated for the presence of MTC lesions, including primary tumors and metastatic lesions. The maximum standardized uptake value (SUVmax) and the SUVmax ratio (SR; defined as SUVmax/background ) were measured for each lesion. Ethical approval was obtained from the institutional review board. All patients signed informed consent prior to enrollment in the study. ***Results:*** The results of our study demonstrate that [$^{68}$Ga] Ga-DOTA-FAPI-04 provides favorable tumour-to-background contrast compared to [$^{68}$Ga] Ga-DOTATATE and [$^{18}$F] -DOPA. In our cohort, [68Ga]Ga-DOTA-FAPI-04 detected the highest number of lesions, with 8, 6, and 1 lesions identified in each patient, respectively, compared to [$^{68}$Ga] Ga-DOTATATE (5,1 and 2) and to [$^{18}$F] -DOPA (0, 3, 0), respectively. Notably, [$^{68}$Ga]Ga-DOTA-FAPI-04 detected more mediastinal lymph nodes in patient one (7 lymph nodes) compared to [$^{68}$Ga] Ga-DOTATATE PET/CT (5 lymph nodes) and and [$^{18}$F] -DOPA (none identified). SR values for [$^{68}$Ga] Ga-DOTA-FAPI-04 had a mean SR value of 9.56, ranged from 2.68 to 30.00. In contrast, [$^{68}$Ga] Ga-DOTATATE had a lower mean SR of 7.97 (range: 4.80-16.67) and [$^{18}$F] -DOPA had the lowest mean SR of 4.3 (range: 3.67-5.11). ***Conclusion:*** Taken together, our findings suggest that [$^{68}$Ga]Ga-DOTA-FAPI-04 has better SR and positivity rate compared to [$^{68}$Ga] Ga-DOTATATE and [$^{18}$F] -DOPA in the detection of lesions, particularly mediastinal lymph nodes, with favorable tumour-to-background contrast. These results support the potential clinical utility of [$^{68}$Ga]Ga-DOTA-FAPI-04 in the management of Medullary Thyroid Carcinoma. ***References:*** Comparison of [68Ga]Ga-DOTA-FAPI-04 and [18F] FDG PET/CT for the diagnosis of primary and metastatic lesions in patients with various types of cancer. EJNMMI (2020)47:1820-1832. https://doi.org/10.1007/s00259-020-04769-z

## EP-0302

### Correlation Between Clinical Characteristics And Effective Washout Time In Patients Treated With High Radioiodine Activities

***C. Guerrero Calatayud****, A. C. Marin, S. Prado Wohlwend, J. R. Cañón Sánchez, N. I. Orrego Castro, S. Montesinos González, A. M. Yepes Agudelo, P. Bello Arques;*
*Hospital La Fe, Valencia, Valencia, SPAIN.*

***Aim/Introduction:*** Correlation between clinical variables and the delay in the effective washout time of 131I in context of differentiated thyroid cancer. ***Materials and Methods:*** Retrospective study of 754 patients treated with 131I from October 2014 to September 2022, comparing those with slow effective washout time of the radiopharmaceutical (>3 days) versus a control group with fast elimination chosen by simple randomization. The effective washout time was obtained from the exponential decay time of the radiopharmaceutical. Age, TNM, basal and stimulated maximum thyroglobulins (Tg) (Tgmax), and anti-thyroglobulin (Ab anti-Tg) were reviewed. ***Results:*** Out of 754 treated patients, 84 were those with slow effective elimination and a fast elimination control group was selected by simple randomization. Respectively, 77.8% vs 63.9% were women, with a mean age of 50 vs 56 years. The diagnosis was most frequently prompted by an incidental finding (26% vs 22%) or a cervical tumor (29.6% vs 38.8%) and the patients treated with a mean activity of 95mCi vs 107mCi. Regarding staging, 59.2% vs 44.5% were T1-T2, N+ in 25.9% vs 36% and M+ in 18.5% vs 16.6%. Median Tg were 1.94 vs 0.27 vs. Tg max 11.76 vs 3.57 and positive Ab anti-Tg in 4 vs 6 patients (these were excluded from thyroglobulin analyses). Tg and Tgmax were compared using the Mann-Whitney test, not observing statistical differences between both groups (p=0.057 and p=0.146 respectively). ***Conclusion:*** No statistically significant differences were observed between fast and slow washout to justify the excretion delay. There is a trend to a delay in 131I washout related to increased levels of thyroglobulin. Given the heterogeneity of the patients, larger series may be necessary to make a statistical inference.

## EP-0303

### Usefulness of 2-[18F]FDG PET/CT in indeterminate thyroid nodules (Bethesda III and IV) for risk stratification: do we still have to rely on FDG positivity? A retrospective monocentric experience

***F. Serani***[1]*, E. Tabacchi*[2]*, L. Calderoni*[1]*, G. Cuzzani*[1]*, S. Chillotti*[3]*, S. Damiani*[4]*, S. Fanti*[5]*;*
[1]*Nuclear Medicine, Alma Mater Studiorum -University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Pathology Unit, Alma Mater Studiorum -University of Bologna, Bologna, ITALY,* [4]*Pathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna-ITALY, Bologna, ITALY,* [5]*Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

***Aim/Introduction:*** Thyroid nodules are common and often incidentally discovered during imaging studies. The gold standard imaging exam is ultrasonography, followed by fine-needle aspiration biopsy (FNAB) to assess cytology and rule out malignancy. The Bethesda System for Reporting Thyroid Cytopathology provides a standardized approach for the interpretation of FNAB results, with Bethesda III and IV categories indicating indeterminate cytology. The challenge of precisely diagnosing indeterminate thyroid nodules prior to surgery has led to exploration of the introduction of molecular testing; in this context the potential utility of 2-[18F]FDG PET/CT (FDG PET) remains ambiguous and warrants further elucidation. We aimed to investigate the usefulness of FDG PET in risk stratification of indeterminate thyroid nodules (Bethesda III and IV). Specifically, we aimed to determine if there is a correlation between FDG positivity and presence of malignancy at final histology. ***Materials and Methods:*** In this retrospective descriptive monocentric experience, we selected patients who had undergone FDG PET and FNAB for thyroid nodules within 6 months (before or after) PET/CT, with subsequent thyroidectomy or hemithyroidectomy within one year of the cytology results, between January 2019 and January 2023, all performed in our institution. A lesion-based analysis was carried on using contingency tables. ***Results:*** 17 patients with 19 indeterminate thyroid nodules (15 Bethesda IV and 4 Bethesda III) were included in the analysis. 16 out of 19

nodules (84%) were positive on FDG PET, with a median SUVmax of 6.60 (IQR 4.50-8.70). Of the 19 nodules, 9 were malignant (7 follicular and 2 papillary carcinomas, with a TNM stage of pT1a in 7/9 and pT3a in 2/9 nodules) on final histology (47.4%) and 10 were found to be benign (6/10 follicular adenomas, 1/10 oncocytic adenoma and 3/10 thyroid follicular nodular disease) at final histology. FDG PET had a positive predictive value (PPV) of 44% and a negative predictive value (NPV) of 11%. Only 42.1% (8/19) of nodules had concordant PET and histology results (negative FDG PET and no malignancy or positive FDG PET and malignancy). ***Conclusion:*** Our experience confirms that FDG positivity in indeterminate thyroid nodules on cytology it is not a definitive criterion for malignancy. Ongoing and future analyses aimed at identifying predictive factors of malignancy such as ultrasonography characteristics, functional FDG PET parameters, radiomics, genetics as combination models and future prospective studies may enable better risk stratification and avoid unnecessary surgery.

**Vulva lesions as characterized by F-18 Fluorodeoxyglucose Positron Emission Tomography/ Computed Tomography**

***Z. Koç***[1], *P. Özcan*[1], *T. İlhan*[2], *S. Gökulu*[2], *Y. Karabulut*[3];
[1]*Mersin University Hospital Nuclear Medicine Dpt., Mersin, TÜRKIYE,* [2]*Mersin University Hospital Gynecologic Oncology Dpt., Mersin, TÜRKIYE,* [3]*Mersin University Hospital Pathology Dpt., Mersin, TÜRKIYE.*

***Aim/Introduction:*** Vulva malignancy (primary or metastatic lesions) has significant FDG accumulation according to previous literature. The aim of this study is to analyze the metabolic imaging characteristics of apparently malignant vulva lesions determined by F-18 FDG PET-CT. ***Materials and Methods:*** 27 female patients (mean: 56 years) with suspicious vulva lesions were retrospectively analyzed. The F-18 FDG PET-CT characteristics of the lesions, the first diagnosis of the patients and other metastatic sites were recorded and compared with pathology and or follow up and pelvic examination results. ***Results:*** The patients' first diagnoses were necessarily malignant (breast (n=5), other gynecologic tumors (n=6), lymphoma (n=5), vulva-vagen (n=4), colon (n=2), primary unknown (n=2), multiple myelom, ewing sarcoma, pancreas. The mean size of the vulva lesion in largest dimension was 15.5 and the mean SUVmax of these lesions was 16.5. The pathologic findings of the vulva lesions were obtained all of the patients. The findings were inflammatory or infectious lesions in 9 and malignant in 14 and normal in others as pathology results. The SUVmax levels of the true positive results (primary vulva lesions (n=4), metastatic lesions (n=5), local invasion (n=2), sarcoma (n=2), lymphoma (n=1)) was 19,35 and false positive results was 14,48. The accuracy of the F-18 FDG PET/CT in estimation of the vulva lesions was 48%. ***Conclusion:*** There are several case reports about these lesions in the literature (1). The results of the studies in malignant vulva tumors has shown advantages in saging and prognostification (2, 3) . There are several false positive causes in the diagnosis of vulva lesions on F-18 FDG PET-BT and this issue should be considered but pelvic examination is necessary in case of increased metabolic activity in a vulva lesion. ***References:*** 1. **Comparison of the diagnostic efficacy between 68Ga-FAPI PET/CT and 18F-FDG PET/CT in gynecological malignancies: A Systemic Review and Meta-analysis**

***C. Zhao****, L. Li;*
*West China Hospital, Sichuan University, Chengdu, CHINA.*

***Aim/Introduction:*** Gynecologic malignancies, including breast, cervical, endometrial, ovarian and fallopian tube malignancies, are critical threats to women's health. $^{68}$Ga-FAPI PET/CT is a novel molecular imaging modality. Whether $^{68}$Ga-FAPI PET/CT has better diagnostic efficiency than $^{18}$F-FDG PET/CT on different tumors is a research hotspot. The purpose of this study is to conduct a meta-analysis to compare the diagnostic efficacy of $^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT on gynecologic malignancies. ***Materials and Methods:*** We searched databases including PubMed, Embase, Cochrane Library and Web of Science from inception until March 29, 2023. Subjects must be diagnosed with gynecologic malignancies by histopathology, and both $^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT were performed at the same period. The literature was independently screened by 2 researchers. RevMan5.3 and Stata software were used to conduct statistical analysis. ***Results:*** A total of 238 records were screened, 8 articles were reviewed and 7 articles were included in the meta-analysis. A total of 196 patients and 603 lesions were included in these 8 articles, which involving breast, ovarian, cervical, endometrial, tubal, and uterus cancers. Based on patients, the diagnostic sensitivities of $^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT on metastatic lymph nodes were 0.94 (95% CI: 0.68,0.99), 0.8 (95% CI: 0.8,0.8), respectively. Based on lesions, the sensitivities of $^{68}$Ga-FAPI PET/CT and $^{18}$F-FDG PET/CT on metastatic lymph nodes were 0.96 (95% CI: 0.83,0.99), 0.73 (95% CI: 0.59,0.84), respectively. The relative risk of $^{68}$Ga-FAPI PET/CT versus $^{18}$F-FDG PET/CT detecting rates was 1.30, 95% CI: 0.78,2.18 (primary, lesion-based, p=0.32 ); 1.12, 95% CI: 0.98,1.28 (lymph node, patient-based, p=0.1 ); 1.28, 95% CI: 1.04,1.57 (lymph node, lesion-based, p=0.02 ); 1.16, 95% CI: 1.00,1.34 (other metastases, patient-based, p=0.04 ); 1.61, 95% CI: 1.12,2.31 (other metastases, lesion-based, p=0.01 ), respectively. The tumor-to-background ratios of $^{68}$Ga-FAPI PET/CT in primary tumor, metastatic lymph nodes and other metastatic lesions were significantly higher than that of $^{18}$F-FDG PET/CT (p<0.05). ***Conclusion:*** $^{68}$Ga-FAPI PET/CT has better diagnostic efficacy than $^{18}$F-FDG PET/CT on the gynecological malignancies.

## EP-0306

### Prognostic value of semiquantitative parameters of18F-FDG PET/CTin the staging of cervical cancer.

***L. Rodríguez Díaz***, *C. Vigil Díaz, A. Laverde Mächler, J. Maraña González, S. Naranjo Sancho, M. Fernández Llana, M. Domínguez Grande, J. Suárez Fernández, N. Martín Fernández, F. González García;*
*Hospital Universitario Central de Asturias, Oviedo, SPAIN.*

***Aim/Introduction:*** Cervical cancer is the fourth most common cancer among women worldwide. $^{18}$F-FDG PET/CT has a relevant role in diagnosis, response evaluation and recurrence detection. The aim of this study is to evaluate the role of $^{18}$F-FDG PET/CT in staging and management of cervical cancer in order to define the prognostic value of visual evaluation and semi-quantitative PET/CT parameters. ***Materials and Methods:*** Retrospective study including 26 patients (age range 30-70 years) with histological diagnosis of cervical cancer, who underwent pretreatment PET/CT between January/2021-June/2022. The variables included were tumor histology, presence of lymphovascular invasion, degree of differentiation classified into low (G1) and high-grade (G2-3), and stage defined as local (stage I) or advanced stage (II-IV), according to MRI results and following the FIGO staging system. PET/CT results were evaluated qualitatively and semi-quantitatively by calculating SUVmax, SUVmean and TLG values. Statistical analysis was performed using non-parametric Mann-Whitney U test. The area under the receiver operating characteristic (ROC) curve and cut-off values were identified. ***Results:*** 5 patients were classified as localized stages, 21 as advanced. 16 patients were classified as high grade, 9 as low grade tumors. Lymphovascular involvement was found in 11 patients. The median SUVmax, SUVmean and TLG values were 17.39 (range 4.56-65.98), 10.30 (range 2.54-41.47) and 418495.2 (35482.4-3330471.0), respectively. Statistically significant higher mean TLG values were found in patients with advanced vs. local stages (500887.0 vs. 72449.4) ($p<0.05$) nd in high-grade tumors vs. low-grade tumors (534991.8 vs. 24921.4) ($p<0.05$). ROC curve analysis revealed an AUC for TLG for stage of 0.90 ($p< 0.05$, IC 95% 0.79-1.02) and of 0.78 for grade ($p< 0.05$, IC 95% 0.60-0.96). A TLG optimal cut-off point of 102883.7 for differentiating local and advanced stage was found to have a sensitivity and specificity of 86% and 60%, respectively. The optimal determined TLG cut-off value of 123794.7 was found to have 81% sensitivity and 56% specificity for grade differentiation. No statistically significant differences were found for lymphovascular invasion. ***Conclusion:*** 18F-FDG PET/CT is an effective staging technique in cervical cancer capable of predicting tumor stage and grade prior treatment. Our series showed statistically significant differences in TLG values in patients with high-grade and advanced stage tumors compared to those with low-grade and local stage tumors.

## EP-0307

### Development and External Testing of Integrating PET/MR Radiomics and Clinical Characteristics to Predict Lymphovascular Space Invasion in Endometrial Carcinoma: A Dual-Center Study

***X. Li***[1,2], *T. Song*[1,2], *B. Cui*[1,2], *J. Li*[1,2], *J. Ma*[1,2], *H. Yang*[1,2], *Y. Wang*[3], *H. Sun*[4], *J. Lu*[1,2];
[1]*Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA,* [2]*Beijing Key Laboratory of Magnetic Resonance Imaging and Brain Informatics, Capital Medical University, Beijing, CHINA,* [3]*GE Healthcare China, Shanghai, CHINA,* [4]*Department of Radiology, Shengjing Hospital of China Medical University, Shenyang, CHINA.*

***Aim/Introduction:*** To investigate the precision and robustness of radiomics based on integrated positron emission tomography/magnetic resonance (PET/MR) imaging for predicting lymphovascular space invasion (LVSI) in endometrial carcinoma (EC) patients. ***Materials and Methods:*** Ninety-three patients with EC from two centers who underwent $^{18}$F-Fluorodeoxyglucose ($^{18}$F-FDG) PET/MR scanning were retrospectively collected and divided into the training, validation, and testing datasets. Clinical characteristics including age, weight, height, International Federation of Gynecology and Obstetrics (FIGO) stage, CA 19-9, and carcinoembryonic antigen (CEA) were collected. The apparent diffusion coefficient (ADC) parameters and conventional PET metabolic parameters, including peak, maximum, and mean standard uptake values ($SUV_{peak}$, $SUV_{max}$ and $SUV_{mean}$), as well as metabolic tumor volume (MTV) and total lesion glycolysis (TLG), were measured by two radiologists. The volume of interest (VOI) for tumors was semi-automatically segmented on PET images. 5106 radiomics features were extracted from VOI on anatomical MRI, ADC maps, and PET images and selected using the minimum redundancy maximum correlation (mRMR) and the the least absolute shrinkage and selection operator (LASSO) algorithms to generate multimodal Rad-scores (Rad-score_PET, Rad-score_MR, and Rad-score_PET/MR). The logistic regression algorithm established PET, MR, PET/MR, and combined machine learning models. The Mann-Whitney test was utilized to examine the differences in Rad-scores distribution between the LVSI and non-LVSI groups. The Spearman's correlation test was used to analyze the correlations between the Rad-scores and other clinicopathological characteristics. Evaluations of machine learning models were performed using receiver operating characteristic curves, calibration curves, and decision curve analysis curves. ***Results:*** Only Rad-score_PET/MR among all Rad-scores of the LVSI group was higher than those of the non-LVSI group in every dataset ($p < 0.001$). And the Rad-score_PET/MR was correlated with LVSI ($r = 0.690$, $p < 0.05$) and slightly correlated with pelvic lymph node metastasis (PLNM) ($r = 0.200$, $p < 0.05$). In the training dataset, the PET/MR model predicted LVSI well (AUC = 0.993). However, the AUC value declined significantly in the validation and testing datasets (AUC = 0.833 and 0.909, respectively). In three datasets, the combined model that integrated clinicopathological features (differentiation degree, $SUV_{max}$, and $SUV_{peak}$) with Rad-score_PET/MR had the highest precision and robustness (AUC = 0.993, 0.900, and 0.923, respectively). ***Conclusion:*** Radiomics based on integrated PET/MR could noninvasively detect LVSI in EC, which could benefit in modifying treatment regimens and predicting prognoses. Moreover, the addition of clinicopathological features can improve the reproducibility of the radiomics model.

## EP-0308

### Potential for time-synchronized PET/MRI with dual tracers of FDG and FES: Utility in the diagnostic capability to distinguish between benign and malignant endometrial lesions

***J. Inukai-Inoue***[1], *M. Nogami*[2,3], *M. Tachibana*[1], *F. Zeng*[2], *K. Kubo*[2], *T. Kurimoto*[4], *T. Tujikawa*[5], *Y. Yoshida*[6], *H. Okazawa*[3], *T. Murakami*[1,2];
[1]*Department of Radiology, Kobe University Graduate School of Medicine, Kobe, JAPAN,* [2]*Department of Radiology, Kobe University Hospital, Kobe, JAPAN,* [3]*Division of Medical Imaging, Biomedical Imaging Research Center, University of Fukui, Fukui, JAPAN,* [4]*GE Healthcare, Hino, JAPAN,* [5]*Department of Radiology, Faculty of Medical Sciences, University of Fukui, Fukui, JAPAN,* [6]*Department of Obstetrics and Gynecology, Faculty of Medical Sciences, University of Fukui, Fukui, JAPAN.*

***Aim/Introduction:*** When using different PET scans with multiple tracers to evaluate lesions, it is difficult to establish the identical region of interest (ROI) in both images using PET information alone. In simultaneous PET/MRI, because the individual PET and MRI have different acquisition times, the MRI-based ROI of PET is inaccurate. This study aimed to generate the MRI-based ROI of PET by reconstructing PET images that perfectly match the MRI acquisition time using MRI active trigger information recorded in the PET list-mode data and evaluate the clinical utility of its quantitative values. ***Materials and Methods:*** Thirteen patients (26 examinations) with endometrial lesions who had undergone $^{18}$F-fluorodeoxyglucose (FDG) and $^{18}$F-fluoroestradiol (FES) PET/MRI of the pelvic region within 1 month were retrospectively evaluated. PET list-mode data obtained by simultaneous acquisition with MRI were analysed using an offline workstation. The start and end times of each MR sequence were recorded by investigating the active triggers for each MRI sequence. PET image reconstruction was performed based on the obtained start and end times to generate time-synchronised PET/MRI fusion images. The Bayesian penalised likelihood algorithm with adaptive β values was used for PET image reconstruction. The ROI was placed on the endometrial lesion on MRI, which was superimposed on the time-synchronised PET to measure the mean SUV (SUVmean) and total lesion glycolysis (TLG). For comparison, the ROI was placed based on PET/MRI fused images without time synchronisation (overlapped PET/MRI). Two radiologists/nuclear medicine physicians visually rated the fusion image accuracy of the overlapped PET/MRI and time-synchronised PET/MRI on a 7-point scale. The diagnostic performance of SUVmean and TLG measured by overlapped and time-synchronised PET/MRI was compared using the ROC analysis based on the histopathologically determined reference standard. The fusion image misregistration of overlapped and time-synchronised PET/MRI was compared using the Wilcoxon signed-rank test. ***Results:*** The FDG/FES ratio of SUVmean and TLG measured by time-synchronised PET/MRI (area under the curve [AUC] = 0.833 and 0.833, respectively) had higher diagnostic performance than that of overlapped PET/MRI (AUC = 0.750 and 0.778, respectively). The score of misregistration for synchronised PET/MRI (0.256 ± 0.568) was lower than that of overlapped PET/MRI (0.679 ± 1.179). ***Conclusion:*** Quantitative FDG and FES PET evaluation could be performed using time-synchronised PET/MRI. The FDG/FES ratio of SUVmean by time-synchronised PET/MRI had a higher diagnostic performance than that by overlapped PET/MRI in distinguishing between benign and malignant endometrial lesions.

## EP-0309

### Comparing CECT, 18F-FDG PET and 68Ga-FAPI PET derived peritoneal carcinomatosis index (PCI) in primary ovarian cancers.

***S. Singh***, *K. Verma, A. Singh;*
*Globe Healthcare, Lucknow, INDIA.*

***Aim/Introduction:*** To compare peritoneal carcinomatosis index (PCI) derived from CECT, 18F-FDG PET and 68Ga-FAPI PET in patients with primary ovarian neoplasm with peritoneal metastases planned for cytoreductive surgery.To investigate the change in management due to difference in findings among these modalities. ***Materials and Methods:*** This is a single center prospective study which included 30 patients with newly diagnosed carcinoma ovary. All patients underwent staging workup by 18F-FDG PET/CT and 68Ga-FAPI PET/CT on different days. Intravenous iodinated contrast was used only in one of the CT scans. Low dose non contrast CT was done when diagnostic CECT was obtained in previous PET study. Peritoneal carcinomatosis index (PCI) was calculated by Sugarbaker PCI index method for each modality. PCI scores were compared among CECT, FDG PET and FAPI PET images, findings were reviewed to note any change in patient management due to PET findings. Imaging was performed on digital PET-CT scanner uMI550 (United Imaging). ***Results:*** Mean age of the patients was 42 years (range 30 to 55). Serous adenocarcinoma was the most common histopathological subtype (21/30) followed by mucinous and clear cell carcinomas. The median PCI scores for CECT, FDG PET and FAPI PET were 18, 24 and 29 respectively and the difference was statistically significant ($p<0.05$). 10 patients (33%) had change in management plan in form of introduction of neoadjuvant chemotherapy due to high PCI score on FDG and FAPI PET findings. FAPI PET PCI score alone changed treatment decision in 6 (20%) patient due to additional lesions. In PET studies, SUV values in peritoneal disease were higher with FAPI PET than FDG. ***Conclusion:*** 68Ga-FAPI PET results in higher PCI score than 18F-FDG PET and introduction of FDG/FAPI studies can change management in upto 33% of patients of carcinoma ovary.

## EP-0310

### Investigation of the Effect of Hormonal Therapy on Endometrial FDG Uptake in Postmenopausal Women

***R. Nakamoto***, *M. Yakami, T. Nobashi, H. Isoda, Y. Nakamoto;*
*Kyoto University Hospital, Kyoto, JAPAN.*

***Aim/Introduction:*** Hormone replacement therapy (HRT) with estrogen for women suffering from menopause has been reported to be associated with a significantly increased endometrial thickness, compared with the thickness in control subjects, when assessed sonographically. However, the effect of hormonal therapy on FDG uptake in the endometrium has not been fully investigated. In this study, we examined the effect of hormone therapy, especially HRT, on FDG uptake in the endometrium of postmenopausal women. ***Materials and Methods:*** Postmenopausal women (no history of gynecological malignancies) aged 45 years and older receiving HRT or tamoxifen for breast cancer treatment (antitumoral hormonal therapy, AHT) who underwent PET/CT screening between June 2016 and April 2023 at our institution were enrolled (HT group). Menopausal status was determined by interview and/or blood data (E2<5pg/ml, FSH>40mIU/ml). As a control group, women not receiving hormonal therapy who had undergone PET/CT screening within 5 years after menopause were enrolled. The endometrial uptake (SUVmax) and 4 levels of the visual score for endometrial uptake (4: significant uptake, 3: recognizable, 2: somehow recognizable, 1: unrecognizable) in both groups were compared. The relationship between endometrial uptake and duration (months) of HRT was examined. ***Results:*** There was a significant difference in FDG uptake of the endometrium between the HT and Control groups (median SUVmax: 2.3 vs 1.9, $P = 0.0021$) (median Visual score: 2 vs 1, $P < 0.0001$). In the HT group, FDG uptake in the endometrium was higher in women receiving HRT (n=14) than in women receiving AHT (n=7) (median SUVmax: 2.45 vs 1.9, $P = 0.0362$) (median Visual score: 3 vs 1, $P = 0.0226$). A significant correlation was found between endometrial uptake and duration of HRT ($\rho = 0.55$, $P = 0.042$). Five women on HRT had high endometrial uptake (range of SUVmax, 3.7-9) (Visual score 4), one of whom was found to have endometrial thickening sonographically and no abnormality on histological examination, while another had increased endometrial

uptake on PET/CT screening the following year (SUVmax, 3.7→11.9) and subsequent endometrial histology revealed endometrial cancer. ***Conclusion:*** There was a trend toward higher FDG uptake in the endometrium of postmenopausal women on HRT for longer periods. We might be careful with the increased endometrial uptake during HRT with estrogen, which contributes to the development of endometrial cancer. ***References:*** Lerman H, et al. Normal and abnormal 18F-FDG endometrial and ovarian uptake in pre- and postmenopausal patients: assessment by PET/CT. J Nucl Med. 2004 Feb;45:266-71.

## EP-0311

### Treatment response evaluation using FDG-PET/CT predicts survival in women with locally advanced cervical cancer

***M. Markus***[1], *H. Sartor*[2], *M. Bjurberg*[3], *E. Trägårdh*[1];
[1]*Clinical Physiology and Nuclear Medicine, Malmö, SWEDEN,* [2]*Radiology Diagnostics, Malmö, SWEDEN,* [3]*Department of Hematology, Oncology and Radiation Physics, Malmö, SWEDEN.*

***Aim/Introduction:*** Cervical cancer is the fourth most common female malignancy worldwide. [18F]-fluorodeoxyglucose (FDG) positron emission tomography with computed tomography (PET-CT) is routinely performed in patients with advanced cervical cancer for staging and evaluation of treatment response. The maximum standardised uptake value (SUVmax) is the most used PET parameter in clinical routine but more advanced metabolic parameters (e.g metabolic tumour volume (MTV) and total lesion glycolysis (TLG)) may better predict survival. Our aim was to investigate the prognostic value of treatment response assessment for SUVmax, MTV and TLG, in women with locally advanced cervical cancer, using overall survival as outcome measure. ***Materials and Methods:*** Women with locally advanced cervical cancer referred for radiochemotherapy at the Department of Oncology at Skåne University Hospital, Sweden 2011-2019 and who underwent one PET-CT scan at baseline one at 6-month follow-up after treatment were included. Treatment response on PET-CT was assessed according to the European Organization for Research and Treatment of Cancer criteria, using SUVmax, MTV and TLG for comparison. The different treatment response outcomes were complete metabolic response (CMR), progressive metabolic disease (PMD), or either partial metabolic regression (PMR) or stable disease (SD). The response outcomes were correlated to overall survival using Cox regression analysis, with CMR as reference. Also, C-index was used to visualize the predictive potential of the different measures. ***Results:*** A total of 133 patients were included. Age- and clinical stage-adjusted analyses showed a statistically significant association ($p<0.001$) between treatment response and overall survival for SUVmax (hazard ratio (HR) for PMD 16, HR for PMR/SD 4.0), MTV (HR for PMD 16, HR for PMR/SD 2.9) and TLG (HR for PMD 16, HR for PMR/SD 2.9). Also, C-index values from adjusted Cox models were comparable between the PET-parameters (SUVmax 0.838, MTV and TLG 0.857). ***Conclusion:*** Treatment response evaluation assessed with FDG-PET/CT is predictive of overall survival. The results were similar for both SUVmax, MTV and TLG.

## EP-0312

### MRI and 18F-FDG PET/CT interrelationship in the postradiotherapy cervical carcinoma early response assessment

***S. Lucic***[1,2], *M. Spirovski*[1,2], *J. Licina*[1,2], *D. Stojanovic*[2], *A. Peter*[2], *M. A. Lucic*[1,2];
[1]*Medical Faculty, University of Novi Sad, Novi Sad, SERBIA,* [2]*Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA.*

***Aim/Introduction:*** Adequate assessment of response and timely detection of tumour recurrence after radiotherapy (RT) treatment is of great importance. Although there is no consensus about the time interval until the first diagnostic examination after RT, MRI as a reliable diagnostic tool is usually performed in first 2-3 months after the end of treatment. Aim of this study was to determine whether 18F-FDG PET/CT could improve early post-RT diagnostic evaluation. ***Materials and Methods:*** Twenty-eight female patients (mean age 55.43±11,78; range 35-85) with locally advanced cervical cancer FIGO stage IIB-IVA treated with combined external beam radiation therapy (EBRT) and intracavitary brachytherapy with concomitant chemotherapy were included in the study. Pelvic and abdominal MRI exam were performed 2-4 months after treatment, followed by 18F-FDG PET/CT within one month after MRI in order to estimate early therapy effects. Studies results were considered as positive, negative and equivocal for rest/recurrent tumour presence, that was proven by control MRI exam done at least six months afterwards. Data sets were statistically analysed with two-tailed Pearson's correlation coefficient (r), and Spearman's rank correlation coefficient (ρ), with the level of confidence determined at $p<0.05$. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy of both techniques were calculated. ***Results:*** Concordant results in 20/28 (71,4%) patients indicated good statistical correlation. In 10/28 (35,7%) patients PET/CT additionally revealed distant metastasis presence. Good correlation was determined for both MRI and 18F-FDG PET/CT results ($r=0.443$ p 0.018 and $\rho=0.439$ p 0.02). In comparison to the 6 months MRI control study, initial MRI results were significantly correlated ($r=0.405$; $p=0.033$ and $\rho=0.457$; $p=0.015$), but 18F-FDG PET/CT results did not demonstrate significant correlation ($r=0.122$; $p=0.537$ and $\rho=0.159$; $p=0.418$). Sensitivity, specificity, PPV, NPV, and diagnostic accuracy of MRI were determined at 66.7%, 70.6%, 54.5% and 80%, respectively, while for PET/CT the values were 60%, 55.5%, 42.6% and 71.4%, respectively. ***Conclusion:*** The ability to detect early therapy response was calculated as slightly lesser for both MRI and PET/CT than we assumed. Even though PET/CT didn't have significant impact on diagnostic confidence, by providing the additional information, it changed the treatment approach in more than one-third of the patients, allowing us to conclude that, subsidiary to MRI, 18F-FDG PET/CT can be helpful in post-RT cervical carcinoma evaluation.

### Utility of 18F FDG PET/CT in rare gynaecological malignancies

***A. Nair S***, *V. Rangarajan, S. Shah, A. Agrawal, N. Purandare, A. Puranik, S. Choudhury;*
*Tata Memorial Hospital, Mumbai, INDIA.*

***Aim/Introduction:*** Gynaecological malignancies are one of the most common cancers in women, with a vast majority being of adeno or squamous histopathologies, and the variations of histopathology is associated with a variation in prognosis and management. The consensus of management are well established for the more common histopathological variants, whereas the data regarding the management of infrequently encountered pathologies like uterine sarcoma, pelvic PNET (peripheral neuroectodermal tumour) are limited due to the rarity of these tumours. ***Materials and Methods:*** This is a retrospective, observational study done in 71 patients with rare gynaecological malignancies (gynaecological malignancies excluding adeno and squamous histopathologies) in whom 18-F FDG PET/CT was done at staging,

response evaluation or evaluation for suspected recurrence. A vast majority of the cases analysed were sarcomas (76%) followed by PNETs (15.5%) and neuroendocrine carcinomas (NEC) (8.5%). The sensitivity, specificity, negative predictive value, positive predictive value and accuracy of 18F FDG PET/CT was calculated for both nodal and distant metastatic lesions in these malignancies with respect to histopathological reports/clinical findings/ follow up data as the standard. ***Results:*** In the 71 patients included, indications for PET/CT were postoperative cancer staging (70.4%), suspected recurrence (15.5%) and post chemotherapy/radiation therapy response evaluation (14.1%). Histopathologically, 54 patients had sarcoma, 11 had PNET and 6 had NEC (neuroendocrine carcinoma) of the genital tract. FDG PET/CT showed 93.3% sensitivity,87.5% specificity, and 88.7% accuracy for nodal metastases. For distant metastases, the sensitivity is 95.5%, specificity is 80.8% and accuracy is 90.1%. Total percentage of extrapelvic metastases: 69.65%. ***Conclusion:*** 18F FDG has a high sensitivity, specificity and accuracy for the evaluation of rare histopathological subtypes of gynaecological malignancies. The detection of extrapelvic metastases in cases considered to be locoregional disease may result in a change of management in these patients who were previously imaged by locoregional standard imaging modalities.

### Prognostic Role of F-18 FDG PET in Uterine Cervical Cancer Patients: 10 Years Experience

***C. Soydal***[1], *M. H. Baltacioglu*[2], *M. Araz*[1], *S. Taskin*[3], *N. O. Kucuk*[1], *U. F. Ortac*[3];
[1]*Ankara University Medical School, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Sbu Trabzon Kanuni Training and Research Hospital Department of Nuclear Medicine, Trabzon, TÜRKIYE,* [3]*Ankara University Medical School, Department of Gynecology and Obstetrics, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The aim of this study was to investigate the role of F-18 FDG PET/CT at the time of staging in predicting the prognosis of patients with uterine cervical cancer. ***Materials and Methods:*** Thirty-two women (mean age: 52.7 ± 12.6) who underwent the F-18 FDG PET/CT for staging between January 2012 and June 2022 of uterine cervix cancer were recruited the study retrospectively. PET/CT images were re-evaluated and metabolic parameters such as SUVmax, SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were calculated for the primary lesion, lymph nodes and distant metastases. Images were also classified according to the presence or absence of pathologic involvement of pelvic and paraaortic lymph nodes. The progression-free and overall survival times of the groups above and below the median value according to metabolic parameters and the groups with and without pelvic-paraaortic lymph node involvement were compared using Kaplan-Meier Analysis. ***Results:*** Primary tumor of 27 (84%) patients were F-18 FDG avid. Medians for SUVmax, SUVmean, MTV and TLG of primary tumors were calculated as 12.4, 6.1, 13.2 cm3 and 87.8 gr/mLxcm3 respectively. Pathological uptake was detected in pelvic 14 (44%) patients and in paraaortic lymph nodes in 3 (10%) patients. Medians for total MTV and TLG were 21.7 cm3 and 91.1 gr/mLxcm3. Disease progression was detected in 7 (22%) of patients within median 20.9 (min-max: 3-82) months follow-up period. The only significant PET parameter to predict PFS was SUVmax of primary tumor (p=0.038). During follow-up period 8 patients died. SUVmax (p=0.007), MTV (p=0.036), TLG (p=0.001) of primary tumor, presence of pathological uptake on pelvic or paraaortic lymph nodes (p=0.015), total MTV (p=0.047) and total TLG (p=0.001) were found statistically significant PET parameters to predict OS. ***Conclusion:*** F-18 FDG PET/CT has a limited role in the evaluation of the primary lesion in uterine cervical cancer staging and is especially recommended for the evaluation of lymph node metastases. Although it cannot give an idea about myometrial and parametrial invasion of the primary lesion, F-18 FDG uptake level can give an idea about the level of differentiation of the disease. There is evidence that metabolic parameters obtained from PET imaging have a prognostic value in many malignancies. However, from our analysis we conclude that metabolic parameters derived from PET imaging may have a role in predicting overall survival in patients with cervical cancer.

### Does Peritoneal Metastasis Evaluation with 18F-FDG PET/MRI Contribute to Prognosis Prediction in Patients with Ovarian Cancer

***M. Baltacioglu***[1], *C. Soydal*[2], *M. Araz*[2], *D. Kuru Oz*[3], *N. O. Kucuk*[2];
[1]*Sbu Trabzon Kanuni Training and Research Hospital Department of Nuclear Medicine, Trabzon, TÜRKIYE,* [2]*Ankara University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE,* [3]*Ankara University Medical School, Department of Radiology, Ankara, TÜRKIYE.*

***Aim/Introduction:*** The entity of peritoneal metastases in patients with ovarian cancer significantly affects the prognosis. Timely and accurate detection of ovarian cancer recurrences is important for disease survival. In this study, in patients who underwent 18F-FDG PET/CT and 18F-FDG PET/MRI for peritoneal metastasis evaluation in ovarian cancer; We aimed to compare the effects of both imaging modalities on prognosis. ***Materials and Methods:*** 45 patients (median age: 58.1 years; min-max: 33-79 years) with ovarian cancer who developed elevated serum Ca-125 during follow-up after primary surgery and underwent 18F-FDG PET/CT followed by PET/MR imaging for peritoneal disease restaging were prospectively included in this study. Peritoneal recurrences were evaluated on both imaging modalities and peritoneal carcinomatosis index (PCI) was calculated for each patient. PET/CT and PET/MR images were evaluated on a patient basis for the presence and localization of peritoneal recurrences. After peritoneal disease staging by PET/CT and PET/MRI, patients received the treatment deemed appropriate by their clinicians and were followed up for survival analysis. The date of death was noted in exitus patients. ***Results:*** In patient-based analysis; PET/MRI was positive in 33 patient (73%), while PET/CT was positive in 27 patient (60%) (p=0.03). The median PCI score was 2 (min-max:0-26) in PET/CT and 4 (min-max:0-26) in PET/MRI (p<0.001). In Kaplan Meier survival analysis, FIGO stage (p<0.001), number of peritoneal lesions detected in PET/CT (p=0.017), PCI score in PET/CT (p=0.014), abdominopelvic lymph node SUVmax value in PET/CT (p=0.007), peritoneal lesion SUVmax value in PET/MRI (p=0.035), abdominopelvic lymph node SUVmax value in PET/MRI (p=0.047) and PCI score in PET/MRI (p=0.027) were found to be parameters associated with overall survival. ***Conclusion:*** Although PET/MRI is more successful than PET/CT in showing peritoneal metastases, peritoneal uptake in PET/CT has been associated with prognosis. This suggests that PET/CT can be used for prognosis in patients with recurrent ovarian cancer.
